# AVA, EEI and AVA Inversion Practicalities

#### Peter Harris Deep Vision Ltd and Sharp Reflections

**Deterministic AVA Inversion Workflow** 

# Seismic data quality

Usually we start with time-migrated gathers ...

They are often sub-optimal for inversion

- Residual multiples
- Other types of noise
- Residual moveout
- Offset-dependent amplitude scaling

# Raw gathers (time mig, NMO corrected)

# Radon demultiple

# **Removed multiple energy**

# Angle muted 50°

# **Evolution of Top Frigg AVO response**

# Seismic data quality

**Multiples** 

Contractors are often conservative. Modern high-resolution Radon transforms can get away with surprisingly tight mutes.

Lots of modern methods for coherent and incoherent noise in different domains

- Prediction methods
- Transform methods

# Seismic data quality

Residual moveout

Sparse velocity picking grids give rise to interpolation errors and mispicks.

Dense, automatic methods don't recover from mispicks in guide function.

How flat is flat??

Velocity and  $\boldsymbol{\eta}$  are negatively correlated.

#### Well log quality What to look for: are logs fit for purpose?

# Tuning

Wedge models are the standard method of understanding tuning and vertical resolution. They usually assume plane-layering.

# Tuning

Convolutional model ...

Power spectrum is  $W(f)\left[r_1^2 + r_2^2 + 2r_1r_2\cos(2\pi f\tau)\right]$ 

f: frequency W(f): spectrum of wavelet  $r_1$ ,  $r_2$ : reflection coefficients  $\tau$ : time separation of the reflections

Rayleigh: resolution of two point diffractors Widess: How thin is a thin bed?

Don't account for noise!

Can beat the Rayleigh criterion using super-resolution methods.

"Super-resolution requires super signal to noise ratios" (Roy White)

How many reflection coefficients? Where are they? How big is each one?

Formulate a simpler problem: one reflection coefficient or two?

Hypothesis test

 $H_0: x(t) = c h(t) * \delta(t) + w(t)$  $H_1: x(t) = a h(t) * \delta(t - d/2) + b h(t) * \delta(t + d/2) + w(t)$ 

h is the wavelet, a, b, c are reflection coefficients, d is the separation between them, w is zero-mean Gaussian noise. Assume data are sampled at  $\Delta t = 1/2B$ , then d = 1 is the Rayleigh limit and we are interested in d < 1.

Make a choice between the hypotheses by a generalised likelihood ratio test: choose  $H_1$  if

$$L_{G}(x) = \frac{p(x; \hat{a}, \hat{b}, \hat{d}, H_{1})}{p(x; \hat{c}, H_{0})} > \gamma$$

 $\gamma$  is determined from the acceptable probability of making an error by deciding H<sub>1</sub> when in fact H<sub>0</sub> is true.

Formulate a simpler problem: one reflection coefficient or two?

Hypothesis test

 $H_0: x(t) = c h(t) * \delta(t) + w(t)$  $H_1: x(t) = a h(t) * \delta(t - d/2) + b h(t) * \delta(t + d/2) + w(t)$ 

h is the wavelet, a, b, c are reflection coefficients, d is the separation between them, w is zero-mean Gaussian noise. Assume data are sampled at  $\Delta t = 1/2B$ , then d = 1 is the Rayleigh limit and we are interested in d < 1.

Make a choice between the hypotheses by a generalised likelihood ratio test: choose  $H_1$  if

$$L_{G}(x) = \frac{p(x; \hat{a}, \hat{b}, \hat{d}, H_{1})}{p(x; \hat{c}, H_{0})} > \gamma$$

 $\gamma$  is determined from the acceptable probability of making an error by deciding H<sub>1</sub> when in fact H<sub>0</sub> is true.

Based on Kay, Fundamentals of Statistical Signal Processing, Prentice Hall.

$$L_{G}(x) = \frac{p(x; \hat{a}, \hat{b}, \hat{d}, H_{1})}{p(x; \hat{c}, H_{0})} > \gamma$$

Assume Gaussian errors and take logarithms, rearrange and write in terms of vectors:

$$x^{T}(\hat{s}_{1} - \hat{s}_{0}) - \frac{1}{2} \|\hat{s}_{1}\|^{2} > \sigma^{2} \log \gamma - \frac{1}{2} \|\hat{s}_{0}\|^{2}$$

 $\hat{s}_k$  is the model of the data using maximum likelihood estimates of a,b,c,d under the appropriate hypothesis.

Note that all the dependence on d is in  $\hat{s}_1$ . At the limit of detection the two sides are equal:

$$f_1(\hat{a}, \hat{b}, \hat{c}, \hat{d}) = f_2(\hat{c}, \sigma^2, \gamma)$$

Can interpret this equation as giving a minimum detectable d for particular reflection coefficients & noise level, or a maximum noise level for a desired separation, or mimimum magnitude of resolvable reflection coefficients for given noise and separation ...

# Noise to signal ratio

#### Separation, d

a=1 in all curves.

The curves for any a,b pair lie inbetween b=1 and b=-1.

#### signal ratio $\frac{1}{\|\hat{s}_{1}\|^{2}} \left( x^{T} \left( \hat{s}_{1} - \hat{s}_{0} \right) - \frac{1}{2} \|\hat{s}_{1}\|^{2} + \frac{1}{2} \|\hat{s}_{0}\|^{2} \right) > \frac{\sigma^{2}}{\|\hat{s}_{1}\|^{2}} \log \gamma$ b=-1.0 0.50 b = -0.50.45 0.40 0.35 0.3 .3 0.30 Minimum acceptable 0.2 0.25 probability of type 1 error 0.20 0.1 0.1 0.15 0.0 10 0.10 2 10 0 Δ b = 1.00.05 logy 0.00 0.00 0.05 0.10 0.15 0.20 0.25 0.30 0.35 0.40 0.45 0.50 0.55 0.60 0.65 0.70 0.75 0.80 0.85 0.90 0.95 1.00

#### Separation, d

a=1 in all curves.

The curves for any a,b pair lie inbetween b=1 and b=-1.

Noise to

Minimum SNR (dB) required to resolve reflection coefficients for  $P(type \ 1 \ error) = 0.05$ 

Separation (d) in samples

a=1 in all curves.

Resolution depends on

- Bandwidth
- Signal to noise ratio
- Size of reflection coefficients
- Acceptable probability of error

The results are optimistic! They assume

- The wavelet is known
- We know that there are exactly one or two reflection coefficients within the time interval analysed

Blue curve: blocked logs, Black curve: initial model Red curve: Inversion result

# Can we obtain density?

NO (from linearised AVA analysis)

- 3 term fit is very unstable
- Very high correlation between density and Zp
- Can try rock physics constraints but they may not be valid globally

YES (from non-linear high-angle analysis)

Downton, Kabir, Skopintseva

• How to preprocess data near/beyond the critical angle?

# Initial models

Trying to fill the low frequency gap

Use smoothed well-logs and interpolate along horizons between wells.

Need a lot of QC: horizons, length of logged interval, interpolation methods.

Simple inverse distance-weighted interpolation along horizons Cokriging along horizons (seismic velocities or other attributes) Etc

Interpreters don't know the requirements for a good horizon!

- Don't need all the fine detail of the target (we will smooth the horizon anyway)
- Should cover the full inversion area if possible (regional horizons)
- Horizons which come too close together cause interpolation artefacts
- Cycle skips can introduce false "faults" in the inversion results (but real faults should be preserved)
- Auto-track busts in bad data areas have to be fixed. These are often found towards the edges of the inversion area away from the prospect, so the interpreter didn't notice or didn't care.
- We do best with 4 6 horizons surrounding the zone of interest, hopefully none too close to it.

Errors in background models often go un-noticed until after the inversion is run. Gott PC tools are essential!

#### Crossplot warping due to background model

shale sand

 1
 2
 3
 4
 5

 1
 2
 3
 4
 5

Smooth background model

Smoothly perturbed background model

Spatial Smoothness and Geological Consistency

No spatial constraints: smoothness comes from background model

What happens if some region has prior probabilities 50% shale, 50% sand? Most likely lithology in neighbouring voxels could switch between sand & shale if there is overlap in **Couseplates Mark** ov random field term. Neighbouring voxels are more likely to be similar lithology. Can make it dip-steered, and respect faults. Could make it a post-processing step after PCUBE or include in inversion.

Markov random field: P(sand) in the middle voxel depends on the PCUBE results (data) and the classification of neighbouring voxels (MRF). Use Bayes theorem to update classification. MCMC, simulated annealing, or other algorithms can be used:

other algorithms can be used: expensive!

Can here to resolve areas where classes overlap in crossplot
