Uncertainty in reservoir evaluation (URE) project

Project initiated and led by Henning Omre, Dept of Math Sciences, NTNU, since 1992. Currently Håkon Tjelmeland, Henning Omre and Jo Eidsvik.

Working with Per Avseth, Børge Arntsen, Bjørn Ursin, Martin Landrø, ++. And with partners (currently 7 companies).

Vision: Provide creative mathematically-based solutions to recognized challenges in reservoir evaluation. Develop methodologies for analysis of spatio-temporal phenomena.

URE project

- Spatio-temporal statistics. Computational statistics.
- Use geophysics and geology to contrain models.
- Lithology and fluid prediction. AVO inversion. History matching.

Propagating Wavefield

Michael's PhD goal: *Prediction of elastic properties from seismic* (waveform) data, with uncertainties. (new ground for URE)

Statistical model formulation

Velocity \boldsymbol{m} with prior $p(\boldsymbol{m})$, usually Gaussian process in (lateral, depth) coordinates.

Seismic data **d**. Likelihood

$$\boldsymbol{d}(\boldsymbol{x}_r,t) = \boldsymbol{g}(\boldsymbol{x}_r,t;\boldsymbol{m},\boldsymbol{\theta}) + \boldsymbol{e}$$

with forward model $g(\cdot)$ and errors $\boldsymbol{e} \sim \text{Normal}(0, \boldsymbol{\Sigma}_{\boldsymbol{e}})$.

Bayes' rule:

 $p(\boldsymbol{m}|\boldsymbol{d}) \propto p(\boldsymbol{d}|\boldsymbol{m})p(\boldsymbol{m})$

・ロト ・ 日 ・ ・ 日 ・ ・ 日 ・ ・ つ へ ()

Approximate solution

Bayes' rule:

 $p(\boldsymbol{m}|\boldsymbol{d}) \propto p(\boldsymbol{d}|\boldsymbol{m})p(\boldsymbol{m})$

Optimize objective function

 $\boldsymbol{O}(\boldsymbol{m}) = (\boldsymbol{m} - \boldsymbol{\mu})^{t} \boldsymbol{\Sigma}^{-1} (\boldsymbol{m} - \boldsymbol{\mu}) + (\boldsymbol{d} - g(\boldsymbol{x}_{r}, t; \boldsymbol{m}, \theta))^{t} \boldsymbol{\Sigma}_{\boldsymbol{e}}^{-1} (\boldsymbol{d} - g(\boldsymbol{x}_{r}, t; \boldsymbol{m}, \theta))$

Prediction:

$$\hat{m} = \operatorname{argmax} \left[O(oldsymbol{m})
ight]$$

Uncertainty from Hessian:

$$\hat{\mathsf{Var}}(\boldsymbol{m}|\boldsymbol{d}) = \left[-\frac{d^2 O(\boldsymbol{m})}{d \boldsymbol{m}^2}\right]^{-1}$$

・ロト ・ 日 ・ エ ヨ ・ ト ・ 日 ・ うらつ

Assumption - Gaussian approximation at mode. Derivatives available.

Sequential formulation

Partitioning the entire data record d into N_c sets

$$p(\boldsymbol{m}|\boldsymbol{d}) \propto p(\boldsymbol{d}|\boldsymbol{m})p(\boldsymbol{m})$$

= $p(\boldsymbol{m})\prod_{i=1}^{N_c} p(\boldsymbol{d}_i|\boldsymbol{d}_{1:i-1}, \boldsymbol{m})$

Sequential model updating (in offset, time and/or frequency).

$$p(\boldsymbol{m}) \rightarrow p(\boldsymbol{m}|\boldsymbol{d}_1) \rightarrow p(\boldsymbol{m}|\boldsymbol{d}_1, \boldsymbol{d}_2) \rightarrow p(\boldsymbol{m}|\boldsymbol{d}_1, \boldsymbol{d}_2, \boldsymbol{d}_3)$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Possibly a robust path to solution.

Kalman-like sequential updating

Linear state-space model, initialised with μ_0 and P_0 :

dynamics: $\boldsymbol{m}_t = \boldsymbol{m}_{t-1}$, observation: $\boldsymbol{d}_t = \boldsymbol{H}_t \boldsymbol{m}_t + \boldsymbol{e}_t, \ \boldsymbol{e}_t \sim \text{Normal}(\boldsymbol{0}, \boldsymbol{R})$

Forecast step for mean and variance:

$$oldsymbol{\mu}_t = oldsymbol{\mu}_{t-1} \ oldsymbol{P}_t = oldsymbol{P}_{t-1}$$

Analysis step for mean and variance:

$$\mu_t = \mu_t + K_t (\mathbf{y}_t - H_t \mu_t)$$
$$\boldsymbol{P}_t = (\boldsymbol{I} - K_t H_t) \boldsymbol{P}_t$$

Kalman gain:

$$\boldsymbol{K}_{t} = \boldsymbol{P}_{t} \boldsymbol{H}_{t}^{T} \left(\boldsymbol{H}_{t} \boldsymbol{P}_{t} \boldsymbol{H}_{t}^{T} + \boldsymbol{R} \right)^{-1}$$

Ensemble based approximation

Prior (and posterior) represented by an ensemble of realisations

$$egin{split} \left\{m{m}^f
ight\}_{i=1}^{N_e} &\sim p(m{m}) \ \left\{m{m}^a
ight\}_{i=1}^{N_e} &\sim p(m{m}|m{d}) \end{split}$$

(ロ) (同) (E) (E) (E) (O)()

• Generally $N_e \ll N_m$ and/or $N_e \ll N_d$.

- ► High dimensional parameter- and data-space. Not many sampling based methods are suitable → choice of Ensemble Kalman Filter.
- Can handle (some degree of) nonlinearity.

Approach for parameter estimation with EnKF

Assimilation cycle update equation:

$$oldsymbol{m}_i^{oldsymbol{a}} = oldsymbol{m}_i^f + \hat{oldsymbol{K}} \left(oldsymbol{d} - oldsymbol{d}_i^f
ight)$$
 with
 $oldsymbol{d}_i^f = oldsymbol{g}(oldsymbol{m}_i^f) + oldsymbol{e}_i, \quad oldsymbol{e}_i \sim ext{Normal}(oldsymbol{0}, oldsymbol{\Sigma}_{oldsymbol{e}}), \ i = 1, \dots, N_e$

with g(·) now defining forward evaluation and partitioning of data.
Estimating Kalman gain matrix K from forecast models and data:

$$\hat{\boldsymbol{K}} = \hat{\boldsymbol{\Sigma}}_{\boldsymbol{m},\boldsymbol{d}} \hat{\boldsymbol{\Sigma}}_{\boldsymbol{d}}^{-1}$$

 Linear correlations can identify (most influential) subset of parameters.

Univariate example - forecast samples

$$m_i \sim p(m), \quad d_i = m_i + N(0, 5^2)$$

Properties and challenges

- Forward model evaluation is costly. And data is non-linear function of parameters.
- Seismograms are non-stationary time series.
- Multicollinearity in data.
- \blacktriangleright Combination of large data space and small ensemble space \rightarrow ensemble collapse.

・ロト ・ 日 ・ ・ 日 ・ ・ 日 ・ ・ つ へ ()

Observations are non-local.

- Project with data from BP.
- \blacktriangleright 1D (layered subsurface) assumptions \rightarrow simpler and faster model.
- Forward model can be implemented in various ways, but here using Erzsol3, an old open source F77 code.

・ロト ・ 日 ・ ・ 日 ・ ・ 日 ・ ・ つ へ ()

Data

- True model based on well log data.
- Observations (synthetic) are CMP gather.
- Data partitioning, blocks of offset-time intervals.

Propagating Wavefield

Summary

- Uncertainty quantification in seismic inversion. Very costly forward model, approximate prediction and uncertainties via ensembles, with useful properties.
- Synthetic models and CMP data showing good results.
- Data partitioning approach required to reduce data size and avoid collapse. Now studying different blocking schemes in time, offset and frequency.
- Standard techniques like localization for Ensemble Kalman filter are difficult for seismic data.
