23. April 2012

## Background

Clustering air guns is a popular way of improving the seismic signal created by an air gun array.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

## Background

Clustering air guns is a popular way of improving the seismic signal created by an air gun array.

The main effect is improving the primary to bubble ratio and the bubble time period of the two (or more) clustered air guns, and is determined by the separation distance and size of the guns (Strandenes and Vaage, 1992).

## Observation

The simplest model of an oscillating air gun, the Rayleigh equation (Rayleigh, 1917):

$$\ddot{R} = \frac{P - P_{\infty}}{\rho R} - \frac{3}{2} \frac{\dot{R}^2}{R},$$

retains its general shape when correcting for a cluster case, but is scaled in period.

## Observations

◆□ > ◆□ > ◆豆 > ◆豆 > ̄豆 = のへぐ

# The idea

- Estimate a characteristic time factor for the single bubble Rayleigh equation.
- Repeat the process for the cluster case.
- Estimate the bubble time period increase for a real air-gun cluster from these two values.

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

While the Rayleigh equation is not the best model for a single gun, we hope that the relative change will still be a good estimator. This implicitly assumes that:

 Clustered air-gun interaction is dominated by fluid flow as opposed to sound pressure proagation.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

## The method

Strandenes and Vaage (1992) determined that cluster dynamics were determined by separation distance and equilibrium radius,  $R_{\rm EQ}$ , which is the radius where the pressure inside the bubble equals the hydrostatic pressure (and temperature, which we will not require, as it is not certain that exact state will be attained). Assuming adiabatic expansion, this means:

$$R_{\rm EQ} = R_0 \left(\frac{P_0}{P_\infty}\right)^{\frac{1}{3\gamma}}$$

We will:

Estimate the bubble wall velocity when R = R<sub>EQ</sub>, by use of an energy balance.

(日) (同) (三) (三) (三) (○) (○)

- Calculate a characteristic time  $T = \frac{R_{EQ}}{U_{EQ}}$
- Estimate relative bubble time period:  $\frac{T_{\text{Cluster}}}{T_{\text{Single}}}$

### Single bubble - Energy balance

At the initial state we will have only potential energy (as the bubble wall has not begun moving). This energy can be defined to be equal to the work done to get the bubble from its steady state,  $P = P_{\infty}$ , to the initial state. We again assume adiabatic expansion and get

$$\begin{split} E_{\rho} &= -\int_{V_{\text{EQ}}}^{V} \Delta P dV \\ &= -\int_{V_{\text{EQ}}}^{V} P_{\infty} \left(\frac{V_{\text{EQ}}}{V}\right)^{\gamma} - P_{\infty} dV \\ &= V P_{\infty} (1 - \beta \frac{\beta^{-\frac{\gamma-1}{\gamma}} \gamma - 1}{\gamma - 1}), \end{split}$$

where  $\beta = \frac{P_0}{P_{\infty}}$  and  $\gamma$  is the adiabatic constant.

## Single bubble - Energy balance

To get the kinetic energy we assume flow as describe by a single monopole potential

$$\phi = \frac{-UR^2}{r}$$

and integrate the kinetic energy over all the fluid to get

$$E_k(R, U) = \int_{\Omega} \frac{1}{2} \rho u^2 dV$$
$$= 4\pi \int_R^{\infty} \frac{1}{2} \rho |\nabla \phi|^2 dr$$
$$= 2\rho \pi U^2 R^3$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

## Single bubble - Energy balance

The energy balance then yields:

$$\begin{split} 2\rho\pi U_{\rm EQ}^2 R_{\rm EQ}^3 &= \frac{4}{3}\pi R_0^3 P_\infty \left(1-\beta \frac{\beta^{-\frac{\gamma-1}{\gamma}}\gamma-1}{\gamma-1}\right) \\ U_{\rm EQ} &= \frac{1}{3}\sqrt{\frac{6P_\infty}{\rho}\frac{\hat{\beta}}{\beta^{\frac{1}{\gamma}}}}, \end{split}$$
 where  $\hat{\beta} = 1-\beta \frac{\beta^{-\frac{\gamma-1}{\gamma}}\gamma-1}{\gamma-1}.$ 

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

# Single bubble - Characteristic time

Our characteristic time for a single bubble is:

$$T_{\text{Single}} = \frac{R_{\text{EQ}}}{U_{\text{EQ}}} = \frac{R_{\text{EQ}}\beta^{\frac{1}{2\gamma}}}{2}\sqrt{\frac{6\rho}{\hat{\beta}P_{\infty}}}.$$

(ロ)、(型)、(E)、(E)、 E) の(の)

In the 2-bubble case, the potential energy will remain the same (per bubble) as in the single bubble case. This means that for our relative bubble time period estimate we do not need to assume anything about the bubble expansion.

In the 2-bubble case, the potential energy will remain the same (per bubble) as in the single bubble case. This means that for our relative bubble time period estimate we do not need to assume anything about the bubble expansion.

The kinetic energy, however, will be considerably more tricky to evaluate.

## Two bubbles - Energy balance

We assume a two monopole potenial, with a distance 2b between the two singularities:

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

### Two bubbles - Energy balance

To evaluate the energy integral we apply Green's identity to get

$$E_{k} = \frac{1}{2}\rho \int_{\Omega} |\nabla \phi|^{2} dV$$
  
=  $-\frac{1}{2}\rho \int_{\partial \Omega} \frac{\partial \phi}{\partial r} \phi dS - \underbrace{\frac{1}{2}\rho \int_{\Omega} \phi \Delta \phi dV}_{0, \text{ as } \phi \text{ is harmonic}}$ 

which has the effect of separating the total energy to the energy contribution from each bubble.

Assuming non-overlapping bubbles, the kinetic energy at equilibrium radius can be evaluated to be (Barker and Landrø, 2012):

$$E_{k} = -\frac{1}{2} \pi \rho U_{EQ}^{2} R_{EQ}^{3} \frac{4 + 6 \kappa - 4 \kappa^{2} - 4 \kappa^{3} + (1 - \kappa^{2}) \ln \left(\frac{\kappa + 1}{\kappa - 1}\right)}{\kappa (\kappa^{2} - 1)},$$

1

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

`

where  $\kappa = \frac{2D}{R_{EQ}}$ .

# Two bubbles - Characteristic time

Following the single bubble procedure we get

$$T_{\mathsf{Cluster}} = rac{1}{4} eta^{rac{1}{2\gamma}} R_{\mathsf{EQ}} \sqrt{rac{6
ho}{\hat{eta} P_{\infty}}} \sqrt{rac{4 \,\kappa + 4 - \ln\left(rac{\kappa - 1}{\kappa + 1}
ight)}{\kappa} + rac{2}{1 - \kappa^2}},$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

### Two bubbles - Characteristic time

Following the single bubble procedure we get

$$T_{\mathsf{Cluster}} = \frac{1}{4} \beta^{\frac{1}{2\gamma}} R_{\mathsf{EQ}} \sqrt{\frac{6\rho}{\hat{\beta}P_{\infty}}} \sqrt{\frac{4\kappa + 4 - \ln\left(\frac{\kappa - 1}{\kappa + 1}\right)}{\kappa} + \frac{2}{1 - \kappa^2}},$$

and by dividing by  $\mathcal{T}_{\mathsf{Single}}$  we get the relative time period estimate

$$\frac{T_{\mathsf{Cluster}}}{T_{\mathsf{Single}}} = \frac{1}{2} \sqrt{\frac{4 \,\kappa + 4 - \ln\left(\frac{\kappa - 1}{\kappa + 1}\right)}{\kappa}} + \frac{2}{1 - \kappa^2}, \qquad \kappa \geq 2.$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

For comparison, Rattray (1951) inferred the following relative time period estimate for cavities near a wall, which is (in our context and notation):

$$\frac{T_{\mathsf{Wall}}}{T_0} = 1 + 0.41 \frac{1}{\kappa}$$

## Real data comparison

▲□▶ ▲圖▶ ▲臣▶ ▲臣▶ 三臣 - のへで

The relative time period estimate seems to match the measured data fairly well, but is limited by the assumption of two distinct spherical bubbles.

The relative time period estimate seems to match the measured data fairly well, but is limited by the assumption of two distinct spherical bubbles.

Naturally, we would like to extend the estimation down to  $\kappa = 0$ .

・ロト・日本・モート モー うへぐ

To extend the domain of validity we drop the assumption of spheres, and instead let the bubbles be represented by isosurfaces in the potential field.

To extend the domain of validity we drop the assumption of spheres, and instead let the bubbles be represented by isosurfaces in the potential field.

The tradeoff is that we can no longer present an analytical expression.

## From spheres to isosurfaces

An example isosurface:

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 三臣 - のへで

## The numerical approach

Since we are using an isosurface in the potential field, the evaluation of the kinetic energy interval will in fact be a lot simpler, as only the iso-constant is needed. This means the method is, for a given  $\kappa$ :

- Determine the constant needed to get an isosurface containing the equilibrium volume.
- ► Divide this by the constant needed in the single bubble (sperical) case, -R \* U.
- Take the square root to get the estimate for U
- Get the relative time period estimate as earlier described.

## Real data comparison

# Clusters with more than 2 guns

Of course, this method can be extended to work for any number of guns as long as the the guns are placed equally on a circle or sphere.

# Clusters with more than 2 guns

Of course, this method can be extended to work for any number of guns as long as the the guns are placed equally on a circle or sphere.

In these cases we have a choice of defining b as either the distance to the nearest gun, or the distance to the center of the cluster.

## Clusters with more than 2 guns

Of course, this method can be extended to work for any number of guns as long as the the guns are placed equally on a circle or sphere.

In these cases we have a choice of defining b as either the distance to the nearest gun, or the distance to the center of the cluster.

In the following slides we will see the estimated relative bubble time period change for a 3-gun symmetric cluster, where b is the distance to the center. Sadly, we have no data to compare to in this case.

# Conclusions

- We have found a simple analytic expression for estimating the relative time period change of two-gun clusters vs. single air guns, when the bubbles are non-overlapping.
- By introducing isosurfaces of the potential as an abstract bubble wall, we can estimate the relative bubble time period of coalescing bubbles as well.
- The relatively good fit for smaller values of κ might indicate that the main form of interaction of guns in clusters is the fluid movement.
