<b>2</b>	<b>Data File Overview .....</b>	<b>24</b>
	<b>Data file structure .....</b>	<b>26</b>
	Keyword data .....	26
	Comments .....	27
	<b>Global keywords .....</b>	<b>27</b>
	<b>ECLIPSE 300 error handling .....</b>	<b>29</b>
	<b>Example data file .....</b>	<b>30</b>
	<b>RUNSPEC section .....</b>	<b>31</b>
	Alphabetic list of RUNSPEC keywords .....	32
	<b>GRID section .....</b>	<b>38</b>
	Rock permeability values .....	41
	Transmissibility multipliers .....	42
	Diffusivity multipliers .....	42
	BOX and ENDBOX keywords .....	42
	Non-neighbor connections (NNCs) .....	43
	Output control .....	44
	Local grid refinement .....	45
	Description of GRID section keywords .....	45
	Transmissibility keywords .....	47
	Transmissibility modifiers .....	48
	Faults .....	48
	Numerical aquifers .....	49
	Dual porosity .....	49

Compressed vertical equilibrium (ECLIPSE 100) .....	50
Diffusivity modifiers .....	50
Independent reservoir regions (ECLIPSE 100) .....	51
Temperature option (ECLIPSE 100) .....	51
Nine-point scheme (ECLIPSE 300) .....	52
Operational keywords .....	52
Local grid refinement .....	53
Tensor permeability .....	54
Geomechanics (ECLIPSE 300) .....	55
Alphabetical list of GRID section keywords .....	55
Example data set .....	62
<b>EDIT section .....</b>	<b>63</b>
Changing cell depths .....	64
Changing pore volumes .....	64
Changing transmissibilities .....	64
Changing diffusivities .....	64
Modifying non-neighbor connections .....	64
Output control .....	65
Alphabetical list of EDIT section keywords .....	65
<b>PROPS section .....</b>	<b>68</b>
Saturation functions .....	69
<i>Two dimensional models for saturation functions (for three phase simulations) .....</i>	<i>70</i>
<i>Stability issues .....</i>	<i>71</i>
Hysteresis .....	72
End point scaling .....	72
Pressure tables .....	72
Rock pressure tables .....	73
Water pressure tables .....	73
Surface densities .....	74
Oil and gas pressure tables (black oil) .....	74
Essential keywords - black oil case .....	74
Standard conditions (ECLIPSE 300) .....	76
Compositional Equation of State data (ECLIPSE 300) .....	76
K-value tables (ECLIPSE 300) .....	77
Diffusion coefficients .....	79
Composition with respect to pressure tables (ECLIPSE 300) .....	79
PROPS section keywords .....	79
<i>Alkaline option .....</i>	<i>79</i>
<i>API tracking (ECLIPSE 100) .....</i>	<i>80</i>
<i>Black Oil fluid PVT property data .....</i>	<i>80</i>
<i>Brine option .....</i>	<i>81</i>
<i>Carbon Dioxide solution in aqueous phase (ECLIPSE 300) .....</i>	<i>81</i>
<i>Carter-Tracy aquifer data .....</i>	<i>82</i>
<i>Chemical reaction keywords (ECLIPSE 300) .....</i>	<i>82</i>
<i>Coal bed methane (ECLIPSE 100) .....</i>	<i>82</i>

Coal bed methane (ECLIPSE 300) .....	83
Compositional EoS and PVT property data (ECLIPSE 300) .....	83
Dual porosity (ECLIPSE 100) .....	85
End point scaling .....	86
Environmental tracers (ECLIPSE 100) .....	88
Foam Model .....	89
GASWAT option (ECLIPSE 300) .....	89
Geomechanics (ECLIPSE 300) .....	90
GI pseudo-compositional model (ECLIPSE 100) .....	90
Gradient option (ECLIPSE 100 special option) .....	90
Initial composition (ECLIPSE 300) .....	91
K Values (ECLIPSE 300) .....	91
Low-Salinity option (ECLIPSE 100) .....	91
Miscible flood option (ECLIPSE 100) .....	91
Molecular diffusion option .....	92
NGLs (ECLIPSE 300) .....	93
Non-Darcy Flow (ECLIPSE 300) .....	93
Output .....	93
Polymer Flood Model .....	93
Relative permeability and capillary pressure data .....	94
Rivers (ECLIPSE 100) .....	97
Rock compressibility and compaction data .....	97
Solid option (ECLIPSE 300) .....	99
Solvent Model (ECLIPSE 100) .....	99
Surface tension effects (ECLIPSE 300) .....	100
Surfactant option .....	100
Temperature option .....	101
Thermal option (ECLIPSE 300) .....	101
Tracer tracking .....	103
Vertical equilibrium (ECLIPSE 100) .....	104
Water component option (ECLIPSE 300) .....	104
ODD3P three-phase relative permeability and capillary pressure hysteresis option (ECLIPSE 300) .....	105
Operational keywords .....	105
Alphabetic list of keywords .....	106
<b>REGIONS section .....</b>	<b>121</b>
REGIONS section keywords .....	121
Output .....	122
Commonly used keywords .....	122
Directional relative permeability .....	122
Dual porosity option (ECLIPSE 100 only) .....	122
Geomechanics option (ECLIPSE 300) .....	122
Hysteresis option (excluding ODD3P) .....	122
WAG hysteresis option .....	123
Other options .....	123

<i>ODD3P three-phase relative permeability and capillary pressure hysteresis option (ECLIPSE 300)</i> .....	124
<i>Operational</i> .....	124
Alphabetical list of keywords .....	125
<b>SOLUTION section</b> .....	<b>128</b>
Equilibration - the EQUIL keyword .....	129
Enumeration .....	129
Thermal enumeration with the NEI keyword .....	130
Flexible restarts .....	130
Initial state output .....	130
Analytic aquifers .....	131
Tracers, brine and API tracking .....	131
Miscellaneous options .....	132
Initial fluid in place .....	132
SOLUTION section keywords .....	132
<i>Output</i> .....	132
<i>Equilibration</i> .....	133
<i>Restarting</i> .....	134
<i>Enumeration</i> .....	134
<i>Aquifer data</i> .....	135
<i>Temperature option (ECLIPSE 100)</i> .....	136
<i>Other options</i> .....	136
<i>Operational keywords</i> .....	137
Dynamic Regions Facility .....	138
Rivers (ECLIPSE 100) .....	138
Tuning (ECLIPSE 300) .....	138
ODD3P option (ECLIPSE 300) .....	138
Alphabetic list of keywords .....	138
<b>SUMMARY section</b> .....	<b>142</b>
Keyword data format .....	142
<i>Format of SUMMARY keywords beginning with A</i> .....	143
<i>Format of SUMMARY keywords beginning with B</i> .....	143
<i>Format of SUMMARY keywords beginning with C</i> .....	144
<i>Format of SUMMARY keywords beginning with F</i> .....	145
<i>Format of SUMMARY keywords beginning with G</i> .....	145
<i>Format of SUMMARY keywords beginning with LB</i> .....	146
<i>Format of SUMMARY keywords beginning with LC</i> .....	146
<i>Format of SUMMARY keywords beginning with LW</i> .....	147
<i>Format of SUMMARY keywords beginning with R</i> .....	147
<i>Format of SUMMARY keywords beginning with S</i> .....	149
<i>Format of SUMMARY keywords beginning with W</i> .....	150
<i>Format of SUMMARY keywords that end in H</i> .....	150
<i>Format of SUMMARY keywords with a component index</i> .....	150
<i>Keywords for special options</i> .....	152
<i>Maximum number of keywords</i> .....	152

<i>Example SUMMARY section</i> .....	152
<i>Summary file names</i> .....	153
Well and group flow quantities .....	153
<i>Miscellaneous well and group quantities</i> .....	170
<i>Secondary group and well quantities (ECLIPSE 300)</i> .....	176
<i>Well list quantities</i> .....	177
Grid block and region quantities .....	178
<i>Equivalent directional keywords for relative permeabilities (ECLIPSE 100)</i> .....	189
Processed scaled end-points .....	190
Reservoir volumes .....	191
Oil recovery efficiencies .....	192
Oil recovery mechanism .....	192
Recovery plant options (ECLIPSE 300 only) .....	193
Analytic aquifer quantities .....	193
Numerical aquifer quantities .....	194
Tracer and API tracking quantities .....	194
Brine option quantities .....	195
Temperature option quantities .....	197
Environmental tracers .....	197
Coal Bed Methane Model (ECLIPSE 100) .....	199
Foam Model .....	199
Gas Field Operations Model .....	200
<i>Simulator performance keyword</i> .....	201
Gas lift optimization facility .....	201
Gas calorific value control option .....	202
Gi pseudo-compositional model .....	202
Local grid refinement and coarsening .....	203
<i>Operational keywords</i> .....	203
<i>Plotting local timestep results in GRAF</i> .....	203
Multisegment wells .....	204
Rivers .....	206
Network option .....	208
Polymer Flood Model .....	209
Pseudo Steady-State (ECLIPSE 100 only) .....	212
Reservoir coupling facility (ECLIPSE 100 only) .....	213
Solvent Model .....	213
Surfactant Model .....	214
Alkaline model .....	215
Wellbore friction model .....	215
Conductive Faults .....	216
User defined quantities .....	216
ODD3P three-phase relative permeability and capillary pressure hysteresis model ...	216
Asphaltene model .....	219
Simulator performance keywords .....	219
Other keywords .....	223

Deprecated keywords .....	224
Deleted keywords .....	225
<b>SCHEDULE section .....</b>	<b>226</b>
Define wells, groups and well connections .....	227
<i>Define well connections and set connection properties</i> .....	228
<i>Define multisegment wells</i> .....	229
<i>Define separators (ECLIPSE 300)</i> .....	231
Well controls and limits .....	231
<i>Production well control data</i> .....	232
<i>Injection well control data</i> .....	232
<i>Vertical flow performance keywords</i> .....	234
<i>Well economic limits and coning control</i> .....	235
Group controls and limits .....	235
<i>Group production control by guide rate</i> .....	235
<i>Group production control by prioritization</i> .....	236
<i>Group economic limits and coning control</i> .....	236
<i>Group injection control</i> .....	236
<i>Group efficiency factor</i> .....	237
<i>Sales gas control (ECLIPSE 100)</i> .....	237
<i>Satellite group flows</i> .....	238
<i>Sustainable capacity test</i> .....	238
Automatic drilling and workover controls .....	238
Action keyword facility .....	239
Periodic testing and cycling wells .....	239
<i>Artificial lift operations (ECLIPSE 100)</i> .....	239
Scale deposition model .....	240
Flash transformation and separator conditions .....	240
Gas processing (ECLIPSE 300) .....	241
Aquifer controls .....	241
Dissolved gas and vaporized oil constraints (ECLIPSE 100) .....	242
Geomechanics option (ECLIPSE 300) .....	242
Grid block property modifications .....	242
Dynamic Regions Facility .....	243
Dual porosity .....	243
Lagrangian Tracer Solver (ECLIPSE 300) .....	244
Simulator controls .....	244
<i>User defined values</i> .....	245
Output .....	245
Conductive Fractures (ECLIPSE 300) .....	246
Adjoint gradient screening option (ECLIPSE 300) .....	246
Advance simulation to new time/date .....	246
Instantaneous gradient option .....	247
Polymer flood model .....	247
<b>OPTIMIZE section .....</b>	<b>247</b>
OPTIMIZE section keywords .....	248

# 1

## New Developments

---

The 2014.1 release of the ECLIPSE suite includes some major developments enhancing the functionality, usability and performance capabilities of the simulators. We have focused on additions to chemical EOR, consistency and robustness of our relative permeability hysteresis models in addition to general client requests. The release also includes performance improvements with a new solver in both the ECLIPSE 100 and ECLIPSE 300 simulators. Licensing has also been significantly simplified, many options now being included into the standard eclipse license, allowing for more ready accessibility to simulator functions. The addition of a new parallel option specifically designed for workstation use is also offered as an alternative to the fully feature parallel/MR feature.

- The changes made to licensing in this release are described.
- The new facilities which have been added to the simulators for this release are described for [ECLIPSE 100](#) and [ECLIPSE 300](#).
- Behavioral changes, which may change the results of a simulation, or alter the form or content of the output, have been made for [ECLIPSE 100](#) and [ECLIPSE 300](#).
- The new keywords added in this release are described for [ECLIPSE 100](#) and [ECLIPSE 300](#).
- Some keywords have been altered in this release and these changes are described for [ECLIPSE 100](#) and [ECLIPSE 300](#).

### Licensing changes

There have been significant changes to licensing in this release.

#### ECLIPSE 100 licensing changes

- An alternative license option for parallel simulation has been introduced called the "block parallel" license. This option allows access to the [PARALLEL](#) option at a level suitable for current desktop machines without having to invest in the fully flexible parallel licenses. The [BPARA](#) keyword has been added to request that a block parallel license is used rather than standard parallel licenses. A simulation can be run with up to eight parallel domains using a single block parallel license. Block parallel licenses may not be "stacked" to run more than eight parallel domains.
- From 2014.1 the following licenses are no longer required or checked out. Functionality previously covered by these licenses is now available as part of the base license.

- Coal Bed Methane Model
- Environmental Tracers
- Flux Boundary Conditions
- Foam Model
- Gas Calorific Value Control
- Polymer Flood Model
- Gi Pseudo-Compositional Model
- Solvent Model
- Surfactant Model

## ECLIPSE 300 licensing changes

- An alternative license option for parallel simulation has been introduced called the "block parallel" license. This option allows access to the [PARALLEL](#) option at a level suitable for current desktop machines without having to invest in the fully flexible parallel licenses. The [BPARA](#) keyword has been added to request that a block parallel license is used rather than standard parallel licenses. A simulation can be run with up to eight parallel domains using a single block parallel license. Block parallel licenses may not be "stacked" to run more than eight parallel domains.
- From 2014.1 the following licenses are no longer required or checked out. Functionality previously covered by these licenses is now available as part of the base license.
  - CO<sub>2</sub> Storage
  - Coal Bed Methane Model
  - Flux Boundary Conditions

## New facilities

### ECLIPSE 100

The new facilities in ECLIPSE 100 are described in the following sections:

- [RUNSPEC section](#)
- [GRID section](#)
- [PROPS section](#)
- [REGIONS section](#)
- [SUMMARY section](#)

### RUNSPEC section

- The [CPR](#) keyword has been added to activate the CPR linear solver, which employs the Constrained Pressure Residual method to solve the linear equations. This can often be useful for more difficult problems, when the standard ORTHOMIN linear solver takes a large number of linear iterations to converge.

- The `MESSAGES` keyword now has a 13<sup>th</sup> item which controls the maximum number of times some messages are output to the PRT file.

## GRID section

- The `MINNNCT` keyword has been extended to allow the user to specify a minimum diffusivity and thermal transmissibility for a non-neighbor connection as well as (or instead of) a minimum transmissibility.

Additionally, the logic has been improved so that values below the threshold are not preserved just because the NNC is preserved for other reasons.

- The `ROCKFRAC` keyword, previously supported in ECLIPSE 300 only, has been added to ECLIPSE 100 to simplify the input of cell volume fractions representing rock in Coal Bed Methane or Shale Gas model runs.
- `Item 215` of the `OPTIONS` keyword can now be used to replace unset enumerated values with the value from an adjacent cell. This can be useful in coarsened models where a representative cell is inactive in the original model.

## PROPS section

- The keywords `SURFSTES` and `ESSNODE` are added to activate the salinity dependent Surfactant model which allows the water-oil surface tension to vary with salinity as well as surfactant concentration. These tables can be output to the PRINT file with `RPTPROPS` argument `SURF`.
- The keyword `LANGMPL` can be used to scale the pressure used to calculate the adsorption capacities for a Coal Bed Methane Model.
- The keyword `EHYSTR` now has a 13<sup>th</sup> item. If set to 1, a modification of the Killough method for the calculation of the hysteresis scanning curve on the wetting phase relative permeability is activated. This modification will, in general, ensure that the scanning curve remains within the region enclosed by the drainage and imbibition bounding curves. This correction is only applicable to the Killough wetting phase relative permeability hysteresis model, in both water-wet and oil-wet systems; if specified with other hysteresis models, it will be ignored.
- The end-point scaling keywords `LSWL`, `LSWLPC`, `LSWCR`, `LSWU`, `LSOWCR`, `LSOGCR`, `LKRW`, `LKRWR`, `LKRO`, `LKRORW`, `LKRORG` and `LPCW` have been added to permit scaling of the low salinity (oil-wet) water and oil saturation table end-points when the `LOWSALT` and `ENDSCALE` options have been specified.
- The end-point scaling keywords `HWSWL`, `HWSWLPC`, `HWSWCR`, `HWSWU`, `HWSOWCR`, `HWSOGCR`, `HWKRW`, `HWKRWR`, `HWKRO`, `HWKRORW`, `HWKRORG` and `HWPCW` have been added to permit scaling of the surfactant (high salinity) water-wet water and oil saturation table end-points when the `SURFACTW` and `ENDSCALE` options have been specified.
- The end-point scaling keywords `LWSWL`, `LWSWLPC`, `LWSWCR`, `LWSWU`, `LWSOWCR`, `LWSOGCR`, `LWKRW`, `LWKRWR`, `LWKRO`, `LWKRORW`, `LWKRORG` and `LWPCW` have been added to permit scaling of the low salinity water-wet water and oil saturation table end-points when the `LOWSALT`, `SURFACTW` and `ENDSCALE` options have been specified.
- The polymer keyword `PLYATEMP` has been added to control temperature dependence of the polymer adsorption tables (keywords `PLYADS` or `PLYADSS`) in the `PROPS` section).

## REGIONS section

- The saturation region keywords [LSNUM](#), [HWSNUM](#) and [LWSNUM](#) have been introduced as aliases to the existing keywords [LWSLTNUM](#), [SURFNUM](#) and [LWLTNUM](#) respectively to provide a more evident association between the saturation region and the end-point scaling array keyword for models utilizing the [ENDSCALE](#), [LOWSALT](#) and [SURFACTW](#) options.

## SUMMARY section

- The SUMMARY section keyword [BTSTSUR](#) that returns the water-oil surface tension that depends on surfactant concentration (when [SURFST](#) is used) can now also be used to output values of water-oil surface tension that depends on surfactant and salt concentrations (when [SURFSTES](#) and [ESSNODE](#) are used).
- The SUMMARY section keywords [BFLOW0I](#), [BFLOW0J](#), [BFLOW0K](#), [BPSHLZI](#), [BPSHLZJ](#), [BPSHLZK](#), [BSHWVISI](#), [BSHWVISJ](#), [BSHWVISK](#), [BVELW0I](#), [BVELW0J](#) and [BVELW0K](#) may now be used in conjunction with the [PLYSHEAR](#) option. These mnemonics were previously compatible only with the [PLYSHLOG](#) option.
- The SUMMARY section keywords [MLINEARP](#), [MSUMLINP](#), [NCPRLINS](#) and [NLINEARP](#) have been added to output performance data for the pressure solve, when using the [CPR](#) linear solver.
- The SUMMARY section keywords [WPIO](#), [WPIG](#), [WPIW](#) and [WPIL](#) have been added to output the well productivity index for the oil, gas, water and liquid phases respectively.
- The SUMMARY section keyword [CPRL](#) has been added to output the average connection pressure for lumped completions.
- The SUMMARY section keywords [SSFRR](#) and [SSCN](#) are now also valid for the salinity dependent surfactant model.
- The SUMMARY keywords [BSRTW0I](#), [BSRTW0J](#), [BSRTW0K](#), [BSRTWI](#), [BSRTWJ](#) and [BSRTWK](#) now display the water shear rates prior to and following shear effects in the relevant direction, for models that combine the brine option with the polymer shear option activated using the [PLYSHLOG](#) and [SHRATE](#) keywords.

## SCHEDULE section

- The keyword [CSKIN](#) has been added to allow connection skin factors to be updated using a user-defined argument.

## ECLIPSE 300

The new facilities in ECLIPSE 300 are described in the following sections:

- [RUNSPEC](#) section
- [GRID](#) section
- [PROPS](#) section
- [SOLUTION](#) section
- [SUMMARY](#) section
- [SCHEDULE](#) section

## RUNSPEC section

- The [WAGHALT](#) keyword has been provided to select an alternative WAG hysteresis model which conforms more closely with the ECLIPSE 100 WAG hysteresis model both in terms of the saturation direction change transitions and in the application of conventional hysteresis to those phases not subject to WAG hysteresis.
- The [CPR](#) keyword has been added to activate the CPR linear solver, which employs the Constrained Pressure Residual method to solve the linear equations. This can often be useful for more difficult problems, when the standard WARP linear solver takes a large number of linear iterations to converge.

## GRID section

- The [MINNNCT](#) keyword has been extended to allow the user to specify a minimum diffusivity and thermal transmissibility for a non-neighbor connection as well as (or instead of) a minimum transmissibility.

Additionally, the logic has been improved so that values below the threshold are not preserved just because the NNC is preserved for other reasons.

## PROPS section

- A polymer model, similar to the ECLIPSE 100 Polymer Flood option, can now be used in ECLIPSE 300. The new model is described in the "[Polymer Flood Model](#)" in the *ECLIPSE Technical Description*. The model is activated when at least one water component is identified as a polymer using the [CWTYPE](#) keyword.
- Item 4 of keyword [REACOPS](#) has been added to allow the user to specify a scaling factor controlling the reaction rate of zero-order reactants in equilibrium deviation reactions (see [EQLDREAC](#) keyword).
- A salinity dependent Surfactant model can be activated using keywords [SURFSTES](#) and [ESSNODE](#) to allow the water-oil surface tension to vary with salinity as well as surfactant concentration. The [SURFSTES](#) tables can be output to the PRINT file with [RPTPROPS](#) argument [SURFSTES](#).
- The effective salinity calculation model required for the salinity dependent Surfactant and Polymer models, is activated using keyword [SALTEFF](#). The salinity nodes can be input with the keywords [ESSNODE](#) and [ESPNOE](#), respectively. The [ESSNODE](#) and [ESPNOE](#) tables can be output to the PRINT file with [RPTPROPS](#) arguments [ESSNODE](#) and [ESPNOE](#).
- The Alkaline model can now be activated with the Surfactant model by setting at least one water component as an alkaline with the [CWTYPE](#) keyword and using keyword [ALSURFST](#). The [ALSURFST](#) table can be output to the PRINT file with [RPTPROPS](#) argument [ALSURFST](#).
- The keyword [LANGMPL](#) can be used to scale the pressure used to calculate the adsorption capacities for a Coal Bed Methane or Shale Gas model.
- The keyword [EHYSTR](#) has now a 13<sup>th</sup> item. If set to 1, a modification of Killough method for the calculation of the hysteresis scanning curve on the wetting phase relative permeability is activated. This modification will, in general, ensure that the scanning curve remains within the region enclosed by the drainage and imbibition bounding curves. This correction is only applicable to the Killough wetting phase relative permeability hysteresis model, in both water-wet and oil-wet systems; if specified with other hysteresis models, it will be ignored.
- The keywords [PLYVISC](#) and [PLYVISCS](#) may be used to specify the polymer viscosity multiplier functions. These tables can be output to the PRINT file with [RPTPROPS](#) arguments [PLYVISC](#) and [PLYVISCS](#), respectively.

- The keyword `PLYOPTS` may be used to set optional parameters for the "Polymer Flood Model" in the *ECLIPSE Technical Description*.

## SOLUTION section

- The arguments `POLY` and `POLYVM` have been added to keywords `RPTSOL` and `RPTRST` to output polymer concentration and polymer viscosity multiplier in polymer flood studies, respectively.
- The arguments `ESALTP` and `ESALTS` have been added to keywords `RPTSOL` and `RPTRST` to output effective salinity values calculated using inputs to keyword `SALTEFF` in polymer and surfactant flood studies, respectively.

## SUMMARY section

- `BSURFST` and `BSURFCP` may now also be used to output water-oil surface tension and capillary pressure respectively as functions of surfactant concentration and effective salinity of the water phase when the salinity dependent Surfactant model is activated by keywords `SURFSTES` and `ESSNODE`.
- `BPOLY` and `BPOLYVM` may be used to output the block values of polymer concentration and polymer viscosity multiplier respectively when the Polymer Flood Model is active. See the "Polymer Flood Model" in the *ECLIPSE Technical Description*.
- `BESALTP` and `BESALTS` may be used to output the block values of effective salinity calculated as defined with keyword `SALTEFF` if item 1 is set to `POLY` or `SURF`, respectively.
- `BALSURF` and `BALSTML` may now be used to output alkaline concentration and alkaline surface tension multiplier determined from data provided in `ALSURFST`.
- The SUMMARY section keywords `WPIL` has been added to output the well productivity index for the liquid phase.
- The SUMMARY section keyword `CPRL` has been added to output the average connection pressure for lumped completions.
- The SUMMARY section keywords `MLINEARP`, `MSUMLINP`, `NCPRLINS` and `NLINEARP` have been added to output performance data for the pressure solve, when using the `CPR` linear solver.

## SCHEDULE section

- The keywords `PLYVISC` and `PLYVISCS` may be used to update the polymer viscosity multipliers previously specified in the `PROPS` section.
- The keyword `CSKIN` has been added to allow connection skin factors to be updated using a user-defined argument.
- The arguments `POLY` and `POLYVM` have been added to keywords `RPTSCHED` and `RPTRST` to output polymer concentration and polymer viscosity multiplier in polymer flood studies, respectively.
- The arguments `ESALTP` and `ESALTS` have been added to keywords `RPTSCHED` and `RPTRST` to output effective salinity values calculated using inputs to keyword `SALTEFF` in polymer and surfactant flood studies, respectively.

## Behavioral changes

### ECLIPSE 100

The behavioral changes in ECLIPSE 100 are described in the following sections:

- [RUNSPEC section](#)
- [GRID section](#)
- [EDIT section](#)
- [PROPS section](#)
- [REGIONS section](#)
- [SOLUTION section](#)
- [SCHEDULE section](#)

### RUNSPEC section

- When using the [SURFACT](#) and [DUALPORO](#) models together, a contribution to the capillary number is now made for the matrix-fracture connection. The behavior can be reverted by setting [item 211](#) of the `OPTIONS` keyword to 1.
- When using the `SURFACT` or [LOWSALT](#) models with `GRAVDR`, the calculation for component cell heights now uses end-points interpolated from the relevant saturation tables. The behavior can be reverted by setting [item 214](#) of the `OPTIONS` keyword to 1.
- The `GRIDOPTS` can now only be specified once.

Pre-2014.1 behavior can be restored by setting [item 223](#) of the `OPTIONS` keyword to 1.

- When the `PARALLEL` option is in use, messages output to the PRT files from the slave processors will be copied to the master PRT file. The pre-2014.1 behavior can be restored by setting [item 219](#) of the `OPTIONS` keyword to 1.
- `Item 13` has been added to the `MESSAGES` keyword to set the print limit for some frequently repeated output messages. This limit is set to 10 by default but can be ignored by setting [item 220](#) of the `OPTIONS` keyword to 1.

### GRID section

- Values set in a work array by the `OPERATE` or `OPERATER` keyword are now preserved to the end of the `GRID` section, or until a keyword is encountered which defines or switches to a different grid (such as `CARFIN`). Prior to 2014.1, values were reset to zero by each invocation of the keyword.
- The logic used to determine how a non-neighbor connection with very small transmissibility should be treated has been improved and standardized across NNC types. The new behavior is described in more detail in the `MINNNCT` keyword, which can be used to customize the minimum values.

This may lead to slight differences in exactly how the number of non-neighbor connections is reported in the PRT file, with more connections created initially and then those which are too small for the new standard test being discarded.

Pre-2014.1 behavior can be restored by setting [item 221](#) of the `OPTIONS` keyword to 1.

- Field units of volumes COALV and PORVF (Coal Bed Methane option) output to the INIT file via [RPTINIT](#) arguments with the same names have been changed from FT3 to RB in order to unify their output with ECLIPSE 300 and postprocessors. For the same reason, COALV and PORVF values previously output as undefined are now reported as zero. These changes do not affect output to the PRT file (keywords [RPTGRID](#) and [RPTGRIDL](#)) which remains as in the previous releases. In addition to these changes, it is now possible to output COALV and PORVF to the INIT file for LGRs in parallel runs.
- The Flux Boundary Conditions option (keyword [USEFLUX](#)) can no longer be used in decks containing [POLYMER](#), [BRINE](#), [SURFACTANT](#), [ALKALINE](#), [SOLVENT](#) or [TRACER](#).

Pre-2014.1 behavior can be restored by setting [item 232](#) of the [OPTIONS](#) keyword to 1.

- The corner point geometry neighbor transmissibility calculations have been enhanced to ensure that cells which do not physically touch can never have a non-zero neighbor transmissibility between them. Pre-2014.1 behavior can be restored by setting [item 236](#) of the [OPTIONS](#) keyword to 1.

## EDIT section

- Values set in a work array by the [OPERATE](#) or [OPERATER](#) keyword are now preserved to the end of the EDIT section, or until a keyword is encountered which defines or switches to a different grid (such as [REFINE](#)). Prior to 2014.1, values were reset to zero by each invocation of the keyword.

## PROPS section

- Connate gas can be included in the end-point scaling calculation of the saturation at which [KRWR](#) occurs in the end-point scaled space by setting [item 212](#) of the [OPTIONS](#) keyword to 1.

By default connate gas is omitted from these calculations.

- Corrections have been made to the calculation of water relative permeability when used as a component in the calculation of the three-phase oil relative permeability for Stone's Second Model [STONE2](#) when end-point scaling and hysteresis have been specified.

Pre-2014.1 behavior can be restored by setting [item 213](#) of the [OPTIONS](#) keyword to 1.

- Values set in a work array by the [OPERATE](#) or [OPERATER](#) keyword are now preserved to the end of the PROPS section, or until a keyword is encountered which defines or switches to a different grid (such as [REFINE](#)). Prior to 2014.1, values were reset to zero by each invocation of the keyword.
- For 2014.1, new versions of the [LOWSALT](#), [SURFACT](#) and [SURFACTW](#) options are available which support separate sets of end-point scaling keywords for scaling the water and oil table saturation functions associated with the high salinity (oil-wet) ([SWL](#) etc.), the low salinity (oil-wet) ([LSWL](#) etc.), the (high salinity) (water-wet) ([HWSWL](#) etc.) and the low salinity water-wet ([LWSWL](#) etc.) saturation regions. Prior to 2014.1, end-point scaling was only available for these options via the single set of end-point scaling keywords [SWL](#) etc. and this was only applied to the high salinity saturation table end-points. Pre-2014.1 behavior can be selected by setting [item 225](#) of the [OPTIONS](#) keyword to 1.
- If the pre-2014.1 version of the [LOWSALT](#), [SURFACT](#) and [SURFACTW](#) options is selected by setting [item 225](#) of the [OPTIONS](#) keyword to 1, a correction has been applied to ensure that the minimum water saturations specified via the end-point scaling keyword [SWL](#) are used for the calculation of the oil and water relative permeabilities. This correction may be reverted by setting [item 210](#) of the [OPTIONS](#) keyword to 1.

- The value of inertial coefficient specified via `VDFLOW` is now applied to all saturation regions when two or more regions have been specified. Pre-2014.1 behavior, for which the value of inertial coefficient was only applied to the first saturation region, can be restored by setting [item 217](#) of the `OPTIONS` keyword to 1.
- In 2014.1, the diffusive flow equation expressed in `FIELD` units has been modified. The pre 2014.1 behavior is restored by multiplying diffusion coefficients by 5.614583, which is the conversion factor between bbl and ft<sup>3</sup>. Diffusion coefficients are input through the `DIFFC` keyword. `METRIC` and `LAB` unit systems remain unchanged.
- For the 2014.1 version, corrections have been made to the input processing of the two-dimensional capillary pressure data specified via the `PCG32D` and `PCW32D` keywords. Prior to 2014.1, only the first table was used for all saturation regions. If more than one table was specified, the second and subsequent tables were ignored. For the 2014.1 version, successive tables are read and allocated to their associated saturation regions. Pre-2014.1 behavior can be restored by setting [item 233](#) of the `OPTIONS` keyword to 1.
- For the 2014.1 version, corrections have been made to the calculation of the saturation used to determine the gas relative permeability at the residual saturation of the displacing phase (`KRGR`) for gas-water models with end-point scaling. Prior to the 2014.1 version, this residual saturation was calculated using the critical oil in water saturation. For the 2014.1 version, this is calculated using the critical water saturation. Pre-2014.1 behavior can be restored by setting [item 234](#) of the `OPTIONS` keyword to 1.
- For the 2014.1 version, Killough hysteresis for water-wet systems has been modified. Corrections have been made to the calculation of the wetting phase relative permeability when subject to hysteresis and end-point scaling. Pre-2014.1 behavior can be restored by setting [item 222](#) of the `OPTIONS` keyword to 1.
- For the 2014.1 version, Killough hysteresis for oil-wet systems has been modified. Corrections have been made to the calculation of the two phase oil to water relative permeability, and connate water saturation has been included in the calculation of oil to gas relative permeability. Pre-2014.1 behavior can be restored by setting [item 229](#) of the `OPTIONS` keyword to 1.
- For the 2014.1 version, corrections have been made in the inverse lookup (used when modeling hysteresis) with three-point end-point scaling (`SCALECRS` keyword activated). Pre-2014.1 behavior can be restored by setting [item 231](#) of the `OPTIONS` keyword to 1.
- By default, prior to polymer shear calculations, ECLIPSE 100 now includes the mobile water saturation in the conversion from flow rate to velocity and, for runs including keyword `SHRATE`, applies a modified conversion factor from velocity to shear rate.
  - If [item 228](#) of `OPTIONS` is set to 1, this activates the pre-2014.1 conversion from flow rate to velocity in which the mobile water saturation is excluded and may be applied to models that use either `PLYSHEAR` or `PLYSHLOG`.
  - If `OPTIONS` item 228 is set to 2, this activates the pre-2014.1 conversion from velocity to shear rate and may only be applied to models that use keyword `SHRATE`.
  - If `OPTIONS` item 228 is set to 3, this activates the pre-2014.1 conversions from flow rate to velocity and from velocity to shear rate and may only be applied to models that use keyword `SHRATE`.

Please see "[Polymer Flood Model](#)" in the *ECLIPSE Technical Description* for precise details of the forms of these conversions.

## REGIONS section

- Values set in a work array by the [OPERATE](#) or [OPERATER](#) keyword are now preserved to the end of the REGIONS section, or until a keyword is encountered which defines or switches to a different grid (such as [REFINE](#)). Prior to 2014.1, values were reset to zero by each invocation of the keyword.

## SOLUTION section

- The calculation of the threshold pressure when defaulting item 3 of the [THPRES](#) keyword will be calculated from the initial conditions considering any phase present in the upstream cell. Pre 2014.1 behavior can be restored by setting [item 238](#) of the [OPTIONS](#) keyword to 1.

## SCHEDULE section

- An error will now be emitted in parallel when a well is defined using [WELSPECL](#) on an LGR that is switched off. This can be downgraded to a warning by setting [item 216](#) of the [OPTIONS](#) to 1.
- For the 2014.1 version, when either [VDFLOW](#) or [VDFLOWR](#) is specified, the non-Darcy component is **not** applied by default to the phase mobility calculations in the well connections under any circumstance. Prior to the 2014.1 version, the non-Darcy component was **only** applied to the well connections if the [FHERCHBL](#) keyword was specified. Pre-2014.1 behavior can be restored by setting [item 218](#) of [OPTIONS](#) to 1. Alternatively if this item is set to 2, the non-Darcy component calculated from the [VDFLOW](#) or [VDFLOWR](#) keyword will be applied to the wells unless the [WDFAC](#) or [WDFACCOR](#) keywords or item 12 of the [COMPDAT](#) (or item 13 of the [COMPDATL](#) keyword have been specified.
- Connection ordering of RFT and PLT data (see [WRFTPLT](#)) is now controlled by the keyword [COMPORD](#) for standard wells, and always follows the TRACK method for multisegment and friction wells. Prior to 2014.1 connections were always output in the order they were input. This behavior can be reproduced setting item 2 of [COMPORD](#) to 'INPUT'.
- When UDAs are used as arguments in the keyword [CECON](#) the values are now only applied to those connections selected in the keyword. In versions earlier than 2014.1, the value is applied to all connections in the well. The pre-2014.1 behavior may be restored by setting [item 224](#) of keyword [OPTIONS](#) to 1.
- For polymer, brine and solvent runs a minor change has been made to the 'TRNC' timestepping control. Pre-2014.1 behavior can be restored by setting [item 230](#) of the [OPTIONS](#) keyword to 1.
- The use of the [WSALT](#) keyword in dual porosity models with local grid refinements is no longer allowed. This restriction can be overridden by setting [item 237](#) of the [OPTIONS](#) keyword to 1; this is not recommended.
- Some changes have been made to the [TRACER](#) solution method to improve convergence in parallel runs when NNCs are present. This could affect any quantity based on passive tracers or environmental tracers. Note that this includes, but is not limited to, [BRINE](#), when not used with [POLYMER](#) and [LOWSALT](#).

## ECLIPSE 300

The behavioral changes in ECLIPSE 300 are described in the following sections:

- [RUNSPEC section](#)
- [GRID section](#)

- [PROPS section](#)
- [SOLUTION section](#)
- [SUMMARY section](#)
- [SCHEDULE section](#)

## RUNSPEC section

- The multi-component water option activated with the [COMPW](#) keyword, cannot be used when the Flux boundary option is used ([DUMPFLUX](#) or [USEFLUX](#) keywords).

## GRID section

- The logic used to determine how a non-neighbor connection with very small transmissibility should be treated has been improved and standardized across NNC types. The new behavior is described in more detail in the [MINNNCT](#) keyword, which can be used to customize the minimum values.

This may lead to slight differences in exactly how the number of non-neighbor connections is reported in the PRT file, with more connections created initially and then those which are too small for the new standard test being discarded.

Pre-2014.1 behavior can be restored by setting [item 311](#) of the [OPTIONS3](#) keyword to 1.

- The Flux boundary option ([DUMPFLUX](#) or [USEFLUX](#) keywords) is not compatible with the multi-component water option which is activated with the [COMPW](#) keyword.

## PROPS section

- For models with end-point scaling specified, corrections have been made to the scaling algorithms for the case where the saturations at which the end-points [KRWR](#), [KRGR](#), [KRORW](#) and [KROrg](#) (relative permeabilities at residual saturation of the displacing phase) occur are the same as the saturations at which [KRW](#), [KRG](#), [KRO](#) and [KRO](#) (relative permeabilities at maximum saturation) respectively occur. This also applies to the imbibition counterparts if hysteresis is being modeled. Pre-2014.1 behavior can be selected by setting [item 306](#) of the [OPTIONS3](#) keyword to 1.
- For models which use the [ODD3P](#) coupled three-phase relative permeability and capillary pressure hysteresis option, warning messages have been suppressed where the oil-water or gas-oil primary capillary pressure curves cross the secondary (increasing) or tertiary (decreasing) capillary pressure curves. Pre-2014.1 behavior can be selected by setting [item 307](#) of the [OPTIONS3](#) keyword to 1.
- Water relative permeability hysteresis for oil-wet reservoirs is now available for all reservoir models for which hysteresis is available. Prior to 2013.2 this was only available for black oil models and for other models only the drainage curve was used.

Pre-2013.2 behavior can be restored by setting [item 310](#) of the [OPTIONS3](#) keyword to 1.

- For models which use three-point endpoint scaling of the saturation functions, (that is, where [item 1](#) of the [SCALECRS](#) keyword has been set to YES), inverse look-up of the saturation functions will also be performed using three-point endpoint scaling. (This form of inverse look-up is typically used for hysteresis calculations.) Pre-2014.1 behavior for the inverse lookup of the saturation functions can be selected by setting [item 312](#) of the [OPTIONS3](#) keyword to 1.
- For models which use the [WAGHYSTR](#) keyword together with end-point scaling and alternative three-phase water relative permeability saturation tables specified via the [WH3NUM](#) keyword, a correction

has been made to prevent these defaulting to the imbibition saturation tables specified via the `IMBNUM` keyword. Pre-2014.1 behavior can be selected by setting [item 314](#) of the `OPTIONS3` keyword to 1.

- For models which use Killough hysteresis for oil-wet systems (item 2 of `EHYSTR` keyword set to 4), a correction has been made in the construction of scanning curves for the oil relative permeability to gas. Pre-2014.1 behavior can be selected by setting [item 316](#) of the `OPTIONS3` keyword to 1.
- For models where hysteresis has been specified via the `HYSTER` option of the `SATOPTS` keyword in the `RUNSPEC` section but the `EHYSTR` keyword has been omitted from the `PROPS` section and, in addition, none of the alternative keywords used for specifying hysteresis, for example, `HYKR`, `HYPC`, `HYST`, `HYSTJ` or `HYSTK` have been specified, corrections have been made to the default hysteresis parameter selection. For the 2014.1 version, if hysteresis has been specified via the `HYSTER` option of the `SATOPTS` keyword but the `EHYSTR` keyword has been omitted, the hysteresis parameters will be assigned to the default values specified for the `EHYSTR` keyword and any alternative definitions associated with alternative hysteresis keywords will be superseded. Pre-2014.1 behavior can be selected by setting [item 320](#) of the `OPTIONS3` keyword to 1.
- For models where negative capillary pressure end-points are specified via either the `PCW` or the `PCG` keywords (or their imbibition counterparts) or where negative capillary pressure end-points are calculated via the `JFUNC` or `JFUNCR` keywords, these values will now be used in the simulation. Prior to 2014.1, if negative capillary pressure end-points were defined via either of these mechanisms, the capillary pressure end-point values used would default to the corresponding saturation table values. Pre-2014.1 behavior can be selected by setting [item 321](#) of the `OPTIONS3` keyword to 1.

## SOLUTION section

- When using enumeration to set the pressure, it is now an error if values are not set explicitly for all active global cells by the end of the `SOLUTION` section. Pre-2014.1 behavior (where the pressure in such cells was defaulted to atmospheric pressure) can be selected by setting [item 313](#) of the `OPTIONS3` keyword to 1.

## SUMMARY section

- Improved consistency of open/shut status reporting for production wells subject to economic limits (keyword `WECON`).
- Region flow rates and totals for wells with cross flow now account for connections that are still net injectors at the point where the well is opened.
- Wells retested for economic viability using the keyword `WTEST` now report zero flow rates when the well remains shut.
- The `SUMMARY` section mnemonic `WDRPR` will now return zero for wells that have left the priority drilling queue.

## SCHEDULE section

- Connection ordering of RFT and PLT data (see `WRF'TPLT`) is now controlled by the keyword `COMPORD` for standard wells, and always follows the `TRACK` method for multisegment wells. Prior to 2014.1 connections were always output in the order they were input. This behavior can be reproduced setting item 2 of `COMPORD` to 'INPUT'.
- For the 2014.1 version, in models with more than one equation of state region, the calculation of the generalized pseudo pressure properties for a given well completion utilizes the equation of state

number associated with the grid block containing the completion rather than the equation of state number associated with the well.

Pre-2014.1 behavior (which utilizes the equation of state number associated with the well rather than the completion) can be restored by setting [item 315](#) of the `OPTIONS3` keyword to 1.

- For the 2014.1 version, if the effective well bore radius, set with `WELSPECS` item 7 and `COMPDAT` item 9, is less than the actual radius, the effective radius will be set to the actual radius. This is in line with the ECLIPSE 100 behavior. The pre-2014.1 behavior can be restored by setting [item 317](#) of the `OPTIONS3` keyword to 1. The ECLIPSE 100 behavior may be changed to the pre-2014.1 ECLIPSE 300 behavior by setting [item 226](#) of the `OPTIONS` keyword to 1.
- For the 2014.1 version, an additional check has been added to avoid negative discriminants in the solution of the quadratic inflow rate used to calculate the D-Factor multiplier for wells or well completions for which D-Factors have been specified via the `WDFAC` keyword, the `WDFACCOR` keyword or item 12 of the `COMPDAT` keyword (or item 13 of the `COMPDATL` keyword). The pre-2014.1 behavior can be restored by setting [item 319](#) of the `OPTIONS3` keyword to 1.
- For the 2014.1 version, if the `MULTX` keyword is modified using `MULTIREG`, the new multipliers are reapplied to the transmissibility only in the region which has been changed. This also applies to all combinations of `MULTX`, `MULTY` and `MULTZ` when modified using `MULTIREG`, `ADDREG` and `EQUALREG`.
- From 2014.1, for the multi-component water option (`COMPW`), the initial composition of analytic aquifers must be specified using the `AQSTREAW` keyword.
- From 2013.2 additional checks have been put in place to ensure that user-defined relative permeabilities for injector completions in locally refined grids defined with the `COMPKRIL` keyword are correctly applied. The pre-2013.2 behavior can be restored by setting [item 309](#) of the `OPTIONS3` keyword to 1.

## New keywords

### ECLIPSE 100

The new keywords in ECLIPSE 100 are described in the following sections:

- [RUNSPEC section](#)
- [GRID section](#)
- [PROPS section](#)
- [REGIONS section](#)
- [SUMMARY section](#)
- [SCHEDULE section](#)

### RUNSPEC section

The new RUNSPEC section keywords are:

- `CPR` Activates the CPR linear solver.
- `BPARA` Requests a block parallel license.

## GRID section

The new GRID section keywords are:

- [ROCKFRAC](#) Inputs rock volume fractions for the Coal Bed Methane or Shale Gas model.

## PROPS section

The new PROPS section keywords are:

- [SURFSTES](#) Water-oil surface tension versus surfactant and salt concentrations
- [ESSNODE](#) Salt concentration nodes for water-oil surface tension
- [LANGMPL](#) Pressure multiplier when computing adsorption capacities for the Coal Bed Methane model.
- [LSWL](#), [LSWLPC](#), [LSWCR](#), [LSWU](#), [LSOWCR](#), [LSOGCR](#), [LKRW](#), [LKRWR](#), [LKRO](#), [LKRORW](#), [LKRORG](#) and [LPCW](#) Low salinity (oil-wet) water and oil saturation table end-points.
- [HWSWL](#), [HWSWLPC](#), [HWSWCR](#), [HWSWU](#), [HWSOWCR](#), [HWSOGCR](#), [HWKRW](#), [HWKRWR](#), [HWKRO](#), [HWKRORW](#), [HWKROORG](#) and [HWPCW](#) Adsorbed surfactant (high salinity) water-wet water and oil saturation table end-points.
- [LWSWL](#), [LWSWLPC](#), [LWSWCR](#), [LWSWU](#), [LWSOWCR](#), [LWSOGCR](#), [LWKRW](#), [LWKRWR](#), [LWKRO](#), [LWKROORG](#) and [LWPCW](#) Adsorbed surfactant low salinity water-wet water and oil saturation table end-points.
- [PLYATEMP](#) Temperature dependence of the polymer adsorption tables.

## REGIONS section

The new REGIONS section keywords are:

- [LSNUM](#) Low salinity (oil-wet) saturation region numbers (abbreviated alias for existing keyword [LWSLTNUM](#)).
- [HWSNUM](#) (High salinity) water-wet saturation region numbers (abbreviated alias for existing keyword [SURFNUM](#)).
- [LWSNUM](#) Low-salinity water-wet saturation region numbers (abbreviated alias for existing keyword [LSLTNUM](#)).

## SUMMARY section

The new SUMMARY keywords are:

- [WPIO](#) Oil phase productivity index
- [WPIG](#) Gas phase productivity index
- [WPIW](#) Water phase productivity index
- [WPIL](#) Liquid phase productivity index
- [CPRL](#) Average connection pressure in a lumped completion

- [MLINEARP](#), [MSUMLINP](#), [NCPRLINS](#) and [NLINEARP](#) may now be used to output performance data for the pressure solve, when using the [CPR](#) linear solver.

## SCHEDULE section

The new SCHEDULE keywords are:

- [CSKIN](#) Updates well connection skin factors.

## ECLIPSE 300

The new keywords in ECLIPSE 300 are described in the following sections:

- [RUNSPEC section](#)
- [PROPS section](#)
- [SUMMARY section](#)
- [SCHEDULE section](#)

## RUNSPEC section

The new RUNSPEC section keywords are:

- [WAGHALT](#) Selects alternative WAG hysteresis model.
- [CPR](#) Activates the CPR linear solver.
- [BPARA](#) Requests a block parallel license.

## PROPS section

The new PROPS section keywords are:

- [PLYVISC](#) Provides a table of water phase viscosity multipliers as a function of polymer concentration.
- [PLYVISCs](#) Provides a table of water phase viscosity multipliers as a function of polymer concentration for salt sensitive studies.
- [ESPNODe](#) Provides a table of effective salinity nodes for salt sensitive polymer flood studies.
- [PLYOPTS](#) Polymer model options.
- [SURFSTES](#) Provides a table of water-oil surface tension versus surfactant and salt concentrations.
- [ESSNODe](#) Salt concentration nodes for water-oil surface tension.
- [ALSURFST](#) Surfactant model: provides a table of water-oil surface tension multipliers as a function of alkaline concentration.
- [SALTEFF](#) Provides a means to compute effective salinity values for polymer and surfactant flood studies.
- [LANGMPL](#) Pressure multiplier when computing adsorption capacities for the Coal Bed Methane or Shale Gas model.

## SUMMARY section

The new SUMMARY section keywords are:

- WPIL Liquid phase productivity index.
- CPRL Average connection pressure in a lumped completion.
- BPOLY Polymer concentration, measured as the mass of polymer per volume of water phase (Polymer option).
- BPOLYVM Polymer viscosity multiplier (Polymer option).
- BALSURF and BALSTML may now be used to output alkaline concentration and alkaline surface tension multiplier determined from data provided in [ALSURFST](#).
- BESALTS and BESALTP may now be used to output effective salinity values computed using data specified by [SALTEFF](#) for Surfactant and Polymer models, respectively.
- MLINEARP, MSUMLINP, NCPRLINS and NLINEARP may now be used to output performance data for the pressure solve, when using the [CPR](#) linear solver.

## SCHEDULE section

The new SCHEDULE keywords are:

- [PLYVISC](#) Provides a table of water phase viscosity multipliers as a function of polymer concentration.
- [PLYVISC](#) Provides a table of water phase viscosity multipliers as a function of polymer concentration for salt sensitive studies.
- [CSKIN](#) Updates well connection skin factors.

## Altered keywords

### ECLIPSE 100

The altered keywords in ECLIPSE 100 are described in the following sections:

- [RUNSPEC section](#)
- [GRID section](#)
- [PROPS section](#)
- [SOLUTION section](#)
- [SCHEDULE section](#)
- [OPTIONS keyword](#)

### RUNSPEC section

The altered RUNSPEC keywords in ECLIPSE 100 are:

- [MESSAGES](#) New item for setting the print limit for some frequently repeated output messages. This limit is set to 10 by default but will be ignored if [item 220](#) of the `OPTIONS` keyword is set to 1.

## GRID section

The altered `GRID` keywords in ECLIPSE 100 are:

- [RPTGRID](#) New argument `ROCKFRAC` enables reporting of rock volume fractions for the Coal Bed Methane and Shale Gas options.
- [RPTGRIDL](#) New argument `ROCKFRAC` enables reporting of rock volume fractions for the Coal Bed Methane and Shale Gas options.
- [RPTINIT](#) New argument `ROCKFRAC` enables reporting of rock volume fractions for the Coal Bed Methane and Shale Gas options.
- [MINNNCT](#) In addition to a minimum transmissibility, it is now possible to specify a minimum diffusivity and/or thermal transmissibility below which a non-neighbor connection will be deleted. Connections are only deleted if all three properties are below the required minimum values.

## PROPS section

The altered `PROPS` keywords in ECLIPSE 100 are:

- [EHYSTR](#) Setting item 13 to 1 enables the construction of the wetting phase relative permeability Killough's hysteresis scanning curve from a restrained imbibition curve. This will prevent errant behavior of the scanning curve, in cases where the original scanning curve deviates from the region bounded by imbibition and drainage curves.
- [RPTPROPS](#) When existing argument `SURF` is requested, the output additionally includes the water-oil surface tension table (`SURFSTES`) and the effective salinity nodes table (`ESSNODE`).

## SOLUTION section

The altered `SOLUTION` keywords in ECLIPSE 100 are:

- [RPTSOL](#) When existing argument `SURFBLK` is requested, the output additionally includes water-oil surface tension (`SURFST` or `SURFSTES`).

## SCHEDULE section

The altered `SCHEDULE` keywords in ECLIPSE 100 are:

- [RPTSCHED](#) When existing argument `SURFBLK` is requested, the output additionally includes water-oil surface tension (`SURFST` or `SURFSTES`).
- The use of the [WSALT](#) keyword in dual porosity models with local grid refinements is no longer allowed. This restriction can be overridden by setting [item 237](#) of the `OPTIONS` keyword to 1; this is not recommended

## OPTIONS keyword

The altered `OPTIONS` are:

Switch	Description
191	This item has been deprecated. To control the number of messages output for dead block connections use item 13 of the <a href="#">MESSAGES</a> keyword or <a href="#">item 220</a> of the <a href="#">OPTIONS</a> keyword.
210	If set to 1, the pre-2014.1 behavior is restored for the calculation of relative permeabilities when using the <a href="#">SURFACT</a> or <a href="#">LOWSALT</a> models with <a href="#">ENDSCALE</a> .
211	If set to 1, the pre-2014.1 behavior is restored for the calculation of the capillary number when using the <a href="#">SURFACT</a> and <a href="#">DUALPORO</a> models.
212	If set to 1, connate gas will be included in the end-point scaling calculation of the saturation at which <a href="#">KRWR</a> occurs in end-point scaled saturation space. By default, connate gas is omitted from these calculations.
213	If set to 1, the pre-2014.1 behavior is restored for the calculation of water relative permeability used as a component in the calculation of the three-phase oil relative permeability for Stone's Second Model <a href="#">STONE2</a> .
214	If set to 1, the pre-2014.1 behavior is restored for the calculation of the component cell heights for the <a href="#">GRAVDR</a> model when used with either the <a href="#">SURFACT</a> or <a href="#">LOWSALT</a> models.
215	If set to 1, unset values for enumerated initial pressures in coarsened grids will be replaced with the value from an adjacent cell.  If set to 2, unset values for all enumerated initial conditions in coarsened grids will be replaced with the value from an adjacent cell.  This can be used to avoid issues where a pre-processor is unable to assign an enumerated value to an inactive cell which is used as the representative cell for its coarsened cell.
216	If set to 1, the error emitted in parallel when a well is defined using <a href="#">WELSPECL</a> on an LGR that is switched off is downgraded to a warning.
217	If set to 1, the pre-2014.1 behavior for <a href="#">VDFLOW</a> is restored such that the value of the inertial coefficient for non-Darcy flow is only applied to the first saturation region when more than one saturation region has been defined. For the 2014.1 version, the inertial coefficient is applied to all saturation regions.
218	If set to 1, the pre-2014.1 behavior is restored for the non-Darcy flow component specified via the <a href="#">VDFLOW</a> or <a href="#">VDFLOWR</a> keyword. Prior to 2014.1 this was <b>only</b> applied to the phase mobility calculations for the well connections if the <a href="#">FHERCHBL</a> keyword had also been specified. For the 2014.1 version, by default, the non-Darcy flow component due to the <a href="#">VDFLOW</a> or <a href="#">VDFLOWR</a> keyword is not applied to the well connections in any circumstance. If the <a href="#">VDFLOW</a> or <a href="#">VDFLOWR</a> flow component is required to be applied to the well connections, this may be enabled by setting this <a href="#">OPTIONS</a> item to 2. Wells or well completions for which D-Factor calculations have been specified via the <a href="#">WDFAC</a> keyword the <a href="#">WDFACCOR</a> keyword or item 12 of the <a href="#">COMPDAT</a> keyword (or item 13 of the <a href="#">COMPDATL</a> keyword) will supersede those due to the <a href="#">VDFLOW</a> or <a href="#">VDFLOWR</a> keyword.
219	If set to 1, the pre-2014.1 message output format for parallel runs is used; messages from slave processors will not appear in the output files for the master process.
220	If set to 1, the message output limit from <a href="#">MESSAGES</a> item 13 is ignored.

Switch	Description
221	If set to 1, the pre-2014.1 behavior for determining when a non-neighbor connection should be deleted based on its transmissibility is restored. Additionally, values which are below the cutoff value for all of transmissibility, diffusivity and thermal transmissibility will be preserved provided that the NNC itself is preserved. Note that, if this option is used, the diffusivity and thermal transmissibility settings from the <a href="#">MINNCT</a> keyword will have no effect.
222	If set to 1, the pre-2014.1 behavior for Killough hysteresis model for water-wet systems will be selected. For the 2014.1 version, corrections have been made to the calculation of the wetting phase relative permeability when subject to hysteresis and end-point scaling.
223	If set to 1, the pre 2014.1 behavior of allowing multiple uses of the <a href="#">GRIDOPTS</a> keyword is restored.
224	If set to 1, the pre-2014.1 behavior for <a href="#">CECON</a> is restored. UDAs used in CECON are applied to all connections in the wells specified with the particular UDA.
225	If set to 1, the pre 2014.1 behavior for modeling the saturation functions for low salinity <a href="#">LOWSALT</a> , surfactant <a href="#">SURFACT</a> and surfactant wettability <a href="#">SURFACTW</a> effects is restored. For the 2014.1 version, extensions have been made to facilitate the end-point scaling of the low salinity saturation functions together with a number of amendments to the calculation process.
226	If set to 1, the effective well bore radius, used in the calculation of the well productivity index, can be larger than the drainage radius. Otherwise, the ratio of the two radii will be set to unity in the calculation of the productivity index. For the ECLIPSE 300 equivalent please refer to <a href="#">item 317</a> of the <a href="#">OPTIONS3</a> keyword.
227	If set to 1, the preferred phase of an injection well is not enforced to match the actual injection phase. For the ECLIPSE 300 equivalent please refer to <a href="#">item 318</a> of the <a href="#">OPTIONS3</a> keyword.
228	By default, prior to polymer shear calculations, ECLIPSE 100 now includes the mobile water saturation in the conversion from flow rate to velocity and, for runs including keyword <a href="#">SHRATE</a> , applies a modified conversion factor from velocity to shear rate. If <a href="#">OPTIONS</a> item 228 is set to 1, this activates the pre-2014.1 conversion from flow rate to velocity in which the mobile water saturation is excluded and may be applied to models that use either <a href="#">PLYSHEAR</a> or <a href="#">PLYSHLOG</a> . If <a href="#">OPTIONS</a> item 228 is set to 2, this activates the pre-2014.1 conversion from velocity to shear rate and may only be applied to models that use keyword <a href="#">SHRATE</a> . If <a href="#">OPTIONS</a> item 228 is set to 3, this activates the pre-2014.1 conversions from flow rate to velocity and from velocity to shear rate and may only be applied to models that use keyword <a href="#">SHRATE</a> . Please see the chapter entitled " <a href="#">Polymer Flood Model</a> " in the <i>ECLIPSE Technical Description</i> for precise details of the forms of these conversions.
229	If set to 1, the pre-2014.1 behavior for the Killough hysteresis model for oil-wet systems will be restored. For the 2014.1 version, corrections have been made in the two phase oil to water relative permeability, and connate water saturation is included in the calculation of oil to gas relative permeability.
230	If set to 1, the pre-2014.1 behavior of the 'TRNC' timestepping control for <a href="#">POLYMER/BRINE</a> and <a href="#">SOLVENT</a> runs will be restored.
231	If set to 1, the pre-2014.1 behavior for inverse lookup (used when modeling hysteresis) with three-point end-point scaling will be restored. For the 2014.1 version, corrections have been made in cases where <a href="#">SCALECRS</a> item 1 has been set to YES.
232	If set to 1, this removes the ban on EOR/tracer functionality with <a href="#">DUMPFLUX</a> and <a href="#">USEFLUX</a> keywords. You must ensure that no information on EOR/tracer functionality is needed from outside the flux boundary.

Switch	Description
233	If set to 1, the pre-2014.1 behavior for the input processing of the two-dimensional capillary pressure data specified via the <a href="#">PCG32D</a> and <a href="#">PCW32D</a> keywords will be restored. Prior to 2014.1, only the first table was used for all saturation regions. If more than one table was specified, the second and subsequent tables were ignored. For the 2014.1 version, successive tables are read and allocated to their associated saturation regions.
234	If set to 1, the pre-2014.1 behavior for the scaling of gas relative permeability at residual saturation of the displacing phase ( <a href="#">KRGR</a> ) for gas-water models with end-point scaling will be restored. Prior to the 2014.1 version, the residual saturation used to determine the gas relative permeability was calculated using the critical oil in water saturation. For the 2014.1 version, this is calculated using the critical water saturation.
235	If set to 1, grid property tables in the PRT file will be printed so that the maximum scaled value always lies between 1 and 10, and no significant digits are lost from that value. The default value of 0 corresponds to earlier versions of the simulator where for some small values only one significant digit would be printed.
236	If set to 1, the pre-2014.1 geometry calculations are used to calculate neighbor transmissibilities for corner point geometry. Prior to the 2014.1 version, in some extreme cases (principally with a perfectly vertical fault which has cells on both sides sloping towards the fault) a small transmissibility value can be calculated between cells which are neighbors in i,j,k space even though the cells do not physically touch. When this switch is used, these cell indices and transmissibility values are also output to the debug file.
237	If set to 1, this removes the ban on brine injection with <a href="#">WSALT</a> in dual porosity models with local grid refinements. The use of this option is not recommended and it is the user's responsibility to ensure that the local grid properties do not differ from global cells.
238	If set to 1, the pre-2014.1 behavior of the default interphase threshold pressure calculation will be activated. For the 2014.1 version, the interphase threshold pressure when defaulting item 3 of the <a href="#">THPRES</a> keyword, will be calculated from the initial conditions considering any phase present in the upstream cell.

Table 1.1: Altered OPTIONS

## ECLIPSE 300

The altered keywords in ECLIPSE 300 are described in the following sections:

- [GRID section](#)
- [PROPS section](#)
- [SOLUTION section](#)
- [SCHEDULE section](#)
- [OPTIONS3 keyword](#)

### GRID section

The altered GRID keywords are:

- [MINNNCT](#) In addition to a minimum transmissibility, it is now possible to specify a minimum diffusivity and/or thermal transmissibility below which a non-neighbor connection will be deleted. Connections are only deleted if all three properties are below the required minimum values.

## PROPS section

The altered PROPS keywords in ECLIPSE 300 are:

- **EHYSTR** Setting item 13 to 1 enables the construction of the wetting phase relative permeability Killough's hysteresis scanning curve from a restrained imbibition curve. This will prevent errant behavior of the scanning curve, in cases where the original scanning curve deviates from the region bounded by imbibition and drainage curves.
- **CWTYPE** The water component type POLY has been added to define a polymer for the Polymer Flood Model.
- **RPTPROPS** arguments:
  - **PLYVISC** outputs the polymer viscosity table specified by the **PLYVISC** keyword.
  - **PLYVISC** outputs the polymer viscosity table specified by the **PLYVISC** keyword.
  - **SURFSTES** outputs the polymer viscosity table specified by the **SURFSTES** keyword.
  - **ESPNO** and **ESSNO** output the effective salinity nodes table specified by the **ESPNO** and **ESSNO** keywords, respectively.
- **REACOPS** Item 4 enables you to specify a scaling factor used when calculating the reaction rate of zero-order reactants in equilibrium deviation reactions.
- **CWTYPE** The water component type ALK has been added to define an alkaline for the Alkaline Model.

## SOLUTION section

The altered SOLUTION keywords are:

- **RPTSOL** New arguments POLY and POLYVM output polymer concentration and polymer viscosity multiplier in polymer flood studies, respectively.
- **RPTRST** New arguments POLY and POLYVM output polymer concentration and polymer viscosity multiplier in polymer flood studies, respectively.
- **RPTSOL** New arguments ESALTP and ESALTS output effective salinity values calculated using inputs to keyword **SALTEFF** in polymer and surfactant flood studies, respectively.
- **RPTRST** New arguments ESALTP and ESALTS output effective salinity values calculated using inputs to keyword **SALTEFF** in polymer and surfactant flood studies, respectively.

## SCHEDULE section

The altered SCHEDULE keywords are:

- **RPTSCHED** New arguments POLY and POLYVM output polymer concentration and polymer viscosity multiplier in polymer flood studies, respectively.
- **RPTRST** New arguments POLY and POLYVM output polymer concentration and polymer viscosity multiplier in polymer flood studies, respectively.
- **RPTSCHED** New arguments ESALTP and ESALTS output effective salinity values calculated using inputs to keyword **SALTEFF** in polymer and surfactant flood studies, respectively.
- **RPTRST** New arguments ESALTP and ESALTS output effective salinity values calculated using inputs to keyword **SALTEFF** in polymer and surfactant flood studies, respectively.

## OPTIONS3 keyword

The altered `OPTIONS3` switches are:

Switch	Description
306	If set to 1, the pre-2014.1 behavior will be restored for models with end-point scaling specified, where the saturations at which the end-points <code>KRWR</code> , <code>KRGR</code> , <code>KRORW</code> and <code>KROG</code> (relative permeabilities at residual saturation of the displacing phase) occur are the same as the saturations at which <code>KRW</code> , <code>KRG</code> , <code>KRO</code> and <code>KRO</code> (relative permeabilities at maximum saturation) respectively occur. For the 2014.1 version, corrections have been made to prevent the maximum scaled relative permeabilities exceeding the maximum specified relative permeabilities under these circumstances. This also applies to the imbibition counterparts if hysteresis is being modeled.
307	If set to 1, warning messages will be issued for models which use the <code>ODD3P</code> coupled three-phase relative permeability and capillary pressure hysteresis option, where the oil-water or gas-oil primary capillary pressure curves cross the secondary (increasing) or tertiary (decreasing) capillary pressure curves.
308	If set to -1, then even when the <code>DPGRID</code> option is set and local grids with corner point geometry are specified, any unset corner depths in the fracture will not be copied from the matrix. This was the default behavior prior to 2014.1.
309	If set to 1, this will revert to the pre-2013.2 behavior of the <code>COMPKRIL</code> keyword for defining user relative permeabilities for injector completions in locally refined grids.
310	If set to 1, this will revert to the pre-2013.2 behavior for the calculation of water relative permeability hysteresis in oil-wet systems. Prior to the 2013.2 version, water relative permeability hysteresis in oil-wet systems was only available for black oil reservoir models. For other models only the drainage curve was used.
311	If set to 1, the pre-2014.1 behavior for determining when a non-neighbor connection should be deleted based on its transmissibility is restored. Additionally, values which are below the cutoff value for all of transmissibility, diffusivity and thermal transmissibility will be preserved provided that the NNC itself is preserved. Note that, if this option is used, the diffusivity and thermal transmissibility settings from the <code>MINNNCT</code> keyword will have no effect.
312	If set to 1, this will revert to the pre-2014.1 behavior for the calculation of the inverse lookup with two-point end-point scaling. If defaulted, inverse lookup will be performed with three-point endpoint scaling.
313	If set to 1, this will revert to the pre-2014.1 behavior for the treatment of pressure by enumeration in cells where no value has been set, where such cells were assumed to have atmospheric pressure. If defaulted, it is an error to have an active global cell without an explicitly set pressure at the end of the <code>SOLUTION</code> section.
314	If set to 1, this will revert to the pre-2014.1 behavior for the modeling of water relative permeability hysteresis scanning curves for models using the <code>WAGHYSTR</code> keyword when end-point scaling has been specified and where the three-phase water relative permeability saturation table numbers have been specified via the <code>WH3NUM</code> keyword.
315	If set to 1, this will revert to the pre-2014.1 behavior for the modeling of generalized pseudo pressure in models with more than one equation of state region. For the 2014.1 version, the generalized pseudo pressure calculations for a given well completion utilize the equation of state properties associated with the grid block containing the completion rather than those associated with the well. Prior to 2014.1, the equation of state region number associated with the well rather than the completion was used.

Switch	Description
316	If set to 1, this will revert to the pre-2014.1 behavior for the modeling of Killough hysteresis in oil-wet systems.
317	If set to 1, this will revert to the pre-2014.1 behavior for the calculation of well productivity indices. If set to 1, the effective well bore radius, used in the calculation of the well productivity index, can be larger than the drainage radius. Otherwise, the ratio of the two radii will be set to unity in the productivity index calculation. For the ECLIPSE 100 equivalent please refer to <a href="#">item 226</a> of the <code>OPTIONS</code> keyword.
318	If set to 1, the preferred phase of an injection well is updated to match the actual injection phase. For the ECLIPSE 100 equivalent please refer to <a href="#">item 227</a> of the <code>OPTIONS</code> keyword.
319	If set to 1, this will revert to the pre-2014.1 behavior for the application of D-Factors for wells or well completions for which values have been specified via the <code>WDFAC</code> keyword, the <code>WDFACCOR</code> keyword or item 12 of the <code>COMPDAT</code> keyword (or item 13 of the <code>COMPDATL</code> keyword). For the 2014.1 version, an additional check has been added to avoid negative discriminants in the solution of the quadratic in flow rate used to calculate the D-Factor multiplier. In all other respects, the calculation itself has not been changed.
320	If set to 1, this will revert to the pre-2014.1 behavior for the defaulting of the hysteresis control parameters when hysteresis has been specified via the <code>HYSTER</code> option of the <code>SATOPTS</code> keyword in the <code>RUNSPEC</code> section but the <code>EHYSTR</code> keyword has been omitted from the <code>PROPS</code> section. For versions prior to 2014.1, neither relative permeability or capillary pressure hysteresis were selected correctly if, in addition to omitting the <code>EHYSTR</code> keyword, none of the alternative keywords used for specifying hysteresis, for example, <code>HYKR</code> , <code>HYPG</code> , <code>HYST</code> , <code>HYSTJ</code> or <code>HYSTK</code> were specified. For the 2014.1 version, if hysteresis has been specified via the <code>HYSTER</code> option of the <code>SATOPTS</code> keyword but the <code>EHYSTR</code> keyword has been omitted, the hysteresis parameters will be assigned to the default values specified for the <code>EHYSTR</code> keyword and any alternative definitions associated with alternative hysteresis keywords will be superseded.
321	If set to 1, this will revert to the pre-2014.1 behavior for the specification of negative capillary pressure end-points via the <code>PCW</code> and <code>PCG</code> keywords and their imbibition counterparts. Prior to 2014.1, if negative values were specified, the values actually used would default to the corresponding saturation table end-point values. For the 2014.1 version, if negative <code>PCW</code> or <code>PCG</code> values are specified, these will be used instead of the saturation table end-point values. This change of behavior also applies to capillary pressure end-points calculated via the <code>JFUNC</code> and <code>JFUNCR</code> keywords.

Table 1.2: Altered `OPTIONS3` switches

## 2

## Data File Overview

An ECLIPSE data input file is split into sections, each of which is introduced by a keyword. A list of all section-header keywords is given below, together with a brief description of the contents of each section. A more detailed breakdown of the section contents may be found in the section overviews which follow immediately after this general overview.

After the section overviews, this manual contains a detailed description of the data for each keyword, in alphabetical keyword order. Some keywords are recognized by both ECLIPSE 100 and ECLIPSE 300, while others are valid in only one of the simulators. A flag table under each keyword heading indicates which simulator(s) the keyword may be used with, and the section(s) in which the keyword is entered. The flag table also indicates whether the keyword is specific to one of the 'special extensions' which are licensed separately.

In keywords that are recognized by both simulators, some data items may apply only to one simulator. These items are distinguished in this manual by **margin notes**, such as *ECLIPSE 100 only*. Furthermore, in data items requiring an option to be selected from a list of available options, some of the options may be valid in only one of the simulators; these options are similarly distinguished by a margin note. Margin notes such as *ECLIPSE 300* are also employed to indicate that a paragraph of text applies to just one of the simulators.

### Data file sections

The data file sections are:

Required?	Section Name	Description
Required	<a href="#">RUNSPEC</a>	Title, problem dimensions, switches, phases present and components for example.
Required	<a href="#">GRID</a>	Specification of geometry of computational grid (location of grid block corners), and of rock properties (porosity and absolute permeability for example) in each grid block.
Optional	<a href="#">EDIT</a>	Modifications to calculated pore volumes, grid block center depths and transmissibilities.

Required?	Section Name	Description
Required	<a href="#">PROPS</a>	Tables of properties of reservoir rock and fluids as functions of fluid pressures, saturations and compositions (including density, viscosity, relative permeability and capillary pressure). Contains the equation of state description in compositional runs.
Optional	<a href="#">REGIONS</a>	Splits computational grid into regions for calculation of: <ul style="list-style-type: none"> <li>• PVT properties (fluid densities and viscosities)</li> <li>• Saturation properties (relative permeabilities and capillary pressures)</li> <li>• Initial conditions (equilibrium pressures and saturations)</li> <li>• Fluids in place (fluid-in-place and inter-region flows)</li> <li>• EoS regions (for compositional runs).</li> </ul> <p>If this section is omitted, all grid blocks are put in region 1.</p>
Required	<a href="#">SOLUTION</a>	Specification of initial conditions in reservoir. May be: <ul style="list-style-type: none"> <li>• Calculated using specified fluid contact depths to give potential equilibrium</li> <li>• Read from a restart file set up by an earlier run</li> <li>• Specified by the user for every grid block</li> </ul> <p>(not recommended for general use)</p>
Optional	<a href="#">SUMMARY</a>	Specification of data to be written to the Summary file after each timestep. Necessary if certain types of graphical output (for example water-cut as a function of time) are to be generated after the run has finished. If this section is omitted no Summary files are created.
Required	<a href="#">SCHEDULE</a>	Specifies the operations to be simulated (production and injection controls and constraints) and the times at which output reports are required. Vertical flow performance curves and simulator tuning parameters may also be specified in the <a href="#">SCHEDULE</a> section.
Optional (ECLIPSE 300 only)	<a href="#">OPTIMIZE</a>	Specifies a reservoir optimization problem (objective function, control parameters and constraints).

Table 2.1: Data file sections

The sections must be specified in the order shown above.

It is recommended that the body of sections that are not frequently changed be held in separate files, which are included in the data using the [INCLUDE](#) keyword.

---

**Note:** The [OPTIMIZE](#) section header must **not** be specified in an included file.

---

## Data file structure

### Keywords

The keywords in the input data file (including section-header keywords) are each of up to 8 characters in length and must start in column 1. All characters up to column 8 are significant. Any characters on the same line as a keyword from column 9 onwards will be treated as a comment.

### Keyword data

The data for a keyword should follow that keyword on a new line. The data may be split up by blanks or new lines, and position on the line is not significant.

### Repeat counts

In the data following a keyword, asterisks may be used to signify repeat counts. A data quantity can be repeated a required number of times by preceding it with the required number and an asterisk. For example, the two following cases are equivalent:

```
SATNUM
1 1 1 1 1 1 1 1 1
2 2 2 2 2 2 2 2 2 /
```

```
SATNUM
10*1 10*2 /
```

There must be no intervening blank spaces next to the asterisk on either side.

### Default values

Certain items of data can be defaulted to a built-in default value. The keyword description indicates when defaults can be applied. There are two ways of setting quantities to their default values. Firstly, by ending a data record prematurely with a slash (/) the quantities remaining unspecified are set to their default values. Secondly, selected quantities positioned before the slash can be defaulted by entering  $n^*$  where  $n$  is the number of consecutive quantities to be defaulted. For example,  $3^*$  causes the next three quantities in the keyword data to be given their default values. There must be no blank space between the number and the asterisk. If there is only one item at a time to be defaulted, then  $1^*$  must be entered. An asterisk by itself is not sufficient.

An example would be the following line, in which well PROD1 is given a minimum economic oil production rate of 2000, its minimum economic gas rate is defaulted to zero, its maximum water cut limit is set to 0.8, its maximum gas-oil ratio and water-gas ratio limits are defaulted to infinity, the workover procedure is set to shut the worst-offending connection, and all remaining items in the record are defaulted:

```
WECON
PROD1 2000 1* 0.8 2* CON /
/
```

## Character strings

When character information, such as well names or mnemonics, is entered you may optionally enter the information within quotes. For example, the following two keyword entries are equivalent:

```
RPTSCHED
PRESSURE SOIL SGAS /
```

```
RPTSCHED
'PRESSURE' 'SOIL' 'SGAS' /
```

Quotes around strings are required when a name:

- contains embedded blanks;
- starts with a number;
- contains non-alphanumeric characters;
- uses the wildcard \* character in well and group name roots, or well name lists.

## Comments

Any lines beginning with the two characters ‘ -- ’ are treated as comments, and are ignored by ECLIPSE. Comment lines (and blank lines also) may be inserted anywhere in the data file. Comments may also be added to the end of lines of data by beginning the comment with the two characters ‘ -- ’, but in this case the comments must not contain any quotes.

Comments can also be included, without the two characters ‘ -- ’, on the same line after a slash (/) which is used to terminate a data record.

## Global keywords

Some keywords may occur in any section of the input file. These keywords and brief descriptions of their functions are listed below.

### Reading and echoing the input file

The [ECHO](#) and [NOECHO](#) keywords turn on and off the echoing of the input file to the print file. The initial default is echoing on.

The [INCLUDE](#) keyword enables data to be read from another named file. It is followed by the name of a file from which input is to be taken. Once read, the file is closed, and input resumed from the main file, starting from the keyword after the [INCLUDE](#).

An example would be:

```
INCLUDE
CASE6G.DATA /
```

The [SKIP](#) keyword causes all subsequent keywords to be skipped (ignored) until an [ENDSKIP](#) keyword is encountered. The [SKIP100](#) keyword skips the intervening keywords when running ECLIPSE 100. Similarly the [SKIP300](#) keyword skips the intervening keywords when running ECLIPSE 300. This family of keywords is intended to ease the porting of data files between the two simulators.

*ECLIPSE 100* The [COLUMNS](#) keyword can be used to reset the left and right margins for reading the input data file. Only data within these margins are read and processed. The default setting for the left and right margins is 1 and 132 respectively.

*ECLIPSE 100* The [FORMFEED](#) keyword sets the formfeed character in the Print file. The default is to use standard FORTRAN carriage control.

## Setting message print and stop limits

ECLIPSE has a message handling system that has six levels of severity:

1. Messages
2. Comments
3. Warnings
4. Problems
5. Errors
6. Bugs

When one of these occurs, it is logged to the short form output, the Print file, the debug file, and optionally the message file (see the [MSGFILE](#) keyword). After a certain number of occurrences (the 'print limit') of a particular type of message the program will not print any more of that type. Also, after a certain number of occurrences (the 'stop limit') of a particular type of message the run automatically stops. The [MESSAGES](#) keyword allows you to modify the default print and stop limits.

*ECLIPSE 100* It is possible to suppress the output of Warning messages by entering the [NOWARN](#) keyword, and subsequently reactivate them with the [WARN](#) keyword. Output of warnings for PVT and VFP table extrapolation may be controlled with [EXTRAPMS](#).

## Controlling debug

The [DEBUG](#) and [DEBUG3](#) keywords control output to the debug file in ECLIPSE 100 and ECLIPSE 300 respectively. Each of the integers following the keyword controls output from a program option or turns on a test. This is intended mainly for program development purposes.

## Ending input files

The [END](#) keyword terminates the reading of data prior to the actual end of an input file. The program does not echo or process data after this. [END](#) may be used in an [INCLUDE](#) file. To end reading of an [INCLUDE](#) file prior to the actual end of file, and return control to the main input file, [ENDINC](#) may be used. [END](#) and [ENDINC](#) are generated automatically at the actual end of the relevant files, and so normally need not be used.

## List of global keywords

Restriction	Keyword	Description
E100 only	<a href="#">COLUMNS</a>	Reset left and right margins for reading data input file
E100 only	<a href="#">DEBUG</a>	Set debug output control switches

Restriction	Keyword	Description
E300 only	DEBUG3	Set debug output control switches
	ECHO	Switch on the echo of the data printed at the start of each run.
	END	Terminate reading the data.
	ENDINC	Terminate reading the Include file and return to the main data file.
	ENDSKIP	Terminates skipping of keywords (SKIP, SKIP100, SKIP300).
E100 only	EXTRAPMS	Request warning messages for PVT and VFP table extrapolation
E100 only	FORMFEED	Sets the formfeed character in the Print file
E100 only	GETDATA	Imports named array data from previous Initial or Restart files. (GRID, EDIT, PROPS, REGIONS and SOLUTION sections.)
	INCLUDE	Insert the contents of a specified file.
	MESSAGES	Reset print and stop limits for messages of all severity types.
	NOECHO	Switch off the echo of the data printed at the start of each run.
E100 only	NOWARN	Suppress warning messages
	SKIP	Skips the following keywords until ENDSKIP is read.
	SKIP100	Instructs ECLIPSE 100 to skip the following keywords until ENDSKIP is read; it is ignored in ECLIPSE 300.
	SKIP300	Instructs ECLIPSE 300 to skip the following keywords until ENDSKIP is read; it is ignored in ECLIPSE 100.
	WARN	Reactivate warning messages after suppression by NOWARN in ECLIPSE 100 only.

## ECLIPSE 300 error handling

In the event of an error arising during keyword input, the offending line is displayed, with question mark (?) characters under the field that is causing difficulties. The error number quoted may be of two types:

- Up to and including 100.

These are errors detected within the ECLIPSE 300 data parser. Descriptions of these errors are given in table 2.2.

- Above 100.

System data errors, usually caused by internal read operations used to convert a character to its value.

Error Code	Description
1	Unable to read next line from input file
2	Length of current line is zero
3	Quote misplaced in stack or data field
4	Slash character (/) found in the wrong place
5	Data field length greater than 24
6	End of file reached

Error Code	Description
7	Invalid character found
8	Zero length stack found
9	Stack length 1 with illegal character
10	Incorrect stack pointers
11	Failed to find character in repeated data field
12	Multiplier for repeated data field has more than 24 characters
13	Error after internal read of multiplier value
14	Negative multiplier for repeated data field
15	character found as first token in stack
16	Unrecognizable number in repeated data field
17	Single field has the wrong data type
18	Empty token next on stack
19	Unknown data type
20	Data read which is not of the type expected, and which cannot easily be converted
21	Error in internal read to convert character data to number
22	Repeated data has filed length of more than 24 characters
23	Error in internal read of repeated data field multiplier
24	More than one exponential character found
29	Previous data type of repeated filed not compatible for current repeated data field
30	Error in internal read of previous repeated data field
31	Unable to convert current value due to error in previous repeated data field
32	Values for margin setting not valid
33	Zero length string found internally

Table 2.2: Error codes reported by the ECLIPSE 300 data parser

## RUNSPEC section

The RUNSPEC section is the first section of an ECLIPSE data input file. It contains the run title, start date, units, various problem dimensions (numbers of blocks, wells, tables and so forth), flags for phases or components present and option switches. It may be preceded only by comments, global keywords (see "Global keywords") and `LOAD`. The RUNSPEC section must always be present, unless the `LOAD` keyword is used to restart a run from a `SAVE` file that contains the RUNSPEC data.

The RUNSPEC section consists of a series of keywords, which turn on the various modeling options, or contain data (for example problem dimensions). For keywords that have associated data, the data record must be terminated by a slash (/). If a data record is terminated early with a slash, the remaining data items are set to their default values. Similarly, if a keyword is omitted all its associated data items are set to their default values. For most runs, the majority of the data items can be defaulted.

The minimum set of RUNSPEC keywords required by ECLIPSE 100 are:

Keyword	Description
<code>TITLE</code>	Title
<code>DIMENS</code>	Number of blocks in X,Y,Z directions
<code>OIL, WATER, GAS, VAPOIL, DISGAS</code>	The active phases present, that is which of the saturations ( $R_s$ or $R_v$ ) vary
<code>FIELD / METRIC / LAB</code>	Unit convention
<code>START</code>	Start date of the simulation. In ECLIPSE 300 the <code>START</code> keyword is only mandatory if the <code>DATES</code> keyword is used.
<code>WELLDIMS</code>	Well and group dimensions

Table 2.3: Minimum RUNSPEC keywords for ECLIPSE 100

The keyword `NOSIM` sets data checking only, with no simulation.

All else can be defaulted to give:

- A Cartesian geometry, dispersed flow model.
- One set of PVT, Saturation, and Equilibration tables.
- One reporting region.
- Unformatted non-unified restart and graphics files.

The minimum set of keywords required by ECLIPSE 300 is similar, except that it is advisable to enter either `COMPS` or `BLACKOIL` according to whether the run is compositional or black oil. **If neither is**

**present the black-oil case will be assumed.** Oil and gas are included automatically, but the `WATER` keyword should be entered if there is a water phase. The `GASWAT` keyword requests water and gas phases only, using an equation of state to define the equilibrium between these phases. For thermal simulations the `THERMAL` keyword should be used with the `COMPS` keyword. An additional unit convention, `PVT-M`, is available.

It is important to distinguish between the number of tables/cells, for example, which means that the exact number of items must be provided in the data file, and the maximum number of wells/groups, for example, which merely gives an upper limit to the number of items that may be specified.

ECLIPSE 300

---

**Note:** `INCLUDE` files should only be used in the `RUNSPEC` section for datasets output using the SimOpt program.

---

**Note:** `INCLUDE` files should not be used with the `PARALLEL` keyword.

---

ECLIPSE 100

**Note:** To maintain compatibility with older data sets, the fixed record structure used by ECLIPSE 100 before 95A is still recognized. However, this allows a limited selection of facilities and it is recommended that you convert the `RUNSPEC` data to the current format. To help interpret older data sets, the original form of the `RUNSPEC` section is documented in "[RUNSPEC section: pre-95A fixed record structure](#)" in the *ECLIPSE Technical Description*. Please note that the `OPTIONS` keyword cannot be used with the fixed record structure.

---

## Alphabetic list of RUNSPEC keywords

### Common keywords

Keyword	Description
<code>ACTDIMS</code>	Dimensions for the ACTION facility.
<code>ACTPARAM</code>	Parameters for controlling ACTION facility functions.
<code>ASPHALTE</code>	Enable the asphaltene modeling
<code>BLACKOIL</code>	Requests black oil mode.
<code>BRINE</code>	Enable brine tracking.
<code>CART</code>	Specify Cartesian geometry.
<code>COAL</code>	Enable the Coal Bed Methane option.
<code>CPR</code>	Activate the CPR linear solver.
<code>DIFFUSE</code>	Enable molecular diffusion.
<code>DIMENS</code>	Specify the grid dimensions.
<code>DUALPERM</code>	Use the Dual Permeability option.
<code>DUALPORO</code>	Use the Dual Porosity option.
<code>DYNRDIMS</code>	Sets up dimensions for the Dynamic Region facility.
<code>ENDSCALE</code>	Use saturation table end point scaling.
<code>FIELD</code>	Use Field unit convention.

Keyword	Description
FLUXOPTS	Options for Flux Boundary models.
FMTHMD	Indicates that the HMD file is to be formatted.
FMTIN	Indicates that the input files are formatted.
FMTOUT	Indicates that the output files are to be formatted.
FULLIMP	Use the Fully Implicit Solution option.
GAS	The run contains gas.
GDIMS	Specify the dimensions for the instantaneous gradient option.
GRAVDR	Use gravity drainage in dual porosity runs.
GRAVDRB	Use the Vertically Discretized Gravity Drainage Model in dual porosity runs.
GRAVDRM	Use the Alternative Gravity Drainage Model in dual porosity runs.
GRIDOPTS	Set options to process grid data.
HMDIMS	Set dimensions for the Gradient option.
IMPES	Use the IMPES Solution option.
INSPEC	Request an Initial Index file.
LAB	Use Lab unit convention.
LGRCOPY	Copy global values to local cells before operations on cells within an LGR. This will apply to all LGRs in the dataset.
MEMORY	Allocate the required memory at start of run.
METRIC	Use metric unit convention.
MISCIBLE	Enable the Miscible Gas Flood option (ECLIPSE 100) Allow properties to depend on surface tension (ECLIPSE 300).
MONITOR	Request output for run-time monitoring.
MSGFILE	Message file output options.
MULTIN	Indicates that input files are multiple.
MULTOUT	Indicates that output files are multiple.
MULTOUTS	Indicates that Summary files are multiple.
MULTREAL	Activates Multi-Realization licensing.
NETWORK	Set dimensions for Extended Network Model.
NINEPOIN	Select the Nine-point option.
NMATRIX	Use the discretized Matrix Dual-porosity Model.
NOHYST	Disable Hysteresis option.
NOINSPEC	Do not write an Initial Index file.
NOMONITO	Disable the output for run-time monitoring.
NONNC	Disallow non-neighbor connections.
NORSSPEC	Do not write a Restart Index file.
NOSIM	Turn off simulation, but continue data checking.

<b>Keyword</b>	<b>Description</b>
NSTACK	Set linear solver stack size.
NUMRES	The grid contains multiple reservoirs.
NUPCOL	Number of timestep iterations in which well targets are updated.
OIL	The run contains oil.
PARALLEL	Select a parallel run
PETOPTS	Sets options for simulator runs fired from Petrel.
RADIAL	Specify radial geometry.
REGDIMS	Set dimensions for regions data.
ROCKCOMP	Enable the rock compaction option.
RSSPEC	Request a Restart Index file.
SATOPTS	Set options for directional and hysteretic relative permeabilities.
SOLID	Indicates a solid phase in the run
START	Specify the start date.
TABDIMS	Set table dimensions.
TITLE	Specify the run title.
UDADIMS	Dimensions for the user defined arguments facility.
UDQDIMS	Dimensions for the user defined quantity facility.
UDQPARAM	Parameters for the user defined quantity facility.
UNCODHMD	Enables unencoded sensitivities from the Gradient option.
UNIFIN	Indicates that input files are unified.
UNIFOUT	Indicates that output files are unified.
UNIFOUTS	Indicates that Summary files are unified.
VFPIDIMS	Set dimensions for injection well VFP tables.
VFPPDIMS	Set dimensions for production well VFP tables.
VISAGE	Activate the VISAGE geomechanics workflow.
WARP	Enable WARP linear solver.
WATER	The run contains water.
WCOMPRES	Reduce the memory requirements of a simulation that contains a large number of wells, some of which have many connections, but most have relatively few connections.
WELLDIMS	Set dimensions for well data.
WSEGDIMS	Set dimensions for multisegment wells.
WSEGSOLV	Sets parameters for the multisegment well iterative linear solver.

## ECLIPSE 100 only keywords

ECLIPSE 100 only keyword	Description
API	Enable the API Tracking option.
ALKALINE	Enable the Alkaline model.
AUTOREF	Set options for auto refinement.
BIGMODEL	Allows large models to run by changing the internal memory accounting
DISGAS	Run contains dissolved gas in live oil.
DISPDIMS	Dimensions dispersion tables
ECLMC	Enable the Multi-Component option.
EQLDIMS	Set dimensions of equilibration tables.
EQLOPTS	Set options for equilibration.
FAULTDIM	Set dimensions for fault data
FOAM	Enable the Foam option.
FRICITION	Enable the Wellbore Friction option.
GASFIELD`	Enable special options in the Gas Field Operations Model.
GIMODEL	Enable the GI Pseudo-compositional option
LGR	Set options for local grid refinement and coarsening.
LICENSES	Reserve ECLIPSE 100 option licenses.
LOWSALT	Enable the Low-Salinity option.
NNEWTF	Enable the non-Newtonian modeling for polymer
NOCASC	Use the linear solver tracer algorithm to solve single phase tracers.
NRSOUT	Sets the maximum number of quantities that can be output to a restart file
OPTIONS	Activate special options within particular facilities in ECLIPSE 100.
PARTTRAC	Activate partitioned tracers for Environmental Tracers or the Surfactant option
PATHS	Set pathname aliases
PEDIMS	Used to set dimensions for a Petro-elastic Model.
PIMTDIMS	Set PI scaling table dimensions
POLYMER	Enable the Polymer Flood Model.
PSTEADY	Automatically runs the simulator to a steady state.
RIVRDIMS	Set river dimensions.
RPTHMD	Specify controls on the output to the HMD file.
RPTRUNSP	Specify controls on the output of RUNSPEC data.
SAMG	Enable algebraic multigrid linear solver. Note that in ECLIPSE 100 its use is restricted to single phase tracers and requires a Water Services license.
SAVE	Request the output of a Save file for fast restarts
SCDPDIMS	Set dimensions for scale deposition tables.

<b>ECLIPSE 100 only keyword</b>	<b>Description</b>
SMRYDIMS	Set maximum number of Summary file quantities.
SOLVENT	Enable the Four-component Solvent Model.
SURFACT	Enable the Surfactant Model.
SURFACTW	Enable modeling of changes of wettability in the Surfactant Model.
TRACERS	Set dimensions and options for tracers
TEMP	Enable the Temperature option.
VAPOIL	The run contains vaporized oil in wet gas.
VE	Enable the Vertical Equilibrium option
VISCD	Enable the Viscous Displacement option.
WPOTCALC	Control calculation of shut and stopped well potentials.

### ECLIPSE 300 only keywords

<b>ECLIPSE 300 only keyword</b>	<b>Description</b>
AIM	Use the AIM Solution option.
AJGRADNT	Use the adjoint gradient screening option.
AQUDIMS	Dimensions for aquifers.
CBMOPTS	Specify the type of adsorption model to be used with the Coal Bed Methane option.
CO2SOL	Allow CO <sub>2</sub> to dissolve in the aqueous phase.
CO2STORE	Activates the CO <sub>2</sub> storage option
COMPS	Requests compositional mode.
COMPSOL	For SOLID, BLACKOIL runs, this keyword must be used to set the number of components.
COMPW	Requests water component model.
DEADOIL	Use the Dead Oil option in thermal simulations.
DOMAIN	Set non-default domain size for phase property evaluation.
DPCDT	Set maximum rate of change of capillary pressure.
E100NOSI	Switch to NOSIM mode if an incompatible ECLIPSE 100 keyword is read.
EOS	Specify which equation of state is to be used.
EOSS	Specify the surface equation of state.
FASTTRAC	Enables shortcuts in tracer calculations.
FMTSAVE	Indicates that the Save files are formatted
FORMOPTS	Formulation options.
FREEZEPC	Freeze all capillary pressures in the run.
FWELLS	Enable the Fractured Well Completion option.

ECLIPSE 300 only keyword	Description
GASSOL	Use the GASSOL option.
GASWAT	Use the water-gas model.
GEOMECH	Selects the geomechanics option
GEODIMS	Sets the number of geomechanics regions in the simulation, sets table dimensions, in terms of the number of rows and columns, for the <a href="#">PERMSTAB</a> and <a href="#">BIOTCTAB</a> keywords.
GPTDIMS	Set gas plant table dimensions.
H2SSOL	Allow H2S to dissolve in the aqueous phase
HEATDIMS	Set heater keyword dimensions in thermal simulations.
HWELLS	Enable the Horizontal Well Completion option.
HYKR	Enable the Relative Permeability Hysteresis option.
HYPC	Enable the Capillary Pressure Hysteresis option.
HYST	Enable the Hysteresis option.
HYSTJ	Enable the Hysteresis option using the Jargon method.
HYSTK	Enable the Hysteresis option using the Killough method.
IMPSAT	Use the IMPSAT Solution option.
ISGAS	The run is gas condensate.
JALS	Activate the JALS linear solver.
KVALUES	Use K-values in the simulation
LAGTRAC	Activates the Lagrangian Tracer Solver option.
LIVEOIL	Use the live oil option in thermal simulations.
LUMPDIMS	Turns on, and dimensions, the LUMPING option.
MULTSAVE	Indicates that Save files are multiple.
MULTIPHA	Allows multi-phase flash for asphaltene prediction.
MEMSAVE	Allow use of Up Front Memory option.
NINEXZ	Select the Nine-point option in the XZ plane.
NINEYZ	Select the Nine-point option in the YZ plane.
NOAIMLGR	Suppress making all refinement cells implicit in AIM runs.
NODPCO	No dual porosity condensation
NODPCDT	Disable the <a href="#">DPCDT</a> option.
NODPPM	No dual porosity permeability multiplier.
NOFREEZE	Suppress use of the <a href="#">FREEZEPC</a> option.
NOHYKR	Do not apply hysteresis to relative permeabilities.
NOHYPC	Do not apply hysteresis to capillary pressure.
NOMIX	Do not interpolate between oil and gas relative permeabilities near the critical point.

ECLIPSE 300 only keyword	Description
NPROCX	Set number of processors in the x-direction for a parallel run.
NPROCY	Set number of processors in the y-direction for a parallel run.
OPTIONS3	Activate special options within particular facilities in ECLIPSE 300.
PDIVX	Select a division of the x-direction for parallel runs.
PDIVY	Select a division of the y-direction for parallel runs.
RESOPT	Activates the Reservoir Optimization license key.
PSPLITX	Specify multiple domain decomposition in the X-direction.
PSPLITY	Specify multiple domain decomposition in the Y-direction.
PSSTA	Use saturation pressure to assign states, instead of Li correlation.
PVT-M	Use PVT-metric unit convention.
REACTION	Define the number of chemical reactions.
ROCKDIMS	Set dimensions for rock over and underburden data in thermal simulations.
RSM	Output extra data to the RSM file.
SCFDIMS	Set dimensions for conductive fractures.
SECTOR	Define a sector model.
SECTBC	Specify boundary conditions for sector model.
SKIPSTAB	Speeds up flash calculations by skipping some one-phase stability calculations
SOLVDIMS	Specifies the solver dimensions for an unstructured grid.
TRACK	Enable the Tracking option.
TCBDIMS	Set temperature cutback table dimensions in thermal simulations.
THERMAL	Enable the Thermal option.
TRCOEF	Enable transport coefficients to be used.
TRPLPORO	Grid for triple porosity.
UNIFSAVE	Indicates that Save files are unified.
VECTABLE	Set the size of the vector property table.
VELDEP	Settings for velocity dependent relative permeability.
WAGHALT	Selects the alternative WAG hysteresis model.

## GRID section

The GRID section determines the basic geometry of the simulation grid and various rock properties (porosity, absolute permeability, net-to-gross ratios) in each grid cell. From this information, the program calculates the grid block pore volumes, mid-point depths and inter-block transmissibilities.

The actual keywords used depend upon the use of the radial or Cartesian geometry options. The program accepts the radial form in a Cartesian run and vice versa, but issues a warning.

The expressions used to calculate quantities related to grid geometry and rock properties are described in the *ECLIPSE Technical Description*.

## Specifying the basic grid dimensions

The reservoir geometry may be set using keywords [CART](#) or [RADIAL](#) in the RUNSPEC section to either

- Cartesian (X,Y,Z)
- Radial (R, Theta, Z)

and may be specified in either of two ways:

### Block Centered Geometry

Where the blocks are horizontal and all eight corners are right angles. Each block is defined by the dimensions of its three sides and the depth of the top surface.

### Corner Point Geometry

Where the locations of all the eight corners are provided independently and there is no requirement that all the angles of the block are right angles.

The program recognizes that the keywords [COORD](#) and [ZCORN](#) specify Corner Point Geometry. Any other specification of the grid block sizes results in Block Centered Geometry.

For complete flexibility, the [GDFILE](#) keyword may be used to specify all the corner point positions of each cell independently.

In addition, Petrel software can export various types of grid geometry (straight pillars, curved pillars or listric pillars) using the Generic Simulation Grid (GSG) file which can be imported using keyword [PETGRID](#).

Since corner point geometry data is usually very voluminous, and difficult to enter by hand, it is recommended that a pre-processor (for example Petrel) is used to construct it. When data is prepared in this way, a [SPECGRID](#) keyword is included, which is read and checked, to confirm that the dimensions used by the pre-processor and simulator agree.

---

**Note:** Block centered and corner point geometry may not be mixed.

---

The number of grid blocks in each direction in the model (NX, NY, NZ) is set by the keyword [DIMENS](#) in the RUNSPEC section.

---

**Note:** The X and R directions have index I, the Y and Theta directions have index J, and the Z direction has index K.

---

All depths and thicknesses are measured along the Z axis, which is taken to be vertical, with larger values indicating greater depths.

The origin in Cartesian geometry is the top left back corner. Coordinates on the X axis are taken to increase from left to right, and on the Y axis from back to front.

In radial geometry, the origin is the center of the model, where usually a well is located. The inner radius of the reservoir must be provided. Refer to keywords [INRAD](#) and [RADFIN](#) for more information. R increases towards the right for Theta = 0; Theta increases in the clockwise direction.

The input is such that data specified using [GRID](#) and [EDIT](#) section keywords is entered always in natural order, the I-index changing most quickly, then the J-index, and the K-index most slowly. This enables the data to be read from the top left corner of a page along a line (I), then next line (J), then turn the page for the next layer (K).

The shape, size, bulk volume and position of each block is determined by block centered or corner point geometry. All other properties of the grid are the average values for the block irrespective of its geometry. Each grid block must have a porosity and a permeability in all directions where there is more than one grid block.

Data may be input as arrays with a value for each of the NX\*NY\*NZ grid blocks, or for all blocks in a part of the grid defined by the keyword `BOX`. A box exists until a new `BOX` is defined, or the keyword `ENDBOX` is read. The default `BOX` is the whole model. The areal dimensions X, Y, R, Theta may be input as vectors such as `DXV(I)` where `DX` varies only with `I` (see, for example, keyword `DXV`).

Alternatively, data may be set to constant values using the `EQUALS` keyword, and manipulated with keywords `ADD`, `MULTIPLY`, `COPY`, `MINVALUE` and `MAXVALUE`. Data can also be edited by flux region, `MULTNUM` region or `OPERNUM` region with the keywords `ADDREG`, `EQUALREG`, `COPYREG` and `MULTIREG`. The flux regions are defined with keyword `FLUXNUM`.

In block centered geometry, the dimensions of every grid block are specified using the keywords in table 2.4. In radial geometry, the outer radius may be specified (using the `OUTRAD` keyword in ECLIPSE 100, or the `RADFIN` keyword in ECLIPSE 300) instead of specifying `DR`, and the program automatically generates spaced grid blocks in the radial direction, geometrically (for ECLIPSE 100), or logarithmically (for ECLIPSE 300). The depth of the top of each grid block is specified using the `TOPS` keyword.

## Essential keywords

Block centered — Cartesian	Block centered - Radial	Corner point
	INRAD	
DXV or DX	DRV or DR or OUTRAD	COORD and ZCORN
DYV or DY	DTHETAV or DTHETA	or GDFILE or
DZ	DZ	PETGRID
TOPS	TOPS	
PORO	PORO	PORO
PERMX	PERMR	PERMX/PERMR
PERMY	PERMTHT	PERMY/PERMTHT
PERMZ	PERMZ	PERMZ

Table 2.4: Essential GRID section keywords used to specify basic grid dimensions

An example for a simple two layer grid 10 by 10 by 2 grid, with 200 ft. by 200 ft. by 10 ft. cells in the top layer and 200 ft. by 200 ft. by 50 ft. cells in the bottom layer would be:

```

DX
200*200 /
DY
200*200 /
DZ
100*10 100*50 /
    
```

or, equivalently:

```

DXV
10*200 /
DYV
10*200 /
    
```

```
DZV
10 50 /
```

If corner point geometry is not being used, the depth as well as the dimensions of each cell must be entered. This may be done using **TOPS** (to specify the cell top depths) or **MIDS** (ECLIPSE 300 only - to specify the cell mid-point depths). In either case only the cells in the top layer need be specified; the depth of cells below may be calculated from the thickness of the cell and that of the cell above.

ECLIPSE 300

**Note:** MIDS should not be confused with **DEPTH**, used to override cell center depths after calculation in the GRID section, and described in the **EDIT** section overview.

In the radial case one further item of geometry information is required, namely, the inner grid block radius. This can be specified using with the **INRAD** keyword, or for ECLIPSE 300 only, the **RADFIN** keyword.

## Net-to-gross ratios

The **NTG** keyword may be used to enter net-to-gross ratios for each cell. Alternatively, **DZNET** may be used to enter net ratios, and the program will calculate net-to-gross thicknesses as  $NTG = DZNET / DZ$  for each cell.

## Cell porosities and pore volumes

Cell porosities must be entered in all runs, and are used to calculate cell pore volumes. The default porosity is zero. Cells with zero pore volume are deemed inactive, and do not occupy storage during the simulation section. Porosities are entered with the **PORO** keyword. Note that porosities are entered as fractions rather than percentages.

Any method that results in a zero pore volume renders a cell inactive. Optionally, the **ACTNUM** keyword may be used to enter a 0 or 1 for each block, a 0 making the cell inactive. The criterion for an inactive cell may be reset using **MINPORV** (or **MINPV**), to set the minimum pore volume allowed:

- **MINDZNET** may be used to specify a minimum cell thickness allowed for an active cell. (ECLIPSE 300)

## Rock permeability values

These are entered for the dimensions present using **PERMX**, **PERMY** and **PERMZ** (or **PERMR**, **PERMTHT** and **PERMZ** for radial runs).

As for other grid keywords, this could be done using the keyword explicitly, or by using the **EQUALS** keyword.

For example, using the grid defined above, with a permeability of 50mD in the first layer, and 33mD in the second layer, it is possible to enter:

```
PERMX
100*50 100*33 /
```

or to use the **EQUALS** keyword:

```
EQUALS
PERMX 50 4* 1 1 /
PERMX 33 4* 2 2 /
```

```

/

```

The `ADD` keyword is similar, but adds the value specified to the grid array. `MULTIPLY` multiplies the array by a given factor. `COPY` can be used to set values for one keyword equal to those for another.

A common example is setting the Y-direction permeabilities equal to the X-direction permeabilities:

```

COPY
PERMX PERMY /

```

The `ADD`, `COPY`, `EQUALS` and `MULTIPLY` keywords are processed as they are read, so that repeat operations are possible on the same section of an array.

## Transmissibility multipliers

Once the cell dimensions and permeabilities are known, the program is in a position to calculate the transmissibilities. The transmissibilities in the program are defined so that  $T_x(I)$  is between blocks  $I$  and  $(I + 1)$ . The expressions for these are given in the "Transmissibility Calculations" in the *ECLIPSE Technical Description*.

Transmissibilities may be modified by the transmissibility multiplier keywords `MULTX`, `MULTY`, `MULTZ`, `MULTR` and `MULTTHT`.

Note that the X-direction multiplier acts on the transmissibility between the cell and its neighbor in the **positive** X-direction. Similar considerations apply to the Y and Z directions.

Transmissibilities across faults identified with the `FAULTS` keyword can be modified with the keyword `MULTFLT`. Refer also to the `MULTX-`, `MULTY-`, `MULTZ-`, `MULTR-` and `MULTTHT-` keywords.

The following applies to ECLIPSE 300. In some `IMPES` runs, convergence can be improved by limiting the transmissibility in the Z-direction. This may be done using the `MAXTRANZ` keyword.

## Diffusivity multipliers

If the `DIFFUSE` option has been used in the `RUNSPEC` section to enable molecular diffusion to be modeled, diffusivities are calculated that reflect the effect of grid block properties upon diffusive flow. The calculation of these is described in "Diffusion" in the *ECLIPSE Technical Description*.

It is possible to set multipliers to act in these calculations, analogous to `MULTX` and similar keywords, in the normal convective flow case. The required keywords are `DIFFMX`, `DIFFMY` and `DIFFMZ` (or, for radial runs, `DIFFMR`, `DIFFMTH` and `DIFFMZ`).

As in the case of transmissibility multipliers, the diffusivity multiplier acts between the cell and its neighbor in the **positive** direction. Refer also to `DIFFMX-`, `DIFFMY-` and `DIFFMZ-` (or, for radial runs, `DIFFMR-`, `DIFFMTH-` and `DIFFMZ-`) keywords.

## BOX and ENDBOX keywords

By default, keywords that supply data over the grid (such as `DX` and `DY`) expect data for the whole grid, that is  $N_x \cdot N_y \cdot N_z$  values.

The **BOX** keyword may be used to modify this range so that values may be entered for a sub-box of cells in the reservoir. **ENDBOX** may be used to revert to the whole grid. The current box is the default range when **EQUALS**, **MULTIPLY**, **ADD** and **COPY** are used.

As an example, consider a 40 by 20 by 8 cell study, in which the first 4 layers have a porosity of 0.07 and the remaining 4 layers have a porosity of 0.03. This might be done using the **BOX** and **ENDBOX** keywords.

```

BOX
1 40 1 20 1 4 /
PORO
3200*0.07 /
ENDBOX

BOX
1 40 1 20 5 8 /
PORO
3200*0.03 /
ENDBOX

```

The **FLUXNUM** keyword may be used (even when neither **DUMPFLUX** nor **USEFLUX** is entered) to identify regions of the field by index number. Values in these regions may then be manipulated with **ADDREG**, **COPYREG**, **EQUALREG** and **MULTIREG**. The **MULTNUM** keyword and the **OPERNUM** keyword can also be used with **ADDREG**, **COPYREG**, **EQUALREG** and **MULTIREG**.

## Non-neighbor connections (NNCs)

If corner point geometry is being used, NNCs are generated to represent faults when layers overlap between columns.

There are several keywords specifically for the generation of non-neighbor flows.

### Common keywords

Keyword	Description
<b>COARSEN</b>	Generates non-neighbor connections generated from using the grid coarsening option.
<b>CIRCLE</b>	may be used in radial studies with more than two cells in the direction to represent flow across the 360 degree to 0 degree boundary.
<b>NOCIRCLE</b>	may be used in local radial grid refinement runs to complete the circle.
<b>NNC</b>	may be used to enter a non-neighbor transmissibility between any two cells in the reservoir. In ECLIPSE 300 this is further enhanced with the <b>NNCGEN</b> keyword.
<b>SIGMA</b>	may be used to specify a coupling parameter for NNCs set up in Dual Porosity runs. The use of this is discussed in "Dual Porosity" in the <i>ECLIPSE Technical Description</i> .
<b>SIGMAGD</b>	may be used to specify a different coupling parameter for gravity drainage. By default, the <b>SIGMA</b> values are used.
<b>PINCH</b>	specifies how missing zero thickness layers are to be treated. NNCs may be generated across the absent layer.
<b>AQUCON</b>	connects a numerical aquifer to the reservoir using NNCs

ECLIPSE 300

By default, non-neighbor connections are not generated across pinched-out layers (or columns), unless keyword **PINCH**(or **PINCHXY**) is entered. The keywords **MINPV** and **MINPVV** may be used to specify a threshold pore volume for a cell to be inactive. Any cells whose pore volumes lie below the threshold are

made inactive. This may be used to inactivate cells with small pore volumes and to create a pinched-out layer, for example.

For further details on transmissibilities see "[Transmissibility Calculations](#)" in the *ECLIPSE Technical Description*.

## ECLIPSE 100 only keywords

- [AQUNNC](#) specified numerical aquifer NNC properties explicitly.

ECLIPSE 100

If the [NEWTRAN](#) keyword is specified, ECLIPSE 100 uses the corner point data to compute the transmissibilities across faults, and automatically generates non-neighbor connections where necessary (unless [NONNC](#) is specified in the [RUNSPEC](#) section). By default, non-neighbor connections are not generated across pinched-out layers (or columns), unless keyword [PINCH](#), or [PINCHREG](#) (or [PINCHXY](#)) is entered.

ECLIPSE 100.

Grids that consist of two or more unconnected regions (coupled only through group control of the wells) can be solved more efficiently as separate units, if they are identified with the [ISOLNUM](#) keyword. Refer to "[Independent Reservoir Regions](#)" in the *ECLIPSE Technical Description*.

## Output control

Output to the print file of GRID section data, both input and calculated, is controlled by the [RPTGRID](#) keyword. This is followed by mnemonics for the required arrays. For example,

```
RPTGRID
DX DY PERMX PERMY PORO /
```

requests output of X and Y cell dimensions and permeabilities, and of the porosities. The maximum and minimum values in each of the GRID arrays are automatically be printed.

ECLIPSE 100

Grid-valued output values in certain types of cell have the decimal point replaced with a special character for ease of identification. See [3.31](#) for details.

As an alternative, the ECLIPSE 100 keyword can be used. This has a series of integer values, with a 0 requesting no output of the appropriate property, an a 1 (or greater) requesting output.

Output is normally generated to a GRID file, which may be read by GRAF to obtain plots of cell positions. This may be prevented, if not required, by the [NOGGF](#) keyword.

An initial file may be requested using the [INIT](#) keyword. This contains arrays such as PORV and DEPTH, which may then be read by GRAF.

The [RPTINIT](#) keyword has been added to allow the user to control GRID and EDIT output, both input and calculated, to the .INIT or .FINIT file. This is followed by mnemonics for the required arrays. For example,

```
RPTINIT
DZ PERMX TRANY PORO /
```

requests output of Z cell dimensions, X cell permeabilities, Y cell transmissibilities and the porosities.

The output applies for both the global grid and for any LGRs contained in the model (for example Cartesian, radial, nested). The PORV information will always be output to the init file. When this keyword is specified along with a series of additional mnemonics, this information will also be output to the .INIT or .FINIT file.

## Local grid refinement

Areas of the grid may be refined using the [CARFIN](#) and [RADFIN](#) keywords (for Cartesian and radial refinements, respectively).

ECLIPSE 300

Cells of Cartesian refinements may be further refined. The simulator treats global and refined cells together in the solution steps. In the [AIM](#) mode, local grids are made implicit unless otherwise requested.

## Description of GRID section keywords

All keywords must start in column 1. All characters up to column 8 are significant.

A list of all keywords which may occur in the GRID section is given below, together with a brief description of their function. A more detailed description may be found by looking up the keyword in the manual.

### Block centered geometry

- [TOPS](#) Depths of top faces of grid blocks for the current input box.
- [DZ](#) Z-direction (vertical) grid block sizes for the current input box.

### Cartesian block centered

Cartesian keywords	Description
<a href="#">DX</a>	X-direction grid block sizes for the current input box (or use <a href="#">DXV</a> ).
<a href="#">DXV</a>	Vector of X-direction grid block sizes or use <a href="#">DX</a> . Simplified version of <a href="#">DX</a>
<a href="#">DY</a>	Y-direction grid block sizes for the current input box (or use <a href="#">DYV</a> ).
<a href="#">DYV</a>	Vector of Y-direction grid block sizes or use <a href="#">DY</a> . Simplified version of <a href="#">DY</a>

### Radial block centered

Restriction	Radial keyword	Description
Required for radial block centered geometry.	<a href="#">INRAD</a>	Sets inner radius of radial grid.
Must be set	<a href="#">DR</a>	R-direction grid block sizes for the current input box (or use <a href="#">DRV</a> or <a href="#">OUTRAD</a> ).
Optional for radial geometry	<a href="#">DRV</a>	Vector of R-direction grid block sizes (or use <a href="#">DR</a> or <a href="#">OUTRAD</a> ). Simplified version of <a href="#">DR</a>
E100 only.	<a href="#">OUTRAD</a>	Sets outer radius of radial grid (or use <a href="#">DR</a> or <a href="#">DRV</a> ).
Must be set	<a href="#">DTHETA</a>	Theta-direction grid block sizes for the current input box (or use <a href="#">DTHETAV</a> ).
	<a href="#">DTHETAV</a>	Vector of Theta-direction grid block sizes (or use <a href="#">DTHETA</a> ). Simplified version of <a href="#">DTHETA</a>

## Corner point geometry

Restriction	Corner point keyword	Description
Either COORD and ZCORN or GDFILE are required for corner point geometry.	COORD	Defines the lines that contain all grid block corner points for each (I, J) and for each reservoir in the grid.
Either COORD and ZCORN or GDFILE are required for corner point geometry.	ZCORN	Point depths of grid block corners.
Either COORD and ZCORN or GDFILE are required for corner point geometry.	GDFILE	Inputs corner point positions for each cell from a GRID file as an alternative to COORD and ZCORN.
Optional	ADDZCORN	Adds a constant value to cell corner point depths
Optional	EQLZCORN	Resets part of the corner point depth array within a specified box
E100 only Required only if > 1, or for completing the circle	COORDSYS	Information about the coordinate system for each reservoir in the grid. Specifies completion of the circle in both corner point and block-centered geometries.
Optional	RESVNUM	Initiates COORD data input for a given reservoir in the grid
Optional	MAPAXES	Inputs map origin from a grid pre-processor, for output to the GRID file
Optional	MAPUNITS	Specifies the units used for MAPAXES data for output to the GRID file
Optional	GRIDUNIT	Specifies the grid data units that can be output by grid pre-processors or by ECLIPSE simulators writing the grid geometry files

## Block properties, all geometries

Restriction	Keyword	Description
	PORO	Grid block porosities for the current input box. Must be set in some way
Optional	DZNET	Grid block net thicknesses (or use NTG).
Optional	NTG	Grid block net-to-gross ratios for current input box (or use DZNET).
Optional	ACTNUM	Identifies active grid blocks.
E300 only	MIDS	Specifies cell mid-point depths
Optional	MINPV	Minimum pore volume that each grid block must have to be active (scalar)
	MINPVV	Minimum pore volumes that grid blocks in the current BOX must have to be active (vector).

Restriction	Keyword	Description
Optional	<a href="#">MULTPV</a>	Pore volume multipliers for the current input box
Must be if radial with $NR > 1$ .	<a href="#">PERMR</a>	R-direction permeabilities for the current input box.
Must be if radial with $NTHETA > 1$ .	<a href="#">PERMTH</a>	Theta-direction permeabilities for the current input box.
Must be set if Cartesian with $NX > 1$ .	<a href="#">PERMX</a>	X-direction permeabilities for the current input box
Must be set if Cartesian with $NY > 1$ .	<a href="#">PERMY</a>	Y-direction permeabilities for the current input box.
Must be set for any system with $NZ > 1$	<a href="#">PERMZ</a>	Z-direction permeabilities for the current input box.
May be used only if both <a href="#">ENDSCALE</a> and item <a href="#">SURFTENS</a> in <a href="#">SATOPTS</a> are entered in the <a href="#">RUNSPEC</a> section.	<a href="#">JFUNC</a>	Activates Leverett J-Function option to scale capillary pressure according to rock porosity and permeability
May be used only if both <a href="#">ENDSCALE</a> and item <a href="#">SURFTENS</a> in <a href="#">SATOPTS</a> are entered in the <a href="#">RUNSPEC</a> section.	<a href="#">JFUNCR</a>	Activates Leverett J-Function option to scale capillary pressure according to rock porosity and permeability on a per saturation region basis.  Each set of saturation function tables may be specified to use either capillary pressures values obtained from direct table look-up or via the Leverett J-Function calculation.

## Transmissibility keywords

All keywords are optional.

### Common keywords

- [NNC](#) Explicit entry of non-neighbor connections.
- [PINCH](#) Generates connections across pinched-out layers.
- [PINCHOUT](#) Generates connections across pinched-out layers.
- [PINCHXY](#) Generates connections across columns that are pinched-out horizontally.

### ECLIPSE 100 only keywords

ECLIPSE 100 only keyword	Description
<a href="#">NEWTRAN</a>	Specifies that corner point data should be used to compute transmissibilities
<a href="#">OLDTRAN</a>	Specifies that block center data should be used to compute transmissibilities.
<a href="#">OLDTRANR</a>	Alternative calculation of transmissibilities using block characteristics
<a href="#">PINCHNUM</a>	Identifies pinchout regions for use by <a href="#">PINCHREG</a> .
<a href="#">PINCHREG</a>	Specifies pinchout data within <a href="#">PINCHNUM</a> regions.

ECLIPSE 100 only keyword	Description
<a href="#">LINKPERM</a>	Treats grid block permeabilities as applying to cell faces.
<a href="#">HALFTRAN</a>	Activates the half-block transmissibility upscaling option.
<a href="#">PERMAVE</a>	Specifies options for averaging grid block permeabilities in the calculation of transmissibilities

## Transmissibility modifiers

Restriction	Keyword	Description
Optional if radial with NR > 1	<a href="#">MULTR</a>	R-direction transmissibility multipliers for the current input box.
Optional if radial with NR > 1	<a href="#">MULTR-</a>	Negative R-direction transmissibility multipliers for the current input box.
Optional if radial with NTHETA > 1	<a href="#">MULTTHT</a>	Theta direction transmissibility multipliers for the current input box.
Optional if radial with NTHETA > 1	<a href="#">MULTTHT-</a>	Negative Theta-direction transmissibility multipliers for the current input box.
Optional if Cartesian with NX > 1	<a href="#">MULTX</a>	X-direction transmissibility multipliers for the current input box.
Optional if Cartesian with NX > 1	<a href="#">MULTX-</a>	Negative X-direction transmissibility multipliers for the current input box.
Optional if Cartesian with NY > 1	<a href="#">MULTY</a>	Y-direction transmissibility multipliers for the current input box.
Optional if Cartesian with NY > 1	<a href="#">MULTY-</a>	Negative Y-direction transmissibility multipliers for the current input box.
Optional if NZ > 1	<a href="#">MULTZ</a>	Z-direction transmissibility multipliers for the current input box.
Optional if NZ > 1	<a href="#">MULTZ-</a>	Negative Z-direction transmissibility multipliers for the current input box.
Optional	<a href="#">MULTREGT</a>	Multiplies transmissibilities between regions defined with <a href="#">FLUXNUM</a> or <a href="#">MULTNUM</a> .
Optional	<a href="#">MULTNUM</a>	Identifies regions for use with <a href="#">MULTREGT</a> , <a href="#">MULTREGD</a> (ECLIPSE 100 only) and <a href="#">MULTREGH</a> (ECLIPSE 100 only). Also defines regions, for editing data with <a href="#">ADDREG</a> , <a href="#">EQUALREG</a> , <a href="#">MULTIREG</a> and <a href="#">COPYREG</a> .

Table 2.5: Transmissibility modifiers

## Faults

Keyword	Description
<a href="#">FAULTS</a>	Identifies fault trajectories for subsequent use by the <a href="#">MULTFLT</a> keyword.

Keyword	Description
MULTFLT	Multipliers for the transmissibility and diffusivity across faults defined by the FAULTS keyword.
THPRESFT	Threshold pressures associated with faults defined by the FAULTS keyword.

## Numerical aquifers

### Common keywords

Restriction	Keyword	Description
Required for numerical aquifer definition	AQUCON	Defines a connection between a numerical aquifer and the reservoir.
Required for Carter-Tracy aquifer definition	AQUCT	Specifies property data for Carter-Tracy aquifer.
Required for numerical aquifer definition	AQUNUM	Defines a numerical aquifer

### ECLIPSE 300 only keywords

Restriction	ECLIPSE 300 only keyword	Description
Required for analytic aquifer definition	AQUANCON	Defines connection data for analytic aquifer.

## Dual porosity

### Common keywords

Keyword	Description
BTOBALFA	Switch on Z-direction block to block matrix-fracture coupling and supply single-value transmissibility connection fraction multiplier.
BTOBALFV	Switch on Z-direction block to block matrix-fracture coupling and supply multiple-value transmissibility connection fraction multipliers.
DIFFMMF	Diffusivity multipliers for matrix-fracture coupling.
DPGRID	Enables user to enter grid data for matrix cells only.
DPNUM	Identifies the extent of the regions in which the single porosity model may be applied in a dual porosity run.
DZMTRX	The vertical dimension of a typical block of matrix material, for the entire grid.
DZMTRXV	The vertical dimension of a typical block of matrix material, for the current box.
NMATOPTS	Controls the Discretized Matrix Dual Porosity option.
NODPPM	Specifies that permeabilities in the fracture cells are not to be multiplied by the fracture porosity.
SIGMA	Matrix-to-fracture coupling factor for the entire grid.
SIGMAV	Matrix-to-fracture coupling factor for the current box.

Keyword	Description
<a href="#">SIGMAGD</a>	Matrix-to-fracture coupling for oil-gas gravity drainage, for the entire grid
<a href="#">SIGMAGDV</a>	Matrix-to-fracture coupling for oil-gas gravity drainage, for the current box.

## ECLIPSE 100 only keywords

ECLIPSE 100 only keyword	Description
<a href="#">LTOSIGMA</a>	Provides an easy way to calculate <a href="#">SIGMA</a> from LX, LY, LZ.
<a href="#">LX</a> , <a href="#">LY</a> , <a href="#">LZ</a>	Inputs the representative matrix block sizes for the viscous displacement option.

## ECLIPSE 300 only keywords

ECLIPSE 300 only keyword	Description
<a href="#">MULTMF</a>	Transmissibility multipliers for matrix-fracture coupling.
<a href="#">PERMMF</a>	Permeability for matrix-fracture coupling.

## Compressed vertical equilibrium (ECLIPSE 100)

Restriction	ECLIPSE 100 only keyword	Description
Optional, CVE runs only	<a href="#">COLLAPSE</a>	Specifies which cells should be collapsed.
Optional, CVE runs only	<a href="#">CRITPERM</a>	Sets a critical permeability to determine which cells are collapsed.
Optional, VE runs only	<a href="#">VEDEBUG</a>	Controls debug output for VE options.

## Diffusivity modifiers

### Common keywords

Restriction	Keyword	Description
Optional if radial with > 1	<a href="#">DIFFMR</a>	R-direction diffusivity multipliers for the current input box.
Optional if radial with > 1	<a href="#">DIFFMR-</a>	Negative R-direction diffusivity multipliers for the current input box.
Optional if radial with > 1	<a href="#">DIFFMTH</a>	Theta-direction diffusivity multipliers for the current input box.
Optional if radial with > 1	<a href="#">DIFFMTH-</a>	Negative Theta-direction diffusivity multipliers for the current input box.
Optional if Cartesian with > 1	<a href="#">DIFFMX</a>	X-direction diffusivity multipliers for the current input box.

Restriction	Keyword	Description
Optional if Cartesian with > 1	<a href="#">DIFFMX-</a>	Negative X-direction diffusivity multipliers for the current input box.
Optional if Cartesian with > 1	<a href="#">DIFFMY</a>	Y-direction diffusivity multipliers for the current input box.
Optional if Cartesian with > 1	<a href="#">DIFFMY-</a>	Negative Y-direction diffusivity multipliers for the current input box.
Optional if > 1	<a href="#">DIFFMZ</a>	Z-direction diffusivity multipliers for the current input box.
Optional if > 1	<a href="#">DIFFMZ-</a>	Negative Z-direction diffusivity multipliers for the current input box.
Optional, dual porosity runs only	<a href="#">DIFFMMF</a>	Matrix-fracture diffusivity multipliers for the current input box.
Optional	<a href="#">MULTFLT</a>	Multipliers for the transmissibility and diffusivity across faults defined by the keyword.

## ECLIPSE 100 only keywords

Restriction	ECLIPSE 100 only keyword	Description
Optional.	<a href="#">MULTREGD</a>	Multipliers for the diffusivity between regions defined with <a href="#">FLUXNUM</a> or <a href="#">MULTNUM</a> .
Optional.	<a href="#">MULTNUM</a>	Identifies regions for use with <a href="#">MULTREGT</a> , <a href="#">MULTREGD</a> and <a href="#">MULTREGH</a>

## Independent reservoir regions (ECLIPSE 100)

- [ISOLNUM](#) Defines the independent reservoir regions, for efficient solution.
- [RPTISOL](#) Generates data for the [ISOLNUM](#) keyword, output to the Debug file.

## Temperature option (ECLIPSE 100)

ECLIPSE 100 only keyword	Description
<a href="#">MULTREGH</a>	Multipliers for the thermal conductivity between regions defined with <a href="#">FLUXNUM</a> or <a href="#">MULTNUM</a> .
<a href="#">MULTNUM</a>	Identifies regions for use with <a href="#">MULTREGT</a> , <a href="#">MULTREGD</a> and <a href="#">MULTREGH</a> .
<a href="#">THCONR</a>	Rock thermal conductivities for the current input box.

## Nine-point scheme (ECLIPSE 300)

ECLIPSE 300 only keyword	Description
NINENUM	Specifies the extent of the nine-point discretization scheme.
MINPORV9	Set a minimum pore volume for calculation of nine-point transmissibilities.
ORTHERRO	Set a minimum orthogonality error for calculation of nine-point transmissibilities.
ORTHERRX	Set a minimum orthogonality error for calculation of nine-point transmissibilities for interfaces in the X-direction.
ORTHERRY	Set a minimum orthogonality error for calculation of nine-point transmissibilities for interfaces in the Y-direction.
ORTHERRZ	Set a minimum orthogonality error for calculation of nine-point transmissibilities for interfaces in the Z-direction.

## Operational keywords

### Common keywords

Keyword	Description
ADD	Adds specified constants to specified arrays in the current input box.
ADDREG	Adds specified constants to specified arrays in a given flux, <a href="#">MULTNUM</a> or <a href="#">OPERNUM</a> region.
BOUNDARY	Defines the section of the grid for which output maps are required.
BOX	Redefines the current input box
COPY	Copies data in the current box from one specified array to another.
COPYBOX	Copies data from one box of cells to another box of the same size.
COPYREG	Copy by <a href="#">FLUXNUM</a> region, <a href="#">MULTNUM</a> region or <a href="#">OPERNUM</a> region.
DUMPFLUX	Output a Flux file.
ENDBOX	Redefines the current input box to encompass the whole grid.
EQUALS	Sets specified arrays to specified constants within the current box.
EQUALREG	Sets specified arrays to specified constants in a given flux, <a href="#">MULTNUM</a> or <a href="#">OPERNUM</a> region.
FLUXNUM	Defines flux regions, for editing data with <a href="#">ADDREG</a> , <a href="#">EQUALREG</a> , <a href="#">MULTIREG</a> and <a href="#">COPYREG</a> , and for inter-region multipliers <a href="#">MULTREGT</a> , <a href="#">MULTREGD</a> and <a href="#">MULTREGH</a>
FLUXREG	Select which flux regions are active in a run.
GRIDFILE	Controls the contents of the Grid Geometry file (for graphical output).
IMPORT	Imports binary data generated by a grid pre-processor.
INIT	Produces initial file for GRAF.
LGRCOPY	Copy global values to local cells before operations on cells within an LGR.
MAXVALUE	Applies a maximum value to specified arrays within the current box.
MINNNCT	Sets a cut-off transmissibility below which an NNC is deleted.
MINVALUE	Applies a minimum value to specified arrays within the current box.

Keyword	Description
MULTIPLY	Multiply specified arrays by specified constants within the current box.
MULTIREG	Multiply specified arrays by specified constants in a given flux, MULTNUM or OPERNUM region.
NOGGF	Specifies that no Grid Geometry file is to be produced (for graphical output).
OPERATE	Performs arithmetic operations on arrays.
OPERATER	Performs arithmetic operations on arrays for a specific region of the grid.
OPERNUM	Defines region on which to perform operations using the OPERATER keyword. The data can also be edited using ADDREG, EQUALREG, MULTIREG and COPYREG.
RPTGRID	Sets report levels for GRID data.
RPTINIT	Controls output to the Initialization file for GRID and EDIT data.
SOLVDIRS	Overrides default settings for principal directions in the linear solver.
SPECGRID	Specification of grid dimensions.
TOPS	Specifies the depths of the top face of each grid cell.
USEFLUX	Use a Flux file.

## ECLIPSE 300 only keywords

ECLIPSE 300 only keyword	Description
CIRCLE	Requests completion of the circle
MAXTRANZ	Maximum Z-direction transmissibility.
MIDS	Specify cell mid-point depths.
MINDZNET	Minimum net thickness for active cell.
XSTC	Specifies oil composition at standard conditions for the Flux option.
YSTC	Specifies gas composition at standard conditions for the Flux option.

## Local grid refinement

### Common keywords

Keyword	Description
CARFIN	Defines a Cartesian local grid refinement.
COARSEN	Specifies a box of cells for grid coarsening.
ENDFIN	Terminates data for local grid refinement.
HRFIN	Local grid size ratios in the R-direction.
HXFIN	Local grid size ratios in the X-direction.
HYFIN	Local grid size ratios in the Y-direction.
HZFIN	Local grid size ratios in the Z-direction.
NXFIN	Number of local cells in each global cell of an LGR in the X-direction.

Keyword	Description
<a href="#">NYFIN</a>	Number of local cells in each global cell of an LGR in the Y-direction.
<a href="#">NZFIN</a>	Number of local cells in each global cell of an LGR in the Z-direction.
<a href="#">RADFIN</a>	Specifies a single-column radial local grid refinement.
<a href="#">REFINE</a>	Initiates data input for a named local grid.
<a href="#">RPTGRIDL</a>	Controls output of GRID section data for local grids.

## ECLIPSE 100 only keywords

ECLIPSE 100 only keyword	Description
<a href="#">AMALGAM</a>	Allow local grids to amalgamate.
<a href="#">AUTOCOAR</a>	Specifies a box of cells for coarsening within an auto refinement.
<a href="#">QMOBIL</a>	Controls the mobile end-point correction in an LGR.
<a href="#">RADFIN4</a>	Specifies a four-column radial local grid refinement
<a href="#">RPTGRIDL</a>	Controls output of GRID section data for local grids.
<a href="#">SMULTX</a> , <a href="#">SMULTY</a> , <a href="#">SMULTZ</a>	Alternative transmissibility multipliers for auto refinement.
<a href="#">VEFIN</a>	Controls Vertical Equilibrium in local grids.

## ECLIPSE 300 only keywords

ECLIPSE 300 only keyword	Description
<a href="#">NOCIRCLE</a>	Turn off completion of circle for local radial refinements.

## Tensor permeability

### Common keywords

- [MPFANUM](#) Identifies regions in which to apply the multipoint discretization or nine point scheme.
- [MPFNNC](#) Sets multi-point transmissibility coefficients.

## ECLIPSE 300 only keywords

ECLIPSE 300 only keyword	Description
<a href="#">GADJUST</a>	Adjusts diagonal permeability tensor.
<a href="#">MPFA</a>	Sets options for tensor permeability.
<a href="#">PERMXX</a>	X-direction tensor permeability coefficient for the current input box.
<a href="#">PERMY</a>	Y-direction tensor permeability coefficient for the current input box.
<a href="#">PERMZZ</a>	Z-direction tensor permeability coefficient for the current input box.
<a href="#">PERMXY</a>	XY-direction tensor permeability coefficient for the current input box
<a href="#">PERMYZ</a>	YZ-direction tensor permeability coefficient for the current input box.

ECLIPSE 300 only keyword	Description
PERMZ	ZX-direction tensor permeability coefficient for the current input box.
TBASIS	Specify basis for tensor permeabilities.

## Geomechanics (ECLIPSE 300)

- **BIOTC** Sets the Biot constant for each grid block.
- **FAULTS** Can define a geomechanics fault where slippage is allowed.
- **GLTHEX** Sets a coefficient of linear thermal expansion for each grid block
- **POISSONR** Sets the Poisson ratio for each grid block.
- **PROPFLOW** Defines parameters to be used with the proponent flowback feature
- **ROCKDEN** Sets the rock density for each grid block.
- **YOUNGMOD** Sets the elastic Young's modulus for each grid block.

## Alphabetical list of GRID section keywords

### Common keywords

Keyword	Description
ACTNUM	Identifies active grid blocks.
ADD	Adds specified constants to specified arrays in the current box.
ADDREG	Adds a constant to the specified array in a given flux, <b>MULTNUM</b> or <b>OPERNUM</b> region.
ADDZCORN	Adds a constant to the cell corner point depths array ZCORN.
AQUCON	Defines a connection between a numerical aquifer and the reservoir.
AQUNUM	Defines a numerical aquifer.
BOUNDARY	Defines the section of the grid for which output maps are required.
BOX	Redefines the current box.
CARFIN	Defines a Cartesian local grid refinement.
COARSEN	Specifies a box of cells for grid coarsening.
COALNUM	Specifies coal regions for the Coal bed Methane option
COORD	Defines the lines that contain all grid block corner points for each (I,J) and for each reservoir in the grid.
COORDSYS	Specifies completion of the circle in both corner point and block-centered geometries. Allocates grid block layers to reservoirs if there is more than one reservoir in the grid.
COPY	Copies data in the current box from one specified array to another.
COPYBOX	Copies data from one box of cells to another box of the same size.
COPYREG	Copy by <b>FLUXNUM</b> region, <b>MULTNUM</b> region or <b>OPERNUM</b> region
DIFFMMF	Matrix-fracture diffusivity multipliers for current input box.

<b>Keyword</b>	<b>Description</b>
DIFFMR	R-direction diffusivity multipliers for current input box.
DIFFMR-	Negative R-direction diffusivity multipliers for current input box.
DIFFMTH	Theta-direction diffusivity multipliers for current input box.
DIFFMTH-	Negative Theta-direction diffusivity multipliers for current input box.
DIFFMX	X-direction diffusivity multipliers for current input box.
DIFFMX-	Negative X-direction diffusivity multipliers for current input box.
DIFFMY	Y-direction diffusivity multipliers for current input box.
DIFFMY-	Negative Y-direction diffusivity multipliers for current input box.
DIFFMZ	Z-direction diffusivity multipliers for current input box.
DIFFMZ-	Negative Z-direction diffusivity multipliers for current input box.
DPGRID	Enables you to enter grid data for matrix cells only.
DPNUM	Identifies single porosity regions in a dual porosity run.
DR	R-direction grid block sizes for the current box.
DRV	Vector of R-direction grid block sizes.
DTHETA	Theta-direction grid block sizes for the current box.
DTHETA V	Vector of theta-direction grid block sizes.
DUMPFLUX	Output a Flux file.
DX	X-direction grid block sizes for the current box.
DXV	Vector of X-direction grid block sizes.
DY	Y-direction grid block sizes for the current box.
DYV	Vector of Y-direction grid block sizes.
DZ	Z-direction (vertical) grid block sizes for the current box.
DZMTRX	The vertical dimension of a typical block of matrix material, for the entire grid.
DZMTRXV	The vertical dimension of a typical block of matrix material, for the current box.
DZNET	Grid block net thicknesses for the current box.
ENDBOX	Redefines the current box to encompass the whole grid.
ENDFIN	Terminates data for a local grid refinement.
EQLZCORN	Resets part of the corner point depth array.
EQUALREG	Sets a specified array to a constant value in a given flux, MULTNUM or OPERNUM region.
EQUALS	Sets specified arrays to specified constants in the current box.
EXTFIN	Specifies an unstructured local grid refinement.
EXTHOST	Specifies the global host cells of an unstructured local grid refinement.
EXTREPGL	Specifies the replaced global cells for an unstructured local grid refinement.
FAULTS	Identifies fault trajectories for subsequent use by MULTFLT keyword.
FILEUNIT	Confirms the units of the data set.
FLUXNUM	Defines flux regions, for editing GRID section data.

Keyword	Description
FLUXREG	Select which flux regions are active in a run.
GDFILE	Inputs corner point positions for each cell from a Grid file.
GDORIENT	Indicates the orientation and handedness of the grid
GRIDFILE	Controls contents of grid geometry file (for graphical output).
GRIDUNIT	Specifies the grid data units that can be output by grid pre-processors or by ECLIPSE simulators writing the grid geometry files
HMMULTPV	Specifies pore volume multipliers (cumulative).
HMMULTxx	Specify history matching multipliers on transmissibility and/or permeability.
HRFIN	Local grid size ratios in the R-direction.
HXFIN	Local grid size ratios in the X-direction.
HYFIN	Local grid size ratios in the Y-direction.
HZFIN	Local grid size ratios in the Z-direction.
IMPORT	Imports binary data generated by a grid pre-processor.
INIT	Produces Initial file for GRAF.
INRAD	Sets inner radius of radial grid.
JFUNC	Activates Leverett J-Function option for scaling capillary pressure.
JFUNCR	Activates Leverett J-Function option for scaling capillary pressure on a per saturation table basis.
LGRCOPY	Copy global values to local cells before operations on cells within an LGR.
MAPAXES	Inputs map origin from a grid pre-processor, for output to the Grid file.
MAPUNITS	Specifies the units used for MAPAXES data.
MAXVALUE	Applies a maximum value to specified arrays within the current box.
MINPV	Sets a minimum pore volume that each cell must have to be active.
MINPVV	Sets a vector of minimum pore volumes that the cells in the current box must have to be active.
MINVALUE	Applies a minimum value to specified arrays within the current box.
MPFANUM	Identifies regions in which to apply the multipoint discretization or nine point scheme.
MPFNNC	Sets multi-point transmissibility coefficients.
MULTFLT	Multipliers for the transmissibility and diffusivity across faults defined by the <a href="#">FAULTS</a> keyword.
MULTIPLY	Multiplies specified arrays by constant values in the current box.
MULTIREG	Multiplies specified arrays by constant values in a flux, MULTNUM or OPERNUM region.
MULTNUM	Identifies multiplier regions for use with MULTTREGT, MULTTREGD and MULTTREGH. Also defines regions, for editing data with ADDREG, EQUALREG, MULTIREG and COPYREG.
MULTPV	Pore volume multipliers for the current box
MULTR	R-direction transmissibility multipliers for the current box.
MULTR-	Negative R-direction transmissibility multipliers for the current box.

Keyword	Description
MULTREGP	Multiplies pore volumes between flux or multiplier regions.
MULTREGT	Multiplies transmissibilities between flux or multiplier regions.
MULTTHT	Theta-direction transmissibility multipliers for the current box.
MULTTHT-	Negative R-direction transmissibility multipliers for the current box.
MULTX	X-direction transmissibility multipliers for the current box.
MULTX-	Negative X-direction transmissibility multipliers for the current box.
MULTY	Y-direction transmissibility multipliers for the current box.
MULTY-	Negative Y-direction transmissibility multipliers for the current box.
MULTZ	Z-direction transmissibility multipliers for the current box.
MULTZ-	Negative Z-direction transmissibility multipliers for the current box.
NNC	Explicit entry of non-neighbor connections.
NOGGF	Stops production of grid geometry file (for graphical output).
NODPPM	Specifies that permeabilities in the fracture cells are not to be multiplied by the fracture porosity.
NTG	Grid block net-to-gross ratios for the current box.
NXFIN	Number of local cells in each global cell of an LGR in the X-direction.
NYFIN	Number of local cells in each global cell of an LGR in the Y-direction.
NZFIN	Number of local cells in each global cell of an LGR in the Z-direction.
OPERATE	Performs arithmetic operations on arrays.
OPERATER	Performs arithmetic operations on arrays for a specific region of the grid.
OPERNUM	Defines region on which to perform operations using the OPERATER keyword. The data can also be edited using ADDREG, EQUALREG, MULTIREG and COPYREG.
PERMR	R-direction permeabilities for the current box.
PERMTHT	Theta-direction permeabilities for the current box.
PERMX	X-direction permeabilities for the current box.
PERMY	Y-direction permeabilities for the current box.
PERMZ	Z-direction permeabilities for the current box.
PINCH	Generates connections across pinched-out layers.
PINCHOUT	Same as keyword PINCH, but threshold thickness cannot be adjusted.
PINCHXY	Generates horizontal (I, J) pinchout connections.
PORO	Grid block porosities for the current box.
RADFIN	Specifies a single-column radial local grid refinement.
REFINE	Initiates data input for a named local grid.
RESVNUM	Initiates COORD data input for a given reservoir in the grid.
ROCKFRAC	Sets the rock volume fraction for each grid block.
RPTGRID	Sets report levels for GRID data.

Keyword	Description
RPTINIT	Controls output to the Initialization file for GRID and EDIT data.
RPTGRIDL	Controls output of GRID section data for local grids.
SIGMA	Matrix-to-fracture coupling factor for the entire grid
SIGMAGD	Matrix-fracture coupling for oil-gas gravity drainage (whole grid).
SIGMAGDV	Matrix-fracture coupling for oil-gas gravity drainage (current box).
SIGMAV	Matrix-to-fracture coupling factor for the current box.
SOLVDIMS	Specifies the solver dimensions for an unstructured local grid refinement.
SOLVDIRS	Overrides default settings for principal directions in the linear solver.
SOLVNUM	Specifies the map from user numbers to solver numbers for an unstructured grid.
SPECGRID	Specification of grid dimensions and characteristics.
THCONR	Rock and fluid thermal conductivities for the current box, for the Temperature and Thermal options.
THPRESFT	Specifies a threshold pressure associated with a named fault.
TOPS	Depths of top faces of grid blocks for the current box.
TRANGL	Specifies the global-local connections and associated transmissibilities for an unstructured local grid refinement.
USEFLUX	Use a Flux file.
ZCORN	Depths of grid block corners.

## ECLIPSE 100 only keywords

Restriction	ECLIPSE 100 only keyword	Description
	AMALGAM	Allow local grids to amalgamate.
	AQUNNC	Specifies numerical aquifer non-neighbor connection properties explicitly.
	AUTOCOAR	Specifies a box of cells for coarsening within an auto refinement
	COLLAPSE	Specifies which cells should be collapsed in Compressed VE option.
	HALF'TRAN	Activates the half-block transmissibility upscaling option
	HMAQUNUM	Activates the calculation of gradients for numerical aquifer parameters.
	HMMLAQUN	Specifies cumulative multipliers on numerical aquifer parameters.
	HMMMREGT	Specifies cumulative inter-region transmissibility multipliers
	HMMULRGT	Activates the calculation of gradients with respect to inter-region transmissibility multipliers.
	IONROCK	Rock ion exchange capacity
	ISOLNUM	Defines the extent of each independent reservoir region.
	LINKPERM	Treats grid block permeabilities as applying to cell faces.
	LTOSIGMA	Provides an easy way to calculate SIGMA from LX, LY, LZ.

Restriction	ECLIPSE 100 only keyword	Description
	LX, LY, LZ	Inputs the representative matrix block sizes for the dual porosity viscous displacement option.
	MULTREGD	Multiplies diffusivities between flux or multiplier regions.
	MULTREGH	Multiplies thermal conductivity between flux or multiplier regions
Do not use with block centered geometry.	NEWTRAN	Specifies that transmissibilities are to be computed using area of contact between blocks. Default for corner point geometry.
	NINENUM	Specifies the extent of the nine-point discretization scheme.
	NMATOPTS	Controls the discretized matrix Dual Porosity option.
	OLDTRAN	Specifies that block center data should be used to compute transmissibilities.
	OLDTRANR	Alternative calculation of transmissibilities using block center data.
	OUTRAD	Sets outer radius of radial grid.
	PEBI	Specifies that an unstructured grid is being used.
	PERMAVE	Sets options for permeability averaging in transmissibilities.
	PINCHNUM	Identifies pinchout regions for use by PINCHREG
	PINCHREG	Specifies pinchout data within PINCHNUM regions.
	QMOBIL	Controls the mobile end-point correction in an LGR.
	RADFIN4	Specifies a four-column radial local grid refinement.
	RPTISOL	Generates data for the ISOLNUM keyword, output to the Debug file.
	SMULTX, SMULTY, SMULTZ	Alternative transmissibility multipliers for auto refinement.
	VEDEBUG	Controls debug output from the Vertical Equilibrium options.
	VEFIN	Controls Vertical Equilibrium in local grids.

## ECLIPSE 300 only keywords

Restriction	ECLIPSE 300 only keyword	Description
	AQUANCON	Defines connection data for analytic aquifer
	AQUCT	Specifies property data for Cater-Tracy aquifer
	BIOTC	Sets the Biot constant for each grid block
Radial geometry only	CIRCLE	Requests completion of circle
	COALNUMR	Redefine coal region numbers in connection with the multi-porosity option.
	CONDFLTS	Specifies geometry of conductive faults.

Restriction	ECLIPSE 300 only keyword	Description
	CONDFRAC	Specifies geometry of a conductive fracture
	CRNDENS	Specifies rock density for each coal region number
	CRITPERM	Sets a critical permeability for cell collapse in Compressed VE
	DZV	Vector of Z-direction grid block sizes
	GADJUST	Adjusts diagonal permeability tensor
	GLTHEX	Sets a coefficient of linear thermal expansion for each grid block.
Thermal	HEATCR	Rock heat capacity
Thermal	HEATCRT	Temperature dependence of rock heat capacity
	MAXTRANZ	Maximum Z-direction transmissibility.
	MIDS	Specify cell mid-point depths.
	MINDZNET	Minimum net thickness for active cell.
	MINPORV9	Set a minimum pore volume for calculation of nine-point transmissibilities.
Thermal	MINROCKV	Sets a minimum rock volume that each cell must have to be active
	MPFA	Sets options for tensor permeability.
	MULTMF	Transmissibility multipliers for matrix-fracture coupling.
	NNCGEN	Allows NNCs to be generated between any two grid cells.
	NOCIRCLE	Turn off completion of circle for local grid refinements.
	ORTHERRO	Set a minimum orthogonality error for calculation of nine-point transmissibilities.
	ORTHERRX	Set a minimum orthogonality error for calculation of nine-point transmissibilities for interfaces in the X-direction.
	ORTHERRY	Set a minimum orthogonality error for calculation of nine-point transmissibilities for interfaces in the Y-direction.
	ORTHERRZ	Set a minimum orthogonality error for calculation of nine-point transmissibilities for interfaces in the Z-direction
	PERMMF	Permeability for matrix-fracture coupling.
	PERMXX	X-direction tensor permeability coefficient for the current input box.
	PERMYY	Y-direction tensor permeability coefficient for the current input box.
	PERMZZ	Z-direction tensor permeability coefficient for the current input box.
	PERMXY	XY-direction tensor permeability coefficient for the current input box.
	PERMYZ	YZ-direction tensor permeability coefficient for the current input box
	PERMZX	ZX-direction tensor permeability coefficient for the current input box
	POISSONR	Sets the Poisson ratio for each grid block.
	PROPFLOW	Defines parameters to be used with the proponent flowback feature

Restriction	ECLIPSE 300 only keyword	Description
Thermal	ROCKCON	Base and cap rock connections to the global grid
Thermal	ROCKCONL	Base and cap rock connections to the local grid refinements
	ROCKDEN	Sets the rock density for each grid block
Thermal	ROCKPROP	Base and cap rock properties
Thermal	SIGMATH	Matrix-fracture thermal conductivity multiplier
	TBASIS	Specify basis for tensor permeabilities
Thermal	THCGAS	Gas phase thermal conductivity
Thermal	THCOIL	Oil phase thermal conductivity
Thermal	THCONMF	Matrix-fracture conductivity
Thermal	THCONSF	Thermal conductivity saturation dependence
Thermal	THCROCK	Rock thermal conductivity
Thermal	THCSOLID	Solid phase thermal conductivity
Thermal	THCWATER	Water phase thermal conductivity
	THFLXTF	Heat transmissibility factor for the flux boundary option.
	YOUNGMOD	Sets the elastic Young's modulus for each grid block.
	XSTC	Specifies gas composition at standard conditions
	YSTC	Specifies oil composition at standard condition.

```

## EDIT section

The EDIT section contains instructions for modifying the pore volumes, block center depths, transmissibilities, diffusivities (for the Molecular Diffusion option), and non-neighbor connections (NNCs) computed by the program from the data entered in the GRID section.

It is entirely optional.

The GRID output array keywords are

DEPTH	PORV	TRANX	TRANR	DIFFX	DIFFR
		TRANY	TRANRHT	DIFFY	DIFFRHT
		TRANZ		DIFFZ	

These keywords may be used in the EDIT section to overwrite data either for the entire reservoir, or for a set of the grid blocks defined using the BOX keyword.

Alternatively, the multiplier keywords

MULTX, MULTR

MULTY, MULTRHT

MULTZ, MULTPV

ECLIPSE 100

MULTX-, MULTR-

ECLIPSE 100

MULTY-, MULTRHT-

ECLIPSE 100

MULTZ-

and the operational keywords

BOX	EQUALS	ADD
ENDBOX	COPY	MULTIPLY
MINVALUE	MAXVALUE	

may be used to modify the arrays exactly as in the GRID section. In addition, the MULTFLT keyword may be used to modify the transmissibility across faults entered using the keyword FAULTS in the GRID section.

## Changing cell depths

The cell center depths obtained in the GRID section calculations are used to obtain hydrostatic pressure differences between cells during the simulation. These may be changed by using the `DEPTH` keyword to set depths for all the cells, or `ADD`, `COPY`, `EQUALS` and `MULTIPLY` to alter boxes of values. Note that changing the depths does not alter the plotted grid.

## Changing pore volumes

As in the case of `DEPTH`, the calculated pore volumes may be changed. The `PORV` keyword may be used to set new values for all the cells, or `EQUALS`, `ADD` and `MULTIPLY` to alter boxes of values.

---

**Note:** If the pore volume value is added to a cell that is inactive, it remains inactive unless the `ACTNUM` array is also modified.

---

ECLIPSE 100

---

**Note:** If a cell is defined with zero pore volume in the GRID section, then making it active by changing the pore volume in the EDIT section using `PORV`, is not allowed with the polymer, surfactant, foam, temperature or environmental tracer options.

---

## Changing transmissibilities

The keywords to overwrite transmissibility values depend upon the use of the radial or Cartesian geometry options. The program accepts the radial form in a Cartesian run and vice versa, but issues a warning.

Cartesian Keyword	Radial Keyword	Description
TRANX	TRANR	X or R direction transmissibilities
TRANY	TRANHT	Y or $\theta$ transmissibilities
TRANZ	TRANZ	Z transmissibilities

Table 2.6: Keywords used to change transmissibility values

As in the case of `PORV` and `DEPTH`, these keywords may be specified with values for the whole field, or used through `ADD`, `COPY`, `EQUALS` and `MULTIPLY` keywords.

## Changing diffusivities

If diffusion is being modeled, the `DIFFUSE` keyword having been specified in the `RUNSPEC` section, the `DIFFX`, `DIFFY` and `DIFFZ` keywords may be used in the same way as the `TRANX`, `TRANY` and `TRANZ` keywords to overwrite the calculated diffusivities (or `DIFFR`, `DIFFHT` and `DIFFZ` in the radial case).

Diffusivities reflect the effect of cell properties upon diffusive flow, and their evaluation is detailed in "Diffusion" in the *ECLIPSE Technical Description*.

## Modifying non-neighbor connections

The keyword `EDITNNC` may be used to modify any non-neighbor connections input directly or generated automatically in the `GRID` section. In other words, this keyword enables the non-neighbor connection transmissibilities (and diffusivities) to be edited directly.

Alternatively, you may wish to use keyword `EDITNNCR` to replace the non-neighbor connection values completely, rather than multiplying the existing ones.

---

**Note:** `TRANX` and related keywords do not change the non-neighbor connection transmissibilities. However, using `MULTX` and related keywords in the `GRID` section do change the transmissibilities, both between neighboring blocks and along automatically-generated non-neighbor connections, from the grid block in the positive direction.

---

**Note:** Similarly, when using the molecular diffusion option, `DIFFX` and similar keywords do not change non-neighbor connection diffusivities, but `DIFFMX` and similar keywords used in the `GRID` section do change the diffusivities in the automatically-generated non-neighbor connections in the positive direction.

---

If `MULTX` and similar keywords are specified in the `EDIT` section, then they act as a multipliers on the edited data. The transmissibility of any NNCs are adjusted just as if the additional multiplier were specified in the `GRID` section.

The keyword `MULTFLT` provides a way of adjusting the transmissibility multipliers in the `EDIT` section, and the NNC transmissibilities across the fault are edited automatically.

---

**Note:** Use of multiplier keywords in the `EDIT` section is not recommended in general, except as modifiers to transmissibilities entered explicitly using `TRANX` and related keywords in the `EDIT` section. Transmissibility multipliers should normally be specified only in the `GRID` section. The multiplier keywords should not be used in the `EDIT` section when the Local Grid Refinement option is employed.

---

## Output control

Output of pore volumes, block center depths, transmissibilities, diffusivities and NNCs is controlled by switches or mnemonics following the `RPTGRID` keyword in the `GRID` section.

However, the values that are printed include the effect of any changes made in the `EDIT` section.

## Alphabetical list of EDIT section keywords

### Common keywords

Restriction	Keyword	Description
	<code>ADD</code>	Adds specified constants to specified arrays in the current input box.
	<code>ADDREG</code>	Adds a constant to the specified array in a flux, <code>MULTNUM</code> or <code>OPERNUM</code> region.
	<code>BOUNDARY</code>	Defines the section of the grid for which output maps are required.
	<code>BOX</code>	Re-defines the current input box. <code>COPY</code> Copies data in the current box from one specified array to another.
	<code>COPYREG</code>	Copy by <code>FLUXNUM</code> region <code>MULTNUM</code> region or <code>OPERNUM</code> region.
	<code>DEPTH</code>	Grid block center depths for the current input box.

Restriction	Keyword	Description
Molecular Diffusion option in radial geometry only	<a href="#">DIFFR</a>	R-direction diffusivities for the current input box
Molecular Diffusion option in Cartesian geometry only	<a href="#">DIFFTHT</a>	Theta-direction diffusivities for the current input box
Molecular Diffusion option in Cartesian geometry only	<a href="#">DIFFX</a>	X-direction diffusivities for the current input box
Molecular Diffusion option in Cartesian geometry only	<a href="#">DIFY</a>	Y-direction diffusivities for the current input box
Molecular Diffusion option in radial or Cartesian geometry	<a href="#">DIFFZ</a>	Z-direction diffusivities for the current input box
	<a href="#">EDITNNC</a>	Modifies non-neighbor connections. <a href="#">EDITNNCR</a> Replaces non-neighbor connections.
	<a href="#">ENDBOX</a>	Re-defines the current input box to encompass the whole grid.
	<a href="#">ENDFIN</a>	Terminates data for a local grid refinement.
	<a href="#">EQUALREG</a>	Sets an array to a constant value in a flux, <a href="#">MULTNUM</a> , or <a href="#">OPERNUM</a> region.
	<a href="#">EQUALS</a>	Sets specified arrays to specified constants within the current box.
	<a href="#">FILEUNIT</a>	Confirms the units of the data set.
	<a href="#">HMMULTPV</a>	History matching pore volume multipliers.
	<a href="#">HMMULTxx</a>	History matching transmissibility multipliers.
	<a href="#">IMPORT</a>	Imports binary data generated by a grid pre-processor.
	<a href="#">LGRCOPY</a>	Copy global values to local cells before operations on cells within an LGR.
	<a href="#">MAXVALUE</a>	Applies a maximum value to specified arrays within the current box.
	<a href="#">MINVALUE</a>	Applies a minimum value to specified arrays within the current box.
	<a href="#">MULTFLT</a>	Applies a transmissibility multiplier to a named fault defined by the <a href="#">FAULTS</a> keyword in the GRID section.
	<a href="#">MULTIPLY</a>	Multiplies specified arrays by specified constants within the current box.
	<a href="#">MULTIREG</a>	Multiplies an array by a constant in a given flux, <a href="#">MULTNUM</a> or <a href="#">OPERNUM</a> region.
	<a href="#">MULTPV</a>	Multiplies the calculated pore volume within the current box.

Restriction	Keyword	Description
	MULTREGT	Multiplies transmissibilities between flux or multiplier regions.
	MULTREGP	Multiplies pore volumes between flux or multiplier regions.
	OPERATE	Performs arithmetic operations on arrays.
	OPERATER	Performs arithmetic operations on arrays for a specific region of the grid (defined using the <code>OPERNUM</code> keyword in the <code>GRID</code> section).
	PORV	Grid block pore volumes for the current input box.
	REFINE	Select local grid refinement for input data.
Thermal	ROCKV	Rock volume
Radial geometry only	TRANR	R direction transmissibilities for the current input box
Radial geometry only	TRANHT	Theta direction transmissibilities for the current input box
Cartesian geometry only	TRANX	X direction transmissibilities for the current input box
Cartesian geometry only	TRANY	Y direction transmissibilities for the current input box
Radial or Cartesian geometry	TRANZ	Z direction transmissibilities for the current input box

## ECLIPSE 100 only keywords

Restriction	ECLIPSE 100 only keyword	Description
Radial geometry only	MULTR	Sets an additional R-direction transmissibility multiplier within the current box.
Radial geometry only	MULTR-	Sets an additional negative R-direction transmissibility multiplier within the current box
	MULTREGD	Multiplies diffusivities between flux or multiplier regions.
	MULTREGH	Multiplies thermal conductivity between flux or multiplier regions
Radial geometry only	MULTTHT	Sets an additional Theta-direction transmissibility multiplier within the current box
Radial geometry only	MULTTHT-	Sets an additional negative Theta-direction transmissibility multiplier within the current box
	MULTX	Sets an additional X-direction transmissibility multiplier within the current box.
	MULTX-	Sets an additional negative X-direction transmissibility multiplier within the current box
	MULTY	Sets an additional Y-direction transmissibility multiplier within the current box.
	MULTY-	Sets an additional negative Y-direction transmissibility multiplier within the current box.

Restriction	ECLIPSE 100 only keyword	Description
	MULTZ	Sets an additional Z-direction transmissibility multiplier within the current box.
	MULTZ-	Sets an additional negative Z-direction transmissibility multiplier within the current box.

## ECLIPSE 300 only keywords

Restriction	ECLIPSE 300 only keyword	Description
	HEATTR	Heat transmissibility values in the R-direction.
	HEATTHT	Heat transmissibility values in the Theta-direction.
	HEATTX	Heat transmissibility values in the X-direction.
	HEATTY	Heat transmissibility values in the Y-direction.
	HEATTZ	Heat transmissibility values in the Z-direction.
Thermal	ROCKV	Rock volume

## PROPS section

The PROPS section of the input data contains pressure and saturation dependent properties of the reservoir fluids and rocks.

### Data input

The data is input in multi-tabular keywords, with only one entry of any keyword being accepted. The number of tables of each type is specified in the RUNSPEC section of data. The correct number of tables must be supplied. The RUNSPEC section also specifies the maximum size of each table. When multiple tables are entered after a keyword, each table is terminated by a slash (/).

The keywords in the PROPS section may be specified in any order. All keywords must start in column 1. All characters up to column 8 are significant.

### Example

```

SWFN
data for table 1 /
data for table 2 /
data for table 3 /

```

### Properties required

The keywords required are determined by whether an ECLIPSE 100 or ECLIPSE 300 Black Oil or an ECLIPSE 300 Compositional Model is used.

The data must always contain the rock compressibility (not strictly required by ECLIPSE 300), and relative permeabilities and capillary pressures as a function of saturation for the phases present.

In a black oil run (ECLIPSE 100 or ECLIPSE 300), the PVT keywords required are determined by the phases selected in the RUNSPEC section (keywords [OIL](#), [WATER](#), [GAS](#), [DISGAS](#), [VAPOIL](#)) and any special options selected (keywords [APIBRINE](#), [COAL](#), [DIFFUSE](#), [ENDSCALE](#), [FOAM](#), [MISCIBLE](#), [POLYMER](#), [ROCKCOMP](#), [SATOPTS](#), [TEMP](#), [TRACERS](#), [VE](#), [SURFACT](#), [SOLVENT](#)) in the RUNSPEC section.

In an ECLIPSE 300 compositional run, the PVT keywords required are determined by the EoS (keyword [EOS](#)) and any special options ([GASWAT](#), [CO2SOL](#), [GASSOL](#), [TRCOEF](#), [MISCIBLE](#)). Specify a black oil run in ECLIPSE 300 by including the [BLACKOIL](#) keyword instead of EOS.

The keyword [TABDIMS](#) in RUNSPEC may be used to set non-default table sizes (or [AQUDIMS](#), [MISCIBLE](#), [ROCKCOMP](#), [TRACERS](#) for the special options).

## Saturation functions

Saturation functions are used to describe properties that depend on the phase saturations, namely the relative permeabilities and capillary pressures.

In two-phase systems there is only one independent saturation and the properties are one dimensional functions.

In three-phase systems there are two independent saturations and properties can be either one or two dimensional functions. A number of ways of modeling three phase properties are available:

- Capillary pressures and the water and gas relative permeabilities are treated as one dimensional functions, but the oil relative permeability is treated as a two dimensional function by interpolating the oil-gas and oil-water relative permeabilities. Interpolation of the oil relative permeability is performed using either the default method or one of Stone's methods.
- Two dimensional tables can be entered for any (or all) of the phase relative permeabilities.
- The Baker methods can be used to describe any (or all) of the phase relative permeabilities as two dimensional functions.

ECLIPSE 300

The methods described above can be applied to individual phases, and different methods can be used for each phase. Two further methods are available that apply to all phases:

ECLIPSE 300

- The IKU three phase method.

ECLIPSE 300

- The ODD3P three phase method.

See "[Saturation Functions](#)" in the *ECLIPSE Technical Description* for further details.

## One dimensional saturation functions

There is a choice of two families of keywords for entering relative permeabilities and capillary pressures as functions of a single saturation. The first family: [SWOF](#) and ([SGOF](#) or [SLGOF](#)), allows you to enter the oil relative permeabilities in the same tables as the water and gas relative permeabilities. The second family: [SWFN](#), [SGFN](#) and ([SOF3](#) or [SOF2](#)), requires the oil relative permeabilities to be entered in a separate table versus oil saturation.

You can select whichever family is best suited to the form of the original data, except that the second family must be used in gas-water runs and runs employing the ECLIPSE 100 Miscible Flood or Solvent options. Keywords from the two families cannot be mixed.

A single saturation function table might be of the form:

```

SWFN
--Sw      Krw      Pcow
 0.22     .0       7.0
 0.3      .0       4.0
 0.5      .24     2.5
 0.8      .65     1.0
 0.9      .83     .5
 1.0      1.00    .0 /

```

As with all keywords, the data may be spaced or split over lines at will, but it is convenient here to place it into columns. In all but the first column, default values may be entered, and these values are filled in by linear interpolation.

The slash character (/) terminates the table above. If a run has more than one saturation table region, these must be entered in sequence, each terminated by a slash character (/). The tables are assigned to blocks later, in the [REGIONS](#) section.

Some saturation values in the left-most column are significant:

$S_{wco}$  The first value in the table is the connate water, 0.22 in this case, the minimum water saturation in a block in the initial state.

$S_{wcr}$  The saturation value at which water becomes mobile is the critical water saturation, 0.3 in this case.

The second column contains water relative permeabilities, and the third the water-oil capillary pressures, defined as  $P_{cow} = P_o - P_w$ .

The gas saturation functions can be input in a similar way using the [SGFN](#) keyword. The first value should be zero, as 'connate' gas does not exist, and the critical gas is defined in the same manner as the critical water. Gas-oil capillary pressures are defined as  $P_{cog} = P_g - P_o$ .

ECLIPSE 100

In gas-water runs the relative permeability and capillary pressure data can be entered with one keyword, [SGWFN](#), [SGFN](#) and [SWFN](#).

## Two dimensional models for saturation functions (for three phase simulations)

In three-phase systems the oil relative permeability is modeled as a two dimensional function.

If the [SOF3](#) table is used,  $K_{row}$  and  $K_{rog}$  are entered as functions of oil saturation. These are the oil relative permeabilities at zero gas saturation and at connate water saturation respectively. These are combined to obtain the three-phase oil relative permeability using a default method, or Stone's method I or II. The keywords are [STONE1](#), [STONE1EX](#) and [STONE2](#).

Other methods are also available to describe the three-phase oil relative permeability that can also be applied to gas and water relative permeabilities:

ECLIPSE 300

The three phase IKU relative permeability is available with the [IKU3P](#) keyword.

ECLIPSE 300

The three phase ODD3P relative permeability is available with the [ODD3P](#) keyword.

ECLIPSE 300

Baker's methods can be used to describe any (or all) of the phase relative permeabilities as two dimensional functions. The keywords are [BAKER1](#) or [BAKER2](#).

The IKU, ODD3P and Baker methods require the [SOF3](#), [SGF3](#) and [SWF3](#) keywords to create the two dimensional data.

The relative permeabilities can also be specified as two dimensional functions, avoiding the need to use a special three-phase model within the simulator, using one (or all) of the keywords [SOF32D](#), [SGF32D](#) and [SWF32D](#).

## Stability issues

The following applies in ECLIPSE 300.

If IMPES or AIM Solution methods are used, large capillary pressures may cause instability. This is limited by imposing a maximum rate at which the capillary pressure may change, see keyword [DPCDT](#).

### Saturation function keyword family (i)

The set of saturation function keywords is summarized below:

- [SWOF](#) If both water and oil are present
- [SGOF](#) or [SLGOF](#) If both gas and oil are present

### Saturation function keyword family (ii)

The keywords are:

- [SOF3](#) For oil in a three-phase run
- [SOF2](#) For oil, if present, in a two-phase run
- [SGFN](#) For gas, if present
- [SWFN](#) For water, if present
- [SGWFN](#) For gas-water runs only

### Two dimensional Saturation functions

Three-phase saturation functions can be described by two-dimensional tables. The keywords are:

- [SOF32D](#) For oil
- [SWF32D](#) For gas
- [SGF32D](#) For water
- [PCG32D](#) Capillary pressure
- [PCW32D](#) Capillary pressure

### Two dimensional interpolation methods

Various interpolation methods can be used to create two dimensional saturation functions. By default gas and water relative permeabilities are one dimensional, and oil relative permeability is two dimensional. Keywords can be used to change the default interpolation method for oil relative permeability or to make the gas and water relative permeability two dimensional. The keywords are:

Simulator	Keyword	Description
	<a href="#">STONE1</a>	Stone model 1 (modified) for three phase oil permeability.

Simulator	Keyword	Description
	<a href="#">STONE1EX</a>	Exponent term for Stone model 1.
	<a href="#">STONE2</a>	Stone model 2 (modified) for three phase oil permeability.
E300 only	<a href="#">BAKER1</a>	Baker interpolation method 1 for three phase permeability. Applies to any specified phase
E300 only	<a href="#">BAKER2</a>	Baker interpolation method 2 for three phase permeability. Applies to any specified phase.
E300 only	<a href="#">IKU3P</a>	IKU interpolation method. Applies to all phases.
E300 only	<a href="#">ODD3P</a>	ODD3P interpolation method. Applies to all phases.
	<a href="#">SOF3</a>	For oil in three-phase models.
E300 only	<a href="#">SGF3</a>	For gas in three-phase models.
E300 only	<a href="#">SWF3</a>	For water in three-phase models.

## Hysteresis

If hysteresis is being used, both imbibition and drainage curves are entered with the appropriate saturation functions above. The region keyword [IMBNUM](#) is then used to assign imbibition table numbers to cells. The [SATOPTS](#) keyword should be used to enable the hysteresis treatment. More details of the hysteresis models can be found under "Hysteresis" in the *ECLIPSE Technical Description*.

If, in addition to conventional hysteresis, WAG hysteresis has been specified via the [WAGHYSTR](#) keyword, the additional region keywords [WH2NUM](#) and [WH3NUM](#) may be optionally used to specify the alternative two-phase and three-phase water relative permeabilities used by the WAG hysteresis model. If these keywords are not specified, this information will be taken from the tables associated with the [SATNUM](#) and [IMBNUM](#) region keywords. The WAG Hysteresis Model is described in more detail in "Hysteresis in WAG Floods" in the *ECLIPSE Technical Description*.

*ECLIPSE 300 only*

.For the [ODD3P](#) option, the primary, secondary and tertiary hysteresis curves are specified using the [PSTNUM](#), [ISTNUM](#) and [DSTNUM](#) keywords respectively. These replace the [SATNUM](#) and [IMBNUM](#) keywords which are used for the other hysteresis models.

## End point scaling

In some cases the relative permeability and capillary pressure tables vary from cell to cell. Rather than enter large numbers of tables it is possible to scale fixed points on a table to new cell-dependent positions. This may be done horizontally - along the saturation axis - or vertically - rescaling the values of  $K_r$  and  $P_c$ .

To use end point scaling, the [ENDSCALE](#) keyword should be included in the RUNSPEC section.

See "Saturation Table Scaling" in the *ECLIPSE Technical Description*.

## Pressure tables

Functions of pressure ([ROCK](#), [PVDO](#), [PVTO](#), [PVTW](#), [PVTG](#)) are entered in a form similar to that of the saturation functions. When multiple tables are entered, these may be associated with cells using the [PVTNUM](#) keyword. In addition, [DENSITY](#) or [GRAVITY](#) keyword data is entered for each pressure table region. An alternative for rock properties is to use the [ROCKNUM](#) keyword to specify rock table number for each cell.

ECLIPSE 300 only

If an equation of state is being used, PVTO and PVTG tables are not required, as the fluid Z-factors and thus densities can be obtained directly. Viscosities are obtained from the Lorentz, Bray and Clark [Ref. 70] correlation, and only the water surface density is used from the DENSITY keyword. If a KVTABLE table is entered and the KVALUES keyword used in the RUNSPEC section, this is used to define liquid and vapor compositions, but at present an equation of state is still required to define phase densities. (The KVTABLE may also be used in the surface separators.)

## Rock pressure tables

The following methods exist for specifying the change in rock pore volume and transmissibility as a function of pressure.

- The **ROCK** keyword sets a reference pressure and compressibility.
- The **ROCKTAB** keyword enables a table of pore volume ratios and transmissibility multipliers to be input against pressure. The pore volume increases with increasing pressure as the rock material compresses. Hysteretic rock compaction tables may also be entered using keyword **ROCKTABH**, when the pore space does not recover during reflation. By default, ECLIPSE tabulates the rock compaction multipliers against fluid pressure unless the **OVERBURD** keyword is used to specify the overburden pressure. In this case, ROCKTAB and ROCKTABH data is tabulated against:
  - effective fluid pressure  $P_{effl}$ , where  $P_{effl} = P_{fluid} - \text{Overburden}$
  - or against:
  - effective stress, where Effective Stress =  $-P_{effl}$

The tabulation used depends on the options chosen in the **ROCKOPTS** keyword.

ECLIPSE 300

- In the Coal Bed Methane option, the **ROCKPAMA** keyword can be used to specify parameters which are used in the Palmer-Mansoori rock model to calculate pore volume and transmissibility multipliers.
- The **ROCKTRMX**, **ROCKTRMY** and **ROCKTRMZ** keywords can be used to define transmissibility as an exponential function of porosity.
- In Dual Porosity runs, keywords **ROCKTSIG** or **ROCKTHSG** may be used to specify pressure tables of the sigma multiplier for matrix-fracture coupling.

See "Rock Compaction" in the *ECLIPSE Technical Description*.

## Water pressure tables

The water compressibility and viscosity may be specified with the **PVTW** keyword. This might take the form:

```
PVTW
--Pref Bref   Cw      Vw      (dVw/dp)/Vw
 4000 1.001  0.000003  0.52  0 /
```

This specifies a reference pressure, the water formation volume factor at this pressure, the compressibility from this pressure and the water viscosity. The last value is a viscosibility, similar to compressibility, but for viscosity. In many cases this is zero. A quadratic function is used for extrapolation.

ECLIPSE 300 only

As an alternative to PVTW, the **WATERTAB** keyword may be used to enter a general variation of water properties with pressure.

When using the Brine option, the water PVT properties must be entered with the [PVTWSALT](#) keyword.

## Surface densities

The three possible surface densities are set using the [DENSITY](#) keyword. This is required when formation volumes are used, in order to define reservoir densities. For compositional runs, the equation of state defines the hydrocarbon reservoir densities, and only the water value is required. [DENSITY](#) always contains three items, even if water is not present in the run.

```
DENSITY
--deno      denw      deng
 45.0000    63.0200    .07020 /
```

If a run has more than one pressure table region set with [TABDIMS](#) in the RUNSPEC section, these must be entered in sequence, each terminated by a slash character (/), for both [DENSITY](#) and the pressure table data such as [ROCK](#) and [PVTW](#). As an alternative to [DENSITY](#), the [GRAVITY](#) keyword enables the same data to be entered in specific gravity form.

When using the Brine option, the water density can also be entered with the [BDENSITY](#) keyword.

## Oil and gas pressure tables (black oil)

These are only relevant to black oil mode runs, as the hydrocarbon densities are obtained from the equation of state in compositional mode.

The PVT properties of live oil can be entered in either of two formats, with either:

- [PVC0](#) and [PMAx](#), or
- [PVTO](#).

The first format assumes that under saturated oil of a particular  $R_s$  value has a compressibility that is independent of the pressure, and that the viscosity of under saturated oil has a pressure-independent derivative. Pressure tables are linearly interpolated, and extrapolated, if required, at constant slope. The second format is more complex, but allows greater flexibility in defining the properties of under saturated oil. It specifies the properties of oil with dissolved gas may be entered in a two dimensional table form.

ECLIPSE 100

Similarly, the PVT properties of dead oil can be entered in either of two formats, with keywords [PVCDO](#) or [PVDO](#). Keyword [PVCDO](#) assumes that dead oil has a constant compressibility and its viscosity has a pressure-independent derivative. Keyword [PVDO](#) is more flexible, allowing the formation volume factor and the viscosity to be input as a table versus pressure.

For gas, [PVDG](#) tabulates the gas formation volume factor and viscosity as a function of pressure.

ECLIPSE 300

The Z-factors for dry gas can be entered directly using the [PVZG](#) keyword.

Finally, the properties of gas with vaporized oil (condensates) may be entered in using the [PVTG](#) keyword.

Oil and gas pressure tables can be prepared with the PVT *i* program.

## Essential keywords - black oil case

The data must contain: surface densities of the fluids, data to calculate the reservoir fluid densities and viscosities, the rock compressibility, and relative permeabilities and capillary pressures as a function of saturation.

The minimum set of keywords required in the PROPS section are listed below.

Restriction	Keywords for surface gravities/densities	Description
E100 only	ROCK	For rock compressibility (unless using the Rock Compaction option)
	PVTO or (PVCO and PMAX)	If live oil is present
E100 only	PVDO or PVCDO	If dead oil is present
E100 only	RSCONST or RSCONSTT	If dead oil is used to model oil having a constant dissolved gas concentration
	PVTG	If wet gas is present
	PVDG or PVZG	If dry gas is present
	RVCONST or RVCONSTT	If dry gas is used to model gas having a constant vaporized oil concentration
E100 only	PVTW	If water is present (but use PVTWSALT instead with the Brine option).

Some keywords are mutually exclusive and cannot be used together. Examples of forbidden combinations are:

- PVTO and RSCONST ( T ). The constant  $R_s$  facility is only for dead oil.
- PVTG and RVCONST ( T ). The constant  $R_v$  facility is only for dry gas.
- SWOF and SGFN. The two saturation keyword families cannot be mixed.

The table below shows the choice of keywords that may be used in various examples of phase combinations. PVZG may be used in place of PVDG for dry gas properties.

Phase Combinations	Keywords
Oil and Dissolved Gas Wet Gas and Vaporized Oil Water	either: PVCO, PMAX, PVTG, PVTW or: PVTO, PVTG, PVTW either: SGOF or SLGOF, SWOF or: SOF3 or SOF32D, SGFN, SWFN
Oil and Dissolved Gas, Dry Gas, Water	either: PVCO, PMAX, PVDG, PVTW or: PVTO, PVDG, PVTW either: SGOF or SLGOF, SWOF or: SOF3 or SOF32D, SGFN, SWFN
Oil and Dissolved Gas, Wet Gas and Vaporized Oil	either: PVCO, PMAX, PVTG or: PVTO, PVTG either: SGOF or SLGOF or: SOF2, SGFN

Phase Combinations	Keywords
Undersaturated Oil and Constant Dissolved Gas, Water	either: <a href="#">PVDO</a> , <a href="#">RSCONST ( T ) .PVTW</a> or: <a href="#">PVCDO</a> , <a href="#">RSCONST ( T )</a> , <a href="#">PVTW</a> either: <a href="#">SWOF</a> or: <a href="#">SOF2</a> , <a href="#">SWFN</a>
Dry Gas	<a href="#">PVDG</a> or <a href="#">PVZG</a>
Dry Gas and Constant Vaporized Oil, Water	<a href="#">RVCONST ( T )</a> , <a href="#">PVDG</a> , <a href="#">PVTW</a> either: <a href="#">SGFN</a> , <a href="#">SWFN</a> or: <a href="#">SGWFN</a>

Table 2.7: PROPS keywords to be used with the different phase combinations in a black oil run

## Standard conditions (ECLIPSE 300)

Surface gas volumes are reported as ideal gas volumes at standard conditions - by default 1 atmosphere and 15.56 °C (60 °F). Oil volumes are reported at final stage separator conditions. The [STCOND](#) keyword can be used to override the default conditions.

## Compositional Equation of State data (ECLIPSE 300)

In compositional mode, the equation of state may be chosen using the [EOS](#) keyword. The single item should start with P, R, S or Z, for Peng-Robinson, Redlich-Kwong, Soave-Redlich-Kwong and Zudkevitch-Joffe equations respectively. A small correction to the Peng-Robinson is available using the [PRCORR](#) keyword. The equations of state are discussed in "[Equations of State](#)" in the *ECLIPSE Technical Description*.

The PROPS section contains keywords to parameterize the equation of state. The following contain  $N_c$  items, where  $N_c$  is the number of hydrocarbon components in the run, specified with [COMPS](#) in the RUNSPEC section:

ECLIPSE 300 only keyword	Description
<a href="#">CNAMEs</a>	Component names
<a href="#">TCRIT</a>	Critical temperatures
<a href="#">PCRIT</a>	Critical pressures
<a href="#">VCRIT</a>	Critical volumes
<a href="#">ZCRIT</a>	Critical Z-factors
<a href="#">VCRITVIS</a>	Critical volumes (for viscosities only)
<a href="#">MW</a>	Molecular weights
<a href="#">ACF</a>	Acentric factors
<a href="#">TBOIL</a>	Boiling points (for Zudkevitch Joffe)
<a href="#">DREF</a>	Reference densities (for Zudkevitch Joffe)
<a href="#">GREF</a>	Reference gravities (for Zudkevitch Joffe)

ECLIPSE 300 only keyword	Description
TREF	Reference temperatures (for Zudkevitch Joffe)
OMEGAA	$\Omega_{a_0}$ values for reservoir
OMEGAB	$\Omega_{b_0}$ values for reservoir
PARACHOR	Parachor values for surface tension evaluation
SSHIFT	Equation of state volume shifts for reservoir

Note that **either** Z-factors or critical volumes should be entered, as these are related by the relationship  $V_c = Z_c RT / P_c$ . The `ZCRITVIS` or `VCRITVIS` keywords need only be entered if different critical volumes are required for the Lorentz-Bray-Clark viscosity correlation. If an alternate method to this default viscosity calculation is required, then the Pedersen et al. viscosity calculation can be used by including the `PEDERSEN` keyword in this PROPS section.

The coefficients of the Lorentz-Bray-Clark correlation may be modified using the `LBCCOEF` or `LBCCOEFR` keywords. A modified form of the Lorentz-Bray-Clark correlation can be invoked by using keyword `VCOMPACT`. For the Pedersen et al. viscosity correlation, the coefficients used in the mixture molecular weight calculation can be modified by multiplicative tuning parameters which may be specified using either the `PEDTUNE` or the `PEDTUNER` keywords.

In addition to the above properties, binary interaction coefficients may be entered with the `BIC` keyword.  $N_c(N_c - 1)/2$  values are entered, the lower triangular part of the interaction coefficient matrix. For example, for a five component system:

```
BIC
0.01
0.01 0.005
0.02 0.0 0.001
0.001 0.0 0.001 0.0005 /
```

To facilitate the matching of PVT data, the simulator allows the use of two sets of EoS data, one for the reservoir and one for the surface conditions. It is possible to use different equation of state parameters for surface conditions using keywords such as `ACFS`, `OMEGAAS`, `OMEGABS`, `BICS` and `SSHIFTS`.

Furthermore, the EoS at the surface (say ZI) may be different from the EoS used for the reservoir (say PR). A different surface EoS may be specified using `EOSS`.

For compositional runs it is also required to enter the reservoir temperature using `RTEMP`, used to define reduced temperatures for the equation of state. Note that this is read in degrees F or degrees C. An alternative is the `TEMPVD` keyword, which allows for a temperature variation with respect to depth in the reservoir, and alters the equation of state coefficients for each cell accordingly. If the equation of state data is prepared using the PVT *i* pre-processor program, the file to be included in the ECLIPSE 300 dataset includes the `NCOMPS` keyword. When data is prepared in this way the `NCOMPS` keyword is read and checked, to confirm that the number of components assumed by pre-processor and simulator agree. `NCOMPS` does not need to be entered.

## K-value tables (ECLIPSE 300)

If K-value tables are to be used in the reservoir (`KVALUES` in RUNSPEC) or for the separators, these may be entered in the PROPS section using the `KVTABLE` keyword as functions of pressure.  $N_c$  K-values are entered at each pressure value. K-value dependence on composition can be model by interpolating between

a set of K-value tables depending on the mole fraction of a nominated component. The K-value tables are supplied using the `KVTABcn` keywords, the interpolation points via the `KVMF` keyword and the component specified with the `KVCOMP` keyword.

Generic table reading routines are used to read many ECLIPSE 300 tables, including `KVTABLE`, `KVTABcn` and `KVTABtn`. If values in a table are defaulted (\*), the table values are constructed using linear interpolation and constant extrapolation. For instance, below are four examples which demonstrate the values used internally when defaults are used in the `KVTABLE` table (with one component).

For Example 1, linear interpolation will be used to define the K-values for the defaulted pressure values of 200 and 300:

```
KVTABLE
--p_oil K-value
 100.0  1
 200.0  *   (internal value used = 2)
 300.0  *   (internal value used = 3)
 400.0  4
/
```

For Example 2, constant extrapolation will be used to define the K-values for the defaulted pressure values of 100 and 400:

```
KVTABLE
--p_oil K-value
 100.0  *   (internal value used = 2)
 200.0  2
 300.0  3
 400.0  *   (internal value used = 3)
/
```

For Example 3, constant extrapolation will be used to define the K-values for the defaulted pressure values of 200, 300 and 400:

```
KVTABLE
--p_oil K-value
 100.0  1
 200.0  *   (internal value used = 1)
 300.0  *   (internal value used = 1)
 400.0  *   (internal value used = 1)
/
```

For Example 4, constant extrapolation will be used to define the K-values for the defaulted pressure values of 100, 300 and 400:

```
KVTABLE
--p_oil K-value
 100.0  *   (internal value used = 2)
 200.0  2
 300.0  *   (internal value used = 2)
 400.0  *   (internal value used = 2)
/
```

As an alternative to entering K-values in tabular form, the `KVGEN` keyword may be used to request that they be generated internally from a given sample. These may be used either to control the interphase equilibrium over the field (the `KVALUES` keyword in the `RUNSPEC` section) or in separator calculations (the `SEPCOND` keyword in the `SCHEDULE` section).

## Diffusion coefficients

ECLIPSE 300

In the Diffusion option is being used (`DIFFUSE` in the `RUNSPEC` section) then normal or activity corrected diffusion coefficients may be specified for each component.

See "Diffusion" in the *ECLIPSE Technical Description*.

## Composition with respect to pressure tables (ECLIPSE 300)

The normal method of defining the initial state of a simulation is by equilibration. However, it is sometimes convenient to specify the initial pressures and saturations explicitly. Great care must be taken to ensure that this the initial state specified is stable and physical. The `XMFPV` and `YMFVP` keywords allow the initial oil and gas compositions, expressed as mole fractions, to be entered as functions of pressure, so that equilibrium compositions may be obtained over a range of pressures. These tables would normally be set up by the PVT *i* program, using a constant volume depletion or differential liberation experiment to define the composition variation with pressure.

## PROPS section keywords

A list of all keywords which may occur in the PROPS section grouped by function is given below, together with a brief description of their use. This is followed by an alphabetic list. A more detailed description may be found by looking up the keyword in the manual.

### Alkaline option

#### Common keywords

Restriction	Keyword	Description
Required if Surfactant option is active.	<code>ALSURFST</code>	Oil/water surface tension multipliers.

#### ECLIPSE 100 only keywords

Restriction	ECLIPSE 100 only keywords	Description
Required if Surfactant option is active.	<code>ALSURFAD</code>	Surfactant adsorption multipliers.
Required if Polymer option is active.	<code>ALPOLADS</code>	Polymer adsorption multipliers.
	<code>ALKADS</code>	Alkaline adsorption functions (tabulated).
	<code>ADSORP</code>	Alkaline adsorption functions (analytical).
Required if <code>ALKADS</code> or <code>ADSORP</code> is specified.	<code>ALKROCK</code>	Alkaline-rock properties.

## API tracking (ECLIPSE 100)

Restriction	ECLIPSE 100 only keyword	Description
API tracking only.	APIGROUP	Allows different groups of oil PVT tables to be used in different PVTNUM regions.

## Black Oil fluid PVT property data

### Common keywords

Restriction	Keyword	Description
DENSITY or GRAVITY required.	DENSITY	Stock tank fluid densities.
DENSITY or GRAVITY	GRAVITY	Stock tank fluid gravities. required.
Required when PVCO is used, otherwise optional.	PMAX	Maximum pressure expected in the simulation run.
PVCO or PVTO required for live oil systems.	PVCO	FVF and viscosity of live oil as functions of bubble point pressure.
PVCO or PVTO required for live oil systems.	PVTO	FVF and viscosity of live oil as functions of pressure and $R_s$ .
For systems with wet gas. This keyword is required.	PVTG	FVF and viscosity of gas as functions of pressure and $R_v$ .
PVDG or PVZG required for dry gas systems	PVDG	FVF and viscosity of dry gas as functions of pressure.
For systems with water, but not with the Brine option. This keyword is required.	PVTW	FVF, compressibility and viscosity of water.

### ECLIPSE 100 only keywords

Restriction	ECLIPSE 100 only keyword	Description
PVCDO or PVDO required for dead or under saturated oil.	PVCDO	FVF and viscosity of dead oil with constant compressibility
PVCDO or PVDO required for dead or under saturated oil.	PVDO	FVF and viscosity of dead oil as functions of pressure.
Dead oil only.	RSCONST	Sets a constant $R_s$ for dead oil over the whole field.
Dead oil only.	RSCONSTT	Sets constant $R_s$ for dead oil, a different value in each PVT region.
PVDG or PVZG required for dry gas systems.	PVZG	Z-factor and viscosity of dry gas as functions of pressure.
Dry gas only.	RVCONST	Sets a constant $R_v$ for dry gas over the whole field.
Dry gas only.	RVCONSTT	Sets constant $R_v$ for dry gas, a different value in each PVT region.

**ECLIPSE 300 keywords**

Restriction	ECLIPSE 300 keyword	Description
Required	<a href="#">WATERTAB</a>	Water pressure tables. Alternative to PVTW for systems with water.

**Brine option****Common keywords**

Restriction	Keyword	Description
Required	<a href="#">PVTWSALT</a>	FVF, compressibility and viscosity of water as functions of salt concentration.
	<a href="#">BDENSITY</a>	Enables the surface density of water to vary with the salt concentration.

**ECLIPSE 100 only keywords**

Restriction	ECLIPSE 100 only keyword	Description
Brine option with dispersion only.	<a href="#">DSPDEINT</a>	When using dispersion on a brine tracer using this keyword the second item of the dispersion table (concentration of the tracer) becomes water density. The interpolation of the dispersion coefficient will then be performed on velocity and water density.
	<a href="#">IONXROCK</a>	Rock ion exchange parameters for cation exchange.
	<a href="#">IONXSURF</a>	Surfactant micelle ion exchange parameters for cation exchange.
	<a href="#">PLYESAL</a>	Coefficients for polymer effective salinity.
	<a href="#">SURFESAL</a>	Coefficients for surfactant effective salinity.

**Carbon Dioxide solution in aqueous phase (ECLIPSE 300)**

This option is for ECLIPSE 300 only. The keywords are:

Restriction	Keyword	Description
<a href="#">CO2SOL</a> and <a href="#">GASSOL</a> options.	<a href="#">RSWVD</a>	Aqueous concentration of dissolved gases versus depth.
	<a href="#">DENAQA</a>	This keyword enables the default Ezrokhi coefficients for the aqua density calculation to be overwritten.
	<a href="#">VISCAQA</a>	This keyword enables the default Ezrokhi coefficients for the aqua viscosity calculation to be overwritten.

**CO2SOL only keywords**

- [SOLUBILI](#) Specify properties of water-CO<sub>2</sub> system.
- [SOLUBILS](#) Specify properties of water-CO<sub>2</sub> system with salt dependencies.
- [SOLUBILT](#) Specify properties of water-CO<sub>2</sub> system with temperature dependencies.
- [SOLUCO2H](#) Specify properties of water-CO<sub>2</sub> system with H<sub>2</sub>S dependencies.

- [SOLUH2SC](#) Specify properties of water-H<sub>2</sub>S system with CO<sub>2</sub> dependencies.

### GASSOL only keywords

- [SOLUAQA](#) Specify properties of a water-multi component gas system.

### CO2STORE only keywords

- [ACTCO2S](#) Activity coefficient model for CO<sub>2</sub>

### Carter-Tracy aquifer data

- [AQUTAB](#) Influence functions used by Carter-Tracy aquifers.

### Chemical reaction keywords (ECLIPSE 300)

Restriction	ECLIPSE 300 only keyword	Description
	<a href="#">EQLDKVCR</a>	K-values for equilibrium deviation reactions
	<a href="#">EQLDREAC</a>	Equilibrium deviation reaction rates
	<a href="#">REACTACT</a>	Reaction activation molar energy
Thermal	<a href="#">REACENTH</a>	Reaction molar enthalpy
	<a href="#">REACCORD</a>	Reaction rate component order
	<a href="#">REACPHA</a>	Reactant phase
	<a href="#">REACPORD</a>	Reaction rate porosity order
	<a href="#">REACRATE</a>	Reaction rate constant
Solid	<a href="#">REACSMAX</a>	Reaction rate solid saturation limit.
Solid	<a href="#">REACSORD</a>	Reaction rate solid order.
	<a href="#">REACTRAC</a>	Tracer dependent reaction rate terms
	<a href="#">STOPROD</a>	Stoichiometric coefficients of products
	<a href="#">STOREAC</a>	Stoichiometric coefficients of reactants

### Coal bed methane (ECLIPSE 100)

Restriction	ECLIPSE 100 only keyword	Description
Either COALADS or COALPP should be specified.	<a href="#">COALADS</a>	Gas/solvent relative adsorption data.
Either COALADS or COALPP should be specified.	<a href="#">COALPP</a>	Gas/solvent partial pressure data.
	<a href="#">DIFFCOAL</a>	Gas diffusion data.
	<a href="#">LANGMPL</a>	Pressure scaling factor for the adsorption capacity for each grid cell.

Restriction	ECLIPSE 100 only keyword	Description
	LANGMUIR	Tables of coal surface gas concentration.
	LANGSOLV	Tables of coal solvent gas concentration.
	MLANG	Maximum surface gas concentration.
	MLANGSLV	Maximum solvent surface concentration.
	ROCKPAMA	Palmer-Mansoori rock model data.
Palmer-Mansoori rock model.	TPAMEPS	Specify strain term as a function of adsorbed gas concentration
Palmer-Mansoori rock model.	TPAMEPSS	Specify strain term as a function of adsorbed solvent concentration

### Coal bed methane (ECLIPSE 300)

ECLIPSE 300 only keyword	Description
DIFFCBM	Diffusion coefficients.
LANGMEXT	Extended Langmuir isotherm data for each component.
LANGMPL	Pressure scaling factor for the adsorption capacity for each grid cell.
LANGMUIR	Langmuir isotherm table data for each component.
LANGMULC	Langmuir multipliers on a cell by cell basis for each component.
LANGMULT	Langmuir multipliers on a cell by cell basis.
RESORB	Re-adsorption factor.
ROCKPAMA	Palmer-Mansoori rock model data.
ROCKPAME	Composition dependent Palmer-Mansoori alike rock model data.
TPAMEPS	Specify the strain term for each component versus gas concentration to be used by ROCKPAMA.

### Compositional EoS and PVT property data (ECLIPSE 300)

Restriction	ECLIPSE 300 only keyword	Description
	ACF	Acentric factors. Required.
Defaults to ACF if not specified	ACFS	Acentric factors for surface EoS
Required	BIC	Binary interaction coefficients for EoS.
Defaults to BIC if not specified	BICS	Binary interaction coefficients for surface EoS
Required	CALVAL / CALVALR	Component calorific values and component calorific values for multiple equation of state regions.

Restriction	ECLIPSE 300 only keyword	Description
For calorific value rate control of groups and wells (and the <code>GASWAT</code> option). Required	<code>CNAMES</code>	Component names.
<code>DENSITY</code> or <code>GRAVITY</code> is required only for water, if present.	<code>DENSITY</code>	Stock tank fluid densities.
<code>DENSITY</code> or <code>GRAVITY</code> is required only for water, if present.	<code>GRAVITY</code>	Stock tank fluid gravities.
Required for Zudkevitch Joffe only.	<code>DREF</code>	Reference densities (for Zudkevitch Joffe EoS).
	<code>FACTLI</code>	Modifies the Li critical temperature correlation.
Required (but assumes default values if omitted).	<code>GREF</code>	Reference gravities (for Zudkevitch Joffe).
Used only if the default coefficients in the Lorentz-Bray-Clark viscosity correlation are changed.	<code>LBCCOEF</code>	Set non-default LBC coefficients.
Used only if the default coefficients in the Lorentz-Bray-Clark viscosity correlation are changed.	<code>LBCCOEFR</code>	Set non-default LBC coefficients for multiple equation of state regions.
	<code>LILIM</code>	Specifies the range for Li-interpolation.
	<code>MW</code>	Molecular weights.
Defaults to <code>MW</code> if not specified. Required	<code>MWS</code>	Molecular weights for surface EoS.
	<code>NCOMPS</code>	Confirm number of components. Confirms the value of <code>NCOMPS</code> set in <code>RUNSPEC</code> .
	<code>OMEGAA</code>	$\Omega_{a0}$ values for reservoir.
Defaults to <code>OMEGAA</code> if not specified. Required.	<code>OMEGAAS</code>	$\Omega_a$ values for surface EoS.
	<code>OMEGAB</code>	$\Omega_{b0}$ values for reservoir. Assumes default values if omitted.
Defaults to <code>OMEGAB</code> if not specified. Required	<code>OMEGABS</code>	$\Omega_b$ values for surface EoS.
	<code>PCRIT</code>	Critical pressures.
Defaults to <code>PCRIT</code> if not specified. Required	<code>PCRITS</code>	Critical pressures for surface EoS.
	<code>PEDERSEN</code>	Allows use of Pedersen viscosity calculation.
Required for Pedersen et al. viscosity calculation only.	<code>PEDTUNE</code>	Provides a single set of multiplicative tuning parameters to modify the mixture molecular weight calculation used in the Pedersen et al. viscosity calculation.

Restriction	ECLIPSE 300 only keyword	Description
Optional for Pedersen et al. viscosity calculation only.	PEDTUNER	Provides multiplicative tuning parameters to modify the mixture molecular weight calculation used in the Pedersen et al. viscosity calculation specified separately for each equation of state region.
Optional for Pedersen et al. viscosity calculation only.	PREF	Reference pressures for the Thermal option.
	PREFS	Reference pressures for surface EoS in the Thermal option.
	PRCORR	Request modified Peng-Robinson EoS.
Optional when using PR EoS	RTEMP	Specify constant reservoir temperature.
RTEMP or TEMPVD is required	SSHIFT	Equation of state volume shifts for reservoir. Defaults to 0 if not specified.
Defaults to SSHIFT if not specified.	SSHIFTS	Equation of state volume shifts for surface EoS.
	STCOND	Specify standard conditions. Defaults if not specified.
	TBOIL	Boiling points (for Zudkevitch Joffe EoS).
Required for Zudkevitch Joffe only Defaults to TBOIL if not specified.	TBOILS	Boiling points for surface (for Zudkevitch Joffe EoS).
	TCRIT	Critical temperatures.
Defaults to TCRIT if not specified.	TCRITS	Critical temperatures for surface EoS.
RTEMP or TEMPVD is required	TEMPVD	Specify constant temperature versus depth.
Required for Zudkevitch Joffe only	TREF	Reference temperatures (for Zudkevitch Joffe).
Defaults to VCRIT if not specified.	VCRITVIS	Critical volumes (for viscosities only).
	ZCRIT	Critical Z-factors.
Defaults to ZCRIT if not specified.	ZCRITS	Critical Z-factors for surface EoS.
Defaults to ZCRIT or if not specified	ZCRITVIS	Critical Z-factors (for viscosities only).

## Dual porosity (ECLIPSE 100)

- [DPKRMOD](#) Modifies the oil relative permeability in dual porosity runs. For dual porosity runs only.
- [INTPC](#) Invokes the dual porosity integrated  $P_c$  option For dual porosity runs only.

## End point scaling

### Common keywords

Restriction	Keyword	Description
Saturation table end point scaling option only.	ENKRVD	Variation of end point relative permeability values with depth.
Saturation table end point scaling option only.	ENPCVD	Variation of maximum capillary pressure values with depth.
Saturation table end point scaling option only.	ENPTVD	Variation of end point saturation values with depth.
Saturation table end point scaling option only.	EPSDBGS	Writes scaled relative permeability curves to the Debug file, for multiple sets of grid blocks.
Saturation table end point scaling option only.	EPSDEBUG	Writes scaled relative permeability curves to the Debug file, for grid blocks in the specified box.
Saturation table end point scaling with hysteresis only.	IKRG, IKRGR, IKRW, IKRWR, IKRO, IKROG, IKRORW	Imbibition curve end point relative permeability values, equivalent to keywords KRG, KRGR, KRW and KRWR for example.
Saturation table end-point scaling option and WAG hysteresis option only.	IKRWH	Scales three-phase water relative permeability values at maximum water saturation, for cells in the current input box.
Saturation table end-point scaling option and WAG hysteresis option only.	IKRWRH	Scales three-phase water relative permeability values at residual oil saturation, for cells in the current input box.
Saturation table end point scaling with hysteresis only.	ISGL, ISGCR, ISGU, ISWL, ISWCR, ISWU, ISOGCR, ISOWCR	Imbibition curve end point scaling data, equivalent to keywords including SGL, SGCR and SGU.
Saturation table end point scaling option only.	KRG	Scales gas relative permeability values at maximum gas saturation, for cells in the current input box.
Saturation table end point scaling option only.	KRGR	Scales gas relative permeability values at residual oil saturation, for cells in the current input box.
Saturation table end point scaling option only.	KRO	Scales oil relative permeability values at maximum oil saturation, for cells in the current input box.
Saturation table end point scaling option only.	KROG	Scales oil relative permeability values at critical gas saturation, for cells in the current input box
Saturation table end point scaling option only.	KROW	Scales oil relative permeability values at critical water saturation, for cells in the current input box.
Saturation table end point scaling option only.	KRW	Scales water relative permeability values at maximum water saturation, for cells in the current input box.

Restriction	Keyword	Description
Saturation table end point scaling and WAG hysteresis option only.	KRWH	Scales two-phase water relative permeability values at maximum water saturation, for cells in the current input box.
Saturation table end point scaling option only.	KRWR	Scales water relative permeability values at residual oil saturation, for cells in the current input box.
Saturation table end point scaling option and WAG hysteresis option only.	KRWRH	Scales two-phase water relative permeability values at residual oil saturation, for cells in the current input box.
Saturation table end point scaling option only.	PCG	Scales the maximum gas capillary pressure, for cells in the current input box.
Saturation table end point scaling option only.	PCW	Scales the maximum water capillary pressure, for cells in the current input box.
Saturation table end point scaling option only.	PPCWMAX	Limits the calculated PCW values when the SWATINIT option is used.
Saturation table end point scaling option only.	SCALECRS	Requests alternative end point scaling method.
Saturation table end point scaling option only.	SGCR	Critical gas saturation for grid cells in the current input box.
Saturation table end point scaling option only.	SGL	Connate gas saturation for grid cells in the current input box.
Saturation table end point scaling option only.	SGU	Maximum gas saturation for grid cells in the current input box. For saturation table end point scaling option only. SOGCR Residual oil-in-gas saturation for grid cells in the current input box.
Saturation table end point scaling option only using the IKU three-phase relative permeability model with IKU3P in the PROPS section	SWGCR	Residual water-in-gas saturation for grid cells in the current input box..
Saturation table end point scaling option only.	SOWCR	Residual oil-in-water saturation for grid cells in the current input box.
Saturation table end point scaling option only.	SWATINIT	Initial water saturation, for grid cells in the current input box, to scale water $P_c$ curves.
Saturation table end point scaling option only.	SWCR	Critical water saturation for grid cells in the current input box.
Saturation table end point scaling option only.	SWL	Connate water saturation for grid cells in the current input box.
Saturation table end point scaling option only.	SWU	Maximum water saturation for grid cells in the current input box.
	TOLCRIT	Controls the method of determining the table critical saturations in pathological end point scaling cases.
Mobile fluid correction cases.	TZONE	Controls the variation of critical end-point with depth.

**ECLIPSE 100 only keywords**

Restriction	ECLIPSE 100 only keyword	Description
Saturation table end point scaling option only.	ENSPCVD	Variation of the scaled connate saturation, for $P_c$ curves only, with depth.
Saturation table end-point scaling with hysteresis only.	IMKRVD	Variation of end point relative permeability values with depth for the imbibition curve
Saturation table end-point scaling with hysteresis only.	IMPCVD	Variation of maximum capillary pressure values with depth for the imbibition curve.
Saturation table end-point scaling with hysteresis only.	IMPTVD	Variation of end point saturation values with depth for the imbibition curve.
Saturation table end point scaling with hysteresis only.	IMSPCVD	Variation of the scaled connate saturation, for $P_c$ curves only, with depth for the imbibition curve.
Saturation table end point scaling with hysteresis only.	IPCG, IPCW	Imbibition curve end point capillary pressure values, equivalent to keywords PCG, PCW.
Saturation table end point scaling with hysteresis only.	ISGLPC, ISWLPC	Imbibition curve end point scaling data, equivalent to keywords SGLPC, SWLPC.
Saturation table end point scaling option only.	NOWARNEP	Suppresses all warning messages resulting from end point consistency checks.
Saturation table end point scaling option only.	SCALELIM	Sets saturation scaling limits for each end point scaling versus depth region.
Saturation table end point scaling option only.	SGLPC	Connate gas saturation, for $P_c$ curves only, for grid cells in the current input box
Saturation table end point scaling option only.	SWLPC	Connate water saturation, for $P_c$ curves only, for grid cells in the current input box.

**ECLIPSE 300 only keywords**

Restriction	ECLIPSE 300 only keyword	Description
Saturation table end point scaling option only using the IKU three-phase relative permeability model with <a href="#">IKU3P</a> in the PROPS section.	SGWCR	Residual gas-in-water saturation for grid cells in the current input box.

**Environmental tracers (ECLIPSE 100)**

Restriction	ECLIPSE 100 only keywords	Description
Optional, required for partitioned tracers	TRACERKP	Partitioning function K(P) for partitioned tracers.
Optional, required for partitioned tracers	TRACERKM	Partitioning functions K(P) for generalized, multi-partitioned tracers.
Optional, required for any adsorbing tracer	TRADS	Tracer adsorption functions (tabulated).

Restriction	ECLIPSE 100 only keywords	Description
Optional, required for any adsorbing tracer	ADSORP	Tracer adsorption functions (analytical).
Optional, required for any decaying tracer	TRDCY	Tracer decay functions.
Optional, required for any diffusing tracer	TRDIF	Tracer diffusion functions.
Optional, required for any adsorbing tracer	TRROCK	Tracer rock properties.

## Foam Model

This option is available in both simulators, though some keywords are only available in ECLIPSE 100.

### Common keywords

Restriction	Keyword	Description
Functional model	FOAMFCN	Gas mobility reduction dependence upon capillary number
Functional model	FOAMFRM	Gas reference mobility reduction factor
Functional model	FOAMFSC	Gas mobility reduction dependence upon surfactant concentration
Functional model	FOAMFSO	Gas mobility reduction dependence upon oil saturation
Functional model	FOAMFST	Gas-water surface tension dependence upon concentration
Functional model	FOAMFSW	Gas mobility reduction dependence upon water saturation

### ECLIPSE 100 only keywords

Restriction	ECLIPSE 100 only keyword	Description
Analytical	ADSORP	Foam adsorption functions
Tabulated	FOAMADS	Foam adsorption functions
Tabular model	FOAMDCYO	Foam decay as a function of oil saturation
Tabular model	FOAMDCYW	Foam decay as a function of water saturation
Tabular model, optional	FOAMMOB	Gas mobility reduction data
Tabular model	FOAMMOBP	Pressure dependence on foam mobility reduction
Tabular model	FOAMMOBS	Shear dependence on foam mobility reduction
	FOAMOPTS	Specifies the Foam Model options.
	FOAMROCK	Specifies the foam rock properties.

## GASWAT option (ECLIPSE 300)

The keywords are:

Restriction	ECLIPSE 300 only keyword	Description
	AQCOEF	A-coefficient terms for water component

Restriction	ECLIPSE 300 only keyword	Description
	<a href="#">BICAQ1</a> <a href="#">BICAQ2</a> <a href="#">BICAQ3</a>	Binary interaction coefficients for aqueous phase
Required for the GASWAT option	<a href="#">CALVAL</a> , <a href="#">CALVALR</a>	Component calorific values and component calorific values for multiple equation of state regions.
Required for the GASWAT option	<a href="#">GSF</a>	Gas saturation functions.
Required for the GASWAT option	<a href="#">WSF</a>	Water saturation functions.
	<a href="#">SALINITR</a> , <a href="#">SALINITY</a>	Reservoir salinity and regional reservoir salinity

## Geomechanics (ECLIPSE 300)

ECLIPSE 300 only keyword	Description
<a href="#">BIOTCTAB</a>	Defines a multiplier for the Biot constant, this being a two-dimensional tabular function of maximum and minimum principal stress.
<a href="#">GEOYLDF</a>	Defines parameters for the plastic yield function in each geomechanics region.
<a href="#">PERMSTAB</a>	Defines a permeability multiplier, this being a two-dimensional tabular function of maximum and minimum principal stress. A table is entered for each geomechanics region.
<a href="#">SCDATABG</a>	Defines a scale damage table to be used together with the proppant flowback feature, keyword <a href="#">PROPFLOW</a> .

## GI pseudo-compositional model (ECLIPSE 100)

- [BGGI](#) Variation of saturated gas FVF with pressure and  $G_i$ .
- [BOGI](#) Variation of saturated oil FVF with pressure and  $G_i$ .
- [GIALL](#) Variation of saturated properties with pressure and  $G_i$
- [GINODE](#)  $G_i$  nodal values. Required
- [RSGI](#) Variation of saturated GOR with pressure and  $G_i$ .
- [RVGI](#) Variation of saturated OGR with pressure and  $G_i$ .

## Gradient option (ECLIPSE 100 special option)

Restriction	ECLIPSE 100 only keyword	Description
	<a href="#">HMMROCK</a>	Cumulative multipliers on rock compressibility.
	<a href="#">HMMROCKT</a>	Cumulative modifiers of rock compaction parameters.
	<a href="#">HMPPROPS</a>	Section heading for end-point scaling modifiers.

Restriction	ECLIPSE 100 only keyword	Description
	HMROCK	Calculate gradients with respect to rock compressibility multipliers.
	HMROCKT	Calculate gradients with respect to rock compaction parameters.
Required if HMROCKT used.	HMREF	Reference pressures for HMROCKT.

## Initial composition (ECLIPSE 300)

- [COMPVD](#) Total composition with respect to depth tables
- [XMFVP](#) Liquid composition with respect to pressure tables
- [YMFVP](#) Vapor composition with respect to pressure tables
- [ZMFVD](#) Total composition with respect to depth tables
- [ZI](#) Enter overall composition

## K Values (ECLIPSE 300)

One of [KVGEN](#), [KVTABLE](#), [KVTABCn](#) is required for the [KVALUES](#) option.

ECLIPSE 300 only keyword	Description
<a href="#">KVGEN</a>	Specify that K-values are to be generated internally.
<a href="#">KVTABLE</a>	Tables of K-values.
<a href="#">KVTABCn</a> , <a href="#">KVMF</a> , <a href="#">KVCOMP</a>	Composition dependent K-values.

## Low-Salinity option (ECLIPSE 100)

Restriction	ECLIPSE 100 only keyword	Description
Required	<a href="#">LSALTFNC</a>	Tables of salt concentration versus fraction of high-salinity and low-salinity saturation functions.

## Miscible flood option (ECLIPSE 100)

Restriction	ECLIPSE 100 only keyword	Description
Miscible Flood option only	<a href="#">MSFN</a>	Allows input of relative permeability curves for miscible displacement. If not entered, a linear function is used.
Miscible Flood option only	<a href="#">PMISC</a>	Enables miscibility to be modeled as a function of pressure.

Restriction	ECLIPSE 100 only keyword	Description
Miscible Flood option only. Required	SDENSITY	Input of the solvent surface density.
	SGCWMIS	Miscible critical gas saturation tables.
Miscible Flood option only.	SORWMIS	Input of the residual oil saturation for the miscible displacement.
Miscible Flood option only. Required	TLMIXPAR	Input of the Todd-Longstaff mixing parameter.

## Molecular diffusion option

### ECLIPSE 100 only keywords

Restriction	ECLIPSE 100 only keyword	Description
Molecular Diffusion option only. Required.	DIFFC	Molecular diffusion coefficients for each PVT region.
Relevant only for Molecular Diffusion option in a dual porosity run	DIFFDIP	Restricts the molecular diffusion calculation to just the matrix-fracture flows in dual porosity runs.

### ECLIPSE 300 only keywords

Restriction	ECLIPSE 300 only keyword	Description
Molecular Diffusion option only. Required.	DIFFGAS	Activity corrected gas diffusion coefficients.
Molecular Diffusion option only. Required.	DIFFWAT	Activity corrected water diffusion coefficients.
Molecular Diffusion option only. Required.	DIFFCGAS	Gas diffusion coefficients.
Molecular Diffusion option only. Required.	DIFFCOIL	Oil diffusion coefficients
Molecular Diffusion option in connection with the CO2STORE, GASWAT and GASSOL options. Required	DIFFCWAT	Water components diffusion coefficients.
Molecular Diffusion option in connection with the CO2STORE or GASWAT option.	DIFFCWG	Water-gas cross phase diffusion coefficients.
Molecular Diffusion option in connection with the CO2STORE or GASWAT option.	DIFFCGW	Gas-water cross phase diffusion coefficients.

Restriction	ECLIPSE 300 only keyword	Description
Molecular Diffusion option only.	<a href="#">DIFFCOG</a>	Oil-gas cross phase diffusion coefficients.
Molecular Diffusion option only.	<a href="#">DIFFCGO</a>	Gas-oil cross phase diffusion coefficients.
	<a href="#">DIFFTGAS</a>	Gas thermal diffusion coefficients.
	<a href="#">DIFFTOIL</a>	Oil thermal diffusion coefficients.

## NGLs (ECLIPSE 300)

- [DNGL](#) Partial densities for NGLs.

## Non-Darcy Flow (ECLIPSE 300)

Restriction	ECLIPSE 300 only keyword	Description
Non-Darcy Flow option. Required	<a href="#">VDFLOW</a>	Specify velocity dependent flow coefficient.
Non-Darcy Flow option. Required	<a href="#">VDFLOWR</a>	Specify velocity dependent flow coefficient for each region.
optional if item 5 of <a href="#">VELDEP</a> is non-zero	<a href="#">VDKRG</a>	Gas velocity dependent relative permeability data. Relevant only for gas velocity dependent relative permeabilities.
	<a href="#">VDKRC</a>	Gas velocity dependent relative permeability data
Relevant only for oil velocity dependent relative permeabilities.	<a href="#">VDKRO</a>	Oil velocity dependent relative permeability data.

## Output

- [RPTPROPS](#) Report levels for PROPS data.
- [FILLEPS](#) Controls the output of end point data in the INIT file.

## Polymer Flood Model

### ECLIPSE 100 Polymer flood keywords

Restriction	ECLIPSE 100 Polymer flood keyword	Description
Required.	<a href="#">PLMIXPAR</a>	Todd-Longstaff mixing data for the Polymer Model.
	<a href="#">PLYADS</a>	Polymer adsorption functions (tabulated).
	<a href="#">PLYADSS</a>	Polymer adsorption functions varying with salinity (tabulated).

Restriction	ECLIPSE 100 Polymer flood keyword	Description
	ADSORP	Polymer adsorption functions (analytical) with optional salinity dependence.
Required	PLYMAX	Polymer/salt concentrations for mixing calculations.
	PLYROCK	Polymer-rock properties.
	PLYSHEAR	Polymer shear thinning/thickening data.
	PLYVISC	Polymer solution viscosity function.
	PLYVISCS	Polymer/salt solution viscosity function.
	SALTNODE	Salt concentration nodes for polymer solution viscosity.
	ADSALNOD	Salt concentration nodes for polymer solution adsorption
	PLYATEMP	Polymer adsorption functions varying with temperature (tabulated).

### ECLIPSE 300 Polymer flood keywords

- [PLYOPTS](#) Options for the Polymer Model.
- [PLYVISC](#) Polymer solution viscosity function.
- [PLYVISCS](#) Polymer/salt solution viscosity function.
- [ESPNODE](#) Effective salinity nodes for polymer solution viscosity.
- [SALTEFF](#) Effective salinity coefficients for effective salinity calculations.

### Relative permeability and capillary pressure data

#### Common keywords

Restriction	Keyword	Description
SGOF or SLGOF required with Family (i) in systems with both gas and oil.	<a href="#">SGOF</a>	Gas relative permeability and capillary pressure and oil relative permeability in gas at connate water, as functions of $S_g$ .
SGOF or SLGOF required with Family (i) in systems with both gas and oil.	<a href="#">SLGOF</a>	Gas relative permeability and capillary pressure and oil relative permeability in gas at connate water, as functions of $S_{liq}$ .
Required with Family (i) in systems with both water and oil.	<a href="#">SWOF</a>	Water relative permeability and capillary pressure oil relative permeability in water, as functions of $S_w$ .
Required with Family (ii) in two or three-phase systems with gas, unless SGWFN is used in a gas-water run.	<a href="#">SGFN</a>	Gas relative permeability and capillary pressure as functions of $S_g$ .

Restriction	Keyword	Description
Required with Family (ii) in two or three-phase systems with water, unless SGWFN is used in a gas-water run.	SWFN	Water relative permeability and capillary pressure as functions of $S_w$ .
Required with Family (ii) for two-phase systems with oil.	SOF2	Oil relative permeability as a function of $S_o$ .
SOF3 or SOF32D required with Family (ii) for three-phase systems.	SOF3	Oil relative permeability as a function of $S_o$ .
	STONE	Use Stone's modified formula number 2 to calculate the three phase oil relative permeability.
	STONE1	Use Stone's modified formula number 1 to calculate the three phase oil relative permeability.
	STONE1EX	Apply an exponent to the saturation terms in Stone's modified formula number 1 method for calculating the three phase oil relative permeability.
	STONE2	Use Stone's modified formula number 2 to calculate the three phase oil relative permeability.
Optional, for STONE1 method only.	SOMGAS	Specifies the minimum oil saturation used in the STONE1 method as a function of the gas saturation.
Optional, for STONE1 method only.	SOMWAT	Specifies the minimum oil saturation used in the STONE1 method as a function of the water saturation.
	SGF32D	Gas relative permeability (for three-phase flows) as 2-D table.
	SWF32D	Water relative permeability (for three-phase flows) as 2-D table.
Optional, for Hysteresis option only.	WAGHYSTR	Activates the WAG Hysteresis option.

### ECLIPSE 100 only keywords

Restriction	ECLIPSE 100 only keyword	Description
Optional for runs involving only gas and water. (The gas and water relative permeability and capillary pressure data could alternatively be supplied using SWFN and SGFN, allocating the capillary pressure to the water phase.)	SGWFN	Gas-water relative permeability and capillary pressure, as functions of $S_g$ .
SOF3 or SOF32D required with Family (ii) for three-phase systems	SOF32D	Oil relative permeability as functions of $S_w$ and $S_g$ in a 2D table.
Optional, if SURFTENS is specified in keyword SATOPTS, or if the Drift Flux Model is used in multisegment wells.	STOG	Tables of oil/gas surface tension.

Restriction	ECLIPSE 100 only keyword	Description
Optional, if SURFTENS is specified in keyword SATOPTS, or if the Drift Flux Model is used in multisegment wells.	STOW	Tables of oil/water surface tension.
Optional, if the Drift Flux Model is used in multisegment wells.	STWG	Tables of water/gas surface tension.
Required for Hysteresis option.	EHYSTR	Curvature parameters and model selection for hysteresis.
Optional, for Hysteresis option only	EHYSTRR	Hysteresis parameters by region.
Optional, for Hysteresis option only.	HYSTCHCK	Activates additional consistency checks between drainage and imbibition curve endpoints when using the Hysteresis option.

### ECLIPSE 300 only keywords

Restriction	ECLIPSE 300 only keyword	Description
TRCOEF option.	ALPHA	Transport coefficient tables.
TRCOEF option	ALPHAD	Transport coefficient tables for drainage processes,
TRCOEF option.	ALPHAI	Transport coefficient tables for imbibition processes,
	IKU3P	Requests IKU three-phase relative permeabilities.
	ODD3P	Requests ODD3P three-phase relative permeability and capillary pressure hysteresis model.
	OPTODD3P	Provides backwards compatibility and saturation switching options for the ODD3P three-phase relative permeability and capillary pressure hysteresis model
	BAKER1	Requests BAKER1 three-phase relative permeabilities
	BAKER2	Requests BAKER2 three-phase relative permeabilities.
	STONEPAR	Modify Stone's number 1 relative permeability model
Optional, if the IKU three-phase Relative Permeability Model is requested with keyword IKU3P. Required for the ODD3P option.	SGF3	Three phase gas saturation functions.

Restriction	ECLIPSE 300 only keyword	Description
Optional, if the IKU three-phase Relative Permeability Model is requested with keyword IKU3P. Required for the ODD3P option.	SWF3	Three phase water saturation functions.
Optional if HYSTK is selected.	DRAINAGE	Forces the Killough relative permeability scanning curve to be below the drainage curve.
Optional, for CO2SOL, H2SSOL and GASSOL options only.	MIXWPERM	Activates the mixed water relative permeability option to take into account the dissolution of gases.
Must be used when MIXWPERM is specified.	MIXACTO	Specifies the oil activity functions for soluble components.
Must be used when MIXWPERM is specified	MIXACTG	Specifies the gas activity functions for soluble components.
	SOR	Residual oil saturation.
	SOROPTS	Residual oil model options.

## Rivers (ECLIPSE 100)

- [RIVRXSEC](#) Defines rivers' cross-section
- [RBEDCONT](#) Defines contact areas between river bed and the grid blocks.
- [DEPTHTAB](#) Depth data for boundary conditions.
- [MASSFLOW](#) Massflow data for boundary conditions.
- [QHRATING](#) Rating data for boundary conditions.

## Rock compressibility and compaction data

### Common keywords

Restriction	Keyword	Description
	OVERBURD	Overburden pressure tables
	RKTRMDIR	Allows directional transmissibility multipliers to be defined in ROCKTAB tables
	ROCKTAB	Rock compaction tables Required if using standard Rock Compaction option
Required if using Hysteretic Rock Compaction option	ROCKTABH	Hysteretic rock compaction tables
	ROCKTHSG	Hysteretic rock compaction tables in dual porosity runs
	ROCKTSIG	Rock compaction tables in dual porosity runs
Optional, for Rock Compaction option only	ROCKOPTS	Controls options associated with the rock compaction facilities

Restriction	Keyword	Description
Optional, for the Coal Bed Methane option only	ROCKPAMA	Palmer-Mansoori rock model data
	TPAMEPS	Volumetric strain values to be used by ROCKPAMA.

### ECLIPSE 100 only keywords

Restriction	ECLIPSE 100 only keyword	Description
ROCKTABW or ROCK2D required for water induced rock compaction	ROCKTABW	Water saturation dependent rock compaction tables
ROCK2D or ROCKTABW required for water induced rock compaction.	ROCK2D	Two-dimensional water induced rock compaction tables
Optional, for 2-D water induced Rock Compaction option only.	ROCK2DTR	Transmissibility modifier tables for 2-D water induced compaction
Required for 2-D water induced Rock Compaction option only.	ROCKWNOD	Saturation nodes for 2-D water induced rock compaction tables
	TPAMEPSS	Volumetric strain values for solvent to be used by ROCKPAMA

### ECLIPSE 300 only keywords

Restriction	ECLIPSE 300 only keyword	Description
	RKPVMNMX	Allows pore volume multiplier limits to be set for the BOBERG model.
Geomechanics. Required if <b>not</b> using Rock Compaction option. Optional when using the second porosity-stress relation. Rock Compaction option only.	ROCK	Rock compressibility
Optional, for the Coal Bed Methane option only.	ROCKPAME	Palmer-Mansoori rock model data
	ROCKPMAT	Thermal Palmer-Mansoori rock model data
	ROCKTRMX	Defines transmissibility variation values in the X-direction in order to define transmissibility as an exponential function of porosity.
	ROCKTRMY	Defines transmissibility variation values in the Y-direction in order to define transmissibility as an exponential function of porosity.

Restriction	ECLIPSE 300 only keyword	Description
	ROCKTRMZ	Defines transmissibility variation values in the Z-direction in order to define transmissibility as an exponential function of porosity.

### Solid option (ECLIPSE 300)

Restriction	ECLIPSE 300 only keyword	Description
	CVTYPE	Define solid phase components
	CVTYPES	Define solid phase components at surface conditions
Chemical reactions	REACSMAX	Reaction rate solid saturation limit
Chemical reactions	REACSORD	Reaction rate solid order
	SCREF	Component solid phase compressibility
	SDREF	Component solid phase reference density
	SOLIDADS	Solid adsorption table
	SOLIDMMC	Solid mobility multiplier (as a function of adsorbed solid concentration)
	SOLIDMMS	Solid mobility multiplier (as a function of adsorbed solid saturation)
	SOLWTAB	Defines an interpolation parameter as a function of adsorbed solid concentration.
	SOLWW	Defines a component weighting factor for calculating the wetting-solid concentration.
Thermal	SPECHS	Component solid specific heat, 1 <sup>st</sup> coefficient
Thermal	SPECHT	Component solid specific heat, 2 <sup>nd</sup> coefficient
	SPREF	Component solid phase reference pressure
	STREF	Component solid phase reference temperature
	STHERMX1	Component solid phase thermal expansion coefficient

### Solvent Model (ECLIPSE 100)

ECLIPSE 100 only keyword	Description
MISC	Miscibility function tables.
MSFN	Miscible saturation functions.
PMISC	Pressure dependent miscibility tables.
PVDS	PVT properties of the solvent.
SDENSITY	Solvent density at surface conditions.

ECLIPSE 100 only keyword	Description
SGCWMIS	Miscible critical gas saturation tables.
SSFN	Gas/solvent saturation functions.

## Surface tension effects (ECLIPSE 300)

Restriction	ECLIPSE 300 only keyword	Description
	MISCEXP	Specify miscibility component.
Required	MISCSTR	Miscibility surface tension reference.
Required	MISCSTRP	Miscibility surface tension reference pressure.
Required	MISCSTRR	Allows the reference miscible surface tension to be set by saturation region number.
	PARACHOR	Parachor values for surface tension evaluation.
	STVP	Surface tension with respect to pressure.

## Surfactant option

### ECLIPSE 100 only keywords

Restriction	ECLIPSE 100 only keyword	Description
Optional, for end point scaling.	SOCRS	Scaled critical oil-in-water saturations at miscible conditions.
Required if SURFSTES is not specified.	SURFST	Oil-water surface tension in the presence of surfactant.
Required if SURFST is not specified	SURFSTES	Salinity dependent oil-water surface tension in the presence of surfactant.
Required if salinity dependent surfactant model is activated by SURFSTES	ESSNODE	Salt concentration nodes for oil-water surface tension.
Required	SURFVISC	Modified water viscosity.
Required	SURFCAPD	Capillary de-saturation data.
	SURFADS	Surfactant adsorption functions (tabulated).
	ADSORP	Surfactant adsorption functions (analytical) with optional salinity dependence
	SURFADDW	Tables of adsorbed surfactant mass versus fraction of oil-wet and water-wet curves, for calculating immiscible relative permeabilities.
Required if SURFADS is present.	SURFROCK	Rock properties.
Required for partitioned tracers.	TRACERKP	Partitioning function K(P) for partitioned tracers.

**ECLIPSE 300 only keywords**

Restriction	ECLIPSE 300 only keyword	Description
Required	<a href="#">SURFST</a>	Oil-water surface tension in the presence of surfactant.
Required if SURFST is not specified	<a href="#">SURFSTES</a>	Salinity dependent oil-water surface tension in the presence of surfactant.
Required if salinity dependent surfactant model is activated by SURFSTES	<a href="#">ESSNODE</a>	Salt concentration nodes for oil-water surface tension.
Required if salinity dependent surfactant model is activated by SURFSTES	<a href="#">SALTEFF</a>	Effective salinity coefficients.
Required	<a href="#">SURFCAPD</a>	Capillary de-saturation data.
	<a href="#">SURFOPTS</a>	Surfactant options.

**Temperature option**

Restriction	Keyword	Description
Temperature option only.	<a href="#">OILVISCT</a>	Inputs tables of oil viscosity versus temperature.
Required for Temperature option.	<a href="#">RTEMP</a>	Specify constant reservoir temperature.
Required for Temperature option.	<a href="#">RTEMPA</a>	Specify constant reservoir temperature.
Required for Temperature option.	<a href="#">SPECHEAT</a>	Inputs tables of fluid specific heat data.
Required for Temperature option.	<a href="#">SPECROCK</a>	Inputs tables of rock specific heat data.
Temperature option only.	<a href="#">TEMPTVD</a>	Requests the use of the flux limited transport scheme.
Temperature option only.	<a href="#">VISCREF</a>	Sets reference conditions for viscosity versus temperature tables.
Temperature option only.	<a href="#">WATVISCT</a>	Inputs tables of water viscosity versus temperature.

**Thermal option (ECLIPSE 300)**

Restriction	ECLIPSE 300 only keyword	Description
Requires KWTABTn	<a href="#">AMFVD</a>	Aqueous mole fractions versus depth
	<a href="#">CREF</a>	Component compressibilities
	<a href="#">CCTYPE</a>	Component liquid compressibility type
	<a href="#">CCTYPES</a>	Component liquid compressibility type at surface conditions
	<a href="#">CGDTYPE</a>	Component gas (EoS) density model
	<a href="#">CGVTYPE</a>	Component gas (EoS LBC) viscosity model
	<a href="#">CODTYPE</a>	Component oil (EoS) density model

Restriction	ECLIPSE 300 only keyword	Description
	COVTYPE	Component oil (EoS LBC) viscosity model
	CVTYPE	Component volatility (dead, live, gaseous)
	CVTYPES	Component volatility (dead, live, gaseous) at surface conditions
	DREF	Fluid densities at the reference pressures and temperatures.
	DREFS	Reference densities for use in the surface calculations
	DREFT	alias for DREF
	DREFTS	alias for DREFS
	ENKRVT	Endpoint relative permeabilities versus temperature
	ENPCVT	Endpoint capillary pressures versus temperature
	ENPTVT	Endpoint saturations versus temperature
	GASVISCF	Gas viscosity function of temperature
	GASVISCT	Gas viscosity table as a function of temperature
	HEATVAP	Component heat of vaporization at standard temperature
	HEATVAPE	Component heat of vaporization
	HEATVAPS	Heat of vaporization exponent
	KVCR	K-value correlation parameters
	KVCRS	K-value correlation parameters at surface conditions
	KVGEN	K-values generated from an EoS.
	KVCRWAT	Water K-value correlation parameters
	KVTABTn	Tables of K-values
	KVTEMP	Temperatures for K-value tables
	KWTABTn	Tables of aqua Kw-values
	KWTEMP	Temperatures for Kw-value tables
	KVWI	Wilson K-value correlation parameters
	OILCOMPR	Oil compressibility, expansion coefficient
	OILMW	Oil molecular weight
	OILSPECH	Oil specific heat
	OILVINDX	Oil viscosity index
	OILVISCC	Oil viscosity-temperature correlations
	OILVISCF	Oil viscosity function
	OILVISCT	Oil viscosity table as a function of T
	OILVTIM	Interpolation method for OILVISCT data
	PREF	Component reference pressures
	PREFS	Component reference pressures for surface EoS
	PREFT	Alias for PREF

Restriction	ECLIPSE 300 only keyword	Description
	PREFTS	Alias for PREFS
	REACENTH	Reaction molar enthalpy
	SPECHA	Component oil specific heat, 1 <sup>st</sup> coefficient
	SPECHB	Component oil specific heat, 2 <sup>nd</sup> coefficient
	SPECHG	Component gas specific heat, 1 <sup>st</sup> coefficient
	SPECHH	Component gas specific heat, 2 <sup>nd</sup> coefficient
	SPECHS	Component solid specific heat, 1 <sup>st</sup> coefficient Solid option
	SPECHT	Component solid specific heat, 2 <sup>nd</sup> coefficient Solid option
Requires KWTABTn	SPECHW1	Component aqua specific heat, 1 <sup>st</sup> coefficient
Requires KWTABTn	SPECHW2	Component aqua specific heat, 2 <sup>nd</sup> coefficient
	THANALB	Analytic water and steam densities
	THANALH	Analytic water and steam enthalpy values
	THERMEX1	Analytic oil viscosities
	THANALV	Component thermal expansion coefficient
	THSVC	Steam viscosity coefficients
	THTABB	Tabular water and steam densities
	THWVC	Water viscosity coefficients
	TRANGE	Expected temperature limits
	TREF	Reference temperatures for fluid densities
	TREFS	Reference temperatures for use in the surface calculations
	TREFT	alias for TREF
	TREFTS	alias for TREFS
	VISCREF	Reference conditions for the viscosity/temperature tables
	WATDENT	Water density temperature dependence
	WATVISCT	Inputs tables of water viscosity versus temperature.
	ZFACT1	Z-factor first coefficient
	ZFACT1S	Surface Z-factor first coefficient
	ZFACTOR	Z-factors zeroth coefficient
	ZFACTORS	Surface Z-factor zeroth coefficient

## Tracer tracking

### Common keywords

The following keywords can be used in both ECLIPSE 100 and ECLIPSE 300.

- [HDISP](#) Mechanical dispersion values.

### ECLIPSE 100 only keywords

Restriction	ECLIPSE 100 only keyword	Description
Required for passive tracer tracking.	<a href="#">TRACER</a>	Names and phases of passive tracers.
tracer tracking only.	<a href="#">TRACITVD</a>	Requests implicit flux limiting scheme, to reduce numerical dispersion.
tracer tracking only.	<a href="#">TRACTVD</a>	Requests explicit flux limiting scheme, to reduce numerical dispersion.
Required for any diffusing tracer.	<a href="#">TRDIF</a>	Tracer diffusion functions.
Required for any dispersing tracer.	<a href="#">TRDIS</a>	Tracer dispersion table numbers.
Required for any dispersing tracer.	<a href="#">DISPERSE</a>	Tracer dispersion tables.
Optional with dispersion only.	<a href="#">DIAGDISP</a>	Enables an alternate form of dispersion.
Optional with dispersion only.	<a href="#">TRNHD</a>	Speeds up dispersion calculation for a tracer when the dispersion is only being used to model constant coefficient non-homogeneous diffusion

### Vertical equilibrium (ECLIPSE 100)

Restriction	ECLIPSE 100 only keyword	Description
Vertical Equilibrium option only.	<a href="#">VEFRAC</a>	Fraction of VE relative permeabilities used in place of rock curves, for the entire grid.
Vertical Equilibrium option only	<a href="#">VEFRACV</a>	Fraction of VE relative permeabilities used in place of rock curves, for the current box.
Vertical Equilibrium option only	<a href="#">VEFRACP</a>	Fraction of VE pseudo capillary pressures used in place of rock curves, for the entire grid.
Vertical Equilibrium option only	<a href="#">VEFRACPV</a>	Fraction of VE pseudo capillary pressures used in place of rock curves, for the current box.

### Water component option (ECLIPSE 300)

ECLIPSE 300 only keyword	Description
<a href="#">CREFW</a>	Compressibility of water components at the reference pressure.
<a href="#">CREFWS</a>	Compressibility of water components for surface calculations.
<a href="#">CWTYPE</a>	Water component type
<a href="#">DREFW</a>	Density of water components at the reference pressure

ECLIPSE 300 only keyword	Description
DREFWS	Density of water components for surface calculations
MWW	Molecular weight of water components
MWWS	Molecular weight of water components for surface calculations
PREFW	Reference pressure for water component density and viscosity calculations
PREFWS	Reference pressure for water component density calculations at surface conditions.
VREFW	Viscosity and viscosibility for water components at the reference pressure
WNAMEs	Water component names

### ODD3P three-phase relative permeability and capillary pressure hysteresis option (ECLIPSE 300)

ECLIPSE 300 only keyword	Description
EPSODD3P	End-point scaling, reference surface tensions and threshold interfacial tensions
HSGRO	Hysteresis end-point (residual) grid-block gas saturations for a gas-oil system
HSGRW	Hysteresis end-point (residual) grid-block gas saturations for a gas-water system
HSORG	Hysteresis end-point (residual) grid-block oil saturations for an oil-gas system
HSORW	Hysteresis end-point (residual) grid-block oil saturations for an oil-water system
HSWRG	Hysteresis end-point (residual) grid-block water saturations for a water-gas system
HSWRO	Hysteresis end-point (residual) grid-block water saturations for a water-oil system
ODD3P	Select the ODD3P three-phase relative permeability and capillary pressure model
OPTODD3P	Provides backwards compatibility and saturation switching options for the ODD3P three-phase relative permeability and capillary pressure hysteresis model
PCODD3P	Capillary pressure calculation control
PCODD3PG	Capillary pressure gas saturation function
PCODD3PW	Capillary pressure water saturation function
PSGRO	Primary end-point (residual) grid-block gas saturations for a gas-oil system
PSGRW	Primary end-point (residual) grid-block gas saturations for a gas-water system
PSORG	Primary end-point (residual) grid-block oil saturations for an oil-gas system
PSORW	Primary end-point (residual) grid-block oil saturations for an oil-water system
PSWRG	Primary end-point (residual) grid-block water saturations for a water-gas system
PSWRO	Primary end-point (residual) grid-block water saturations for a water-oil system

### Operational keywords

These may be used with keywords that specify arrays over grid cells.

## Common keywords

Keyword	Description
ADD	Adds specified constants to specified arrays in the current input box.
ADDREG	Add by MULTNUM, FLUXNUM or OPERNUM region.
BOX	Redefines the current input box.
COPY	Copies data in the current box from one specified array to another.
COPYBOX	Copies data from one box of cells to another box of the same size.
COPYREG	Copy by FLUXNUM, MULTNUM or OPERNUM region.
ENDBOX	Redefines the current input box to encompass the whole grid.
ENDFIN	End input for local grid refinement.
EQUALREG	Set by FLUXNUM, MULTNUM or OPERNUM region.
EQUALS	Sets specified arrays to specified constants within the current box.
IMPORT	Imports binary data generated by a grid pre-processor.
MAXVALUE	Applies a maximum value to specified arrays within the current box.
MINVALUE	Applies a minimum value to specified arrays within the current box.
MULTIPLY	Multiplies specified arrays by specified constants within the current box.
MULTIREG	Multiply by FLUXNUM, MULTNUM or OPERNUM region.
OPERATE	Performs arithmetic operations on arrays.
OPERATER	Performs arithmetic operations on arrays for a specific region of the grid (defined using the OPERNUM keyword in the GRID section).
REFINE	Initiates data for a named local grid.

## ECLIPSE 300 keywords only

- BOUNDARY Set area of grid to be printed.
- LGRCOPY Copy global values to local cells before operations on cells within an LGR.

## Alphabetic list of keywords

### Common keywords

Keyword	Description
ACTCO2S	Activity coefficient model for CO <sub>2</sub> . CO2STORE only
ADD	Adds specified constants to specified arrays in the current box.
ADDREG	Adds by MULTNUM, FLUXNUM or OPERNUM region.
AQUTAB	Carter-Tracy aquifer influence functions.
BOX	Redefines the current box.
COPYREG	Copy by MULTNUM, FLUXNUM or OPERNUM region.

Keyword	Description
COPY	Copies data in the current box from one specified array to another.
COPYBOX	Copies data from one box of cells to another box of the same size.
DENSITY	Stock tank fluid densities.
ENDBOX	Redefines the current box to encompass the whole grid.
ENDFIN	End data for a local grid refinement.
ENKRVD	Variation of end point relative permeability values with depth.
ENPCVD	Variation of maximum capillary pressure values with depth.
ENPTVD	Variation of saturation table end points with depth.
EPSDBGS	Outputs scaled relative permeability curves to the Debug file for multiple sets of grid block.
EPSDEBUG	Outputs scaled relative permeability curves to the Debug file.
EQLDKVCR	K-values for equilibrium deviation reactions.
EQLDREAC	Equilibrium deviation reaction rates.
EQUALREG	Set by MULTNUM, FLUXNUM or OPERNUM region.
EQUALS	Sets specified arrays to specified constants in the current box.
ESSNODE	Effective salinity nodes for salt sensitive surfactant flood studies.
FILEUNIT	Confirms the units of the data set.
FOAMFRM	Gas reference mobility reduction factor (functional model).
FOAMFSC	Gas mobility reduction dependence upon surfactant concentration (functional model).
FOAMFSO	Gas mobility reduction dependence upon oil saturation (functional model).
FOAMFST	Gas-water surface tension dependence upon concentration (functional model).
FOAMFSW	Gas mobility reduction dependence upon water saturation (functional model).
GRAVCONS	Sets a user-defined gravity constant.
GRAVITY	Stock tank fluid gravities.
IKRG, IKRGR, IKRW, IKRWR, IKRO, IKROGR, IKRORW	Imbibition curve end point relative permeability values, equivalent to KRG for example.
IMPORT	Imports binary data generated by a grid pre-processor.
KRG	Scales gas relative permeability values at maximum gas saturation, for cells in the current input box.
KRGR	Scales gas relative permeability values at residual oil saturation, for cells in the current input box.
KRO	Scales oil relative permeability values at maximum oil saturation, for cells in the current input box.
KRORG	Scales oil relative permeability values at critical gas saturation, for cells in the current input box.

Keyword	Description
KRORW	Scales oil relative permeability values at critical water saturation, for cells in the current input box.
KRW	Scales water relative permeability values at maximum water saturation, for cells in the current input box.
KRWR	Scales water relative permeability values at residual oil saturation, for cells in the current input box.
LCUNIT	Set units for linear combination of phases.
MAXVALUE	Applies a maximum value to specified arrays within the current box.
MINVALUE	Applies a minimum value to specified arrays within the current box.
MULTIPLY	Multiplies specified arrays by constant values in the current box.
MULTIREG	Multiply by <a href="#">MULTNUM</a> , <a href="#">FLUXNUM</a> or <a href="#">OPERNUM</a> region.
OILVISCT	Tables of oil viscosity versus temperature.
OILVTIM	Interpolation method for <a href="#">OILVISCT</a> data.
OPERATE	Performs arithmetic operations on arrays.
OPERATER	Performs arithmetic operations on arrays for a specific region of the grid (defined using the <a href="#">OPERNUM</a> keyword in the <a href="#">GRID</a> section).
OVERBURD	Overburden pressure tables.
PCRITS	Critical pressures for surface EoS.
PCW	Scales the maximum water capillary pressure, for cells in the current input box.
PLYVISC	Polymer solution viscosity function.
PLYVISCS	Polymer/salt solution viscosity function.
PMAX	Maximum pressure expected in the simulation.
PPCWMAX	Limits the calculated PCW values when the <a href="#">SWATINIT</a> option is used.
PVCO	FVF and viscosity of live oil as functions of bubble point pressure.
PVDO	FVF and viscosity of dead oil as functions of pressure.
PVTW	FVF, compressibility and viscosity of water.
PVZG	Z-factor and viscosity of dry gas as functions of pressure.
REFINE	Specify data for local grid refinement.
RKTRMDIR	Allows directional transmissibility multipliers to be defined in <a href="#">ROCKTAB</a> tables.
ROCK2D	Two-dimensional water induced rock compaction tables.
ROCKOPTS	Controls options associated with the rock compaction facilities.
RPTPROPS	Report levels for PROPS data.
RTEMP	Specifies a constant reservoir temperature.
SCALECRS	Requests alternative end point scaling method.
SGCR	Critical gas saturation for grid cells in the current input box.
SGF32D	Gas relative permeability (for three-phase flows) as a 2D table.
SGFN	Gas relative permeability and capillary pressure as functions of $S_g$ .

Keyword	Description
SGL	Connate gas saturation for grid cells in the current input box.
SGOF	Gas relative permeability and cap pressure, and oil relative permeability in gas, versus $S_g$ .
SGU	Maximum gas saturation for grid cells in the current input box.
SLGOF	Gas relative permeability and cap pressure, and oil relative permeability in gas, versus $S_{liq}$ .
SOF2	Oil relative permeability as a function of $S_o$ in two phase system.
SOF3	Oil relative permeability as a function of $S_o$ in three phase system.
SOF32D	Oil relative permeability as a 2D function of $S_w$ and $S_g$ in three phase systems.
SOMGAS	Minimum oil saturation for STONE1 method, as a function of the gas saturation.
SOMWAT	Minimum oil saturation for STONE1 method, as a function of the water saturation.
SOWCR	Residual oil-in-water saturation for cells in the current box.
STONE	Stone's formula for three phase oil relative permeability.
STONE1	Stone's formula 1 for three phase oil relative permeability.
STONE1EX	Exponent applied to saturation terms in Stone's formula 1 for three phase oil relative permeability.
STONE2	Stone's formula 2 for three phase oil relative permeability.
SURFST	Oil-water surface tension in the presence of surfactant.
SURFCAPD	Capillary de-saturation data.
SWATINIT	Initial water saturation, for cells in the current input box, to scale the water Pc curves.
SWCR	Critical water saturation for grid cells in the current input box.
SWF32D	Water relative permeability (for three-phase flows) as 2-D table.
SWFN	Water relative permeability and capillary pressure as functions of $S_w$ .
SWL	Connate water saturation for grid cells in the current input box.
SWOF	Water relative permeability and cap pressure, and oil relative permeability in water, versus $S_w$ .
SWU	Maximum water saturation for grid cells in the current input box.
TOLCRIT	Controls the method of determining the table critical saturations in pathological end point scaling cases.
TPAMEPS	Volumetric strain values in ROCKPAMA.
TRACER	Names and phases of passive tracers.
TZONE	Controls the variation of critical end-point with depth.
VISCREP	Reference conditions for viscosity versus temperature tables.
WATVISCT	Tables of water viscosity versus temperature.

## ECLIPSE 100 only keywords

ECLIPSE 100 only keyword	Description
ADSORP	Analytical adsorption functions.
ALKADS	Alkaline adsorption functions.
ALKROCK	Alkaline-rock properties.
ALPHAI	Transport coefficient tables for imbibition processes.
ALPOLADS	Polymer adsorption multipliers as a function of alkaline concentration.
ALSURFAD	Surfactant adsorption multipliers as a function of alkaline concentration.
ALSURFST	Oil/water surface tension multipliers as a function of alkaline concentration.
APIGROUP	Allows different groups of oil PVT tables to be used in different <code>PVTNUM</code> regions when using API Tracking.
BGGI	Variation of saturated gas FVF with pressure and $G_i$ .
BOGI	Variation of saturated oil FVF with pressure and $G_i$ .
DEPTHTAB	Depth data for boundary conditions.
DIFFFC	Molecular diffusion coefficients for each PVT region.
DIFFFDP	Restricts the molecular diffusion calculation to just the matrix-fracture flows in dual porosity runs.
DPKRMOD	Modifies the oil relative permeability in dual porosity runs.
EHYSTR	Curvature parameters and model selection for hysteresis.
EHYSTRR	Hysteresis parameters by region.
ENSPCVDV	Variation of the scaled connate saturation, for $P_c$ curves only, with depth.
FILLEPS	Controls the output of end point data in the <code>INIT</code> file.
FOAMADS	Foam adsorption functions.
FOAMFCN	Gas mobility reduction dependence upon capillary number (functional model).
FOAMDCYO	Foam decay as a function of oil saturation (tabular model).
FOAMDCYW	Foam decay as a function of water saturation (tabular model).
FOAMMOB	Gas mobility reduction data (tabular model).
FOAMMOBP	Pressure dependence on foam mobility reduction (tabular model).
FOAMMOBS	Shear dependence on foam mobility reduction (tabular model).
FOAMOPTS	Specifies the Foam Model options.
FOAMROCK	Specifies the foam rock properties.
GIALL	Variation of saturated properties with pressure and $G_i$ .
GINODE	$G_i$ nodal values.
HMMROCK	Cumulative multipliers on rock compressibility.
HMMROCKT	Cumulative modifiers of rock compaction parameters.
HMPROPS	Section heading for end-point modifiers.

<b>ECLIPSE 100 only keyword</b>	<b>Description</b>
HMROCK	Calculate gradients with respect to rock compressibility multipliers.
HMROCKT	Calculate gradients with respect to rock compaction parameters.
HMRREF	Reference pressures for HMROCKT.
HYDRHEAD	Reference quantities for hydraulic head calculation.
HYDRO	Defines hydrocarbon type.
HYMOBGDR	Change the way secondary drainage curves are computed in hysteresis runs with soluble gas.
HYSTCHCK	Activates additional consistency checks between drainage and imbibition curve endpoints when using the Hysteresis option.
IMKRVD	Imbibition end point relative permeabilities versus depth.
IMPCVD	Variation of maximum capillary pressure values with depth for the imbibition curve.
IMPTVD	Imbibition end point saturation values versus depth.
IMSPCVD	Variation of the scaled connate saturation, for $P_c$ curves only, with depth for the imbibition curve.
INTPC	Invokes the dual porosity integrated $P_c$ option.
IONXROCK	Rock ion exchange parameters for cation exchange.
IONXSURF	Surfactant micelle ion exchange parameters for cation exchange.
IPCG, IPCW	Imbibition curve end point capillary pressure values, equivalent to PCG, PCW. Imbibition curve end point scaling data, equivalent to SGL etc.
ISGLPC, ISWLPC	Imbibition curve end point scaling data, equivalent to SGLPC and SWLPC.
LSALTFNC	Specifies tables of salt concentration versus weighting factor for high-salinity/low-salinity saturation functions.
MASSFLOW	Massflow data for boundary conditions.
NOWARNEP	Suppresses all warning messages resulting from end point consistency checks
PECOEFS	Specifies petro-elastic fluid and rock properties, and other Petro-elastic Model options.
PEKTABx	Pressure dependent petro-elastic frame bulk modulus functions.
PEGTABx	Pressure dependent petro-elastic frame shear modulus functions.
PLMIXPAR	Todd-Longstaff mixing data for the Polymer model.
PLYESAL	Coefficients for polymer effective salinity.
REACT	Reaction activation molar energy
ROCKWNOD	Saturation nodes for 2-D water induced rock compaction tables.
RSCONST	Sets a constant $R_s$ for dead oil over the whole field.
RSCONSTT	Sets constant $R_s$ for dead oil, a different value in each PVT region.
RSGI	Variation of saturated GOR with pressure and $G_i$ .
RVGI	Variation of saturated OGR with pressure and $G_i$ .

<b>ECLIPSE 100 only keyword</b>	<b>Description</b>
RVCONST	Sets a constant $R_v$ for dry gas over the whole field.
RVCONSTT	Sets constant $R_v$ for dry gas, a different value in each PVT region.
SALTNODE	Salt concentration nodes for polymer solution viscosity.
SCALELIM	Sets saturation scaling limits for each end point scaling versus depth region.
SDENSITY	Input of the solvent surface density.
SGCWMIS	Miscible critical gas saturation tables.
SGLPC	Connate gas saturation, for Pc curves only, for cells in the current input box.
SGWFN	Gas-water relative permeability and capillary pressure, as functions of $S_g$ .
SOCRS	Scaled critical oil-in-water saturations at miscible conditions.
SORWMIS	Input of the residual oil saturation for miscible displacement.
SPECHEAT	Tables of fluid specific heat data.
SPECROCK	Tables of rock specific heat data.
STOG	Tables of oil/gas surface tension.
STOW	Tables of oil/gas surface tension.
SURFADDW	Tables of water/gas surface tension.
SURFESAL	Tables of adsorbed surfactant mass vs. fraction of oil-wet and water-wet curves, for calculating immiscible relative permeabilities.
STWG	Coefficients for surfactant effective salinity.
SWLPC	Connate water saturation, for Pc curves only, for cells in the current input box.
TEMPTVD	Requests flux limited transport for the Temperature option.
TLMIXPAR	Input of the Todd-Longstaff mixing parameter.
TPAMEPSS	Volumetric strain values for solvent in ROCKPAMA.
TRACERKM	Partitioning functions $K(P)$ for generalized, multi-partitioned tracers.
TRACERKP	Partitioning function $K(P)$ for partitioned tracers.
TRACTVD	Requests explicit flux limiting scheme to reduce tracer numerical dispersion.
TRACITVD	Requests implicit flux limiting scheme, to reduce numerical dispersion.
VEFRAC	Fraction of VE relative permeabilities used in place of rock curves, for the entire grid.
VEFRACP	Fraction of VE pseudo capillary pressures used in place of rock curves, for the entire grid.
VEFRACPV	Fraction of VE pseudo capillary pressures used in place of rock curves, for the current box.
VEFRACV	Fraction of VE relative permeabilities used in place of rock curves, for the current box.
WAGHYSTR	Activates the WAG Hysteresis option.

## ECLIPSE 300 only keywords

Restriction	ECLIPSE 300 only keyword	Description
	ACF	Acentric factors.
	ACFDET	Acentric factor for detailed components
	ACFS	Acentric factors for surface production system
	ALPHA	Transport coefficient tables.
	ALPHAD	Transport coefficient tables for drainage processes.
Thermal only	AMFVD	Aqueous mole fractions versus depth.
	BIC	Binary interaction coefficients.
	BICAQ1BICAQ2BICAQ3	Binary interaction coefficients for aqueous phase.
	BICS	Binary interaction coefficients for surface EoS.
Geomechanics only	BIOTCTAB	Defines a multiplier for the Biot constant, this being a two-dimensional tabular function of maximum and minimum principal stress.
	BOUNDARY	Set area of grid to be printed.
	CALVAL	Component calorific values.
	CALVALR	Component calorific values for multiple equation of state regions.
	CATYPE	Component type for asphaltene modeling.
Thermal only	CCTYPE	Component liquid compressibility type.
Thermal only	CCTYPES	Component liquid compressibility type at surface conditions.
	CNAMES	Component names.
Thermal only	CGDTYPE	Component gas (EoS) density model.
Thermal only	CGVTYPE	Component gas (EoS LBC) viscosity model.
Thermal only	CODTYPE	Component oil (EoS) density model.
Thermal only	COVTYPE	Component oil (EoS LBC) viscosity model.
	COMPVD	Total composition with respect to depth
Thermal only	CREF	Component compressibilities.
	CREFW	Compressibility of water components at the reference pressure.
	CREFWS	Compressibility of water components for surface calculations
	CVTYPE	Component volatility (dead, live, gaseous).
	CVTYPES	Component volatility (dead, live, gaseous) at surface conditions.
	CWTYPE	Water component type.
	DETAILMF	Initial make-up of a lumped component in terms of its detailed components versus depth.

Restriction	ECLIPSE 300 only keyword	Description
	DETAILVD	Initial make-up of a lumped component in terms of its detailed components versus depth.
	DIFFAGAS	Activity corrected gas diffusion coefficients.
	DIFFAOIL	Activity corrected oil diffusion coefficients.
	DIFFCGAS	Gas diffusion coefficients.
	DIFFCGO	Gas-Oil cross phase diffusion coefficients.
CO2STORE or GASWAT	DIFFCGW	Gas-Water cross phase diffusion coefficients
	DIFFCOIL	Oil diffusion coefficients.
	DIFFCOG	Oil-Gas cross phase diffusion coefficients.
GASWAT, CO2STORE or GASSOL	DIFFCWAT	Water diffusion coefficients.
GASWAT, CO2STORE or GASSOL	DIFFCWG	Water-Gas cross phase diffusion coefficients
	DIFFTGAS	Gas thermal diffusion coefficients.
	DIFFTOIL	Oil thermal diffusion coefficients.
	DNGL	Partial densities for NGLs.
	DRAINAGE	Forces the Killough relative permeability scanning curve to be below the drainage curve.
	DREF	Reference densities.
	DREFS	Reference densities for surface EoS.
Thermal only	DREFT	Alias for DREF.
Thermal only	DREFTS	Alias for DREFS.
	DREFW	Density of water components at the reference pressure.
	DREFWS	Density of water components for surface calculations.
Thermal only	ENKRVT	Endpoint relative permeabilities versus temperature.
Thermal only	ENPCVT	Endpoint capillary pressures versus temperature.
Thermal only	ENPTVT	Endpoint saturations versus temperature.
	EOS	Specify which equation of state is to be used.
	EOSS	Specify surface equation of state.
ODD3P option.	EPSODD3P	End-point scaling, reference surface tensions and threshold interfacial tensions.
Thermal only	EQLDKVCR	K-values for equilibrium deviation reactions
Thermal only	EQLDREAC	Equilibrium deviation reaction rates

Restriction	ECLIPSE 300 only keyword	Description
	ESPNODE	Effective salinity nodes for salt sensitive polymer flood studies.
	ESSNODE	Effective salinity nodes for salt sensitive polymer flood studies
	FACTLI	Modify Li critical temperature correlation.
	FVST	Specifies miscibility variation with surface tension.
Thermal only	GASVISCF	Gas viscosity function of temperature.
Thermal only	GASVISCT	Gas viscosity table as a function of temperature.
Geomechanics only	GEOYLDF	Defines parameters for the plastic yield function in each geomechanics region.
	GRES	Reference gravities for EoS.
	GRES	Reference gravities for surface EoS.
	GSF	Gas saturation functions.
Thermal only	HEATVAP	Component heat of vaporization.
Thermal only	HEATVAPE	Heat of vaporization exponent.
Thermal only	HEATVAPS	Component heat of vaporization at standard temperature.
ODD3P option.	HSGRO	Hysteresis end-point (residual) grid-block gas saturations for a gas-oil system
ODD3P option.	HSGRW	Hysteresis end-point (residual) grid-block gas saturations for a gas-water system
ODD3P option.	HSORG	Hysteresis end-point (residual) grid-block oil saturations for an oil-gas system
ODD3P option.	HSORW	Hysteresis end-point (residual) grid-block oil saturations for an oil-water system
ODD3P option.	HSWRG	Hysteresis end-point (residual) grid-block water saturations for a water-gas system
ODD3P option.	HSWRO	Hysteresis end-point (residual) grid-block water saturations for a water-oil system
	HYDRO	Defines hydrocarbon type.
	IKU3P	Requests IKU three-phase relative permeabilities.
	KRGDI	Gas relative permeability damage initiation.
	KRGDM	Gas relative permeability damage multipliers.
	KRODI	Oil relative permeability damage initiation.
	KRODM	Oil relative permeability damage multipliers.
	KRWDI	Water relative permeability damage initiation.
	KRWDM	Water relative permeability damage multipliers.
	KVCOMP	Interpolation component for composition dependent K-values.

Restriction	ECLIPSE 300 only keyword	Description
	KVCR	K-value correlation parameters.
Thermal only	KVCRS	K-value correlation parameters at surface conditions.
Thermal only	KVCRWAT	Water K-value correlation parameters.
Thermal only	KVGEN	Specify that K-values are to be generated internally.
	KVMF	Interpolation mole fractions for composition dependent K-values.
	KVTAB <sub>Cn</sub>	Tables of K-values.
	KVTABLE	Tables of K-values.
	KVTAB <sub>Tn</sub>	Tables of K-values.
Thermal only	KVTEMP	Temperatures for K-value tables.
Thermal only	KVWI	Wilson K-value correlation parameters.
Thermal only	KWTAB <sub>Tn</sub>	Tables of aqua Kw-values.
Thermal only	KWTEMP	Temperatures for Kw-value tables.
Thermal only	LBCCOEF	Set non-default LBC coefficients.
	LBCCOEFR	Set non-default LBC coefficients for multiple equation of state regions.
	LGRCOPY	Copy global values to local cells before operations on cells within an LGR.
	LILIM	Specifies the range for Li-interpolation.
	LUMPING	Set up names of tracers describing detailed composition of a lumped hydrocarbon component.
	MISCEXP	Miscibility exponent.
	MISCSTR	Miscibility surface tension reference.
	MISCSTRP	Miscibility surface tension reference pressure.
	MISCSTRR	Allows the reference miscible surface tension to be set by saturation region number.
	MSFN	Relative permeability curves for miscible displacement.
	MW	Molecular weights.
	MWDETAIL	Molecular weights for detailed components.
	MWS	Molecular weights for surface EoS.
	MWW	Molecular weight of water components.
	MWWS	Molecular weight of water components for surface calculations.
	NCOMPS	Confirm number of components.
	ODD3P	ODD3P three-phase relative permeability and capillary pressure hysteresis option.

Restriction	ECLIPSE 300 only keyword	Description
ODD3P option	OPTODD3P	Provides backwards compatibility and saturation switching options
	OILCOMPR	Oil compressibility, expansion coefficient.
Thermal only	OILMW	Oil molecular weight.
Thermal only	OILSPECH	Oil specific heat.
Thermal only	OILVINDX	Oil viscosity index.
Thermal only	OILVISCC	Oil viscosity-temperature correlation
Thermal only	OILVISCF	Oil viscosity function.
Thermal only	OMEGAA	Overrides default $\Omega_a$ values.
	OMEGAADE	Overrides default $\Omega_a$ values for detailed composition.
	OMEGAAS	Overrides default surface $\Omega_a$ values.
	OMEGAASD	Overrides default surface $\Omega_a$ values for detailed composition.
	OMEGAB	Overrides default $\Omega_b$ values.
	OMEGABDE	Overrides default $\Omega_b$ values for detailed composition.
	OMEGABS	Overrides default surface $\Omega_b$ values.
	OMEGABSD	Overrides default surface $\Omega_b$ values for detailed composition.
	PARACHOR	Component parachors.
	PCG	Scales the maximum gas capillary pressure, for cells in the current input box.
	PCRIT	Critical pressures.
	PCRITDET	Critical pressures for detailed components.
	PCRITSDE	Critical pressures for surface EoS for detailed components.
ODD3P option	PCODD3P	Capillary pressure calculation control.
ODD3P option.	PCODD3PG	Capillary pressure gas saturation function
ODD3P option.	PCODD3PW	Capillary pressure water saturation function
	PERMSTAB	Defines a permeability multiplier, this being a two-dimensional tabular function of maximum and minimum principal stress.
	PLYOPTS	Options for the polymer model.
	PREFS	Component reference pressures for surface EoS.
Thermal only	PREFW	Reference pressure for water component density and viscosity calculations.
	PREFWS	Reference pressure for water component density calculations at surface conditions.

Restriction	ECLIPSE 300 only keyword	Description
ODD3P option.	PSGRO	Primary end-point (residual) grid-block gas saturations for the gas-oil system
ODD3P option.	PSGRW	Primary end-point (residual) grid-block gas saturations for the gas-water system
ODD3P option	PSORG	Primary end-point (residual) grid-block oil saturations for the oil-gas system
ODD3P option	PSORW	Primary end-point (residual) grid-block oil saturations for the oil-water system for the option.
ODD3P option	PSWRG	Primary end-point (residual) grid-block water saturations for the water-gas system
ODD3P option.	PSWRO	Primary end-point (residual) grid-block water saturations for the water-oil system
	REACLIMS	Pressure and temperature limits for reaction rate calculations.
	REACPORD	Reaction rate porosity order.
	REACSMAX	Maximum solid saturation in chemical reaction rates.
	REACSORD	Order of solid term in chemical reaction rates.
	RKPVMNMX	Allows pore volume multiplier limits to be set for the BOBERG model.
	ROCKTRMX	Define transmissibility variation values in the X-direction in order to define transmissibility as an exponential function of porosity.
	ROCKTRMY	Define transmissibility variation values in the Y-direction in order to define transmissibility as an exponential function of porosity.
	ROCKTRMZ	Define transmissibility variation values in the Z-direction in order to define transmissibility as an exponential function of porosity.
	RSWVD	Aqueous concentration of CO <sub>2</sub> versus depth.
	SALTEFF	Coefficients to calculate effective salinity
Polymer and Surfactant models.	SALINITY	Reservoir salinity.
	SALINITR	Regional reservoir salinity.
Geomechanics only	SCDATABG	Defines a scale damage table to be used together with the proppant flowback feature.
Thermal only	SCREF	Component solid phase compressibility.
Thermal	SDREF	Component solid phase reference density.
Thermal	SGF3	Three-phase gas saturation functions.
	SOGCR	Residual oil-in-gas saturation for cells in the current box.

Restriction	ECLIPSE 300 only keyword	Description
	SOLIDADS	Solid adsorption table.
	SOLIDMMC	Solid mobility multiplier (as a function of adsorbed concentration).
	SOLIDMMS	Solid mobility multiplier (as a function of adsorbed saturation).
	SOLUBILI	Specify properties of Water-CO <sub>2</sub> systems.
	SOLUBILS	Specify properties of Water-CO <sub>2</sub> systems with salt dependencies.
	SOLUCO2H	Specify properties of Water-CO <sub>2</sub> systems with H <sub>2</sub> S dependencies.
	SOLUH2SC	Specify properties of Water-H <sub>2</sub> S systems with CO <sub>2</sub> dependencies.
	SOLWTAB	Defines an interpolation parameter as a function of adsorbed solid concentration.
	SOLWW	Defines a component weighting factor for calculating the wetting-solid concentration.
	SOR	Residual oil saturation.
	SOROPTS	Residual oil model options.
	SPECHA	Component oil specific heat, 1 <sup>st</sup> coefficient.
	SPECHB	Component oil specific heat, 2 <sup>nd</sup> coefficient.
	SPECHG	Component gas specific heat, 1 <sup>st</sup> coefficient.
	SPECHH	Component gas specific heat, 2 <sup>nd</sup> coefficient.
	SPECHS	Component solid specific heat, 1 <sup>st</sup> coefficient.
	SPECHT	Component solid specific heat, 2 <sup>nd</sup> coefficient.
	SPECHW1	Component aqua specific heat, 1 <sup>st</sup> coefficient.
	SPECHW2	Component aqua specific heat, 2 <sup>nd</sup> coefficient.
	SPREF	Component solid phase reference pressure.
	SSHIFT	Equation of state shift parameters.
	SSHIFTS	Equation of state shift parameters for surface EoS.
	STCOND	Specify standard conditions.
	STONEPAR	Modify Stone's formula 1 three phase oil relative permeability
	STOPROD	Stoichiometric coefficients of products.
	STOREAC	Stoichiometric coefficients of reactants.
	STREF	Component solid phase reference temperature.
	STHERMX1	Component solid phase thermal expansion coefficient.
	STVP	Surface tension with respect to pressure.

Restriction	ECLIPSE 300 only keyword	Description
	SURFOPTS	Surfactant options
	SWF3	Three phase water saturation functions.
	TBOIL	Component boiling points.
	TBOILS	Component boiling points for surface EoS.
	TCRIT	Critical temperatures.
	TCRITDET	Critical temperatures for detailed components.
	TCRITS	Critical temperatures for surface EoS.
	TCRITSDE	Critical temperatures for surface EoS for detailed components
	TEMPVD	Temperature vs. depth data.
	THANALB	Analytic water and steam densities.
	THANALH	Analytic water and steam enthalpy values.
	THANALV	Analytic oil viscosities.
	THERMEX1	Component thermal expansion coefficient.
	THSVC	Steam viscosity coefficients.
	THTABB	Tabular water and steam densities.
	THWVC	Water viscosity coefficients.
	TRANGE	Expected temperature limits.
	TREF	Reference temperatures.
	TREFS	Reference temperatures for surface EoS.
Thermal	TREFT	Alias for TREF
Thermal	TREFTS	Alias for TREFS.
	VCOMPACT	Compact volumes.
	VCRIT	Critical volumes.
	VCRITDET	Critical volumes for detailed components.
	VCRITS	Critical volumes for surface EoS.
	VCRITSDE	Critical volumes for surface EoS for detailed components.
	VCRITVIS	Critical volumes for viscosity calculations.
	VDFLOW	Specify velocity dependent flow coefficient.
	VDKRO	Oil velocity dependent relative permeability data.
	VDKRG	Gas velocity dependent relative permeability data.
	VDKRGC	Gas velocity dependent relative permeability data.
	VREFW	Viscosity and viscosibility for water components at the reference pressure.
Thermal	WATDENT	Water density temperature dependence.
	WATERTAB	Water pressure tables.

Restriction	ECLIPSE 300 only keyword	Description
	WNAMEs	Water component names.
GASWAT case	WSF	Water saturation functions
	XMFVP	Liquid composition with respect to pressure tables.
	YMFVP	Vapor composition with respect to pressure tables.
	ZCRIT	Critical Z-factors.
	ZCRITDET	Critical Z-factors for detailed components.
	ZCRITS	Critical Z-factors for surface EoS
	ZCRITSDE	Critical Z-factors for surface EoS for detailed components.
	ZCRITVIS	Critical Z-factors for viscosity calculations.
	ZI	Enter overall composition
	ZMFVD	Total composition with respect to depth tables.
Thermal	ZFACTOR	Z-factors.

## REGIONS section

The REGIONS section divides the computational grid into regions for:

- Calculation of saturation functions (relative permeability and capillary pressure)
- Calculation of PVT properties (fluid densities, FVFs, viscosities)
- Equilibration (setting initial pressures and saturations)
- Reporting of fluids in place and inter-region flows
- Calculation of directional relative permeabilities
- Calculation of saturation functions for imbibition (Hysteresis option)
- Calculation of ROCKTAB properties for the Rock Compaction option
- Calculation of initial tracer concentrations (Tracer Tracking option)
- Calculation of the saturation table end points from depth tables (for the saturation table End Point Scaling option)
- Calculation of mixture properties (Miscible Flood option)
- Specifying pressure maintenance regions.

ECLIPSE 300

If there is no REGIONS section, ECLIPSE puts all grid blocks into a single region for all the above operations.

## REGIONS section keywords

A list of all keywords that may occur in the REGIONS section, grouped by function, is given below, together with a brief description of their function. This is followed by an alphabetic list. A more detailed description may be found by looking up the keyword in the manual.

Keywords must start in column 1. All characters up to column 8 are significant.

## Output

- [RPTREGS](#) Report levels for REGIONS data.

## Commonly used keywords

- [FIPNUM](#) Fluid-in-Place regions.
- [SATNUM](#) Saturation table regions.
- [EQLNUM](#) Equilibration regions.
- [PVTNUM](#) PVT data regions.

Additional sets of fluid-in-place regions

Extra sets of region numbers, in addition to standard FIPNUM set.

*ECLIPSE 100 only*

Regions number representing the gas, oil and water zones at equilibration.

## Directional relative permeability

Restriction	Keyword	Description
Keywords should not be used unless DIRECT is selected in keyword <a href="#">SATOPTS</a> .	<a href="#">KRUNUMX</a> , <a href="#">KRUNUMY</a> , <a href="#">KRUNUMZ</a>	Saturation table numbers for the +X, +Y, +Z faces of a grid block.
Keywords should not be used unless IRREVERS is also selected in keyword <a href="#">SATOPTS</a> .	<a href="#">KRUNUMX-</a> , <a href="#">KRUNUMY-</a> , <a href="#">KRUNUMZ-</a>	Saturation table numbers for the -X, -Y, -Z faces of a grid block.

## Dual porosity option (ECLIPSE 100 only)

- [KRUNUMMF](#) Matrix-fracture flow saturation tables numbers.
- [IMBNUMMF](#) Matrix-fracture imbibition region numbers.

Only concerns dual porosity runs (keyword [DUALPORO](#) in RUNSPEC) using the Hysteresis option (item HYSTER in keyword [SATOPTS](#)).

## Geomechanics option (ECLIPSE 300)

- [YLDNUM](#) Defines a geomechanics region number for each grid block.

## Hysteresis option (excluding ODD3P)

Restriction	Keyword	Description
	<a href="#">IMBNUM</a>	Imbibition saturation table numbers for all faces of every grid block in current box.

Restriction	Keyword	Description
Keywords should not be used unless HYSTER and DIRECT are selected in keyword SATOPTS.	IMBNUMX, IMBNUMY, IMBNUMZ	Imbibition saturation table numbers for the +X, +Y, +Z face of a grid block.
Keywords should not be used unless IRREVERS is also selected in keyword SATOPTS.	IMBNUMX- , IMBNUMY- , IMBNUMZ-	Imbibition saturation table numbers for the -X, -Y, -Z faces of a grid block.

## WAG hysteresis option

Restriction	Keyword	Description
This keyword is optional if WAGHYSTR has been specified but should not be specified otherwise.	WH2NUM	Two-phase water relative permeability saturation region numbers.
This keyword is optional if WAGHYSTR has been specified but should not be specified otherwise.	WH3NUM	Three-phase water relative permeability saturation region numbers.

## Other options

### Common keywords

Keyword	Description
ENDNUM	End point scaling regions.
TNUM	Tracer tracking regions.
MISCNUM	Miscible Flood option regions.
OPERNUM	Defines region on which to do operations using the OPERATER keyword. The data can also be edited using ADDREG, EQUALREG, MULTIREG and COPYREG.
ROCKNUM	Rock compaction regions.
SURFNUM	Surfactant miscible regions.

### ECLIPSE 100 only keywords

ECLIPSE 100 only keyword	Description
TRKPF	Partitioned tracer K(P) partitioning function regions.
LSLTWNUM	Low-salinity (water-wet) saturation function regions.
LWSLTNUM	Low-salinity (oil-wet) saturation function regions.
PENUM	Petro-elastic Model regions.
RESIDNUM	Vertical Equilibrium residual flow option regions.
SURFWNUM	Surfactant adsorption function regions.

**ECLIPSE 300 only keywords**

<b>ECLIPSE 300 only keyword</b>	<b>Description</b>
ALPHANUM	Transport coefficient regions.
ALPHANUD	Transport coefficient regions for drainage processes.
ALPHANUI	Transport coefficient regions for imbibition processes.
EOSNUM	Equation of state regions.
PMANUM	Pressure maintenance regions.
SOLWNUM	Solid wettability regions.
THERMNUM	Thermal regions.

**ODD3P three-phase relative permeability and capillary pressure hysteresis option (ECLIPSE 300)**

<b>ECLIPSE 300 only keyword</b>	<b>Description</b>
PSTNUM	Grid-block primary saturation table numbers.
ISTNUM	Grid-block secondary hysteresis saturation table numbers.
DSTNUM	Grid-block tertiary hysteresis saturation table numbers.
SDRGO	Gas phase initial grid-block saturation direction indicators for the gas-oil system.
SDRGW	Gas phase initial grid-block saturation direction indicators for the gas-water system.
SDROG	Oil phase initial grid-block saturation direction indicators for the gas-oil system.
SDROW	Oil phase initial grid-block saturation direction indicators for the oil-water system.
SDRWG	Water phase initial grid-block saturation direction indicators for the gas-water system.
SDRWO	Water phase initial grid-block saturation direction indicators for the oil-water system.

**Operational**

These may be used with keywords that specify arrays over grid cells.

**Common keywords**

<b>Keyword</b>	<b>Description</b>
ADDREG	Add by FLUXNUM, MULTNUM or OPERNUM region.
BOX	Redefines the current input box.
COPY	Copies data in the current box from one specified array to another.
COPYBOX	Copies data from one box of cells to another box of the same size.
COPYREG	Copy by FLUXNUM, MULTNUM or OPERNUM region.
ENDBOX	Redefines the current input box to encompass the whole grid.
ENDFIN	End input for local grid refinement.

Keyword	Description
EQUALREG	Set by FLUXNUM, MULTNUM or OPERNUM region.
EQUALS	Sets specified arrays to specified constants within the current box.
IMPORT	Imports binary data generated by a grid pre-processor.
MULTIPLY	Multiplies specified arrays by specified constants within the current box.
MULTIREG	Multiply by FLUXNUM, MULTNUM or OPERNUM region.
OPERATE	Performs arithmetic operations on arrays.
OPERATER	Performs arithmetic operations on arrays for a specific region of the grid.
REFINE	Initiates data for a named local grid.

### ECLIPSE 300 only keywords

ECLIPSE 300 only keyword	Description
BOUNDARY	Set area of grid to be printed
LGRCOPY	Copy global values to local cells before operations on cells within an LGR.

## Alphabetical list of keywords

### Common keywords

Keyword	Description
ADD	Adds specified constants to specified arrays in the current input box.
ADDREG	Adds specified constants to specified arrays in a FLUXNUM, MULTNUM or OPERNUM region.
BOUNDARY	Defines section of grid for which output maps are required.
BOX	Redefines the current input box.
COPY	Copies data in the current input box from one array to another.
COPYBOX	Copies data from one box of cells to another box of the same size.
COPYREG	Copies one array to another within a FLUXNUM, MULTNUM or OPERNUM region.
ENDBOX	Redefines the current input box so that it covers the whole grid.
ENDNUM	Saturation table end point region for every grid block in the current input box.
EQLNUM	Equilibration region for every grid block in the current input box.
EQUALS	Sets specified arrays to constants within the current input box.
EQUALREG	Sets specified arrays to constants within a FLUXNUM, MULTNUM or OPERNUM region.
FILEUNIT	Confirms the units of the data set.
FIPNUM	Standard fluid-in-place region numbers, for every grid block in the current input box.
HMxxxxxxx	Family of history-matching regions for use with the Gradient option.
IMBNUM	Imbibition table region for every grid block in the current input box (if using the hysteresis option).

Keyword	Description
IMBNUMX	Imbibition region for +X face of every grid block in the current input box (if using hysteresis with directional relative permeabilities).
IMBNUMX-	Imbibition region for -X face of every grid block in the current input box (if using hysteresis with irreversible directional relative permeabilities).
IMBNUMY	Imbibition region for +Y face of every grid block in the current input box (if using hysteresis with directional relative permeabilities).
IMBNUMY-	Imbibition region for -Y face of every grid block in the current input box (if using hysteresis with irreversible directional relative permeabilities).
IMBNUMZ	Imbibition region for +Z face of every grid block in the current input box (if using hysteresis with directional relative permeabilities).
IMBNUMZ-	Imbibition region for -Z face of every grid block in the current input box (if using hysteresis with irreversible directional relative permeabilities).
IMPORT	Imports binary data generated by a grid pre-processor.
KRNUMX	$K_r$ region for +X face of every grid block in the current input box (if using directional relative permeabilities).
KRNUMX-	$K_r$ region for -X face of every grid block in the current input box (if using irreversible directional relative permeabilities).
KRNUMY	$K_r$ region for +Y face of every grid block in the current input box (if using directional relative permeabilities).
KRNUMY-	$K_r$ region for -Y face of every grid block in the current input box (if using irreversible directional relative permeabilities).
KRNUMZ	$K_r$ region for +Z face of every grid block in the current input box (if using directional relative permeabilities).
KRNUMZ-	$K_r$ region for -Z face of every grid block in the current input box (if using irreversible directional relative permeabilities).
MISCNUM	Miscibility table region for every grid block in the current input box (if using the Miscible Flood option).
MULTIPLY	Multiplies specified arrays by specified constants within the current box.
MULTIREG	Multiply by FLUXNUM, MULTNUM or OPERNUM region.
OPERATE	Performs arithmetic operations on arrays.
OPERATER	Performs arithmetic operations on arrays for a specific region of the grid.
OPERNUM	Defines region on which to do operations using the OPERATER keyword. The data can also be edited using ADDREG, EQUALREG, MULTIREG and COPYREG.
PVTNUM	PVT region for every grid block in the current input box.
ROCKNUM	Rock compaction table region for every grid block in the current input box (if using the Rock Compaction option).
RPTREGS	Switches on output of data in REGIONS section.
SATNUM	Saturation table region for every grid block in the current input box. (If directional relative permeability tables are being used, SATNUM regions are still used in the equilibration calculation and by the wells.)

Keyword	Description
SURFNUM	Surfactant miscible regions
TNUM	Initial tracer concentration region for every grid block in the current input box (If Tracer Tracking option is activated).
WH2NUM	Two-phase water relative permeability saturation region numbers. This keyword is optional if WAGHYSTR has been specified but should not be specified otherwise.
WH3NUM	Three-phase water relative permeability saturation region numbers. This keyword is optional if WAGHYSTR has been specified but should not be specified otherwise.

## ECLIPSE 100 only keywords

ECLIPSE 100 only keyword	Description
FIP	Additional sets of fluid-in-place region numbers, for every grid block in the current input box.
FIPOWG	Creates a family of FIP regions to represent the gas, oil and water zones at equilibration
IMBNUMMF	Imbibition table region of matrix-fracture flows, for every grid block in the current input box (if using both the dual porosity and the hysteresis option).
KRNUMMF	$K_r$ region for matrix-fracture flows, for every grid block in the current input box (if using the Dual Porosity option).
LSLTWNUM	Low-salinity (oil-wet) saturation function regions.
LWSLTNUM	Low-salinity (water-wet) saturation function regions.
PENUM	Petro-elastic Model regions.
RESIDNUM	Relative permeability table numbers for Vertical Equilibrium residual flow option.
SURFWNUM	Table numbers for the water-wet saturation functions and the mass of adsorbed surfactant versus fraction of oil-wet to water-wet curves, to use for each grid block, for the Surfactant option.
TRKPF	Region numbers for selecting which K(P) table to use for each partitioned tracer.

## ECLIPSE 300 only keywords

Restriction	ECLIPSE 300 only keyword	Description
ODD3P option	DSTNUM	Grid-block tertiary hysteresis saturation table numbers
	ALPHANUD	Defines transport coefficient table regions for drainage processes.
ODD3P option	ALPHANUI	Defines transport coefficient table regions for imbibition processes.
	ALPHANUM	Defines transport coefficient table regions.
	EOSNUM	Equation of state regions.
	ISTNUM	Grid-block secondary hysteresis saturation table numbers
	LGRCOPY	Copy global values to local cells before operations on cells within an LGR.

Restriction	ECLIPSE 300 only keyword	Description
	PMANUM	Defines pressure maintenance regions (See the <a href="#">GPMaint</a> keyword).
ODD3P option	PSTNUM	Grid-block primary saturation table numbers
ODD3P option	SDRGO	Gas phase initial grid-block saturation direction indicators for the gas-oil system
ODD3P option	SDRGW	Gas phase initial grid-block saturation direction indicators for the gas-water system
ODD3P option	SDROG	Oil phase initial grid-block saturation direction indicators for the gas-oil system
ODD3P option	SDROW	Oil phase initial grid-block saturation direction indicators for the oil-water system
ODD3P option	SDRWG	Water phase initial grid-block saturation direction indicators for the gas-water system
ODD3P option	SDRWO	Water phase initial grid-block saturation direction indicators for the oil-water system
SOLID option	SOLWNUM	Solid wettability region numbers.
	TRACKREG	Tracer <a href="#">TRACK</a> ing regions.
	THERMNUM	Thermal regions.

## SOLUTION section

The SOLUTION section contains sufficient data to define the initial state (pressure, saturations, compositions) of every grid block in the reservoir.

The keywords in the SOLUTION section may be specified in any order. All keywords must start in column 1. All characters up to column 8 are significant.

This data may take any one of the following forms:

### Equilibration

Initial pressures and saturations are computed by ECLIPSE using data entered with the [EQUIL](#) keyword (for example the fluid contact depths).

### Restart

The initial solution may be read from a Restart file created by an earlier run of ECLIPSE. The name of the Restart file is entered using the [RESTART](#) keyword.

### Enumeration

You may specify the initial solution explicitly for every grid block

See "[Initializing the Study](#)" in the *ECLIPSE Technical Description* for more information

## Equilibration - the EQUIL keyword

A line of EQUIL data must be specified for each equilibration region. (Cells may be assigned to equilibration regions using EQLNUM in the REGIONS section). If there is more than one equilibration region, it is important that they are non-communicating.

The EQUIL data specifies the initial pressure at a reference depth, the initial water-oil and gas-oil contact depths and the capillary pressures at these depths, and the equilibration options. For example:

```
EQUIL
9035 3600 9209 0 9035 0 1 1 20 /
```

This specifies:

- The pressure at datum depth of 9035 is 3600.
- Water oil contact ( $P_{cow} = 0$ ) is at 9209 ft.
- Gas-oil contact ( $P_{cog} = 0$ ) is at 9035 ft.
- 20 sub-intervals used in each cell for initial averaging.

When capillary pressure exists, an initial saturation distribution is found that matches this against the hydrostatic pressure gradient due to phase density differences. The 20 refers to the number of sub-intervals averaged to obtain the initial solution. The default is 1 sub-interval. One sub-interval should be used if an initial gas oil contact is present in a compositional run, or to obtain exact initial quiescence.

Composition variation with depth in the initial state may be specified in the black oil case using keywords such as RSVD (or PBVD), to specify  $R_s$  or  $P_{bub}$ ; and RVVD (or PDVD) to specify  $R_v$  or  $P_{dew}$ . Either RSVD or PBVD is optional, to set  $R_s$  or  $P_{bub}$  versus depth. Either RVVD or PDVD is optional, to set  $R_v$  or  $P_{dew}$  versus depth.

In the compositional case, the compositions can be initialized using ZMFVD and COMPVD, described in the discussion of the PROPS section, or a constant composition may be entered with the ZI keyword in the PROPS section.

## Enumeration

You may specify the initial solution for every grid block using the following keywords

---

**Note:** The Enumeration option is not recommended for use in general.

---

## Common keywords

Keyword	Description
PRESSURE	Cell pressures
SWAT	Water saturations
SGAS	Gas saturations
RS	Liquid gas-oil ratios

Keyword	Description
RV	Vapor oil-gas ratios
PBUB	Initial bubble point pressures
PDEW	Initial dew point pressures

## ECLIPSE 100 only keywords

- [PRVD](#) Pressure versus depth variation.

## ECLIPSE 300 only keywords

- [SOIL](#) Oil saturations

In the compositional case, all of [PRESSURE](#), [SWAT](#), [SGAS](#), [SOIL](#) may be used, and the initial composition is defined by the following keywords.

- [XMF](#) Liquid phase compositions
- [YMF](#) Vapor phase compositions

The [XMFVP](#) and [YMFVP](#) keywords, entered in the PROPS section, may be used as an alternative to XMF and YMF to define initial phase compositions.

In the thermal case the temperature must be specified.

- [TEMPI](#) Temperature

The [TEMPVD](#) keyword entered in the PROPS section may be used as an alternative to TEMPI.

As an alternative to entering these for the whole reservoir, the [ADD](#), [COPY](#), [EQUALS](#) and [MULTIPLY](#) keywords may be used to define values for [PRESSURE](#), [SWAT](#), [SGAS](#), [RS](#), [RV](#).

See also the [GETSOL](#) and [GETDATA](#) keywords.

## Thermal enumeration with the NEI keyword

ECLIPSE 300

For the [THERMAL](#) option, the oil phase composition can be specified using the [NEI](#) keyword, instead of the [XMF](#) and [YMF](#) keywords. The simulator then finds a composition that is in thermodynamic equilibrium at the specified pressure and temperature and that gives the correct phase saturations. See "[Initialization with NEI](#)" in the *ECLIPSE Technical Description*.

## Flexible restarts

Flexible restarts may be specified using the [RESTART](#) keyword in place of the [EQUIL](#) keyword of a normal equilibration run. This loads up the initial solution written when Restart files have been requested by the [RPTRST](#) or [OUTSOL](#) keyword. A flexible restart only loads the initial solution - all other quantities such as transmissibilities and pore volumes are recalculated from the data supplied.

## Initial state output

Output of the initial solution to the Print file is controlled by the [RPTSOL](#) keyword. This is followed by a series of mnemonics, each specifying a solution quantity to be written. For example:

```
RPTSOL
PRESSURE SOIL SWAT SGAS /
```

This requests output of the initial pressure and phase saturations. A large number of quantities can be output, and are listed under the RPTSOL keyword. It is only required that sufficient characters be entered to specify the required mnemonics uniquely.

## Analytic aquifers

Carter-Tracy, Fetkovich, Constant Flux and Constant Head analytic aquifers may be specified with the following keywords (see also keyword [AQUDIMS](#)):

Aquifer Type	Description
Carter-Tracy aquifers	<a href="#">AQUCT</a> and <a href="#">AQUANCON</a> / <a href="#">AQANCONL</a> ( <a href="#">AQUTAB</a> in PROPS section)
Fetkovich aquifers	<a href="#">AQUFETP</a> and <a href="#">AQUANCON</a> / <a href="#">AQANCONL</a> , or <a href="#">AQUFET</a> (ECLIPSE 100 only)
Constant flux aquifers	<a href="#">AQUFLUX</a> and <a href="#">AQUANCON</a> / <a href="#">AQANCONL</a>
Constant head gas aquifers	<a href="#">AQUCHGAS</a> and <a href="#">AQUANCON</a> / <a href="#">AQANCONL</a>
Constant head water aquifers	<a href="#">AQUCHWAT</a> and <a href="#">AQUANCON</a> / <a href="#">AQANCONL</a>

Table 2.8: Analytical aquifer keywords

ECLIPSE 300 only

Gas composition for [AQUCHGAS](#) and, for the [GASWAT](#) and [CO2STORE](#) options, water composition for [AQUCHWAT](#), [AQUCT](#), [AQUFETP](#) and [AQUFLUX](#): [AQSTREAM](#)

For the multi-component water option ([COMPW](#)), water composition for [AQUCHWAT](#), [AQUCT](#), [AQUFETP](#) and [AQUFLUX](#), [AQSTREAW](#):

Restriction	Keyword	Description
E100 only	<a href="#">AQUALIST</a>	Aquifer lists

Table 2.9: Aquifer lists

See "[Aquifer Modeling Facilities](#)" in the *ECLIPSE Technical Description* for more information

## Tracers, brine and API tracking

The API option (RUNSPEC keyword [API](#)), the Brine option (RUNSPEC keyword [BRINE](#)), and the Tracer Tracking option (RUNSPEC keyword [TRACERS](#)) require the initial distribution to be provided by keywords as follows:

	API	Brine	Tracers
Equilibration	<a href="#">APIVD</a>	<a href="#">SALTVD</a>	<a href="#">TVDP</a>
	one table per equilibration region		
Enumeration	<a href="#">OILAPI</a>	<a href="#">SALT</a>	<a href="#">TBLK</a>
	for each grid block		

Table 2.10: SOLUTION keywords for specifying initial distribution for API

See "[API Tracking](#)", "[Brine Tracking](#)" and "[Tracer Tracking](#)" in the *ECLIPSE Technical Description* for further information.

## Miscellaneous options

- **THPRES** specifies the threshold pressure (see RUNSPEC keyword **EQLOPTS**).

## Initial fluid in place

ECLIPSE 300

An initial fluid in place report is always provided. In a compositional case, it is possible to set up a field separator, to define initial separator oil and gas, and used to calculate separator oil and gas in place throughout the run. (This is independent of the separator conditions in the well model).

The **FIELDSEP** keyword might take the following form:

```
FIELDSEP
1 80 815 /
2 60 14.7 /
/
```

This specifies a two stage separator, with the second stage representing the stock tank. The temperature and pressure is specified for each stage. The temperature is in degrees F or degrees C. The default coupling is from the liquid output of the first stage to the second. More complex configurations or more stages may be entered. If a **FIELDSEP** keyword is entered, this becomes the default separator conditions for wells in the **SCHEDULE** section.

A gas plant table may be used instead of a flash calculation for a separator stage (see item 7 of keyword **FIELDSEP**). In almost all gases, a single stage only is required. Gas plant tables are defined with keyword **GPTABLE**, **GPTABLEN** or **GPTABLE3**.

A recovery plant option, enabled by the **RECOVERY** keyword, may be used that takes all the gas exported from the field and processes this into NGLs and remaining gas. All other field quantities, such as GOR and gas-injection are reported prior to this processing. The aim of this facility is to model processing of the gas produced by the reservoir through facilities such as coolers, which can extract additional liquids from the stock tank gas.

The **FIPSEP** keyword allows different separators to be defined for different fluid-in-place regions. This would be of use if different separation processes were used in different reservoirs that are within a single simulation.

ECLIPSE 100

In the black oil case, an initial fluid-in-place report must be specified using the mnemonic in **RPTSOL**. The surface conditions are determined from the formation volume factors and surface density data entered in the **PROPS** section.

## SOLUTION section keywords

A list, by function, of keywords that may occur in the **SOLUTION** section is given below, together with a brief description of their function. An alphabetic list follows. A more detailed description may be found by looking up the keyword in the manual

### Output

Restriction	Keyword	Description
Optional	<b>RPTSOL</b>	Report arguments for <b>SOLUTION</b> data.
Optional	<b>BOUNDARY</b>	Defines section of grid for which output maps are required.

Restriction	Keyword	Description
Optional	DATUM	Defines datum depth for output of depth corrected pressures.
Optional	DATUMR	Defines datum depth for output of depth corrected pressures for each FIP region.
Optional	DATUMRX	Defines datum depth for output of depth corrected pressures for each FIP region in each FIP set

## Equilibration

### Common keywords

Restriction	Keyword	Description
Required for equilibration.	EQUIL	Fluid contact depths and other equilibration parameters.
Optional for equilibration in live oil systems.	RSVD	Variation of solution GOR with depth.
Optional for equilibration in live oil systems.	PBVD	Variation of bubble point pressure with depth.
Optional for equilibration in wet gas systems.	RVVD	Variation of vapor OGR with depth.
Optional for equilibration in wet gas systems.	PDVD	Variation of dew point pressure with depth.
Required for equilibration when using Brine option.	SALTVD	Variation of salt concentration with depth.
Optional for initialization of tracer concentration.	TVDP	Variation of tracer concentration with depth.
Optional.	THPRES	Threshold pressures for flow between equilibration regions.

### ECLIPSE 100 only keywords

Restriction	ECLIPSE 100 only keyword	Description
Required for equilibration when using API tracking.	APIVD	Variation of oil API with depth

### ECLIPSE 300 only keywords

Restriction	ECLIPSE 300 only keyword	Description
Optional.	OLDEQUIL	Perform Equilibration using pre-2000A method
Optional, for the CO2SOL and GASSOL options.	.RSWVD	Aqueous concentration of dissolved gases versus depth
Thermal only	AMFVD	Aqueous mole fractions versus depth.

## Restarting

The RESTART keywords are:

- [OUTSOL](#) Controls solution output for GRAF and flexible restarts. Optional
- [RESTART](#) Name of the restart file.
- [RPTRST](#) Report arguments for restart data. Optional

## Enumeration

### Common keywords

Restriction	Keyword	Description
Either RS or PBUB required for enumeration in live oil systems.	<a href="#">PBUB</a>	Bubble point pressures in every grid block.
Either RV or PDEW required for enumeration in wet gas systems.	<a href="#">PDEW</a>	Dew point pressures in every grid block.
Either PRESSURE or PRVD is required for enumeration.	<a href="#">PRESSURE</a>	Pressures in every grid-block
Either RS or PBUB required for enumeration in live oil systems.	<a href="#">RS</a>	Solution gas-oil ratios in every grid block.
Either RV or PDEW required for enumeration in wet gas systems.	<a href="#">RV</a>	Vapor oil-gas ratios in every grid block.
Required for enumeration when using Brine option.	<a href="#">SALT</a>	Salt concentration values in every grid block.
Required for enumeration in two/three-phase systems with gas.	<a href="#">SGAS</a>	Gas saturation in every grid-block.
Required for enumeration in two/three-phase systems with water	<a href="#">SWAT</a>	Water saturation in every grid-block
Required for enumeration of tracer concentrations.	<a href="#">TBLK</a>	Initializes concentration of tracers in every grid block

### ECLIPSE 100 only keywords

Restriction	ECLIPSE 100 only keyword	Description
Required for enumeration when using API tracking	<a href="#">OILAPI</a>	Oil API gravity values in every grid block
Either PRESSURE or PRVD is required for enumeration.	<a href="#">PRVD</a>	Pressure versus depth.
	<a href="#">SFOAM</a>	Initial Foam concentrations.
	<a href="#">SPOLY</a>	Initial Polymer concentrations.
	<a href="#">SURF</a>	Initial Surfactant concentrations

Restriction	ECLIPSE 100 only keyword	Description
Optional for systems with both live oil and wet gas.	VAPPARS	Parameters controlling vaporization of oil in under saturated gas

### ECLIPSE 300 only keywords

Restriction	ECLIPSE 300 only keyword	Description
Optional	AMF	Cell initial aqueous phase composition in GASWAT option.
Optional.	NEI	Specify compositions for non-equilibrium initialization.
	ROMF	Cell residual oil composition. SOR option.
Optional, for the CO2SOL and GASSOL options.	RSW	Aqueous concentration of dissolved gases in every grid block.
Either RV or PDEW required for enumeration in wet gas systems.	RV	Vapor oil-gas ratios in every grid block.
Solid option.	SMF	Cell initial solid composition.
Optional.	SOIL	Oil saturation in every grid-block.
SOR option.	SOILR	Cell residual oil saturation.
Solid option.	SSOLID	Solid saturation in every grid-block.
Optional.	XMF	Cell initial oil composition.
Optional.	YMF	Cell initial gas composition.
Optional.	ZMF	Cell initial total composition.

## Aquifer data

### Common keywords

Restriction	Keyword	Description
	AQANTRC	Initialize concentration of water phase tracers in each analytic aquifer.
	AQUANCON	Connects an analytic aquifer, which was defined by AQUCT, AQUFETP, AQUFLUX, AQUCHWAT and AQUCHGAS, to one or more reservoir cells.
	AQUANCONL	Connects an analytic aquifer which was defined by AQUCT, AQUFETP, AQUFLUX, AQUCHWAT and AQUCHGAS, to one or more reservoir cells located within local grid refinements

Restriction	Keyword	Description
Required in compositional run with AQUCHGAS aquifer.  Optional for the GASWAT or CO2STORE options.	AQSTREAM	Sets composition of gas stream for AUCHGAS aquifer.  For the GASWAT and CO2STORE options, sets water composition for AUCHWAT, AUCT, AUFETP and AUFUX.
	AUCHGAS	Constant head gas aquifer data specification.
	AUCHWAT	Constant head aquifer data specification.
	AUCT	Carter-Tracy aquifer property data specification.
For use with AQUANCON / AQUANCONL	AUFETP	Fetkovich aquifer property data specification
	AUFUX	Constant flux aquifer data specification.

### ECLIPSE 100 only keywords

ECLIPSE 100 only keyword	Description
AQANNC	Specifies analytic aquifer connections explicitly.
AUFET	Complete Fetkovich aquifer specifications.
AUFUX	Constant flux aquifer data specification.
AQUALIST	Aquifer lists.
RAINFALL	Specifies monthly flux rates for constant flux aquifers.

### ECLIPSE 300 only keywords

ECLIPSE 300 only keyword	Description
AQSTREAMW	For the multi-component water option (COMPW), sets water composition for AUCHWAT, AUCT, AUFETP and AUFUX.

### Temperature option (ECLIPSE 100)

RTEMP or RTEMPA or RTEMPVD required when using the Temperature option.

- RTEMP Sets the initial reservoir temperature in each grid block.
- RTEMPA Sets the initial reservoir temperature in each grid block.
- RTEMPVD Sets the initial reservoir temperature versus depth.

### Other options

#### Common keywords

Option	Keyword	Description
Coal Bed Methane	GASCONC	Initial coal gas concentration.

Option	Keyword	Description
Coal Bed Methane	<a href="#">GASSATC</a>	Initial saturated coal gas concentration.

### ECLIPSE 100 only keywords

Option	Keyword	Description
Coal Bed Methane	<a href="#">GCVD</a>	Initial coal gas concentration with depth.
Gi (enumeration only)	<a href="#">GI</a>	Initial Gi values.
Coal Bed Methane	<a href="#">SCVD</a>	Initial coal solvent concentration with depth.
Solvent	<a href="#">SSOL</a>	Initial solvent saturation.

### ECLIPSE 300 only keywords

Option	Keyword	Description
Coal Bed Methane	<a href="#">GASADCO</a>	Initial coal gas concentration for each component.
Coal Bed Methane	<a href="#">GASADEC</a>	Initial saturated/equilibrium coal gas concentration for each component.
Coal Bed Methane	<a href="#">GASCCMP</a>	Specify the component number for GASCONC and GASSATC.
<a href="#">THERMAL</a>	<a href="#">TEMPI</a>	Initial temperatures.
Coal Bed Methane	<a href="#">SORBFRAC</a>	Scale initial adsorbed gas in the coal.
Coal Bed Methane	<a href="#">SORBPRES</a>	Specify the initial sorption pressure for the adsorbed gas in the coal.

## Operational keywords

### Common keywords

Restriction	Keyword	Description
Optional.	<a href="#">ADD</a>	Add value to an array.
Optional.	<a href="#">ADDREG</a>	Add by <a href="#">FLUXNUM</a> , <a href="#">MULTNUM</a> or <a href="#">OPERNUM</a> region.
Optional.	<a href="#">BOX</a>	Redefines the current input box.
Optional.	<a href="#">COPY</a>	Copies data in the current box from one specified region to another.
Optional.	<a href="#">COPYREG</a>	Copy by <a href="#">FLUXNUM</a> , <a href="#">MULTNUM</a> or <a href="#">OPERNUM</a> region.
Optional.	<a href="#">ENDBOX</a>	Redefines the current input box to encompass the whole grid.
Optional.	<a href="#">ENDFIN</a>	End input for local grid refinement.
Optional.	<a href="#">EQUALREG</a>	Set by <a href="#">FLUXNUM</a> , <a href="#">MULTNUM</a> or <a href="#">OPERNUM</a> region.
Optional.	<a href="#">EQUALS</a>	Set array to constant.
Optional.	<a href="#">IMPORT</a>	Imports binary data generated by a grid pre-processor.
Optional.	<a href="#">MULTIPLY</a>	Multiply array to constant.
Optional.	<a href="#">MULTIREG</a>	Multiply array by <a href="#">FLUXNUM</a> , <a href="#">MULTNUM</a> or <a href="#">OPERNUM</a> region.
Optional.	<a href="#">OPERATE</a>	Performs arithmetic operations on arrays.

Restriction	Keyword	Description
Optional.	<a href="#">OPERATER</a>	Performs arithmetic operations on arrays for a specific region of the grid (defined using the <a href="#">OPERNUM</a> keyword in the <a href="#">GRID</a> or <a href="#">REGIONS</a> section).
Optional.	<a href="#">REFINE</a>	Initiates data for a named local grid.

### ECLIPSE 100 only keywords

- [GETDATA](#) Obtained named solution arrays from a restart of Initial file. Optional.
- [GETGLOB](#) Get global solution arrays from Restart file. Optional.

### ECLIPSE 300 only keywords

- [GETSOL](#) Obtain initial solution arrays from a Restart file. Optional.

## Dynamic Regions Facility

- [DYNAMICR](#) Defines regions based on when a set of conditions are satisfied. These regions may be static or allowed to change dynamically.
- [ENDDYN](#) Indicates the end of a [DYNAMICR](#) keyword sequence.

## Rivers (ECLIPSE 100)

- [RIVERSYS](#) Defines a river system.

## Tuning (ECLIPSE 300)

- [FCCRIT](#) Flash convergence criteria. Optional.

## ODD3P option (ECLIPSE 300)

- [DBGODD3P](#) Diagnostic information for [ODD3P](#) option. Optional.

## Alphabetic list of keywords

### Common keywords

Restriction	Keyword	Description
	<a href="#">ADD</a>	Add value to an array.
	<a href="#">ADDREG</a>	Add by <a href="#">FLUXNUM</a> , <a href="#">MULTNUM</a> or <a href="#">OPERNUM</a> region.
	<a href="#">AQANCONL</a>	Connects an analytic aquifer which was defined by <a href="#">AQUCT</a> , <a href="#">AQUFETP</a> , <a href="#">AQUFLUX</a> , <a href="#">AQUCHWAT</a> and <a href="#">AQUCHGAS</a> , to one or more reservoir cells located within local grid refinements.
	<a href="#">AQANTRC</a>	Initializes concentration of water phase tracers in each analytic aquifer.
	<a href="#">AQUANCON</a>	Connects an analytic aquifer which was defined by <a href="#">AQUCT</a> , <a href="#">AQUFETP</a> , <a href="#">AQUFLUX</a> , <a href="#">AQUCHWAT</a> and <a href="#">AQUCHGAS</a> , to one or more reservoir cells.

Restriction	Keyword	Description
	AQUCHGAS	Constant head gas aquifer data specification.
	AQUCHWAT	Constant head water aquifer data specification.
	AQUCT	Carter-Tracy aquifer property data specification.
for use with AQUANCON/ AQANCONL	AQUFETP	Fetkovich aquifer property data specification
	AQUFLUX	Constant flux aquifer data specification.
	BOUNDARY	Defines section of grid for which output maps are required.
	BOX	Redefines the current box.
	COPY	Copies data in the current box from one specified region to another.
	COPYREG	Copy by FLUXNUM, MULTNUM or OPERNUM region.
	DATUM	Defines datum depth for output of depth corrected pressures.
	DATUMR	Defines datum depth for each FIP region.
	DATUMRX	Defines datum depth for each FIP region in each FIP set.
	DYNAMICR	Defines regions based on when a set of conditions are satisfied. These regions may be static or allowed to change dynamically.
	ENDBOX	Redefines the current box to encompass the whole grid.
	ENDDYN	Indicates the end of a DYNAMICR keyword sequence.
	ENDFIN	End input for local grid refinement.
	EQUALREG	Set by FLUXNUM, MULTNUM or OPERNUM region.
	EQUALS	Set array to constant.
	EQUIL	Fluid contact depths and other equilibration parameters.
	FILEUNIT	Confirms the units of the data set.
	GASCONC	Initial coal gas concentration.
	GASSATC	Initial coal gas saturated concentration.
	IMPORT	Imports binary data generated by a grid pre-processor.
	MULTIPLY	Multiply array by constant.
	MULTIREG	Multiply array by FLUXNUM, MULTNUM or OPERNUM region.
	OPERATE	Performs arithmetic operations on arrays.
	OPERATER	Performs arithmetic operations on arrays for a specific region of the grid (defined using the OPERNUM keyword in the GRID or REGIONS section).
	PBUB	Bubble point pressures in every grid block.
	PBVD	Variation of bubble point pressure with depth.
	PDEW	Dew point pressures in every grid block.
	PDVD	Variation of dew point pressure with depth.
	PRESSURE	Pressures in every grid-block.
	REFINE	Initiates data for a named local grid.

Restriction	Keyword	Description
	RESTART	Name of the restart file.
	RPTRST	Report arguments for restart data
	RPTSOL	Report arguments for SOLUTION data.
	RS	Solution gas-oil ratios in every grid-block.
	RSVD	Variation of solution GOR with depth
	RTEMPA	Sets the initial reservoir temperature in each grid block.
	RTEMPVD	Sets the initial reservoir temperature versus depth.
	RV	Vapor oil-gas ratios in every grid-block.
	RVVD	Variation of vapor OGR with depth.
	SALT	Salt concentrations in every grid block.
	SALTVD	Variation of salt concentration with depth.
	SGAS	Gas saturation in every grid-block.
	SWAT	Water saturation in every grid-block.
	TBLK	Initializes concentration of tracers in each grid cell.
	THPRES	Threshold pressures for flow between equilibration regions.
	TVDP	Variation of tracer concentration with depth.
	VISDATES	Specify VISAGE geomechanics stress step dates.
	VISOPTS	Specify VISAGE geomechanics workflow options.

## ECLIPSE 100 only keywords

ECLIPSE 100 only keyword	Description
APIVD	Variation of oil API with depth.
AQANNC	Specifies analytic aquifer connections explicitly.
AQUFET	Complete Fetkovich aquifer specifications.
GCVD	Initial coal gas concentration with depth.
GETDATA	Read named arrays from an ECLIPSE restart of Initial file.
GETGLOB	Get global solution arrays from Restart file.
GI	Initial Gi values.
OILAPI	Oil API gravity values in every grid-block.
PRVD	Pressure versus depth.
RIVERSYS	Defines a river system.
SCVD	Initial coal solvent concentration with depth
SSOL	Initial solvent saturation
VAPPARS	Parameters controlling vaporization of oil in under saturated gas

## ECLIPSE 300 only keywords

Restriction	ECLIPSE 300 only keyword	Description
	AMF	Specifies cell initial aqueous composition explicitly.
	AQSTREAM	Sets gas composition for use with AQUCHGAS aquifer and, for the GASWAT and CO2STORE options, water composition for use with AQUCHWAT, AQUCT, AQUFETP and AQUFLUX.
	AQSTREAMW	For the multi-component water option (COMPW), sets water composition for use with AQUCHWAT, AQUCT, AQUFETP and AQUFLUX.
	DBGODD3P	Debug output for ODD3P option.
	FCCRIT	Flash convergence criteria.
	FIELDSEP	Introduces a field separator
	FIPSEP	Introduces a separator to be used in a fluid-in-place region.
	GASADCO	Initial coal gas concentration.
	GASADCO	Initial coal gas equilibrium/saturated concentration.
	GETSOL	Obtain initial solution arrays from a Restart file.
	GPTABLE	Tables of gas plant recovery factors.
	GPTABLEN	Gas plant table with NGL recoveries.
	GPTABLE3	Gas plant table with oil, NGL and gas recoveries.
	NEI	Specify compositions for non-equilibrium initialization
	OLDEQUIL	Perform Equilibration using pre-2000A method.
	OUTSOL	Controls solution output for GRAF and flexible restarts
	RECOVERY	Recovery plant table.
SOR option.	ROMF	Cell residual oil composition.
	RSW	Aqueous concentration of CO <sub>2</sub> in every grid block.
	RSWVD	Aqueous concentration of CO <sub>2</sub> versus depth.
	SMF	Cell initial solid composition.
	SOIL	Oil saturation in every grid-block.
SOR option.	SOILR	Cell residual oil saturation.
	SSOLID	Solid saturation in every grid-block.
	TEMPI	Initial temperatures.
water component model	WI	Initial water composition
water component model	WMF	Cell initial water composition

Restriction	ECLIPSE 300 only keyword	Description
water component model	WMFVD	Initial water composition as a function of depth
	XMF	Cell initial oil composition.
	YMF	Cell initial gas composition
	ZMF	Cell initial total composition.

## SUMMARY section

The SUMMARY section specifies a number of variables that are to be written to Summary files after each timestep of the simulation. The graphics post-processor may be used to display the variation of variables in the Summary files with time and with each other. If there is no SUMMARY section, ECLIPSE does not create any Summary files.

The keywords that may be specified in the SUMMARY section are shown in the following tables. All are optional, and no significance attaches to the order in which they are specified. All keywords must start in column 1. All characters up to column 8 are significant.

## Keyword data format

Summary vector keywords can have one of three formats:

- keyword with no data;
- keyword with a list of data, terminated by a slash (/). Sometimes the list can be defaulted (left blank);
- keyword followed by a set of records, each record terminated by a slash (/). A blank record is used to terminate the keyword

Examples of these three formats are:

```
FPR
WBHP
'WELL1' 'WELL2' 'WELL3' /
BPR
1 1 1 /
1 1 2 /
1 1 3 /
/
```

**Note:** When inputting a user defined name (for example well name, well list name, group name) it is important to enclose the name in quotes for example ' PROD1 '. Failure to do so may lead to unexpected results.

For more information on the SUMMARY file format for different keyword groups, see the information starting with ["Format of SUMMARY keywords beginning with A"](#).

For more information on SUMMARY keywords with a component index see, ["Format of SUMMARY keywords with a component index"](#).

## Format of SUMMARY keywords beginning with A

Keywords that begin with the letter 'AA' are followed by a list of analytic aquifer numbers terminated by a slash (/). Keywords that begin with the letter 'AN' are followed by a list of numerical aquifer numbers terminated by a slash (/).

For example,

```
AAQR
 1 2 /
```

specifies that analytic aquifers 1 and 2 are to be stored in the summary files. If a null list of aquifers is specified, data is stored in the Summary file for all analytic (liquid or gas depending on the keyword) or numerical aquifers.

ECLIPSE 300

Keywords that begin with the letter 'AAC' or 'ANC' are followed by a list of pairs composed of a respectively analytic or numerical aquifer number and a component number. Each pair must begin on a fresh line and must be terminated by a slash (/). The list is terminated by a line that begins with a slash. The component number can be defaulted, in which case all components allowed in the given aquifer will be stored in the summary file.

For example,

```
AACMR
 1 2 /
 /
```

specifies that component 2 for analytic aquifer 1 is to be stored in the summary file. If a null list is specified, data is stored in the summary file for all analytic or numerical aquifers and all components allowed in them.

The keyword ALL is an exception to this rule. There are no data associated with it.

Output for both water aquifer (AQUCT, AQUFLUX, AQUCHWAT, AQUFETP, and AQUFET (ECLIPSE 100 only)), and gas aquifer (AQUCHGAS) rates and totals are done using these mnemonics. Must ensure that correct aquifer number is specified for this output.

ECLIPSE 100

Keywords which begin with the letters 'AL' are followed by a list of analytic aquifer list names terminated by a slash (/). For example,

```
ALQR
'AQLIST1'
'AQLIST2'
 /
```

specifies that the aquifer list influx rate for aquifer lists AQLIST1 and AQLIST2 are to be stored in the summary file.

## Format of SUMMARY keywords beginning with B

Keywords that begin with the letter 'B' are followed by a list of sets of block coordinates. Each set of coordinates must begin on a fresh line and must be terminated by a slash (/). The list is terminated by a line that begins with a slash.

For example,

```
BOSAT
 8 1 14 /
```

```

9 1 14 /
12 3 6 /
/

```

Keywords that begin with a B and ends with a \_X are used to report linear interpolated values and thus require a different format. The input XYZ coordinates are validated and updated against the input cell block IJK coordinates, which can be defaulted in simple grids to allow ECLIPSE automatic calculation. When IJK coordinates are updated, a message is output. When IJK coordinates cannot be found given input XYZ coordinates, a WARNING message is issued and a block centered value is reported for cell IJK.

A reference height can be defined in place of global value specified in HYDRHEAD. The reference height is used only for pressure and hydraulic head keywords BPR\_X, BHD\_X and BHDF\_X. Each set of coordinates must begin on a fresh line and must be terminated by a slash (/). The list is terminated by a line that begins with a slash.

For example,

```

BPR_X
-- I J K Cell X Y Z Coordinate Reference-Height GroupName
  8 1 14 238.5 -78.5 -2.5 1* 'AP' /
 1* 1* 1* 122.5 -46.5 -7.5 100.0 'AP' /
/

```

If the discretized matrix block option for dual porosity is active (keyword [NMATRIX](#) in the RUNSPEC section), the solution inside the matrix cells can be obtained by appending the required ring number to the end of the following summary keywords: BOSAT, BWSAT, BGSAT, BPR, BRS and BRV. Keywords without a ring number appended refer to the outermost matrix ring adjacent to the fracture.

For example,

```

BPR3
3 3 6 /
4 3 6 /
/

```

ECLIPSE 300

Block keywords that require a component index, such as BMLSC, BXMF, BYMF, BGMCO and BGMCG are described in [Format of SUMMARY keywords with a component index](#).

## Format of SUMMARY keywords beginning with C

Keywords that begin with the letter C must be followed by a list of well-reservoir connections (the well name and the three block coordinates). Each connection must be specified on a fresh line and terminated by a slash (/). The three grid block coordinates may be defaulted for a well, which will cause the appropriate quantity to be output for **all** connections in the well. The list of well connections is terminated by a line beginning with a slash (/).

**Note:** If the connection coordinates are defaulted, as for well PROD3 below, ECLIPSE reserves a number of summary vectors equal to the maximum number of connections per well (NCWMAX, set in RUNSPEC section keyword [WELLDIMS](#)). If this number is much greater than the actual number of connections in well PROD3 then defaulting the connections can become quite wasteful.

For example,

```

COFR
'PROD1' 10 3 7 /
'PROD1' 10 3 8 /
'PROD2' 4 2 5 /

```

```
'PROD3' /
/
```

The well name may be defaulted by using the character '\*'. If both the well name and the connection coordinates are defaulted (as in the example below), then the requested summary quantities are output for all well connections in the global model. If the well name is defaulted but the connection coordinates are provided, then the requested summary quantities will be output for all wells with a connection in the specified block. Please note that well name templates are currently not allowed.

```
COFR
-- Well Name Cell
-- '*' /
/
```

Keywords beginning with the letter 'C' and ending with the letter 'L' output the corresponding connection quantity totaled over all the connections that belong to the same lumped completion (see keyword [COMPLUMP](#)). Any connection within the lumped completion can be specified to define the completion. Note that the well name may not be defaulted for a lumped completion quantity.

ECLIPSE 300

For the conductive faults option the summary keywords (see table 2.72) should be followed by a list of conductive fault names and should be terminated by a slash (/). Defaulting the fault name list results in output for all conductive faults. For example,

```
CFOSAT
'FLT1' 'FLT2' / -- Oil saturation in faults 'FLT1' and 'FLT2'
CFPRES
/ -- Pressure in all faults
```

ECLIPSE 300

Completion keywords that require a component index, such as CZMF, CKFR and CKFT are described in "[Format of SUMMARY keywords with a component index](#)".

## Format of SUMMARY keywords beginning with F

ECLIPSE 300

Field keywords that require a component index, such as FXMF, FYMF, FZMF, FCMPR, FCMO, , FCGMI and FCGMM are described in "[Format of SUMMARY keywords with a component index](#)".

All other keywords that begin with the letter 'F' have no associated data.

## Format of SUMMARY keywords beginning with G

Keywords that begin with 'G' must be followed by a list group names enclosed in quotes. The list is terminated by a slash (/).

For example,

```
GWCT
'PLAT1' 'PLAT2'
'PLAT3'
/
```

specifies that the water cut for the three named groups of wells are to be stored on the summary files.

If a null list is specified, data is stored for all groups.

ECLIPSE 300

Group keywords that require a component index are described in "[Format of SUMMARY keywords with a component index](#)".

## Format of SUMMARY keywords beginning with LB

A local block (LB) keyword should be followed by a list of LGR names and local block coordinates. Each block must be specified on a fresh line, terminated by a slash (/), and the list of blocks is terminated by a line containing only a slash (/).

Note, in ECLIPSE 100 global block data associated with LGR host cells can be accessed via the B\*SUMMARY keywords. For ECLIPSE 300 block data associated with LGR host cells is not available and data should either be requested for unrefined cells using the B\* keywords, or refined cells using the LB\* keywords.

```
LBOSAT
-- LGR Name      Local Cell
  'LGR1'         1  1  1 /
  'LGR2'         1  2  3 /
/
```

There is a known limitation for tracer block quantities as the tracer name should be appended to the LB\* keyword. As the total number of characters in the SUMMARY keyword cannot exceed 8, the tracer name may need to be reduced in consequence.

Local block interpolation keyword begin with a LB and ends with a \_X are used to report linear interpolated values and thus require a different format. The local LGR grid name should be included. The input XYZ coordinates are validated and updated against the input local cell block IJK coordinates, which can be defaulted in simple grids to allow ECLIPSE automatic calculation. When local IJK coordinates are updated, a message is output. When local IJK coordinates cannot be found given input XYZ coordinates, a WARNING message is issued and value is reported as block centered value for cell IJK.

A reference height can be defined in place of global value specified in HYDRHEAD. The reference height is used only for pressure and hydraulic head keywords LBPR\_X, LBHD\_X and LBHDF\_X. Each set of coordinates must begin on a fresh line and must be terminated by a slash (/). The list is terminated by a line that begins with a slash.

```
LBPR_X
-- LGR Name Local I J K Cell X Y Z Coordinate Ref-Height GroupName
  'LGR1'     1  1  1      122.1 -63.4 -1.4 100.0      'ALP' /
  'LGR2'     1  2  3      122.1 -68.4 -3.4 1*          'ALP' /
/
```

## Format of SUMMARY keywords beginning with LC

A local well connection (LC) keyword should be followed by a list of LGR names, well names and the local block coordinates. Each connection must be specified on a fresh line and terminated by a slash (/). The list of connections is terminated by a line containing only a slash (/).

```
LCOPT
-- LGR Name Well Name Local Cell
  'LGR1'     'WELL1'   1  1  1 /
  'LGR2'     'PROD'    2  2  2 /
  'LGR3'     'PROD2'   2  2  2 /
/
```

If the connection coordinates are defaulted for a well (as in well PROD2 in the example below), the corresponding quantity is output for **all** connections in the well (within the specified LGR).

```
LCOFR
-- LGR Name Well Name Local Cell
  'LGR1'     'WELL1'   1  1  1 /
  'LGR2'     'PROD'    2  2  2 /
```

```
'LGR3'      'PROD2'      /
/
```

The well name may be defaulted by using the character '\*' (as in the examples below). If both the well name and the local connection coordinates are defaulted, then the requested summary quantities are output for all well connections in the specified LGR. If the well name is defaulted but the connection coordinates are provided, then the requested summary quantities will be output for all wells with a connection in the specified local block.

```
LCOFR
-- LGR Name  Well Name  Local Cell
' LGR1 '    '*'      /
' LGR2 '    '*'      2 2 2 /
/
```

**Note:** If the connection coordinates are defaulted, ECLIPSE 100 reserves a number of Summary vectors equal to the maximum number of connections per well (NCWMAX, set in RUNSPEC section keyword [WELLDIMS](#)). If this number is much greater than the actual number of connections in the local grid well, defaulting the connection coordinates can become quite wasteful.

## Format of SUMMARY keywords beginning with LW

Local well (LW) keywords should be followed by a list of LGR names and well names. Each line of data should be terminated with a slash (/) and the set of records must end with a blank line, containing only a slash (/).

If the well name contains wildcard characters then the template will be matched during the simulation period. See ["Well name and well list template matching"](#) in the *ECLIPSE Technical Description*. Alternatively, if the well name is defaulted then all wells within the named LGR are stored in the summary file. For example:

```
LWOPR
-- LGR Name  Well Name
' LGR1 '    'WELL1' /
' LGR2 '    'PROD'  /
' LGR3 '    /
/
```

ECLIPSE 100

For LGR amalgamations, any LGR within the amalgamation may be used to locate the well. The entered LGR is used in the summary output.

ECLIPSE 300

The keywords with a separator stage index are not available for local wells.

## Format of SUMMARY keywords beginning with R

### Inter-region keywords

Keywords that begin with the letter 'R' and have the letters 'FT' at characters 3 and 4 or at characters 4 and 5 (for example RGFTL and RNLFT) are used to specify that the total flow of a particular phase between particular pairs of fluid-in-place regions is to be stored in the summary files. Keywords that begin with the letter 'R' and have the letters 'FR' at characters 3 and 4 or at characters 4 and 5 (for example RGFR and RNLFR) are used to specify that the rate flow of a particular phase between particular pairs of fluid-in-place regions is to be stored in the summary files. An exception to this pattern is RORFR which is a region summary keyword. Each pair of region numbers must be specified on a fresh line, and terminated by a

slash (/). The list is terminated by a line beginning with a slash (/). Such keywords are described as “inter-region flow”.

For example,

```
RWFT
 1 2 /
 1 3 /
 2 3 /
 /
```

ECLIPSE 300

Additionally, keywords that start with RKFT or RKFR accept a component number appended to the fluid-in-place region pair. This component number can be defaulted, in which case all components will be stored in the summary file.

For example,

```
RKFT
 1 2 4 /
 1 3 4 /
 2 3 /
 /
```

Inter-region keywords can be obtained for the additional set of fluid-in-place regions by compounding them with the first 3 characters of the name of the set of fluid-in-place regions. Summary quantities having less than 5 characters should be extended to 5 characters with an underscore before adding the 3-character region set name.

ECLIPSE 300

Component flow keywords that start with RKFR and RKFT are available for the standard FIPNUM set only and cannot be compounded with FIP set name.

```
ROFR_FST      Inter-region oil flow rate from region 1 to 2
 1 2 /        of the set of regions named FST
 /
ROFR+FST      Positive contribution of Inter-region oil flow rate
 1 2 /        from region 1 to 2 of the set of regions named FST
 /
```

## Region keywords

Other keywords which begin with the letter 'R' (for example RWIP) are followed by a list of fluid-in-place region numbers which is terminated by a single slash (/). The region numbers are not organized in pairs.

For example,

```
ROIP
 5 6
 8 /
```

specifies that the oil in place in regions 5, 6 and 8 is to be stored in the summary files. If a null list of regions is specified, data is stored in the Summary file for all regions.

For example:

```
RGIPG
 /
```

If additional sets of fluid-in-place regions are being used (defined with keyword [FIP](#) in the [REGIONS](#) section), then the [SUMMARY](#) keywords beginning with the letter R are available to request output from these additional sets of regions. In this case, the region quantity keyword should be compounded with the first 3

characters of the name of the set of fluid-in-place regions specified with the FIP keyword. SUMMARY keywords with less than 5 characters (for example ROIP) should be extended to five characters with underscores before appending the three-character region set name. For example:

```

ROIPLFST   for the oil-in-place in the liquid phase for region 2
 2 /       of the set of regions named FST
ROIP_SND   for the total oil-in-place in all the regions in the
 /         set named SND
RPR__THR   for the pressure in all the regions in the set named
 /         THR

```

At present the keywords associated with tracers within a region (that is those beginning with RT) are not available for the additional sets of fluid-in-place regions.

ECLIPSE 300

Some keywords which begin with the letter 'R' and which are not inter-region flow keywords accept a component number as noted in their description (for instance RCOM, RCWM, RCGMI and RCGMM). Such summary keywords are specified using two items, the first corresponding to the region number and the second corresponding to the component index. The component number can be defaulted, in which case data for all components will be output in the summary file. For example:

```

RCOM       Molar amount of component 2 dissolved in oil, within
1 2 /     region 1 of standard FIP set.
 /
RCGMIFST   Molar amount of all components trapped in gas, within
2 /       region 2 of the set of region named FST
 /

```

## Format of SUMMARY keywords beginning with S

Keywords that begin with 'S' request data for a segment of a multisegment well or river and must be followed by a list records consisting of well names and segment numbers, with each record terminated by a slash(/). The final record should be followed by a further slash. For example:

```

SOFR
'WELL1' 2 /
'WELL1' 3 /
'WELL2' /
 /

```

If the segment number is omitted from a record then data for all segments for that well will be stored.

**Note:** If the segment number is defaulted, as for well WELL2 above, ECLIPSE will reserve a number of summary vectors equal to the maximum number of segments per well (NSEGMX, set in the RUNSPEC section keyword [WSEGDIMS](#)). If this number is much greater than the actual number of segments in well WELL2 then defaulting the segment numbers can become quite wasteful. This also applies to SUMMARY keywords that begin with 'S' applied to river reaches.

ECLIPSE 100

The well name may be defaulted. Data for all wells and all segments can be generated by using the appropriate keyword followed by an empty record containing a single slash.

ECLIPSE 300

If the well name is omitted, a wildcard used or a well list used then no data will be stored for that record.

ECLIPSE 300

Segment keywords that require a component index, such as SKFR and SCWGFR are described in "[Format of SUMMARY keywords with a component index](#)".

The SUMMARY keywords STEPTYPE, [SEPARATE](#) and [SUMTHIN](#) are exceptions to the above and take no arguments.

## Format of SUMMARY keywords beginning with W

Keywords that begin with 'w' must be followed by a list of well names enclosed in quotes. The list is terminated by a slash (/). For example:

```
WBHP
'WELL1' 'WELL2' 'WELL3' /
```

If a null list is specified, data is stored for all wells. For example,

```
WBHP
/
```

A well name or well list template containing wildcard characters may be supplied to a keyword beginning with the letter 'w'. The template will then be matched during the course of the simulation, see "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description*.

Keywords beginning with the letter 'w' and ending with the letter 'l' are for lumped completions (with the exception of WMCTL) and are an alternative form of the equivalent keyword which begins with the letter 'c'. They should be followed by a well name and the index of the required lumped completion. They output the corresponding connection quantity totaled over all the connections that belong to the same lumped completion (see keyword [COMPLUMP](#)). For example,

```
WOPRL
'P1' 2 /
```

The mnemonic name written to the Summary file for these well keywords has the lumped completion index appended after additional underscore characters (for example, WOPRL\_\_2). If the completion index is less than 10, two underscore characters are used. If it is less than 100 and bigger than 9, one underscore character is used. If it is less than 1000 and bigger than 99, no underscore character is used.

ECLIPSE 300

Well keywords that require a component index, such as WXMF and WYMF are described in "[Format of SUMMARY keywords with a component index](#)".

## Format of SUMMARY keywords that end in H

The keywords that end with the letter H (for example WOPRH, WWPRH, WGPRH, WWCTH, WGORH, WGRH, WWGRH) refer to the observed production/injection history of history matching wells specified in keywords [WCONHIST](#) and [WCONINJH](#) as long as the description mentions WCONHIST or WCONINJH. These quantities are included to enable you to compare, for example, the calculated water cut WWCT with the observed water cut WWCTH. They are ignored if applied to wells that are not history matching wells. Group and field keywords ending in H (for example GOPRH, FWPRH) refer to the sum of their subordinate well flows, with the flows of all history matching wells replaced with their historical rates specified in WCONHIST and WCONINJH. Thus, for example, FWCT can be compared with FWCTH to determine how well the field water cut matches its observed value.

## Format of SUMMARY keywords with a component index

ECLIPSE 300

Keywords that provide information at a component level must have the component number appended to any other data associated with the keyword. For group type keywords a line of data must contain a single group name followed by a component number terminated by a slash (/). For well type keywords a line of data can either contain a single well name or a well name template containing wildcard characters, followed by a component number and terminated by a slash (/). If a well name template is supplied then it will be

matched during the simulation period. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description*.

When rates and totals are being reported for groups or wells at a component level, they are positive for production and negative for injection.

For example,

```
WXMF
  'PROD1' 7 /
  'PROD2' / -- list all components
/
```

or:

```
GXMF
  'PLAT1' 7 /
  'PLAT1' 8 /
  'PLAT2' / -- list all components
/
```

or, to get the 7<sup>th</sup>, 8<sup>th</sup> and 9<sup>th</sup> component values of BXMF at grid block (21,7,13) and all components of grid block (21,7,14):

```
BXMF
21 7 13 7 /
21 7 13 8 /
21 7 13 9 /
21 7 14 / -- list all components
/
```

or (note that this format is different from that used for keywords beginning with B or W):

```
FZMF
1 /
FZMF
2 /
FZMF
/ -- list all components
```

or:

```
CZMF
  'PROD1' 7 7 1 7 /
  'PROD1' 7 7 1 8 /
  'PROD2' 7 7 1 / -- list all components
/
```

or:

```
SKFR
  'PROD1' 7 1 /
  'PROD1' 8 2 /
  'PROD2' 3 / -- list all components
/
```

Note that keywords FREAC and FREAT allow multiple reaction numbers:

```
FREAC
1 2/ -- Reaction rates summed over all cells for reactions 1 and 2
```

```

FREAT
/  -- Reaction totals summed over all cells for all reactions

```

For keywords that start with B, C, S, F, G or W the component number can be defaulted, in which case all components will be stored in the summary file.

Keywords that begin with A and accept a component number are described in ["Format of SUMMARY keywords beginning with A"](#).

Keywords that begin with R and accept a component number are described in ["Format of SUMMARY keywords beginning with R"](#).

The mnemonic name written to the Summary file has the component index appended after an additional underscore character (for example, W<sub>XMF\_7</sub>). In rare cases the underscore will be omitted to ensure the composite name does not exceed 8 characters (for example, although the molar rate of component 3 in the gas from the 2nd separator stage of a well is written as WCGMR2\_3, the molar rate of component 15 has to be written as WCGMR215).

#### Water components

For the multi-component water option, the water component index starts at  $N_c+1$  and ends at  $N_c+N_w$  where  $N_c$  is the number of components given by [COMPS](#) and  $N_w$  is the number of water components given by the [COMPW](#) keyword. The water component indices can be used for the summary mnemonics described in ["SUMMARY section keywords"](#) in the *ECLIPSE Technical Description* manual.

## Keywords for special options

The keywords that refer specifically to network pressures or the Polymer, Brine, Solvent and Coal bed methane options should only be used when these options are active. These are ECLIPSE Special Options, and you are referred to the relevant sections of the *ECLIPSE Technical Description* manual for further details.

## Maximum number of keywords

The total number of quantities that are written to the Summary file must not exceed NSUMMX set in RUNSPEC keyword [SMRYDIMS](#).

---

**Note:** For example, WOPR applied to four individual wells counts as four separate quantities towards this total.

---

It is quite simple to construct a context-independent SUMMARY section that can be [INCLUDE](#)d in any run, and which provides sufficient data for many requirements.

## Example SUMMARY section

Here is an example of a context independent SUMMARY section:

```

SUMMARY  =====
-- Field oil prod rate.
-- Cumulative oil prod for field and for every well.
FOPR
FOPT
WOPT
/
-- Field wat inj rate. Cumulative wat inj for field and for every
-- well.
FWIR
FWIT
WWIT

```

```

/
-- Field gas inj rate. Cumulative gas inj for field and for every
-- well.
FGIR
FGIT
WGIT
/
-- Instantaneous GOR for field and for every well.
FGOR
WGOR
/
-- Instantaneous water cuts for field and for every well.
FWCT
WWCT
/

## Summary file names

A fresh Summary file is created at each report time. They have names like `BASE.S0011` which is the Summary file containing data for all timesteps in the period between reports 10 and 11 in a run whose file-name root is 'BASE'.

ECLIPSE also creates a file called `BASE.SMSPEC`, which contains a specification of the data in the Summary files. The naming convention can vary slightly according to the make of computer.

These files may be formatted (for transfer between computers of different makes, or just for readability), or unformatted (the default). The files are formatted if keyword `FMTOUT` is present in the `RUNSPEC` section. Formatted files have slightly different names, to distinguish them from unformatted files. The file names are of the form `BASE.A0011` and `BASE.FSMSPEC`.

## Well and group flow quantities

The well and group oil flow quantities are given in the table below. Notes for this table:

- See ["Format of SUMMARY keywords with a component index"](#).

E100	E300	Field	Group	Well	Connection	Completion	Information
x	x				COFR	COFRL	Oil Flow Rate (+ve=prod -ve=inj)
x	x					WOFRL	Oil Flow Rate (as above)
x	x					COPRL	Oil Flow Rate (as above)

E100	E300	Field	Group	Well	Connection	Completion	Information
x	x					WOPRL	Oil Flow Rate (as above)
x					COFRF		Free Oil Flow Rate
x					COFRS		Solution oil flow rate (vaporized oil)
x					COFRU		Sum of connection oil flow rates upstream of, and including, this connection
x	x	FOPR	GOPR	WOPR	COPR		Oil Production Rate
	x	FOPRA	GOPRA	WOPRA			Oil Production Rate above GOC
	x	FOPRB	GOPRB	WOPRB			Oil Production Rate below GOC
	x	FOPTA	GOPTA	WOPTA			Oil Production Total above GOC
	x	FOPTB	GOPTB	WOPTB			Oil Production Total below GOC
	x	FOPR1	GOPR1	WOPR1			Oil Production Rate above GOC (molar method)
	x	FOPR2	GOPR2	WOPR2			Oil Production Rate below GOC (molar method)
	x	FOPT1	GOPT1	WOPT1			Oil Production Total above GOC (molar method)
	x	FOPT2	GOPT2	WOPT2			Oil Production Total below GOC (molar method)
	x	FOMR	GOMR	WOMR			Oil Mass Rate
	x	FOMT	GOMT	WOMT			Oil Mass Total
	x	FODN	GODN	WODN			Oil Density at Surface Conditions
x	x	FOPRH	GOPRH	WOPRH			Oil Production Rate History ( <a href="#">WCONHIST</a> )
x	x	FOPRT	GOPRT	WOPRT			Oil Production Rate Target/Limit
x	x		GOPRL				Oil Production Rate Target/Limit (as above)
x		FOPRF	GOPRF	WOPRF			Free Oil Production Rate
x		FOPRS	GOPRS	WOPRS			Solution Oil Production Rate (vaporized oil)
x	x	FOPT	GOPT	WOPT	COPT	COPTL	Oil Production Total
x	x					WOPTL	Oil Production Total (as above)
x	x	FOPTH	GOPTH	WOPTH			Oil Production Total History ( <a href="#">WCONHIST</a> )
x		FOPTF	GOPTF	WOPTF	COPTF		Free Oil Production Total
x		FOPTS	GOPTS	WOPTS	COPTS		Solution Oil Production Total (vaporized oil)
x	x	FOIR	GOIR	WOIR			Oil Injection Rate

E100	E300	Field	Group	Well	Connection	Completion	Information
x		FOIRH	GOIRH	WOIRH			Oil Injection Rate History (WCONINJH)
x	x	FOIRT	GOIRT	WOIRT			Oil Injection Rate Target/Limit
x	x		GOIRL				Oil Injection Rate Target/Limit (as above)
x	x	FOIT	GOIT	WOIT			Oil Injection Total
x					COIT	COITL	Oil Injection Total (as above)
x						WOITL	Oil Injection Total (as above)
x		FOITH	GOITH	WOITH			Oil Injection Total History (WCONINJH)
x	x	FOPP	GOPP	WOPP			Oil Potential Production rate
x					COPP		Oil Potential Production rate (as above)
x	x	FOPP2	GOPP2	WOPP2			Oil Potential Production rate (including values calculated on shut/stopped wells)
x		FOPI	GOPI	WOPI	COPI		Oil Potential Injection rate
x		FOPI2	GOPI2	WOPI2			Oil Potential Injection rate (including values calculated on shut/stopped wells)
x	x		GOPGR	WOPGR			Oil Production Guide Rate
x			GOIGR	WOIGR			Oil Injection Guide Rate
	x	FOVPR	GOVPR	WOVPR			Oil Voidage Production Rate
	x	FOVPT	GOVPT	WOVPT			Oil Voidage Production Total
	x	FOVIR	GOVIR	WOVIR			Oil Voidage Injection Rate
	x	FOVIT	GOVIT	WOVIT			Oil Voidage Injection Total
	x	FOnPR	GOnPR	WOnPR			nth separator stage oil rate (n = 1 to 99).  Note that the oil volume rate is calculated at the temperature and pressure of the separator stage and not at stock tank conditions
	x	FOnPT	GOnPT	WOnPT			nth separator stage oil total (n = 1 to 99)
	x	FEOR	GEOR				Export Oil Rate
	x	FEOT	GEOT				Export Oil Total
	x	FEOMF	GEOMF				Export Oil Mole Fraction. See Note 1.

Table 2.11: Well and group oil flows

The well and group water flow quantities are given in the table below. Notes for this table:

1. See “Format of SUMMARY keywords with a component index”.

E100	E300	Field	Group	Well	Connection	Completion	Information
x	x				CWFR	CWFRL	Water Flow Rate (+ve=prod - ve=inj)
x	x					WWFRL	Water Flow Rate (as above)
x	x					CWPRL	Water Flow Rate (as above)
x	x					WWPRL	Water Flow Rate (as above)
x					CWFRU		Sum of connection water flow rates upstream of, and including, this connection
x	x	FWPR	GWPR	WWPR	CWPR		Water Production Rate
	x	FWMR	GWMR	WWMR			Water Mass Rate
	x	FWMT	GWMT	WWMT			Water Mass Total
x	x	FWPRH	GWPRH	WWPRH			Water Production Rate History ( <a href="#">WCONHIST</a> )
x	x	FWPRT	GWprt	WWPRT			Water Production Rate Target/Limit
x	x		GWpRL				Water Production Rate Target/Limit (as above)
x	x	FWPT	GWPT	WWPT	CWPT	CWPTL	Water Production Total
x	x					WWPTL	Water Production Total (as above)
x	x	FWPTH	GWPTH	WWPTH			Water Production Total History ( <a href="#">WCONHIST</a> )
x	x	FWIR	GWIR	WWIR	CWIR	CWIRL	Water Injection Rate
x	x					WWIRL	Water Injection Rate (as above)
x	x	FWIRH	GWIRH	WWIRH			Water Injection Rate History ( <a href="#">WCONINJH</a> )
x	x	FWIRT	GWIRT	WWIRT			Water Injection Rate Target/Limit
x	x		GWIRL				Water Injection Rate Target/Limit (as above)
x	x	FWIT	GWIT	WWIT	CWIT	CWITL	Water Injection Total
x	x					WWITL	Water Injection Total (as above)
x	x	FWITH	GWITH	WWITH			Water Injection Total History ( <a href="#">WCONINJH</a> )
x	x	FWPP	GWPP	WWPP			Water Potential Production rate
x					CWPP		Water Potential Production rate (as above)
x	x	FWPP2	GWPP2	WWPP2			Water Potential Production rate (including values calculated on shut/stopped wells)

E100	E300	Field	Group	Well	Connection	Completion	Information
x	x	FWPI	GWPI	WWPI			Water Potential Injection rate
x					CWPI		Water Potential Injection rate (as above)
x	x			WWIP			Water Potential Injection rate (as above)
x	x	FWPI2	GWPI2	WWPI2			Water Potential Injection rate (including values calculated on shut/stopped wells)
x	x			WWIP2			Water Potential Injection rate (including values calculated on shut/stopped wells) (as above)
x	x		GWPGR	WWPGR			Water Production Guide Rate
x	x		GWIGR	WWIGR			Water Injection Guide Rate
	x	FWVPR	GWVPR	WWVPR			Water Voidage Production Rate
	x	FWVPT	GWVPT	WWVPT			Water Voidage Production Total
	x	FWVIR	GWVIR	WWVIR			Water Voidage Injection Rate
	x	FWVIT	GWVIT	WWVIT			Water Voidage Injection Total
x		FWPIR	GWPIR	WWPIR			Ratio of produced water to injected water expressed as a percentage
	x	FWMPR	GWMPR	WWMPR			Water component molar production rate. See Note 1.
	x	FWMPT	GWMPPT	WWMPPT			Water component molar production total. See Note 1.
	x	FWMIR	GW MIR	WW MIR			Water component molar injection rate. See Note 1.
	x	FWMIT	GW MIT	WW MIT			Water component molar injection total. See Note 1.

Table 2.12: Well and group water flows

The well and group gas flow options are given in the table below. Notes for this table:

1. See “[Format of SUMMARY keywords with a component index](#)”
2. See OPTIONS3 keyword [item 108](#) for alternative reporting of this quantity during the surface gas production balancing group control mode.

E100	E300	Field	Group	Well	Connection	Completion	Information
x	x				CGFR	CGFRL	Gas Flow Rate (+ve=prod - ve=inj)
x	x					WGFRL	Gas Flow Rate (as above)
x	x					CGPRL	Gas Flow Rate (as above)
x	x					WGPRL	Gas Flow Rate (as above)
x					CGFRF		Free Gas Flow Rate

E100	E300	Field	Group	Well	Connection	Completion	Information
x					CGFRS		Solution Gas Flow Rate
x					CGFRU		Sum of connection gas flow rates upstream of, and including, this connection
x	x	FGPR	GGPR	WGPR	CGPR		Gas Production Rate Note: In the presence of lift gas (see the <a href="#">VFPPROD</a> keyword), the produced gas reported does not include produced lift gas, only produced formation gas.
	x	FGPRA	GGPRA	WGPRA			Gas Production Rate above GOC
	x	FGPRB	GGPRB	WGPRB			Gas Production Rate below GOC
	x	FGPTA	GGPTA	WGPTA			Gas Production Total above GOC
	x	FGPTB	GGPTB	WGPTB			Gas Production Total below GOC
	x	FGPR1	GGPR1	WGPR1			Gas Production Rate above GOC (molar method)
	x	FGPR2	GGPR2	WGPR2			Gas Production Rate below GOC (molar method)
	x	FGPT1	GGPT1	WGPT1			Gas Production Total above GOC (molar method)
	x	FGPT2	GGPT2	WGPT2			Gas Production Total below GOC (molar method)
	x	FGMR	GGMR	WGMR			Gas Mass Rate
	x	FGMT	GGMT	WGMT			Gas Mass Total
	x	FGDN	GGDN	WGDN			Gas Density at Surface Conditions
x	x	FGPRH	GGPRH	WGPRH			Gas Production Rate History ( <a href="#">WCONHIST</a> )
x	x	FGPRT	GGPRT	WGPRT			Gas Production Rate Target/Limit
x	x		GGPRL				Gas Production Rate Target/Limit (as above)
x		FGPRF	GGPRF	WGPRF			Free Gas Production Rate
x		FGPRS	GGPRS	WGPRS			Solution Gas Production Rate
x	x	FGPT	GGPT	WGPT	CGPT	CGPTL	Gas Production Total
x	x					WGPTL	Gas Production Total (as above)

E100	E300	Field	Group	Well	Connection	Completion	Information
x	x	FGPTH	GGPTH	WGPTH			Gas Production Total History (WCONHIST)
x		FGPTF	GGPTF	WGPTF	CGPTF		Free Gas Production Total
x		FGPTS	GGPTS	WGPTS	CGPTS		Solution Gas Production Total
x	x	FGIR	GGIR	WGIR	CGIR	CGIRL	Gas Injection Rate
x	x					WGIRL	Gas Injection Rate (as above)
x	x	FGIRH	GGIRH	WGIRH			Gas Injection Rate History (WCONINJH)
x	x	FGIRT	GGIRT	WGIRT			Gas Injection Rate Target/Limit
x	x		GGIRL				Gas Injection Rate Target/Limit (as above)
x	x	FGIT	GGIT	WGIT	CGIT	CGITL	Gas Injection Total
x	x					WGITL	Gas Injection Total (as above)
x	x	FGITH	GGITH	WGITH			Gas Injection Total History (WCONINJH)
x	x	FGPP	GGPP	WGPP			Gas Potential Production rate
x	x				CGPP		Gas Potential Production rate (as above)
x	x	FGPP2	GGPP2	WGPP2			Gas Potential Production rate (including values calculated on shut/stopped wells)
x		FGPPS	GGPPS	WGPPS			Solution (dissolved) Gas Potential Production rate
x		FGPPS2	GGPPS2	WGPPS2			Solution (dissolved) Gas Potential Production rate (including values calculated on shut/stopped wells)
x		FGPPF	GGPPF	WGPPF			Free Gas Potential Production rate
x		FGPPF2	GGPPF2	WGPPF2			Free Gas Potential Production rate (including values calculated on shut/stopped wells)
x	x	FGPI	GGPI	WGPI			Gas Potential Injection rate
x	x				CGPI		Gas Potential Injection rate (as above)
x	x			WGIP			Gas Potential Injection rate (as above)
x	x	FGPI2	GGPI2	WGPI2			Gas Potential Injection rate (including values calculated on shut/stopped wells)

E100	E300	Field	Group	Well	Connection	Completion	Information
x	x			WGIP2			Gas Potential Injection rate (including values calculated on shut/stopped wells) (as above)
x	x		GGPGR	WGPGR			Gas Production Guide Rate
x	x		GGIGR	WGIGR			Gas Injection Guide Rate
x	x	FSGR	GSGR				Sales Gas Rate
x	x	FGSR	GGSR				Sales Gas Rate (as above)
x	x	FSGT	GSGT				Sales Gas Total
x	x	FGST	GGST				Sales Gas Total (as above)
	x	FSMF	GSMF				Sales Gas Mole Fraction. See Note 1.
	x	FFGR	GFGR				Fuel Gas Rate, at and below this group
	x	FFGT	GFGT				Fuel Gas cumulative Total, at and below this group
	x	FFMF	GFMF				Fuel Gas Mole Fraction. See Note 1.
x		FGCR	GGCR				Gas Consumption Rate, at and below this group
x		FGCT	GGCT				Gas Consumption Total, at and below this group
x		FGIMR	GGIMR				Gas Import Rate, at and below this group
x		FGIMT	GGIMT				Gas Import Total, at and below this group
x	x	FGLIR	GGLIR	WGLIR			Gas Lift Injection Rate (Assumes ALQ = gas lift injection rate. Well rates are multiplied by their efficiency factors when summing up group and field rates.)
	x	FWGPR	GWGPR	WWGPR			Wet Gas Production Rate
	x	FWGPT	GWGPT	WWGPT			Wet Gas Production Total
	x	FWGPRH	GWGPRH	WWGPRH			Wet Gas Production Rate History ( <a href="#">WCONHIST</a> )
	x	FWGIR	GWGIR	WWGIR			Wet Gas Injection Rate
	x	FWGIT	GWGIT	WWGIT			Wet Gas Injection Total
	x	FEGR	GEGR				Export Gas Rate. See Note 2.
	x	FEGT	GEGT				Export Gas Total. See Note 2.

E100	E300	Field	Group	Well	Connection	Completion	Information
	x	FEMF	GEMF				Export Gas Mole Fraction. See Note 1.
	x	FEXGR	GEXGR				Excess Gas Rate. See Note 2.
	x	FEXGT	GEXGT				Excess Gas Total. See Note 2.
	x	FRGR	GRGR				Re-injection Gas Rate. See Note 2.
	x	FRGT	GRGT				Re-injection Gas Total. See Note 2.
	x	FGnPR	GGnPR	WGnPR			nth separator stage gas rate (n = 1 to 99).  Note that the gas volume rate is calculated at standard conditions and not at the temperature and pressure of the separator stage
	x	FGnPT	GGnPT	WGnPT			nth separator stage gas total (n = 1 to 99)
	x	FGVPR	GGVPR	WGVPR			Gas Voidage Production Rate
	x	FGVPT	GGVPT	WGVPT			Gas Voidage Production Total
	x	FGVIR	GGVIR	WGVIR			Gas Voidage Injection Rate
	x	FGVIT	GGVIT	WGVIT			Gas Voidage Injection Total
	x	FGQ	GGQ	WGQ	CGQ		Gas Quality

Table 2.13: Well and group gas flows

The well and group liquid flow options are:

E100	E300	Field	Group	Well	Connection	Completion	Information
x	x				CLFR	CLFRL	Liquid Flow Rate (+ve=prod - ve=inj)
x	x					WLFRL	Liquid Flow Rate (as above)
x	x	FLPR	GLPR	WLPR			Liquid Production Rate
x	x	FLPRH	GLPRH	WLPRH			Liquid Production Rate History ( <a href="#">WCONHIST</a> )
x	x	FLPRT	GLPRT	WLPRT			Liquid Production Rate Target/Limit
x	x		GLPRL				Liquid Production Rate Target/Limit (as above)
x	x	FLPT	GLPT	WLPT	CLPT	CLPTL	Liquid Production Total
x	x					WLPTL	Liquid Production Total (as above)

E100	E300	Field	Group	Well	Connection	Completion	Information
x	x	FLPTH	GLPTH	WLPTH			Liquid Production Total History (WCONHIST)

Table 2.14: Well and group liquid flows

The well and group linearly combined flow options are:

E100	E300	Field	Group	Well	Information
x	x	FJPR	GJPR	WJPR	Linearly Combined Production Rate
x	x	FJPRH	GJPRH	WJPRH	Linearly Combined Production Rate History (WCONHIST)
x	x	FJPRT	GJPRT	WJPRT	Linearly Combined Production Rate Target/Limit
x	x		GJPRL		Linearly Combined Production Rate Target/Limit (as above)
x	x	FJPT	GJPT	WJPT	Linearly Combined Production Total
x	x	FJPTH	GJPTH	WJPTH	Liquid Production Total History (WCONHIST)

Table 2.15: Well and group linearly combined flows

The well and group reservoir volume flow options are:

E100	E300	Field	Group	Well	Connection	Completion	Information
x	x				CVFR	CVFRL	Reservoir (Res) Volume Flow Rate (+ve=prod -ve=inj)
x	x					WVFRL	Res Volume Flow Rate (as above)
	x					CVFRL	Res Volume Production Flow Rate
	x					WVFRL	Res Volume Production Flow Rate (as above)
x	x					CVIRL	Res Volume Injection Flow Rate
x	x					WVIRL	Res Volume Injection Flow Rate (as above)
x	x	FVPR	GVPR	WVPR			Res Volume Production Rate
	x				CVPR		Res Volume Production Rate
x	x	FVPRT	GVPRT	WVPRT			Res Volume Production Rate Target/Limit
x	x		GVFRL				Res Volume Production Rate Target/Limit (as above)
x	x	FVPT	GVPT	WVPT	CVPT	CVPTL	Res Volume Production Total
x	x					WVPTL	Res Volume Production Total (as above)
x	x		GVFGR	WVFGR			Res Volume Production Guide Rate
x	x	FVIR	GVIR	WVIR	CVIR		Res Volume Injection Rate
x	x	FVIRT	GVIRT	WVIRT			Res Volume Injection Rate Target/Limit

E100	E300	Field	Group	Well	Connection	Completion	Information
x	x		GVIRL				Res Volume Injection Rate Target/ Limit (as above)
x	x	FVIT	GVIT	WVIT	CVIT	CVITL	Res Volume Injection Total
x	x					WVITL	Res Volume Injection Total (as above)

Table 2.16: Well and group reservoir volume flows

The group export flow options are given in the table below. Notes for this table:

1. See OPTIONS3 keyword [item 108](#) for alternative reporting of this quantity during the surface gas production balancing group control mode.
2. See “[Format of SUMMARY keywords with a component index](#)”

E300	Field	Group	Information
x	FEGR	GEGR	Export Gas Rate. See Note 1.
x	FEGT	GEGT	Export Gas Total. See Note 1.
x	FEOR	GEOR	Export Oil Rate
x	FEOT	GEOT	Export Oil Total
x	FENR	GENR	Export NGL Rate
x	FENT	GENT	Export NGL Total
x	FEMF	GEMF	Export Gas Mole Fraction. See Note 2.
x	FEOMF	GEOMF	Export Oil Mole Fraction. See Note 2.
x	FENMF	GENMF	Export NGL Mole Fraction. See Note 2.

Table 2.17: Group export flows (ECLIPSE 300)

The well and group calorific value flow options are:

E300	Field	Group	Well	Connection	Information
x	FCVPR	GCVPR	WCVPR	CCVPR	Calorific Value Production Rate
x	FCVPT	GCVPT	WCVPT		Calorific Value Production Total
x	FCVPP	GCVPP	WCVPP		Calorific Value Production Potential
x	FCVPP2	GCVPP2	WCVPP2		Calorific Value Production Potential (including values calculated on shut/stopped wells)

Table 2.18: Well and group calorific value flows (ECLIPSE 300)

The well and group production ratio options are:

E100	E300	Field	Group	Well	Connection	Completion	Information
x	x	FWCT	GWCT	WWCT	CWCT	CWCTL	Water Cut
x	x					WWCTL	Water Cut (as above)
x	x	FWCTH	GWCTH	WWCTH			Water Cut History ( <a href="#">WCONHIST</a> )
x	x	FGOR	GGOR	WGOR	CGOR	CGORL	Gas-Oil Ratio

E100	E300	Field	Group	Well	Connection	Completion	Information
x	x					WGORL	Gas-Oil Ratio (as above)
x	x	FGORH	GGORH	WGORH			Gas-Oil Ratio History (WCONHIST)
x	x	FOGR	GGR	WGR	COGR	COGRL	Oil-Gas Ratio
x	x					WOGRL	Oil-Gas Ratio (as above)
x	x	FOGRH	GGRH	WGRH			Oil-Gas Ratio History (WCONHIST)
x	x	FWGR	GWGR	WWGR	CWGR	CWGRL	Water-Gas Ratio
x	x					WWGRL	Water-Gas Ratio (as above)
x	x	FWGRH	GWGRH	WWGRH			Water-Gas Ratio History (WCONHIST)
x	x	FGLR	GGLR	WGLR	CGLR		Gas-Liquid Ratio
x						CGLRL	Gas-Liquid Ratio
x						WGLRL	Gas-Liquid Ratio (as above)
x		FGLRH	GGLRH	WGLRH			Gas-Liquid Ratio History (WCONHIST)
x				WBGLR			Bottom hole Gas-Liquid Ratio

Table 2.19: Well and group production ratios

The well pressure and PI options are given in the table below. Notes for this table:

- No units are given in FIELD, as noted in "The productivity index" in the *ECLIPSE Technical Description*

E100	E300	Well	Connection	Completion	Information
x	x		CPR		Connection Pressure
x	x			CPRL	Average Connection Pressure in lumped completion
x	x	WBHP			Bottom Hole Pressure
x	x	WBHPH			Bottom Hole Pressure History (WCONHIST, WCONINJH)
x	x	WTHP			Tubing Head Pressure
x	x	WTHPH			Tubing Head Pressure History (WCONHIST, WCONINJH)
x	x	WPI	CPI		Productivity Index of well's preferred phase. See Note 1.
x	x	WPIO			Oil phase PI
x	x	WPIG			Gas phase PI
x	x	WPIW			Water phase PI
x	x	WPIL			Liquid phase PI
x	x		CTFAC		Connection Transmissibility Factor

E100	E300	Well	Connection	Completion	Information
x	x		CDBF		Blocking factor for generalized pseudo-pressure method
x	x	WBP			One-point Pressure Average (see keywords <a href="#">WPAVE</a> and <a href="#">WWPAVE</a> )
x	x	WBP4			Four-point Pressure Average (see keywords <a href="#">WPAVE</a> and <a href="#">WWPAVE</a> )
x	x	WBP5			Five-point Pressure Average (see keywords <a href="#">WPAVE</a> and <a href="#">WWPAVE</a> )
x	x	WBP9			Nine-point Pressure Average (see keywords <a href="#">WPAVE</a> and <a href="#">WWPAVE</a> )
x	x	WPI1			Productivity Index based on the value of WBP. See Note 1.
x	x	WPI4			Productivity Index based on the value of WBP4. See Note 1.
x	x	WPI5			Productivity Index based on the value of WBP5. See Note 1.
x	x	WPI9			Productivity Index based on the value of WBP9. See Note 1.
x		WHD			Hydraulic head in well based on the reference depth given in <a href="#">HYDRHEAD</a> and the well's reference depth. Requires Water Services license.
x		WHDF			Hydraulic head in well based on the reference depth given in <a href="#">HYDRHEAD</a> and the well's reference depth calculated at freshwater conditions. Requires Water Services license.

Table 2.20: Well pressures and PIs

The well and group control options are:

E100	E300	Field	Group	Well	Information
x	x			WSTAT	Well State Indicator: 1.0 = PROD (Producer), 2.0 = INJ (Injector), 3.0 = SHUT (Shut for reasons other than priority control), 4.0 = STOP (Stopped for reasons other than priority control), 5.0 = PSHUT (Priority Shut), 6.0 = PSTOP (Priority Stop).  The output is rendered as mnemonics in the .RSM file.

E100	E300	Field	Group	Well	Information
x	x			WMCTL	<p>Mode of Control:</p> <p>0.0 = SHUT/STOP,</p> <p>1.0 = ORAT,</p> <p>2.0 = WRAT,</p> <p>3.0 = GRAT,</p> <p>4.0 = LRAT,</p> <p>5.0 = RESV,</p> <p>6.0 = THP,</p> <p>7.0 = BHP,</p> <p>9.0 = CRAT,</p> <p>11.0 = GOR Penalty,</p> <p>12.0 = Drawdown,</p> <p>13.0 = NGL,</p> <p>30.0 = Availability,</p> <p>31.0 = REIN,</p> <p>32.0 = TMRA,</p> <p>33.0 = WGRA,</p> <p>34.0 = CVAL,</p> <p>-1.0 = well under group control (ECLIPSE 300),</p> <p>-ve if rate target was set by group (ECLIPSE 100),</p> <p>41.0 = STRA (Thermal: Steam Rate),</p> <p>42.0 = SATP (Thermal: Saturated Pressure),</p> <p>43.0 = SATT (Thermal: Saturated Temperature).</p> <p>The output is rendered as mnemonics in the .RSM file.</p>

E100	E300	Field	Group	Well	Information
x	x	FMCTP	GMCTP		<p>Mode of Control for group Production:</p> <p>0.0 = NONE,            1.0 = ORAT,            2.0 = WRAT,            3.0 = GRAT,            4.0 = LRAT,            5.0 = RESV,            6.0 = PRBL,            7.0 = ENERGY,            8.0 = WGRA,            9.0 = CRAT (E100), 9.0 = CVAL (E300),            10.0=PBGS,            11.0=PBWS,            12.0 = CRAT (E300),            -ve if rate target was set by higher group.</p> <p>The output is rendered as mnemonics in the .RSM file.</p>

E100	E300	Field	Group	Well	Information
x	x	FMCTG	GMCTG		Mode of Control for group Gas Injection: 0.0 = NONE, 1.0 = RATE, 2.0 = RESV, 3.0 = REIN, 4.0 = VREP, 8.0 = WGRA, 9.0 = Availability, -ve if rate target was set by higher group. The output is rendered as mnemonics in the .RSM file.

Table 2.21: Well and group control modes

The group well count options are:

E100	E300	Field	Group	Well	Information
x	x	FMWPT	GMWPT		Total number of production wells
x	x	FMWPR	GMWPR		Number of production wells currently flowing
x	x	FMWPA	GMWPA		Number of abandoned production wells
x	x	FMWPU	GMWPU		Number of unused production wells
x	x	FMWPG	GMWPG		Number of producers on group control
x	x	FMWPO	GMWPO		Number of producers controlled by own oil rate limit
x	x	FMWPS	GMWPS		Number of producers on own surface rate limit control
x	x	FMWPV	GMWPV		Number of producers on own reservoir volume rate limit control
x	x	FMWPP	GMWPP		Number of producers on pressure control
x		FMWPL	GMWPL		Number of producers using artificial lift (with ALQ > 0.0)
x	x	FMWIT	GMWIT		Total number of injection wells
x	x	FMWIN	GMWIN		Number of injection wells currently flowing
x	x	FMWIA	GMWIA		Number of abandoned injection wells
x	x	FMWIU	GMWIU		Number of unused injection wells
x	x	FMWIG	GMWIG		Number of injectors on group control
x	x	FMWIS	GMWIS		Number of injectors on own surface rate limit control
x	x	FMWIV	GMWIV		Number of injectors on own reservoir volume rate limit control
x	x	FMWIP	GMWIP		Number of injectors on pressure control
x	x			WMCON	The number of connections capable of flowing in the well
x	x	FMWDR	GMWDR		Number of drilling events this timestep
x	x	FMWDT	GMWDT		Number of drilling events in total

E100	E300	Field	Group	Well	Information
x	x	FMWWO	GMWWO		Number of workover events this timestep
x	x	FMWWT	GMWWT		Number of workover events in total
	x		GMWL		Number of wells grouped together in a well list (either static or dynamic)

Table 2.22: Group well counts

The well and group energy rate options are:

E100	E300	Field	Group	Well	Information
x	x	FEPR	GEPR	WEPR	Energy Production Rate
x	x	FEPT	GEPT	WEPT	Energy Production Total
	x	FEIR	GEIR	WEIR	Energy Injection Rate
	x	FEIT	GEIT	WEIT	Energy Injection Total
	x	FHTR		WHTR	Heater energy rate (WHTR requires heater names)
	x	FHTT		WHTT	Heater energy total (WHTT requires heater names)
	x			WENE	Molar Energy (specified)
	x			WENO	Molar Energy of oil (specified)
	x			WENG	Molar Energy of gas (specified)
	x			WENW	Molar Energy of water (specified)
	x			WAEN	Molar Energy (actual)
	x			WAEO	Molar Energy of oil (actual)
	x			WAEG	Molar Energy of gas (actual)
	x			WAEW	Molar Energy of water (actual)
	x			WENR	Energy Rate
	x			WEOR	Energy rate for oil
	x			WEGR	Energy rate for gas
	x			WEWR	Energy rate for water
	x			WENT	Cumulative energy
	x			WERO	Ratio of oil energy to total energy
	x			WERG	Ratio of gas energy to total energy
	x			WERW	Ratio of water energy to total energy
	x			WPOFF	Difference between the bottom hole pressure and the highest water saturation pressure in the grid blocks connected to the well
	x			WTOFF	Difference between the water saturation temperature at the bottom hole pressure and the hottest grid block connected to the well

E100	E300	Field	Group	Well	Information
	x			WTSUB	Difference between the water saturation temperature at the bottom hole pressure and the well bore temperature at the bottom hole reference point

Table 2.23: Well and group energy rates

The solid production totals mnemonics are:

E300	Field	Group	Well	Information
x	F <sub>SMR</sub>	G <sub>SMR</sub>	W <sub>SMR</sub>	Solid mass production rate
x	F <sub>SMT</sub>	G <sub>SMT</sub>	W <sub>SMT</sub>	Solid mass production total
x	F <sub>SVR</sub>	G <sub>SVR</sub>	W <sub>SVR</sub>	Solid volume production rate
x	F <sub>SVT</sub>	G <sub>SVT</sub>	W <sub>SVT</sub>	Solid volume production total

Table 2.24: Solid production totals (ECLIPSE 300 Solid option)

## Miscellaneous well and group quantities

The miscellaneous well and group quantity options are given in the table below. Notes for this table:

- See “Format of SUMMARY keywords with a component index”.

E100	E300	Field	Group	Well	Connection	Information
x	x				CDSM	Current mass of scale deposited
x	x				CDSML	Current mass of scale deposited per unit perforation length
x	x				CDSF	PI multiplicative factor due to scale damage
x	x		GEFF	WEFF		Efficiency Factor
x	x			WEFFG		Product of efficiency factors of the well and all its superior groups
x				WALQ		Well Artificial Lift Quantity
x	x			WMVFP		VFP table number used by the well
	x	FNLPR	GNLPR	WNLPR		NGL Production Rate
	x	FNLPT	GNLPT	WNLPT		NGL Production Total
	x	FNLPRH	GNLPRH	WNLPRH		NGL Production Rate History ( <a href="#">WCONHIST</a> )
	x	FNLPTH	GNLPTH	WNLPTH		NGL Production Total History ( <a href="#">WCONHIST</a> )
	x			WNLprt		NGL Production Rate Target

E100	E300	Field	Group	Well	Connection	Information
	x	FAMF	GAMF	WAMF	CAMF	Component aqueous mole fraction, from producing completions. Note that the mnemonic CAMF is only compatible with the multi-component water COMPW option. The other mnemonics are compatible with the CO2SOL / H2SSOL / GASSOL / KWTABTn / CO2STORE with THERMAL options, in addition to the multi-component water option. See Note 1.
	x	FXMF	GXMF	WXMF		Liquid Mole Fraction. Group and Field level mnemonics only include production wells. See Note 1.
	x	FYMF	GYMF	WYMF		Vapor Mole Fraction. Group and Field level mnemonics only include production wells. See Note 1.
	x	FXMF <sup>n</sup>	GXMF <sup>n</sup>	WXMF <sup>n</sup>		Liquid Mole Fraction for nth separator stage (n = 1 to 99). Group and Field level mnemonics only include production wells. See Note 1.
	x	FYMF <sup>n</sup>	GYMF <sup>n</sup>	WYMF <sup>n</sup>		Vapor Mole Fraction for nth separator stage (n = 1 to 99). Group and Field level mnemonics only include production wells. See Note 1.
	x	FZMF	GZMF	WZMF	CZMF	Total Mole Fraction. Group and Field level mnemonics only include production wells. See Note 1.
	x	FCMPR	GCMPR	WCMPR		Hydrocarbon Component Molar Production Rates. See Note 1.
	x	FCMPT	GCMPT	WCMPT		Hydrocarbon Component Molar Production Totals. For a well that is both injecting and producing, the total component molar production has to exceed the total component molar injection before a value is reported. See Note 1.
	x	FCMIR	GCMIR	WCMIR		Hydrocarbon Component Molar Injection Rates. See Note 1.
	x	FCMIT	GCMIT	WCMIT		Hydrocarbon Component Molar Injection Totals. For a well that is both producing and injecting, the total component molar injection has to exceed the total component molar production for a value to be reported. See Note 1.
	x			WCGIR		Hydrocarbon Component Gas Injection Rate. See Note 1.
	x			WCGPR		Hydrocarbon Component Gas Production Rate. See Note 1.

E100	E300	Field	Group	Well	Connection	Information
	x			WCOPR		Hydrocarbon Component Oil Production Rate. See Note 1.
	x	FHMIR	GHMIR	WHMIR		Hydrocarbon Molar Injection Rate
	x	FHMIT	GHMIT	WHMIT		Hydrocarbon Molar Injection Total
	x	FHMPR	GHMPR	WHMPR		Hydrocarbon Molar Production Rate
	x	FHMPT	GHMPT	WHMPT		Hydrocarbon Molar Production Total
	x	FCHMR	GCHMR	WCHMR	CKFR	Hydrocarbon Component Molar Flow Rate. See Note 1.
	x	FCHMT	GCHMT	WCHMT	CKFT	Hydrocarbon Component Molar Flow Total. See Note 1.
	x	FCWGPR	GCWGPR	WCWGPR		Hydrocarbon Component Wet Gas Production Rate. See Note 1.
	x	FCWGPT	GCWGPT	WCWGPT		Hydrocarbon Component Wet Gas Production Total. See Note 1.
	x	FCWGIR	GCWGIR	WCWGIR		Hydrocarbon Component Wet Gas Injection Rate. See Note 1.
	x	FCWGIT	GCWGIT	WCWGIT		Hydrocarbon Component Wet Gas Injection Total. See Note 1.
	x	FCGMR	GCGMR	WCGMR		Hydrocarbon component molar rates in the gas phase. See Note 1.
	x	FCGMT	GCGMT	WCGMT		Hydrocarbon component molar totals in the gas phase. See Note 1.
	x	FCOMR	GCOMR	WCOMR		Hydrocarbon component molar rates in the oil phase. See Note 1.
	x	FCOMT	GCOMT	WCOMT		Hydrocarbon component molar totals in the oil phase. See Note 1.
	x	FCNMR	GCNMR	WCNMR		Hydrocarbon component molar rates in the NGL phase. See Note 1.
	x	FCNWR	GCNWR	WCNWR		Hydrocarbon component mass rates in the NGL phase
	x	FCGMRn	GCGMRn	WCGMRn		Hydrocarbon component molar rates in the gas phase for nth separator stage (n = 1 to 9). See Note 1.
	x	FCGRn	GGRn	WGRn		Hydrocarbon component molar rates in the gas phase for nth separator stage (n = 1 to 99). See Note 1.
	x	FCOMRn	GCOMRn	WCOMRn		Hydrocarbon component molar rates in the oil phase for nth separator stage (n = 1 to 9). See Note 1.
	x	FCORn	GORn	WORn		Hydrocarbon component molar rates in the oil phase for nth separator stage (n = 1 to 99). See Note 1.

E100	E300	Field	Group	Well	Connection	Information
	x	FMUF	GMUF	WMUF		Make-up fraction (calculated at reinjecting wells)
	x	FAMR	GAMR			Make-up gas rate (calculated at source of reinjection gas)
	x	FAMT	GAMT			Make-up gas total (calculated at source of reinjection gas)
x	x				CDFAC	D-factor for flow dependent skin factor
x	x			WTHT		Tubing Head Temperature
	x			WMMW		Mean molecular weight of wellstream
x	x	FGSPR	GGSPR			Target sustainable rate for most recent sustainable capacity test for gas.
x	x	FGSRL	GGSRL			Maximum tested rate sustained for the test period during the most recent sustainable capacity test for gas.
x	x	FGSRU	GGSRU			Minimum tested rate not sustained for the test period during the most recent sustainable capacity test for gas.
x	x	FGSSP	GGSSP			Period for which target sustainable rate could be maintained for the most recent sustainable capacity test for gas. If the target sustainable rate was maintained for the entire test period, this is equal to the test period.
x	x	FGSTP	GGSTP			Test period for the most recent sustainable capacity test for gas.
x	x	FOSPR	GOSPR			Target sustainable rate for most recent sustainable capacity test for oil.
x	x	FOSRL	GOSRL			Maximum tested rate sustained for the test period during the most recent sustainable capacity test for oil.
x	x	FOSRU	GOSRU			Minimum tested rate not sustained for the test period during the most recent sustainable capacity test for oil.
x	x	FOSSP	GOSSP			Period for which target sustainable rate could be maintained for the most recent sustainable capacity test for oil. If the target sustainable rate was maintained for the entire test period, this is equal to the test period.
x	x	FOSTP	GOSTP			Test period for the most recent sustainable capacity test for oil.
x	x	FWSPR	GWSPR			Target sustainable rate for most recent sustainable capacity test for water.

E100	E300	Field	Group	Well	Connection	Information
x	x	FWSRL	GWSRL			Maximum tested rate sustained for the test period during the most recent sustainable capacity test for water.
x	x	FWSRU	GWSRU			Minimum tested rate not sustained for the test period during the most recent sustainable capacity test for water.
x	x	FWSSP	GWSSP			Period for which target sustainable rate could be maintained for the most recent sustainable capacity test for water. If the target sustainable rate was maintained for the entire test period, this is equal to the test period.
x	x	FWSTP	GWSTP			Test period for the most recent sustainable capacity test for water.
	x	FGPRG	GGPRG			Gas production rate (production summed then separated)
	x	FOPRG	GOPRG			Oil production rate (production summed then separated)
	x	FNLPRG	GNLPRG			NGL production rate (production summed then separated)
	x	FXMFG	GXMFG			Liquid mole fraction (production summed then separated). See Note 1.
	x	FYMFG	GYMFG			Vapor mole fraction (production summed then separated). See Note 1.
	x	FCOMRG	GCOMRG			Hydrocarbon component molar rates in the oil phase (production summed then separated). See Note 1.
	x	FCGMRG	GCGMRG			Hydrocarbon component molar rates in the gas phase (production summed then separated). See Note 1.
	x	FCNMRG	GCNMRG			Hydrocarbon component molar rates in the NGL phase (production summed then separated). See Note 1.
x	x			WPWE0		Well drilled indicator. Set to one if the well was drilled this timestep and zero at other times.
x	x			WPWE1		Connections opened indicator. Set to the number of connections opened in the well this timestep if the well is not shut or stopped.
x	x			WPWE2		Connections closed indicator. Set to the number of connections closed in the well this timestep. This will not include connections closed by a CON+ workover.

E100	E300	Field	Group	Well	Connection	Information
x	x			WPWE3		Connections closed to bottom indicator. Set to 1 if all connections are closed by CON workovers, or if all connections below a connection are closed by a CON+ workover. Set to zero at other timesteps.
x	x			WPWE4		Well stopped indicator. Set to one if the well is stopped this timestep and zero otherwise.
x	x			WPWE5		Injector to producer indicator. Set to one if the well is switched from being an injector to a producer this timestep. Set to zero otherwise.
x	x			WPWE6		Producer to injector indicator. Set to one if the well is switched from being a producer to an injector this timestep. Set to zero otherwise.
x	x			WPWE7		Well shut indicator. Set to one if the well is shut this timestep and zero otherwise.
x	x			WPWEM		<a href="#">WELEVNT</a> output mnemonic.
x	x			WDRPR		Well drilling priority.
x	x			WBHWCn		Derivative of well BHP with respect to parameter n (n=1 to 99). See <a href="#">GWRTWCV</a> .
x	x			WGFWCn		Derivative of well gas flow rate with respect to parameter n, n=1 to 99. See <a href="#">GWRTWCV</a> .
x	x			WOFWCn		Derivative of well oil flow rate with respect to parameter n, n=1 to 99. See <a href="#">GWRTWCV</a> .
x	x			WWFWCn		Derivative of water flow rate with respect to parameter n, n=1 to 99. See <a href="#">GWRTWCV</a> .

Table 2.25: Miscellaneous well and group quantities

ECLIPSE 300 Thermal

The miscellaneous well quantity options are:

E300	Field	Group	Well	Information
x			WSQU	Injected steam quality
x			WTEMP	Temperature
x	FSTPR	GSTPR	WSTPR	Steam production rate
x	FSTPT	GSTPT	WSTPT	Steam production total
x	FOSRC	GOSRC		Cumulative oil steam ratio
x	FSORC	GSORC		Cumulative steam oil ratio
x	FHSRC	GHSRC		Cumulative hydrocarbon steam ratio
x	FSHRC	GSHRC		Cumulative steam hydrocarbon ratio

Table 2.26: Miscellaneous well quantities (ECLIPSE 300 Thermal)

## Secondary group and well quantities (ECLIPSE 300)

The secondary group and well quantities are:

E300	Field	Group	Well	Information
x			WDOPR	Secondary well oil production rate.
x			WDWPR	Secondary well water production rate.
x			WDGPR	Secondary well gas production rate.
x			WDLPR	Secondary well liquid production rate.
x			WDVPR	Secondary well reservoir volume production rate.
x			WDOPT	Secondary well oil production total.
x			WDWPT	Secondary well water production total.
x			WDGPT	Secondary well gas production total.
x			WDLPT	Secondary well liquid production total.
x			WDVPT	Secondary well reservoir volume production total.
x			WDWIR	Secondary well water injection rate.
x			WDGIR	Secondary well gas injection rate.
x			WDWIT	Secondary well water injection total.
x			WDGIT	Secondary well gas injection total.
x			WDOGR	Secondary well oil-gas ratio.
x			WDGOR	Secondary well gas-oil ratio.
x			WDGLR	Secondary well gas-liquid ratio.
x			WDWGR	Secondary well water-gas ratio.
x			WDWCT	Secondary well water cut.
x			WDTEM	Secondary well temperature.
x			WDPR	Secondary well pressure.
x	FDOPR	GDOPR		Oil production rate including secondary well contributions.
x	FDWPR	GDWPR		Water production rate including secondary well contributions.
x	FDGPR	GDGPR		Gas production rate including secondary well contributions.
x	FDLPR	GDLPR		Liquid production rate including secondary well contributions.
x	FDVPR	GDVPR		Reservoir volume production rate including secondary well contributions.
x	FDOPT	GDOPT		Oil production total including secondary well contributions.
x	FDWPT	GDWPT		Water production total including secondary well contributions.
x	FDGPT	GDGPT		Gas production total including secondary well contributions.
x	FDLPT	GDLPT		Liquid production total including secondary well contributions.
x	FDWIR	GDWIR		Water injection rate including secondary well contributions
x	FDGIR	GDGIR		Gas injection rate including secondary well contributions.
x	FDWIT	GDWIT		Water injection total including secondary well contributions.

E300	Field	Group	Well	Information
x	FDGIT	GDGIT		Gas injection total including secondary well contributions.
x	FDOGR	GDOGR		Oil-gas ratio including secondary well contributions.
x	FDGOR	GDGOR		Gas-oil ratio including secondary well contributions.
x	FDGLR	GDGLR		Gas-liquid ratio including secondary well contributions.
x	FDWGR	GDWGR		Water-gas ratio including secondary well contributions.
x	FDWCT	GDWCT		Water cut including secondary well contributions.

Table 2.27: Secondary group and well quantities (ECLIPSE 300)

## Well list quantities

The well list quantity options are:

E300	Well list	Information
x	GOPR	Oil Production Rate
x	GOPT	Oil Production Total
x	GWPR	Water Production Rate
x	GWPT	Water Production Total
x	GWIR	Water Injection Rate
x	GWIT	Water Injection Total
x	GGPR	Gas Production Rate
x	GGPT	Gas Production Total
x	GGIR	Gas Injection Rate
x	GGIT	Gas Injection Total
x	GVPR	Voidage Production Rate
x	GVPT	Voidage Production Total
x	GVIR	Voidage Injection Rate
x	GVIT	Voidage Injection Total
x	GLPR	Liquid Production Rate
x	GLPT	Liquid Production Total
x	GGOR	Gas to Oil Ratio
x	GAGR	Oil to Gas Ratio
x	GWCT	Water Cut
x	GWGR	Water to Gas Ratio
x	GGLR	Gas to Liquid Ratio
x	GOPRH	Oil Production Rate History ( <a href="#">WCONHIST</a> )
x	GGPRH	Gas Production Rate History ( <a href="#">WCONHIST</a> )
x	GWPRH	Water Production Rate History ( <a href="#">WCONHIST</a> )
x	GLPRH	Liquid Production Rate History ( <a href="#">WCONHIST</a> )

E300	Well list	Information
x	GOPH	Oil Production Total History (WCONHIST)
x	GGPH	Gas Production Total History (WCONHIST)
x	GWPH	Water Production Total History (WCONHIST)
x	GLPH	Liquid Production Total History (WCONHIST)
x	GGIRH	Gas Injection Rate (WCONINJE)
x	GWIRH	Water Injection Rate (WCONINJE)
x	GGITH	Gas Injection Total (WCONINJE)
x	GWITH	Water Injection Total (WCONINJE)

Table 2.28: Well list quantities (ECLIPSE 300)

## Grid block and region quantities

The grid block and region oil quantity options given in the table below. Notes for this table:

1. See "Initial fluid in place".
2. See "Format of SUMMARY keywords with a component index".

E100	E300	Field	Region	Block	Information
x	x			BOSAT	Oil SATuration
x	x			BSOIL	Oil Saturation (same as BOSAT)
	x			BSOILM	Mobile Oil Saturation (SOR option)
	x			BSOILR	Residual Oil Saturation (SOR option)
	x			BCOILR	Residual Oil compressibility (SOR option)
x	x	FOSAT	ROSAT		Oil SATuration average value
x	x	FOIP	ROIP	BOIP	Oil In Place (in liquid and wet gas phases). See Note 1.
x	x	FOIPL	ROIPL	BOIPL	Oil In Place (Liquid phase). See Note 1.
x	x	FOIPG	ROI PG	BOIPG	Oil In Place (Gas phase). See Note 1.
	x	FOIPR			Oil Reservoir Volume in Place
	x	FCOM	RCOM		Molar amount of specified component dissolved in oil. See Note 2.
	x	FOIPA	ROI PA		Oil in Place above TRACK depth. See Note 1.
	x	FOIPB	ROI PB		Oil in Place below TRACK depth. See Note 1.
x	x	FPPO	RPPO	BPPO	Oil Potential (or "depth corrected pressure")
x	x			BVOIL	Oil Viscosity
x	x			BOVIS	Oil VIScosity (same as BVOIL)
x		FOVIS	ROI VIS		Oil VIScosity average value
x	x			BDENO	Oil reservoir Density
x	x			BODEN	Oil reservoir DENsity (same as BDENO)

E100	E300	Field	Region	Block	Information
x		FODEN	RODEN		Oil reservoir DENsity average value
	x			BBOIL	Oil Reservoir Molar Densities
	x			BFUGO	Hydrocarbon component FUGacities in Oil ( <a href="#">DIFFUSE</a> option only, see Note 2).
x			ROP		Net oil production from a region
x	x		ROPR		Oil Production Rate. In ECLIPSE 300, this is calculated as the sum of (connection molar rate multiplied by well separator oil rate per mole) for all connections in the region.
x	x		ROPT		Oil Production Total
x	x		ROIR		Oil Injection Rate
x	x		ROIT		Oil Injection Total
x	x			BFLOOI	Inter-block oil flow rate in the positive I direction. This value is, by default, calculated based on the first FIP set.
x	x			BFLOOJ	Inter-block oil flow rate in the positive J direction. This value is, by default, calculated based on the first FIP set.
x	x			BFLOOK	Inter-block oil flow rate in the positive K direction. This value is, by default, calculated based on the first FIP set.
x				BVELOI	Oil velocity for positive I direction.
x				BVELOJ	Oil velocity for positive J direction.
x				BVELOK	Oil velocity for positive K direction.

Table 2.29: Grid block and region oil quantities

The grid block and region water quantity options are given in the table below. Notes for this table:

1. See [“Format of SUMMARY keywords with a component index”](#).

E100	E300	Field	Region	Block	Information
x	x			BWSAT	Water SATuration
x	x			BSWAT	Water Saturation (same as BWSAT)
x	x	FWSAT	RWSAT		Water SATuration average value
x	x	FWIP	RWIP	BWIP	Water In Place
	x		RNLIP		NGL In Place
	x	FWIPR			Water Reservoir Volume in Place
	x	FCWM	RCWM		Molar amount of specified component dissolved in water. See Note 1.
	x	FWCD	RWCD		CO <sub>2</sub> (“carbon dioxide”) dissolved in water phase ( <a href="#">CO2STORE</a> option only)
x	x	FPPW	RPPW	BPPW	Water Potential (or “depth corrected pressure”)
x	x			BVWAT	Water Viscosity
x	x			BWVIS	Water VIScosity (same as BVWAT)

E100	E300	Field	Region	Block	Information
x		FWVIS	RWVIS		Water VIScosity average value
x	x			BDENW	Water reservoir Density
x	x			BWDEN	Water reservoir DENsity (same as BDENW)
x		FWDEN	RWDEN		Water reservoir DENsity average value
	x			BBWAT	Water Reservoir Molar Densities
	x			BXWAT	Fractional Saturation of Water (Gravity Drainage Option only)
x			RWP		Net water production from a region (minus injection from wells and analytic aquifers)
x	x		RWPR		Water Production Rate
x	x		RWPT		Water Production Total
x	x		RWIR		Water Injection Rate
x	x		RWIT		Water Injection Total
x	x			BFLOWI	Inter-block water flow rate in the positive I direction.
x	x			BFLOWJ	Inter-block water flow rate in the positive J direction.
x	x			BFLOWK	Inter-block water flow rate in the positive K direction.
x				BVELWI	Water velocity in the positive I direction.
x				BVELWJ	Water velocity in the positive J direction.
x				BVELWK	Water velocity in the positive K direction.

Table 2.30: Grid block and region water quantities

The grid block and region gas quantity options are given in the table below. Notes for this table:

1. See ["Initial fluid in place"](#).
2. See ["Format of SUMMARY keywords with a component index"](#).

E100	E300	Field	Region	Block	Information
x	x			BGSAT	Gas SATuration
x	x			BSGAS	Gas Saturation (same as BGSAT)
x	x	FGSAT	RGSAT		Gas SATuration average value
x	x	FGIP	RGIP	BGIP	Gas In Place (in liquid and gas phases). See Note 1.
x	x	FGIPL	RGIPL	BGIPL	Gas In Place (Liquid phase). See Note 1.
x	x	FGIPG	RGIPG	BGIPG	Gas In Place (Gas phase). See Note 1.
	x	FAGIP			Gas In Place (Aqueous phase) (compatible with <a href="#">CO2SOL</a> , <a href="#">H2SSOL</a> and <a href="#">GASSOL</a> )
	x	FGIPA	RGIPA		Gas in Place above <a href="#">TRACK</a> depth. See Note 1.
	x	FGIPB	RGIPB		Gas in Place below <a href="#">TRACK</a> depth. See Note 1.
	x	FGIPR			Gas Reservoir Volume in Place

E100	E300	Field	Region	Block	Information
	x	FCGMI	RCGMI		Molar amount of specified component trapped in gas. See Note 2.
	x	FCGMM	RCGMM		Molar amount of specified component mobile in gas. See Note 2.
	x	FGCDI	RGCDI		CO <sub>2</sub> (“carbon dioxide”) trapped (immobile) in gas phase (CO2STORE option only)
	x	FGCDM	RGCDM		CO <sub>2</sub> (“carbon dioxide”) mobile in gas phase (CO2STORE option only)
x	x	FPPG	RPPG	BPPG	Gas Potential (or “depth corrected pressure”)
x	x			BVGAS	Gas Viscosity
x	x			BGVIS	Gas VISCosity (same as BVGAS)
x		FGVIS	RGVIS		Gas VISCosity average value
x	x			BDENG	Gas reservoir Density
x	x			BGDEN	Gas reservoir DENsity (same as BDENG)
x		FGDEN	RGDEN		Gas reservoir DENsity average value
	x			BBGAS	Gas Reservoir Molar Densities
	x			BFUGG	Hydrocarbon component FUGacities in Gas (DIFFUSE option only, see Note 2)
	x			BXGAS	Fractional Saturation of Gas (Gravity Drainage Option only)
x			RGP		Net gas production from a region (minus injection)
x	x		RGPR		Gas Production Rate. In ECLIPSE 300, this is calculated as the sum of (connection molar rate multiplied by well separator gas rate per mole) for all connections in the region.
x			RGPRF		Free Gas Production Rate
x			RGPRS		Solution Gas Production Rate
x	x		RGPT		Gas Production Total
x			RGPTF		Free Gas Production Total
x			RGPTS		Solution Gas Production Total
x	x		RGIR		Gas Injection Rate
x	x		RGIT		Gas Injection Total
	x		RNLPR		NGL Production Rate
	x		RNLPT		NGL Production Total
x	x			BFLOGI	Inter-block gas flow rate in the positive I direction. This value is, by default, calculated based on the first FIP set.
x	x			BFLOGJ	Inter-block gas flow rate in the positive J direction. This value is, by default, calculated based on the first FIP set.
x	x			BFLOGK	Inter-block gas flow rate in the positive K direction. This value is, by default, calculated based on the first FIP set.
x				BVELGI	Gas velocity in the positive I direction.

E100	E300	Field	Region	Block	Information
x				BVELGJ	Gas velocity in the positive J direction.
x				BVELGK	Gas velocity in the positive K direction.

Table 2.31: Grid block and region gas quantities

ECLIPSE 300

The grid block solid quantity options are:

E300	Block	Information
x	BBSOL	Solid reservoir molar density
x	BDENS	Solid Density
x	BHSOL	Solid molar enthalpy (Thermal option)
x	BSDEN	Solid DENSity (same as BDENS)
x	BSOLADS	Adsorbed solid concentration
x	BSOLADW	Adsorbed wetting-solid concentration
x	BSOLWET	Solid wettability interpolation parameter
x	BSSAT	Solid SATuration
x	BSSOLID	Solid Saturation (same as BSSAT)
x	BSSFRAC	Suspended Solid FRACTION
x	BSMMULT	Solid Mobility MULTiplier

Table 2.32: Grid block solid quantities (ECLIPSE 300)

The block mobility quantity options are: given in the table below. Notes for this table:

- See [“Format of SUMMARY keywords with a component index”](#).

E300	Block	Information
x	BGMCO	Generalized mobilities of hydrocarbon components in oil. See Note 1.
x	BGMCG	Generalized mobilities of hydrocarbon components in gas. See Note 1.
x	BGMCW	Generalized mobilities of water
x	BGMRV	Generalized mobilities of reservoir volume

Table 2.33: Block mobility quantities (ECLIPSE 300)

The inter-region flow quantity options are given in the table below. Notes for this table:

- See [“Format of SUMMARY keywords with a component index”](#).

E100	E300	Region	Information
	x	ROFR	Inter-region oil flow rate
	x	ROFR+	Inter-region oil flow rate (+ve contributions)
	x	ROFR-	Inter-region oil flow rate (-ve contributions)
	x	ROFT	Inter-region oil flow total (in liquid and wet gas phases)
	x	ROFT+	Inter-region oil flow total (in liquid and wet gas phases) (+ve contributions)
	x	ROFT-	Inter-region oil flow total (in liquid and wet gas phases) (-ve contributions)

E100	E300	Region	Information
x		ROFTL	Inter-region oil flow total (liquid phase)
x		ROFTG	Inter-region oil flow total (gas phase)
	x	RGFR	Inter-region gas flow rate
	x	RGFR+	Inter-region gas flow rate (+ve contributions)
	x	RGFR-	Inter-region gas flow rate (-ve contributions)
x	x	RGFT	Inter-region gas flow total (in liquid and gas phases)
	x	RGFT+	Inter-region gas flow total (in liquid and gas phases) (+ve contributions)
	x	RGFT-	Inter-region gas flow total (in liquid and gas phases) (-ve contributions)
		RGFTL	Inter-region gas flow total (liquid phase)
		RGFTG	Inter-region gas flow total (gas phase)
	x	RWFR	Inter-region water flow rate
	x	RWFR+	Inter-region water flow rate (+ve contributions)
	x	RWFR-	Inter-region water flow rate (-ve contributions)
x	x	RWFT	Inter-region water flow total
	x	RWFT+	Inter-region water flow total (+ve contributions)
	x	RWFT-	Inter-region water flow total (-ve contributions)
	x	RKFR	Inter-region component flow rates. See Note 1.
	x	RKFR+	Inter-region component flow rates (+ve contributions). See Note 1.
	x	RKFR-	Inter-region component flow rates (-ve contributions). See Note 1.
	x	RKFT	Inter-region component flow totals. See Note 1.
	x	RKFT+	Inter-region component flow totals (+ve contributions). See Note 1.
	x	RKFT-	Inter-region component flow totals (-ve contributions). See Note 1.
	x	REFR	Inter-region energy flow rates (Thermal option)
	x	REFR+	Inter-region energy flow rates (+ve contributions) (Thermal option)
	x	REFR-	Inter-region energy flow rates, (-ve contributions) (Thermal option)
	x	REFT	Inter-region energy flow totals (Thermal option)
	x	REFT+	Inter-region energy flow totals (+ve contributions) (Thermal option)
	x	REFT-	Inter-region energy flow totals (-ve contributions) (Thermal option)
	x	RNLFR	Inter-region NGL flow rates
	x	RNLFR+	Inter-region NGL flow rates (+ve contributions)
	x	RNLFR-	Inter-region NGL flow rates (-ve contributions)
	x	RNLFT	Inter-region NGL flow totals
	x	RNLFT+	Inter-region NGL flow totals (+ve contributions)
	x	RNLFT-	Inter-region NGL flow totals (-ve contributions)

Table 2.34: Inter-region flow quantities

**Note:** For some rare situations the reported regional flow total and the regional fluid in place changes might show some mismatch. In order to improve the reported value you can use `OPTIONS3` item 206.

The miscellaneous grid block and region quantity options are given in the table below. Notes for this table:

1. See “[Format of SUMMARY keywords with a component index](#)”.
2. See “[Aqueous speciation](#)” in the *ECLIPSE Technical Description*

E100	E300	Field	Region	Block	Information
x	x			BPR	Oil phase Pressure
				BPRESSUR	Oil phase Pressure (same as BPR)
x				BWPR	Water phase Pressure
x				BGPR	Gas phase Pressure
x	x	FPR	RPR		Pressure average value (same as FPRH/RPRH unless, for ECLIPSE 100, item 31 of OPTIONS is set)
x	x	FPRH	RPRH		Pressure average value (Hydrocarbon Pore-Volume Weighted)
x	x	FPRP	RPRP		Pressure average value (Pore-Volume Weighted)
x		FPRGZ	RPRGZ		P/Z (gas) average value weighted by gas content of blocks at surface conditions
x				BRS	Gas-oil ratio (in liquid phase)
x		FRS	RRS		Gas-oil ratio (in liquid phase) average value
x				BRV	Oil-gas ratio (in gas phase)
x		FRV	RRV		Oil-gas ratio (in gas phase) average value
	x	FCHIP			Component Hydrocarbon as Wet Gas. See Note 1.
	x	FCMIP			Component Hydrocarbon as Moles. See Note 1.
x				BPBUB	Bubble point pressure
x				BPDEW	Dew point pressure
x				BRSSAT	Saturated gas-oil ratio (in oil phase)
x				BRVSAT	Saturated oil-gas ratio (in gas phase)
x				BSTATE	Gas-oil state indicator. Hydrocarbon states are: 1 Gas only (with vaporized oil) 2 Gas and Oil 3 Oil only (with dissolved gas)
x		FPPC	RPPC	BPPC	Initial Contact Corrected Potential
x	x			BOKR	Oil relative permeability
x	x			BWKR	Water relative permeability
x	x			BGKR	Gas relative permeability
x	x			BKRO	Oil relative permeability
x	x			BKROG	Two-phase oil relative permeability to gas
x	x			BKROW	Two-phase oil relative permeability to water

E100	E300	Field	Region	Block	Information
x	x			BKRG	Gas relative permeability
	x			BKRGO	Two-phase gas relative permeability to oil (BAKER1, BAKER2 and IKU3P three-phase relative permeability models)
	x			BKRGW	Two-phase gas relative permeability to water (BAKER1, BAKER2 and IKU3P three-phase relative permeability models)
x	x			BKRW	Water relative permeability
	x			BKRWG	Two-phase water relative permeability to gas (BAKER1, BAKER2 and IKU3P three-phase relative permeability models)
	x			BKRWO	Two-phase water relative permeability to oil (BAKER1, BAKER2, and IKU3P three-phase relative permeability models)
x				BRK	Water relative permeability reduction factor due to polymer
x				BEWKR	Water effective relative permeability due to polymer
x	x			BWPC	Water-Oil capillary pressure
x	x			BGPC	Gas-Oil capillary pressure
	x			BPCO	Oil Capillary Pressures
	x			BPCG	Gas Capillary Pressures
	x			BPCW	Water Capillary Pressures
x	x			BGTRP	Trapped gas saturation (WAG hysteresis only)
x	x			BGTPD	Dynamic trapped gas saturation (WAG hysteresis only)
x				BGSHY	Departure saturation from drainage to imbibition for gas capillary pressure hysteresis
x				BGSTRP	Trapped gas critical saturation for gas capillary pressure hysteresis
x				BWSHY	Departure saturation from drainage to imbibition for water capillary pressure hysteresis
x				BWSMA	Maximum wetting saturation for water capillary pressure hysteresis. This also represents the maximum wetting phase saturation used to determine scanning curves in relative permeability hysteresis, whether the Carlson or Killough model is used.
	x			BMLSC	Hydrocarbon molar density (moles per reservoir volume). See Note 1. When the multi-component water option is enabled, the water components are allowed as described in the link above.
	x			BMLST	Total hydrocarbon molar density (moles per reservoir volume).

E100	E300	Field	Region	Block	Information
	x			BMWAT	Water molar density (moles per reservoir volume). When the multi-component water option is enabled, this relates to the last component.
	x			BROMLS	Residual oil moles/ reservoir volume ( <a href="#">SOR</a> option). See Note 1.
	x			BJV	In (K) values. See Note 1.
	x			BVMF	Vapor mole fraction.
	x			BPSAT	Saturation Pressures. The value depends on the cell hydrocarbon state: for single phase gas it will usually be the dew point pressure; for single phase oil it will usually be the bubble point pressure; for two phase cells it will be the cell pressure.
	x			BAMF	Component aqueous mole fraction. ( <a href="#">KWTABTn</a> , or <a href="#">CO2STORE</a> with <a href="#">THERMAL</a> , or <a href="#">CO2SOL</a> / <a href="#">H2SSOL</a> / <a href="#">GASSOL</a> and with multi-component water <a href="#">COMPW</a> options). See Note 1.
	x			BXMF	Liquid hydrocarbon component mole fraction. See Note 1.
	x			BYMF	Vapor hydrocarbon component mole fraction / vapor steam ( <a href="#">THERMAL</a> option) mole fraction. See Note 1.
	x			BSMF	( <a href="#">CO2STORE</a> with <a href="#">SOLID</a> option only) Solid hydrocarbon component mole fraction. See Note 1.
	x			BSTEN	Surface Tension.
	x			BFMISC	Miscibility Factor.
	x	FREAC		BREAC	Reaction rate. The reaction number is given as a component index. See Note 1.
	x	FREAT			Reaction total. The reaction number is given as a component index. See Note 1.
x				BHD	Hydraulic head.
x				BHDF	Hydraulic head at fresh water conditions.
x				BPR_X	Pressure interpolated at a defined coordinate.
x				BHD_X	Hydraulic head interpolated at a defined coordinate.
x				BHDF_X	Hydraulic head at fresh water conditions interpolated at a defined coordinate.
x				BSCN_X	Brine concentration interpolated at a defined coordinate.
x				BCTRA_X	Tracer concentration interpolated at a defined coordinate. Implies a tracer name TRA and this name needs to start with T
x				LBPR_X	Pressure interpolated at a defined coordinate within a local grid
x				LBHD_X	Hydraulic head interpolated at a defined coordinate within a local grid

E100	E300	Field	Region	Block	Information
x				LBHDF_X	Hydraulic head at freshwater conditions interpolated at a defined coordinate within a local grid
x				LBSCN_X	Brine concentration interpolated at a defined coordinate within a local grid.
x				LBCTRA_X	Tracer concentration interpolated at a defined coordinate within a local grid. Implies a tracer name TRA and this name needs to start with T
	x			BAQSP	(CO2STORE option only) Molar density of ions. See Note 2. The species number is given as component index. See Note 1. If no component number is given, all species are selected.
	x			BAQPH	(CO2STORE option only) Aqueous pH level. See Note 2.
	x			BBTFORG	Forchheimer beta factor for gas phase.
	x			BBTFORO	Forchheimer beta factor for oil phase.
	x			BKFRI	Inter-block component flow rate in the positive I direction. See Note 1.
	x			BKFRJ	Inter-block component flow rate in the positive J direction. See Note 1.
	x			BKFRK	Inter-block component flow rate in the positive K direction. See Note 1.

Table 2.35: Miscellaneous grid block and region quantities

The field, grid block and region quantity options are:

E300	Field	Region	Block	Information
x			BTEMP	Temperature
x			BENERGY	Internal energy/bulk volume
x			BHOIL	Molar Enthalpy of Oil
x			BHGAS	Molar Enthalpy of Gas
x			BHWAT	Molar Enthalpy of Water
x			BSPENOIL	Molar Energy of Oil
x			BSPENGAS	Molar Energy of Gas
x			BSPENWAT	Molar Energy of Water
x			BSPENROC	Specific Internal Energy of Rock
x			BGMEO	Enthalpy mobility of Oil
x			BGMEG	Enthalpy mobility of Gas
x			BGMEW	Enthalpy mobility of Water
x			BTCMULT	Saturation dependent conductivity factor
x			BSFOIL	Saturation of foamy oil. Calculated as the saturation of the components in the oil phase with gas-like compressibility types.

E300	Field	Region	Block	Information
x			BSFSOL	Saturation of foamy solids. Calculated as the saturation of the components in the solid phase with gas-like compressibility types.
x	FERCK	RERCK		Energy in Rock
x	FEOIL	REOIL		Energy in Oil
x	FEGAS	REGAS		Energy in Gas
x	FEWAT	REWAT		Energy in Water
x	FETOT	RETOT		Total Energy
x	FEAVE	REAVE		Average Energy Density
x	FERPC	RERPC		Energy Percentage in Rock
x	FEOPC	REOPC		Energy Percentage in Oil
x	FEGPC	REGPC		Energy Percentage in Gas
x	FEWPC	REWPC		Energy Percentage in Water

Table 2.36: Field, grid block, region quantities (ECLIPSE 300 Thermal)

The rock quantity options are:

E300	Field	Information
x	FHLR	Rate of heat loss to surrounding rocks.
x	FHLT	Cumulative heat loss to surrounding rocks.

Table 2.37: Rock quantities (ECLIPSE 300 Thermal)

The default average field pressure is the hydrocarbon pore volume weighted average defined as:

$$FPRH = \frac{\sum HCPV \cdot p}{\sum HCPV} \quad \text{Eq. 2.1}$$

where  $HCPV = PV(1-S_w)$  is the hydrocarbon pore volume and  $p$  is the oil phase pressure.

The pore volume weighted average pressure is defined as:

$$FPRP = \frac{\sum PV \cdot p}{\sum PV} \quad \text{Eq. 2.2}$$

The pore volumes used are those at reference conditions (that is uncompactd pore volumes).

The potential (or “depth corrected pressure”) average calculations are detailed in "Potential Calculations" in the *ECLIPSE Technical Description*.

ECLIPSE 100

The FPRGZ and RPRGZ keywords calculate the P/Z according to:

$$\frac{p}{Z} = \frac{\sum \left( PV \cdot \frac{S_g}{B_g} \right) \cdot \frac{T}{T_{sc}} \cdot \frac{P_{sc}}{B_g}}{\sum \left( PV \cdot \frac{S_g}{B_g} \right)} \quad \text{Eq. 2.3}$$

where  $S_g$  = gas saturation

$B_g$  = gas formation volume factor

$T$  = reservoir temperature (keyword [RTEMP](#))

$T_{sc}$  = temperature at standard conditions (288K=520R)

$P_{sc}$  = pressure at standard conditions (14.7psia)

## Equivalent directional keywords for relative permeabilities (ECLIPSE 100)

ECLIPSE 100

If any of the following options are active:

- Directional  $K_r$  ('DIRECT' in RUNSPEC keyword [SATOPTS](#))
- Directional End-Point Scaling ('DIRECT' in RUNSPEC keyword [ENDSCALE](#))
- Vertical Equilibrium (RUNSPEC keyword [VE](#))
- Two-point Upstreaming for miscible option ('TWOPOINT' in RUNSPEC keyword [MISCIBLE](#)),

the following keywords may be used:

E100	Block	Information
x	BOKRX	Oil relative permeability in the X direction.
x	BOKRX-	Oil relative permeability in the -X direction.
x	BOKRY	Oil relative permeability in the Y direction.
x	BOKRY-	Oil relative permeability in the -Y direction.
x	BOKRZ	Oil relative permeability in the Z direction.
x	BOKRZ-	Oil relative permeability in the -Z direction.
x	BWKRX	Water relative permeability in the X direction.
x	BWKRX-	Water relative permeability in the -X direction.
x	BWKRY	Water relative permeability in the Y direction.
x	BWKRY-	Water relative permeability in the -Y direction.
x	BWKRZ	Water relative permeability in the Z direction.
x	BWKRZ-	Water relative permeability in the -Z direction.
x	BGKRX	Gas relative permeability in the X direction.
x	BGKRX-	Gas relative permeability in the -X direction.
x	BGKRY	Gas relative permeability in the Y direction.
x	BGKRY-	Gas relative permeability in the -Y direction.
x	BGKRZ	Gas relative permeability in the Z direction.
x	BGKRZ-	Gas relative permeability in the -Z direction.
x	BOKRI	Oil relative permeability in the I direction.
x	BOKRI-	Oil relative permeability in the -I direction.
x	BOKRJ	Oil relative permeability in the J direction.
x	BOKRJ-	Oil relative permeability in the -J direction.
x	BOKRK	Oil relative permeability in the K direction.

E100	Block	Information
x	BOKRK-	Oil relative permeability in the -K direction.
x	BWKRI	Water relative permeability in the I direction.
x	BWKRI-	Water relative permeability in the -I direction.
x	BWKRJ	Water relative permeability in the J direction.
x	BWKRJ-	Water relative permeability in the -J direction.
x	BWKRK	Water relative permeability in the K direction.
x	BWKRK-	Water relative permeability in the -K direction.
x	BGKRI	Gas relative permeability in the I direction.
x	BGKRI-	Gas relative permeability in the -I direction.
x	BGKRJ	Gas relative permeability in the J direction.
x	BGKRJ-	Gas relative permeability in the -J direction.
x	BGKRK	Gas relative permeability in the K direction.
x	BGKRK-	Gas relative permeability in the -K direction.
x	BOKRR	Oil relative permeability in the R (RADIAL) direction.
x	BOKRR-	Oil relative permeability in the -R (RADIAL) direction.
x	BOKRT	Oil relative permeability in the T (THETA) direction.
x	BOKRT-	Oil relative permeability in the -T (THETA) direction.
x	BWKRR	Water relative permeability in the R (RADIAL) direction.
x	BWKRR-	Water relative permeability in the -R (RADIAL) direction.
x	BWKRT	Water relative permeability in the T (THETA) direction.
x	BWKRT-	Water relative permeability in the -T (THETA) direction.
x	BGKRR	Gas relative permeability in the R (RADIAL) direction.
x	BGKRR-	Gas relative permeability in the -R (RADIAL) direction.
x	BGKRT	Gas relative permeability in the T (THETA) direction.
x	BGKRT-	Gas relative permeability in the -T (THETA) direction.

Table 2.38: Block directional relative permeability quantities (ECLIPSE 100)

## Processed scaled end-points

Refer to "Output of scaled end-points" in the *ECLIPSE Technical Description*.

The processed scaled end-point block quantities are:

E300	Block	Information
x	BPSWL	Processed scaled connate water saturation
x	BPSWCR	Processed scaled critical water saturation
x	BPSWU	Processed scaled maximum water saturation
x	BPSGL	Processed scaled connate gas saturation

E300	Block	Information
x	BPSGCR	Processed scaled critical gas saturation
x	BPSGU	Processed scaled maximum gas saturation
x	BPSOWCR	Processed scaled critical oil-in-water saturation
x	BPSOGCR	Processed scaled critical oil-in-gas saturation
x	BPKRW	Processed scaled water relative permeability at maximum water saturation
x	BPKRG	Processed scaled gas relative permeability at maximum gas saturation
x	BPKRO	Processed scaled oil relative permeability at maximum oil saturation
x	BPKRWR	Processed scaled water relative permeability at residual oil saturation
x	BPKRGR	Processed scaled gas relative permeability at residual oil saturation
x	BPKRORG	Processed scaled oil relative permeability at critical gas saturation
x	BPKRORW	Processed scaled oil relative permeability at critical water saturation
x	BPPCG	Processed scaled maximum gas-oil capillary pressure
x	BPPCW	Processed scaled maximum water-oil capillary pressure

Table 2.39: Processed scaled end-points

## Reservoir volumes

The reservoir volume options are:

E100	E300	Field	Region	Block	Information
x	x	FRPV	RRPV	BRPV	Pore Volume at Reservoir conditions
	x			BPORV	Cell Pore Volumes at Reference conditions
x		FOPV	ROPV	BOPV	Pore Volume containing Oil
x		FWPV	RWPV	BWPV	Pore Volume containing Water
x		FGPV	RGPV	BGPV	Pore Volume containing Gas
x	x	FHPV	RHPV		Pore Volume containing Hydrocarbon (or “Hydrocarbon Pore Volume”)
x				BHPV	Pore Volume containing Hydrocarbon (as above)
x		FRTM	RRTM	BRTM	Transmissibility Multiplier associated with rock compaction
x	x			BPERMMOD	Transmissibility Multiplier associated with rock compaction (as above) If directional transmissibility multipliers are defined, this mnemonic (or BRTM in ECLIPSE 100) is equivalent to BPERMMDX.
x	x			BPERMMDX BPERMMDY BPERMMDZ	Directional Transmissibility Multipliers in the x, y and z directions respectively, associated with rock compaction. These keywords are available when <a href="#">RKTRMDIR</a> is defined in both ECLIPSE 100 and ECLIPSE 300, or when <a href="#">ROCKTRMX</a> , <a href="#">ROCKTRMY</a> and <a href="#">ROCKTRMZ</a> are defined in ECLIPSE 300.
x	x			BPORVMOD	Pore Volume Multiplier associated with rock compaction

E100	E300	Field	Region	Block	Information
x	x			BSIGMMOD	Dual Porosity Sigma Multiplier associated with rock compaction
	x			BPVDP	Pressure Derivatives of Pore Volumes
	x			BSVOL	Specific Volume of Fluids

Table 2.40: Reservoir volumes

## Oil recovery efficiencies

The oil recovery options are:

E100	E300	Field	Region	Information
x	x	FOE	ROE	$(OIP(\text{initial}) - OIP(\text{now})) / OIP(\text{initial})$
x	x	FOEW	ROEW	Oil Production from Wells / OIP(initial)
x	x	FOEIW	ROEIW	$(OIP(\text{initial}) - OIP(\text{now})) / \text{Initial Mobile Oil with respect to Water}$
x	x	FOEWW	ROEWW	Oil Production from Wells / Initial Mobile Oil with respect to Water
x	x	FOEIG	ROEIG	$(OIP(\text{initial}) - OIP(\text{now})) / \text{Initial Mobile Oil with respect to Gas}$
x	x	FOEWG	ROEWG	Oil Production from Wells / Initial Mobile Oil with respect to Gas

Table 2.41: Oil recovery efficiencies

## Oil recovery mechanism

The oil recovery mechanism options are:

E100	Field	Region	Information
x	FORMR	RORMR	Total stock tank oil produced by rock compaction
x	FORMW	RORMW	Total stock tank oil produced by water influx
x	FORMG	RORMG	Total stock tank oil produced by gas influx
x	FORME	RORME	Total stock tank oil produced by oil expansion
x	FORMS	RORMS	Total stock tank oil produced by solution gas
x	FORMF	RORMF	Total stock tank oil produced by free gas influx
x	FORMX	RORMX	Total stock tank oil produced by 'traced' water influx
x	FORMY	RORMY	Total stock tank oil produced by other water influx
x	FORFR	RORFR	Fraction of total oil produced by rock compaction
x	FORFW	RORFW	Fraction of total oil produced by water influx
x	FORFG	RORFG	Fraction of total oil produced by gas influx
x	FORFE	RORFE	Fraction of total oil produced by oil expansion
x	FORFS	RORFS	Fraction of total oil produced by solution gas
x	FORFF	RORFF	Fraction of total oil produced by free gas influx
x	FORFX	RORFX	Fraction of total oil produced by 'traced' water influx

E100	Field	Region	Information
x	FORFY	RORFY	Fraction of total oil produced by other water influx

Table 2.42: Oil recovery mechanism (ECLIPSE 100)

ECLIPSE 100

**Note:** The oil recovery mechanism keywords are not available in runs with vaporized oil present.

See also "Recovery Mechanisms" in the *ECLIPSE Technical Description*.

## Recovery plant options (ECLIPSE 300 only)

The recovery plant options are given in the table below. Notes for this table:

1. See "Format of SUMMARY keywords with a component index".

E300	Field	Information
x	FNRR	NGL recovery volume rate
x	FNRT	NGL recovery volume total
x	FNRM	NGL recovery molar rate
x	FGRR	Gas remaining volume rate
x	FGRT	Gas remaining volume total
x	FGRM	Gas remaining molar rate
x	FXNR	NGL recovery composition. See Note 1.
x	FYGR	Gas remaining composition. See Note 1.

Table 2.43: Keywords to obtain reports of recovered NGLs and gas (ECLIPSE 300 only)

## Analytic aquifer quantities

The analytic aquifer options are given in the table below. Notes for this table:

1. See "Format of SUMMARY keywords with a component index".

E100	E300	Field	Aquifer	Aquifer List	Information
x	x	FAQR	AAQR		Aquifer influx rate (for liquid aquifer)
x				ALQR	Aquifer influx rate (for liquid aquifer) (as above)
x	x	FAQT	AAQT		Cumulative aquifer influx (for liquid aquifer)
x				ALQT	Cumulative aquifer influx (for liquid aquifer) (as above)
x	x	FAQRG	AAQRG		Aquifer influx rate (for gas aquifer)
x				ALQRG	Aquifer influx rate (for gas aquifer) (as above)
x	x	FAQTG	AAQTG		Cumulative aquifer influx (for gas aquifer)
x				ALQTG	Cumulative aquifer influx (for gas aquifer) (as above)
	x		AACMR		Aquifer component molar influx rate (for multi-component aquifer). See Note 1.

E100	E300	Field	Aquifer	Aquifer List	Information
	x		AACMT		Aquifer component molar influx totals (for multi-component aquifer). See Note 1.
x	x		AAQP		Aquifer pressure (excludes constant flux aquifer as given by <a href="#">AQUFLUX</a> ).
	x	FAQER	AAQER		Aquifer thermal energy influx rate (Thermal option)
	x	FAQET	AAQET		Cumulative aquifer thermal energy influx (Thermal option)
	x		AAQTEMP		Aquifer temperature
	x		AAQENTH		Aquifer molar enthalpy (Thermal option)
x	x		AAQTD		Aquifer dimensionless time (Carter-Tracy aquifers only)
x	x		AAQPD		Aquifer dimensionless pressure (Carter-Tracy aquifers only)

Table 2.44: Analytic aquifer quantities

## Numerical aquifer quantities

The numerical aquifer options given in the table below. Notes for this table:

1. See “[Format of SUMMARY keywords with a component index](#)”.

E100	E300	Field	Aquifer	Information
x	x	FNQR	ANQR	Aquifer influx rate
x	x	FNQT	ANQT	Cumulative aquifer influx
x	x		ANQP	Aquifer pressure (average pressure weighted by water volume)
	x		ANCMR	Aquifer component molar influx rate. See Note 1.
	x		ANCMT	Aquifer component molar influx totals. See Note 1.

Table 2.45: Numerical aquifer quantities

## Tracer and API tracking quantities

The tracer and API tracking options are:

E100	E300	Field	Group	Well	Connection	Region	Block	Information
x	x				CTFR			Tracer Flow Rate (+ or -)
x	x	FTPR	GTPR	WTPR	CTPR			Tracer Production Rate
x	x	FTPT	GTPT	WTPT	CTPT			Tracer Production Total
x	x	FTPC	GTPC	WTPC	CTPC			Tracer Production Concentration
x	x	FTIR	GTIR	WTIR	CTIR			Tracer Injection Rate
x	x	FTIT	GTIT	WTIT	CTIT			Tracer Injection Total
x	x	FTIC	GTIC	WTIC	CTIC			Tracer Injection Concentration

E100	E300	Field	Group	Well	Connection	Region	Block	Information
	x	FTMR	GTMR	WTMR				Traced mass Rate
	x	FTMT	GTMT	WTMT				Traced mass Total
	x	FTQR	GTQR	WTQR				Traced molar Rate
	x	FTCM	GTCM	WTCM				Tracer Carrier molar Rate
	x	FTMF	GTMF	WTMF				Traced molar fraction
	x	FTVL	GTVL	WTVL				Traced liquid volume rate
	x	FTVV	GTVV	WTVV				Traced vapor volume rate
	x	FTTL	GTTL	WTTL				Traced liquid volume total
	x	FTTV	GTTV	WTTV				Traced vapor volume total
	x	FTML	GTML	WTML				Traced mass liquid rate
	x	FTMV	GTMV	WTMV				Traced mass vapor rate
	x	FTLM	GTLM	WTLM				Traced mass liquid total
	x	FTVM	GTVM	WTVM				Traced mass vapor total
x							BTCNF	Tracer Concentration (Free)
x							BTCNS	Tracer Concentration (Solution)
	x						BTCN	Tracer Concentration
x		FTIPT				RTIPT	BTIPT	Tracer In Place (Total)
x		FTIPF				RTIPF	BTIPF	Tracer In Place (Free)
x		FTIPS				RTIPS	BTIPS	Tracer In Place (Solution)
x						RTFTF		Tracer inter-region Flow Total (Free)
x						RTFTS		Tracer inter-region Flow Total (Solution)
x						RTFTT		Tracer inter-region Flow Total (Total)
x		FAPI	GAPI	WAPI	CAPI	RAPI	BAPI	Oil API (for API tracking). (F,G,W,C)API are for production wells

Table 2.46: Tracer and API tracking quantities

Keywords which belong specifically to the Tracer Tracking option (that is with T as the second letter in the list above) should be compounded with the name of the tracer to which they refer. For example, if the field production rate of a tracer called OL1 is required on the Summary files, then the keyword FTPROL1 should be used.

## Brine option quantities

The brine options are:

E100	E300	Field	Group	Well	Connection	Region	Block	Information
x	x				CSFR			Salt Flow Rate (+ or -)

E100	E300	Field	Group	Well	Connection	Region	Block	Information
x	x	FSPR	GSPR	WSPR	CSPR			Salt Production Rate
x	x	FSPT	GSPT	WSPT	CSPT			Salt Production Total
x	x	FSIR	GSIR	WSIR	CSIR			Salt Injection Rate
x	x	FSIT	GSIT	WSIT	CSIT			Salt Injection Total
x	x						BSCN	Salt Cell Concentration
x	x	FSPC	GSPC	WSPC	CSPC			Salt Production Concentration
x	x	FSIC	GSIC	WSIC	CSIC			Salt Injection Concentration
x	x	FSIP						Salt In Place
x						RSIP	BSIP	Salt In Place (as above)
x						RSFT		Salt inter-region Flow Total
x							BEWV_SAL	Effective water viscosity due to salt concentration. Does not apply if the Polymer option is active; in that case, this vector will always be zero.

Table 2.47: Brine option quantities

The outputs for the Multi-Component Brine are:

E100	Field	Group	Well	Connection	Block	Information
x				CTFRANI		Anion Flow Rate
x	FTPRANI	GTPRANI	WTPRANI			Anion Production Rate
x	FTPTANI	GTPTANI	WTPTANI	CTPTANI		Anion Production Total
x	FTIRANI	GTIRANI	WTIRANI			Anion Injection Rate
x	FTITANI	GTITANI	WTITANI	CTITANI		Anion Injection Total
x					BTCNFANI	Anion Flowing Concentration
x				CTFRCAT		Cation Flow Rate
x	FTPRCAT	GTPRCAT	WTPRCAT			Cation Production Rate
x	FTPTCAT	GTPTCAT	WTPTCAT	CTPTCAT		Cation Production Total
x	FTIRCAT	GTIRCAT	WTIRCAT			Cation Injection Rate
x	FTITCAT	GTITCAT	WTITCAT	CTITCAT		Cation Injection Total
x					BTCNFCAT	Cation Flowing Concentration
x					BTRADCAT	Cation Rock Associated Concentration
x					BTSADCAT	Cation Surfactant Associated Concentration.
x					BESALSUR	Effective Salinity with respect to Surfactant

E100	Field	Group	Well	Connection	Block	Information
x					BESALPLY	Effective Salinity art Polymer

Table 2.48: Outputs for Multi-Component Brine (ECLIPSE 100)

## Temperature option quantities

Information about the temperatures in the reservoir can be output to the Summary file in an analogous manner to the tracer output. For the heat equation the three-character mnemonic that should be appended to summary quantities is 'HEA'.

E100	Field	Group	Well	Region	Block	Description
x	FTPCH EA	GTPCH EA	WTPCH EA			Production Temperature
x	FTICHEA	GTICHEA	WTICHEA			Injection Temperature
x	FTPRHEA	GTPRHEA	WTPRHEA			Energy flows (Production)
x	FTPTHEA	GTPTHEA	WPTTHEA			Energy Production Total
x	FTIRHEA	GTIRHEA	WTIRHEA			Energy flows (Injection)
x	FTITHEA	GTITHEA	WTITHEA			Energy Injection Total
x					BTCNFHEA	Block Temperature
x	FTIPTHEA			RTIPTHEA	BTIPTHEA	Difference in Energy in place between current and initial time

Table 2.49: Summary output for Temperature option (ECLIPSE 100)

## Environmental tracers

The following keywords control output of data specific to tracers:

E100	E300	Field	Group	Well	Connection	Region	Block	Information
x	x				CTFR			Tracer Flow Rate (+ or -)
x	x	FTPR	GTPR	WTPR	CTPR			Tracer Production Rate
x	x	FTPT	GTPT	WTPT	CTPT			Tracer Production Total
x	x	FTPC	GTPC	WTPC	CTPC			Tracer Production Concentration
x	x	FTIR	GTIR	WTIR	CTIR			Tracer Injection Rate
x	x	FTIT	GTIT	WTIT	CTIT			Tracer Injection Total
x	x	FTIC	GTIC	WTIC	CTIC			Tracer Injection Concentration
x							BTCNF	Tracer Concentration (Free)
x							BTCNS	Tracer Concentration (Solution)
x							BTCN#	Tracer concentration in phase # (1,2,3,...)
x		FTIPT				RTIPT	BTIPT	Tracer In Place (Total)
x		FTIPF				RTIPF	BTIPF	Tracer In Place (Free)

E100	E300	Field	Group	Well	Connection	Region	Block	Information
x		FTIPS				RTIPS	BTIPS	Tracer In Place (Solution)
x		FTIP#				RTIP#	BTIP#	Tracer In Place in phase # (1,2,3,...)
x						RTFTT		Tracer inter-region Flow (Total)
x						RTFTF		Tracer inter-region Flow (Free)
x						RTFTS		Tracer inter-region Flow (Solution)
x						RTFT#		Tracer inter-region Flow in phase # (1,2,3,...)
x		FTADS				RTADS		Tracer Adsorption total
x							BTADS	Tracer Adsorption
x		FTDCY				RTDCY	BTDCY	Decayed tracer
x		FTIRF	GTIRF	WTIRF	CTIRF			Tracer Injection Rate (Free)
x		FTIRS	GTIRS	WTIRS	CTIRS			Tracer Injection Rate (Solution)
x		FTPRF	GTPRF	WTPRF	CTPRF			Tracer Production Rate (Free)
x		FTPRS	GTPRS	WTPRS	CTPRS			Tracer Production Rate (Solution)
x		FTITF	GTITF	WTITF	CTITF			Tracer Injection Total (Free)
x		FTITS	GTITS	WTITS	CTITS			Tracer Injection Total (Solution)
x		FTPTF	GTPTF	WTPTF	CTPTF			Tracer Production Total (Free)
x		FTPTS	GTPTS	WTPTS	CTPTS			Tracer Production Total (Solution)
x		FTICF	GTICF	WTICF	CTICF			Tracer Injection Concentration (Free)
x		FTICS	GTICS	WTICS	CTICS			Tracer Injection Concentration (Solution)
x		FTPCF	GTPCF	WTPCF	CTPCF			Tracer Production Concentration (Free)
x		FTPCS	GTPCS	WTPCS	CTPCS			Tracer Production Concentration (Solution)

Table 2.50: Environmental tracer SUMMARY output controls

The keywords above should be compounded with the name of the tracer to which they refer. For example, if the field production rate of a tracer called OL1 is required on the Summary files, then the keyword FTPROL1 should be used in the SUMMARY section.

For partitioned tracers, the concentration, flow, and amount in place in a specific phase can be output by using either the F (Free) and S (Solution) specifiers, or by using the phase number #. For a tracer partitioning into the components oil, water and gas, the F and S specifiers are no longer sufficient to

uniquely determine the phase of interest. In this case the phase number must be used. For example, BTCN3OL1 refers to the block concentration of tracer OL1 in phase 3 as specified in the list of phases when defining the tracer partitioning functions (see keyword [TRACERKM](#)). If the S (Solution) specifier is still used for a tracer partitioning into 3 or more phases, the concentration output will be the concentration in the last phase as defined in [TRACERKM](#).

**Note:** BTADS reports the amount of adsorped tracer per unit mass of rock in a given block (for example 'kg/kg'). The corresponding region and field keywords, RTADS and FTADS, report the total amount of adsorped tracer (for example 'kg').

## Coal Bed Methane Model (ECLIPSE 100)

This model is for ECLIPSE 100 only. The following keywords control output of data specific to the Coal bed Methane Model:

E100	Field	Group	Well	Region	Block	Information
x	FMPR	GMPR	WMPR			Methane Production Rate
x	FMPT	GMPT	WMPT			Methane Production Total
x	FMIR	GMIR	WMIR			Methane Injection Rate
x	FMIT	GMIT	WMIT			Methane Injection Total
x	FCGC			RCGC	BCGC	Bulk Coal Gas Concentration (concentration in the coal matrix)
x	FCSC			RCSC	BCSC	Bulk Coal Solvent Concentration (concentration in the coal matrix)

Table 2.51: Coal Bed Methane (ECLIPSE 100)

**Note:** Methane production is identical to the gas production unless the solvent option is active. In that case, the gas production rate is the total gas + solvent production rate.

## Foam Model

The following keywords control output of data specific to the Foam Model.

E100	E300	Field	Group	Well	Connection	Information
x					CTFRFOA	Flow Rate (+ or -)
x		FTPRFOA	GTPRFOA	WTPRFOA		Production Rate
x		FTPTFOA	GTPTFOA	WTPTFOA	CTPTFOA	Production Total
x		FTIRFOA	GTIRFOA	WTIRFOA		Injection Rate
x		FTITFOA	GTITFOA	WTITFOA	CTITFOA	Injection Total
x		FTIPTFOA				In Solution
x		FTADSFOA				Adsorption total
x		FTDCYFOA				Decayed tracer

E100	E300	Field	Group	Well	Connection	Information
x		FTMOBFOA				Gas mobility factor (excluding shear)

Table 2.52: Foam SUMMARY field, group, well and connection output keywords

E100	E300	Field	Region	Block	Information
x		FTPRFOA			Production Rate
x		FTPTFOA			Production Total
x		FTIRFOA			Injection Rate
x		FTITFOA			Injection Total
x				BTCNFFOA	Concentration
	x			BFOAM	Surfactant concentration
x				BTCNMFOA	Capillary number
	x			BFOAMCNM	Capillary number
x		FTIPTFOA	RTIPTFOA	BTIPTFOA	In Solution
x			RTFTTFOA		Inter-region Flow Total
x		FTADSFOA	RTADSFOA		Adsorption total
x				BTADSFOA	Adsorption
x		FTDCYFOA	RTDCYFOA	BTDCYFOA	Decayed tracer
x		FTMOBFOA	RTMOBFOA	BTMOBFOA	Gas mobility factor (excluding shear)
	x			BFOAMMOB	Gas mobility factor
x				BTHLFFOA	Decay Half life
	x			BFOAMST	Gas-water surface tension

Table 2.53: Foam SUMMARY, field, region and block output keywords

## Gas Field Operations Model

The following items are relevant to the Gas Field Operations Model:

E100	E300	Field	Group	Well	Information
x	x	FSGR	GSGR		Sales Gas Rate
x	x	FGSR	GGSR		Sales Gas Rate (as above)
x	x	FSGT	GSGT		Sales Gas Total
x	x	FGST	GGST		Sales Gas Total (as above)
x	x	FGDC	GGDC	WGDC	Gas Delivery Capacity
x	x	FGDCQ	GGDCQ		Field/Group Gas DCQ
x			GMCPL		Group Multi-level Compressor Level
x	x		GPR		Group nodal PPressure in network When using the Extended Network Model, the names must correspond to network nodes instead of groups

E100	E300	Field	Group	Well	Information
x			GPRDC		Group PPressure at Delivery Capacity When using the Extended Network Model, the names must correspond to network nodes instead of groups
x		FGCR	GGCR		Gas consumption rate, at and below this group
x		FGCT	GGCT		Gas consumption cumulative total, at and below this group
	x	FFGR	GFGR		Fuel Gas rate, at and below this group
	x	FFGT	GFGT		Fuel Gas cumulative total, at and below this group
x		FGIMR	GGIMR		Gas import rate, at and below this group
x		FGIMT	GGIMT		Gas import cumulative total, at and below this group
x	x			NGOPAS	Number of iterations to converge DCQ in first pass
x				WGPRFP	Well Gas Production Rate from end of First Pass
x				WTHPFP	Well Tubing Head Pressure from end of First Pass
x				WBHPFP	Well Bottom Hole Pressure from end of First Pass
x			GPRFP		Group or node PPressure in network from end of First Pass
x			GGPRNBFP		Gas flow rate along Group's or node's outlet branch in network, from end of First Pass

Table 2.54: Gas field operations SUMMARY output controls

The mnemonics FGPR, GGPR, FGPT, GGPT refer to the **gross** gas produced from the formation, without allowing for consumption. GGDC and WGDC refer to the group and well gas sales rates when the field is operating at its delivery capacity. GGDCQ should be used only for contract groups in cases where two or more groups have separate gas supply contracts (see keyword [GSWINGF](#)). FGDCQ should be used when there is a single contract applied to the FIELD (keyword [SWINGFAC](#)). GPR provides the group nodal pressures when there is a production network. GPRDC may be used to obtain the group nodal pressures that exist then the field is operating at delivery capacity. When using the Extended Network Model, the names must correspond to network nodes instead of groups. The mnemonics WGPRFP, WTHPFP, WBHPFP , GPRFP, GGPRNBFP extract data from the first pass of the Gas field operations Model. However, these mnemonics do not refer to continuous quantities but rather the values of these quantities at the end of the first pass. Inclusion of any of these mnemonics in the summary section will force an additional iteration of the first pass in order that converged data is recorded.

## Simulator performance keyword

NGOPAS Outputs the number of iterations used to converge the DCQ in the first pass of the contract period.

## Gas lift optimization facility

The following keywords control output of data specific to the Gas Lift Optimization facility:

E100	E300	Field	Group	Well	Information
x	x	FGLIR	GGLIR	WGLIR	Gas Lift Injection Rate (Assumes ALQ = gas lift injection rate. Well rates are multiplied by their efficiency factors when summing up group and field rates.)
x	x			WOGLR	Well Oil Gas Lift Ratio (This is the incremental change in the field's production rate with respect to the addition of another gas lift increment to that well. The denominator in this expression may optionally include a weighted version of the incremental change in gas production rate.)

Table 2.55: Gas lift optimization SUMMARY output controls

**Note:** In the presence of gas lift optimization, the produced gas reported (for example using the FGPR, GGPR and WGPR keywords) does not include produced lift gas, only produced formation gas.

## Gas calorific value control option

The following items are relevant to the Gas Calorific Value Control option:

E100	E300	Field	Group	Well	Information
x		FGCV	GGCV	WGCV	Gas Calorific Value
x	x	FGQ	GGQ	WGQ	Gas molar Quality
x	x	FEPR	GEPR	WEPR	Energy Production Rate
x	x	FEPT	GEPT	WEPT	Energy Production Total (cumulative)
x		FESR	GESR		Energy Sales Rate
x		FEST	GEST		Energy Sales Total (cumulative)
x		FEDC	GEDC	WEDC	Energy Delivery Capacity
x		FEDCQ	GEDCQ		Energy DCQ

Table 2.56: Gas calorific value control SUMMARY output controls

The energy production rates and totals (FEPR, GEPR, FEPT, GEPT) refer to the **gross** energy produced from the formation, without allowing for consumption. The energy sales rates and totals (FESR, GESR, FEST, GEST) refer to the energy produced, minus the energy injected, minus the energy of any consumed gas. The energy delivery capacity and DCQ are available only when using the Gas Field Operations Model. GEDC and WEDC refer to the group and well energy sales rates when the field is operating at its delivery capacity. GEDCQ should be used only for contract groups in cases where two or more groups have separate gas supply contracts (see keyword [GSWINGF](#)). FEDCQ should be used when there is a single contract applied to the FIELD (keyword [SWINGFAC](#)).

## Gi pseudo-compositional model

ECLIPSE 100 only

The following keywords control output of data specific to the Gi Model:

E100	Block	Information
x	BGI	Block Gi value

Table 2.57: Gi pseudo-compositional SUMMARY output controls

## Local grid refinement and coarsening

ECLIPSE 100

In ECLIPSE 100 LGR runs, two sets of summary data are output. The usual Summary files contain summary data produced at the global timesteps. In addition summary file quantities are output at the local timesteps; this local data is output to a separate LGR file.

The local timestep summary data is stored in a file with the following name:

- ROOT.FLGR (or ROOT.FLG)

Formatted

- ROOT.LGR

Unformatted

The creation of local timestep Summary files can be prevented by using the NOSUMLGR keyword in the SUMMARY section. For example, when running lgr-in-place there is little point in dumping Summary files for the local timesteps since the global and local timesteps are all synchronized.

Due to the local timestepping used on grid refinements in ECLIPSE 100, it is possible to request global grid summary quantities for wells that are defined on a local grid. This is not possible in ECLIPSE 300.

Summary data for the local grid is requested by using SUMMARY keywords with the first letter L. Three types of keyword are available:

- LB\* Local Block data
- LC\* Local Connection data
- LW\* Local Well data

The keywords available are the same as the global keyword with the 'L' added to the front. For example LWBHP requested the WBHP for the local well.

Note that the maximum number of characters in a SUMMARY keyword is 8. This may introduce limitations in very specific cases for example in tracer block quantities.

Keywords that begin with LB are described in ["Format of SUMMARY keywords beginning with LB"](#).

Keywords that begin with LC are described in ["Format of SUMMARY keywords beginning with LC"](#).

Keywords that begin with LW are described in ["Format of SUMMARY keywords beginning with LW"](#).

### Operational keywords

ECLIPSE 100 only

NOSUMLGR Prevents the creation of local timestep summary files.

### Plotting local timestep results in GRAF

ECLIPSE 100 only

When loading the data into GRAF, you are prompted to say whether the local timestep data should be loaded along with the usual summary files. If the local timestep data (from the ROOT.LGR file) is loaded, a set of vectors is created for each local grid. These sets of vectors (with their own time vector) are identified by having a different 'origin'.

You are prompted for the origin for each local grid. However these origins can be defaulted to an 8 character string of the form:

- AAA\_BBBB

where AAA is the first three characters of the root name for the run and

BBBB is the first four characters of the LGR name.

For example, run ROOT containing LGRs called SOUTH and NORTH would produce sets of vectors with origins ROO\_SOUT and ROO\_NORT .

---

**Note:** This means it is useful to give LGRs names that differ in the first 4 characters.

---

The global timestep data is treated in the usual way in GRAF.

## Multisegment wells

The keywords controlling output of segment data specific to multisegment wells are given in the table below. Notes for this table:

1. See “[Format of SUMMARY keywords with a component index](#)”.

E100	E300	Segment	Information
x	x	SOFR	Segment Oil Flow Rate
x		SOFRF	Segment Free Oil Flow Rate
x		SOFRS	Segment Solution Oil Flow Rate (vaporized oil)
x	x	SWFR	Segment Water Flow Rate
x	x	SGFR	Segment Gas Flow Rate
x		SGFRF	Segment Free Gas Flow Rate
x		SGFRS	Segment Solution Gas Flow Rate
	x	SKFR	Segment Component Flow Rate. See Note 1.
	x	SCWGFR	Segment Component Flow Rate as Wet Gas. See Note 1.
	x	SHFR	Segment Enthalpy Flow Rate (Thermal option)
x	x	SWCT	Segment Water Cut
x	x	SGOR	Segment Gas Oil Ratio
x	x	SOGR	Segment Oil Gas Ratio
x	x	SWGR	Segment Water Gas Ratio
x	x	SPR	Segment PPressure
x	x	SPRD	Segment PPressure Drop
x	x	SPRDF	Segment PPressure Drop component due to Friction
x	x	SPRDH	Segment PPressure Drop component due to Hydrostatic head
x	x	SPRDA	Segment PPressure drop due to Acceleration head
x	x	SPRDM	Segment frictional PPressure Drop Multiplier (keyword <a href="#">WSEGMULT</a> )
x		SPPOW	Working power of a pull through pump (keyword <a href="#">WSEGPULL</a> )
x	x	SOFV	Segment Oil Flow Velocity
x	x	SWFV	Segment Water Flow Velocity

E100	E300	Segment	Information
x	x	SGFV	Segment Gas Flow Velocity
x	x	SOHF	Segment Oil Holdup Fraction
x	x	SWHF	Segment Water Holdup Fraction
x	x	SGHF	Segment Gas Holdup Fraction
x	x	SDENM	Segment fluid mixture density
x		SOVIS	Segment oil viscosity
x		SWVIS	Segment water viscosity (pure water)
x		SGVIS	Segment gas viscosity
x		SEMVIS	Segment effective mixture viscosity (water/polymer)
x	x	SGLPP	Segment Gas-Liquid Profile Parameter, C0 (drift flux slip model)
x	x	SGLVD	Segment Gas-Liquid Drift Velocity, Vd (drift flux slip model)
x	x	SOWPP	Segment Oil-Water Profile Parameter, C0 (drift flux slip model)
x	x	SOWVD	Segment Oil-Water Drift Velocity, Vd (drift flux slip model)
	x	SOIMR	Segment Oil Import Rate (keyword <a href="#">WSEGEXSS</a> )
x	x	SGIMR	Segment Gas Import Rate (keyword <a href="#">WSEGEXSS</a> )
x	x	SWIMR	Segment Water Import Rate (keyword <a href="#">WSEGEXSS</a> )
	x	SHIMR	Segment Enthalpy Import Rate (keyword <a href="#">WSEGEXSS</a> ) (Thermal option)
	x	SORMR	Segment Oil Removal Rate (keyword <a href="#">WSEGEXSS</a> )
	x	SGRMR	Segment Gas Removal Rate (keyword <a href="#">WSEGEXSS</a> )
	x	SWRMR	Segment Water Removal Rate (keyword <a href="#">WSEGEXSS</a> )
	x	SHRMR	Segment Enthalpy Removal Rate (keyword <a href="#">WSEGEXSS</a> ) (Thermal option)
	x	SOIMT	Segment Oil Import Total (keyword <a href="#">WSEGEXSS</a> )
x	x	SGIMT	Segment Gas Import Total (keyword <a href="#">WSEGEXSS</a> )
x	x	SWIMT	Segment Water Import Total (keyword <a href="#">WSEGEXSS</a> )
	x	SHIMT	Segment Enthalpy Import Total (keyword <a href="#">WSEGEXSS</a> ) (Thermal option)
	x	SORMT	Segment Oil Removal Total (keyword <a href="#">WSEGEXSS</a> )
	x	SGRMT	Segment Gas Removal Total (keyword <a href="#">WSEGEXSS</a> )
	x	SWRMT	Segment Water Removal Total (keyword <a href="#">WSEGEXSS</a> )
	x	SHRMT	Segment Enthalpy Removal Total (keyword <a href="#">WSEGEXSS</a> ) (Thermal option)
x		SAPI	Segment API value
x		SCFR	Segment polymer flow rate (Polymer flood option)
x		SCCN	Segment polymer concentration (Polymer flood option)
x		SSFR	Segment brine flow rate (Surfactant and Polymer flood option)
x		SSCN	Segment brine concentration (Surfactant and Polymer flood option)
x		STFR	Segment tracer flow rate

E100	E300	Segment	Information
x		STFC	Segment tracer concentration
x		SFD	Segment diameter for Karst Conduit Calcite Dissolution
	x	SPSAT	Segment $P_{sat}$ . The value depends on the segment hydrocarbon state: for single phase gas it will usually be the dew point pressure; for single phase oil it will usually be the bubble point pressure; for two phase segments it will be the segment pressure.
	x	STEM	Segment Temperature
	x	SENE	Segment Energy Density (Thermal option)
	x	SSQU	Segment Steam Quality (Thermal option)
	x	SCVPR	Segment Calorific Value Production Rate
	x	SGQ	Segment Gas Quality
	x	SCSA	Segment Cross Sectional Area. This is specified using the <a href="#">WSEGVALV</a> keyword, and can change if the cross sectional area is used as a reservoir optimization parameter using the <a href="#">OPTPARS</a> keyword.
x	x	SSTR	Strength of ICD on segment (see keywords <a href="#">WSEGVALV</a> , <a href="#">WSEGAICD</a> and <a href="#">WSEGSICD</a> )
x	x	SFOPN	Setting of segment (see keywords <a href="#">WSEGVALV</a> , <a href="#">WSEGAICD</a> , <a href="#">WSEGSICD</a> , <a href="#">WSEGTABL</a> , <a href="#">WSEGLABY</a> and <a href="#">WSEGFLIM</a> )

Table 2.58: Multisegment wells SUMMARY output controls

The segment flow rates reported are the flow rates of each phase through the tubing past the segment's end nearest the well head. Positive values represent flow towards the well head (production), while negative values represent flow away from the well head (injection). The flow rates refer to the sum of free and dissolved phases at surface conditions, equivalent to the reported well rates. The flow velocities refer to the local flow velocities of the free phases through the segment. The flow velocities of all the phases should be equal unless you are using a built-in Multi-phase Flow Model that allows slip. The holdup fractions refer to the local volume fraction of the segment occupied by each free phase.

For drift-flux segments, the phases can flow in different directions. Therefore phase flow ratios (such as SWCT, SGOR, SOGR and SWGR) may be negative, and the water cut (SWCT) could be infinite if the oil and water flow volumes are the same, but in different directions, so the net liquid flow is zero.

ECLIPSE 100

The tracer flow rate and concentration keywords should be compounded with the name of the tracer to which they refer (for example STFROL1 and STFCOL1 give the flow rate and concentration of the tracer OL1).

## Rivers

The following keywords control output of reach data specific to rivers

E100	Segment	Information
x	SRRQR	Reach flow at current time
x	SRRQT	Reach cumulative flow
x	SRBQR	Branch flow at current time
x	SRBQT	Branch cumulative flow

E100	Segment	Information
x	SRTQR	River total flow at current time
x	SRTQT	River total cumulative flow
x	SRRFLOW	Reach flux through cross-sectional area at current time
x	SRRAREA	Reach area at current time
x	SRRDEPTH	Reach depth at current time
x	SRREXCH	Exchange flux at current time
x	SRRFRODE	Reach Froude number at current time
x	SRRHEAD	Reach hydraulic head at current time
x	SRTFR	Reach tracer flow rate
x	SRTFC	Reach tracer concentration
x	SRSFR	Reach brine flow rate through connections
x	SRSFC	Reach brine concentration

Table 2.59: River SUMMARY output controls

The river reach controls are:

E100	Connection	Information
x	CRREXCH	Exchange flux at current time
x	CRRPROT	Connection cumulative water production
x	CRRINJT	Connection cumulative water injection

Table 2.60: River reach SUMMARY controls

For example,

```

SRRFLOW
-- FLUX FOR REACH 12
MYRIVER 12 /
/

SRBQR
-- FLOW FOR BRANCH 1
MYRIVER 1 /
/

SRTQR
--TOTAL FLOW FOR ENTIRE RIVER
MYRIVER /
/

SRBQT
--CUMULATIVE FLOW FOR BRANCH 1
MYRIVER 1 /

SRTFRFFF
-- TRACER 'FFF' FLOW RATE FOR REACH 1
MYRIVER 1 /

CRRPROT
--CUMULATIVE WATER PRODUCTION FOR BLOCK 11 20 2
MYRIVER 11 20 2 /

SRSFR
-- BRINE FLOW TO REACHES 11 AND 12
MYRIVER 11 /
    
```

MYRIVER 12 /  
/

## Network option

The following keywords control output of data specific to the Network option.

When using the Extended Network Model, the list of names following these keywords must correspond to network nodes instead of **GRUPTREE** groups.

E100	E300	Group	Information
x	x	GPR	Group or node PResure in the production network
x	x	GPRG	Group or node PResure in the gas injection network
x	x	GPRW	Group or node PResure in the water injection network
x	x	GPRB	Pressure drop along the group's or node's outlet branch in the production network
x	x	GPRBG	Pressure drop along the group's or node's inlet branch in the gas injection network
x	x	GPRBW	Pressure drop along the group's or node's inlet branch in the water injection network
x	x	GALQ	ALQ in the group's or node's outlet branch in the production network. No units are given, as there are several possible definitions for this quantity.
x	x	GOPRNB	Oil flow rate along the group's or node's outlet branch in the production network
x	x	GWPRNB	Water flow rate along the group's or node's outlet branch in the production network
x	x	GGPRNB	Gas flow rate along the group's or node's outlet branch in the production network
	x	GLPRNB	Liquid flow rate along the group's or node's outlet branch in the production network
x	x	GWIRNB	Water flow rate along the group's or node's inlet branch in the water injection network
x	x	GGIRNB	Gas flow rate along the group's or node's inlet branch in the gas injection network
x		GOMNR	Group or node minimum oil rate as specified with <b>GNETDP</b> in the production network
x		GGMNR	Group or node minimum gas rate as specified with <b>GNETDP</b> in the production network
x		GWMNR	Group or node minimum water rate as specified with <b>GNETDP</b> in the production network
x		GLMNR	Group or node minimum liquid rate as specified with <b>GNETDP</b> in the production network
x		GOMXR	Group or node maximum oil rate as specified with <b>GNETDP</b> in the production network

E100	E300	Group	Information
x		GGMXR	Group or node maximum gas rate as specified with GNETDP in the production network
x		GWMXR	Group or node maximum water rate as specified with GNETDP in the production network
x		GLMXR	Group or node maximum liquid rate as specified with GNETDP in the production network
x		GMNP	Group or node minimum pressure as specified with GNETDP in the production network
x		GMXP	Group or node maximum pressure as specified with GNETDP in the production network
x		GPRINC	Group or node pressure increment as specified with GNETDP in the production network
x		GPRDEC	Group or node pressure decrement as specified with GNETDP in the production network

Table 2.61: Network SUMMARY output controls

## Polymer Flood Model

The following keywords control output of data specific to the ECLIPSE 100 Polymer Flood Model:

E100	Field	Group	Well	Connection	Region	Block	Information
x				CCFR			Polymer Flow Rate (+ or -)
x	FCPR	GCPR	WCPR	CCPR			Polymer Production Rate
x	FCPC	GCPC	WCPC	CCPC			Polymer Production Concentration
x	FCPT	GCPT	WCPT	CCPT			Polymer Production Total
x	FCIR	GCIR	WCIR	CCIR			Polymer Injection Rate
x	FCIC	GCIC	WCIC	CCIC			Polymer Injection Concentration
x	FCIT	GCIT	WCIT	CCIT			Polymer Injection Total
x						BCCN	Polymer Concentration
x	FCIP				RCIP	BCIP	Polymer In Solution
x					RCFT		Polymer inter-region Flow Total
x						BEPVIS	Effective polymer solution viscosity
x						BVPOLY	Effective polymer solution viscosity (as above)
x						BEMVIS	Effective mixture (water/polymer) viscosity
x						BEWV_POL	Effective water viscosity
x	FCAD				RCAD		Polymer Adsorption total
x						BCAD	Polymer Adsorption concentration

E100	Field	Group	Well	Connection	Region	Block	Information
x						BCDCS	Polymer thermal degradation - total mass degraded in previous timestep
x						BCDCR	Polymer thermal degradation - total degradation rate
x						BCDCP	Polymer thermal degradation - solution degradation rate
x						BCDCA	Polymer thermal degradation - adsorbed degradation rate
x						BCABnnn	Adsorbed polymer by highest temperature band at which RRF was calculated - see keyword <a href="#">PLYTRRFA</a> . The band number nnn can range from 001 to 999, but must be less than or equal to the argument of <a href="#">PLYTRRFA</a>
x				CSFR			Salt Flow Rate (+ or -)
x	FSPR	GSPR	WSPR	CSPR			Salt Production Rate
x	FSPT	GSPT	WSPT	CSPT			Salt Production Total
x	FSIR	GSIR	WSIR	CSIR			Salt Injection Rate
x	FSIT	GSIT	WSIT	CSIT			Salt Injection Total
x						BSCN	Salt Cell Concentration
x	FSIP						Salt In Place
x					RSIP	BSIP	Salt In Place (as above)
x					RSFT		Salt inter-region Flow Total
x						BFLOW0I	Inter-block water flow rate in the positive I direction multiplied by the corresponding shear multiplier ( <a href="#">PLYSHLOG</a> and <a href="#">PLYSHEAR</a> options only)
x						BFLOW0J	Inter-block water flow rate in the positive J direction multiplied by the corresponding shear multiplier ( <a href="#">PLYSHLOG</a> and <a href="#">PLYSHEAR</a> options only)
x						BFLOW0K	Inter-block water flow rate in the positive K direction multiplied by the corresponding shear multiplier ( <a href="#">PLYSHLOG</a> and <a href="#">PLYSHEAR</a> options only)

E100	Field	Group	Well	Connection	Region	Block	Information
x						BVELW0I	Water velocity in the positive I direction multiplied by the corresponding shear multiplier (PLYSHLOG and PLYSHEAR options only)
x						BVELW0J	Water velocity in the positive J direction multiplied by the corresponding shear multiplier (PLYSHLOG and PLYSHEAR options only)
x						BVELW0K	Water velocity in the positive K direction multiplied by the corresponding shear multiplier (PLYSHLOG and PLYSHEAR options only)
x						BPSHLZI	Viscosity multiplier due to sheared water flow in the positive I direction (PLYSHLOG and PLYSHEAR options only)
x						BPSHLZJ	Viscosity multiplier due to sheared water flow in the positive J direction (PLYSHLOG and PLYSHEAR options only)
x						BPSHLZK	Viscosity multiplier due to sheared water flow in the positive K direction (PLYSHLOG and PLYSHEAR options only)
x						BSRTW0I	Water shear rate in the positive I direction prior to shear effects (PLYSHLOG option with keyword SHRATE)
x						BSRTW0J	Water shear rate in the positive J direction prior to shear effects (PLYSHLOG option with keyword SHRATE)
x						BSRTW0K	Water shear rate in the positive K direction prior to shear effects (PLYSHLOG option with keyword SHRATE)
x						BSRTWI	Water shear rate in the positive I direction following shear effects (PLYSHLOG option with keyword SHRATE)

E100	Field	Group	Well	Connection	Region	Block	Information
x						BSRTWJ	Water shear rate in the positive J direction following shear effects (PLYSHLOG option with keyword SHRATE)
x						BSRTWK	Water shear rate in the positive K direction following shear effects (PLYSHLOG option with keyword SHRATE)
x						BSHWVISI	Shear viscosity of the water/polymer solution due to shear thinning/thickening in the positive I direction (PLYSHLOG and PLYSHEAR options only)
x						BSHWVISJ	Shear viscosity of the water/polymer solution due to shear thinning/thickening in the positive J direction (PLYSHLOG and PLYSHEAR options only)
x						BSHWVISK	Shear viscosity of the water/polymer solution due to shear thinning/thickening in the positive K direction (PLYSHLOG and PLYSHEAR options only)

Table 2.62: ECLIPSE 100 Polymer flood SUMMARY output controls

The following keywords control output of data specific to the ECLIPSE 300 Polymer Flood Model:

E300	Block	Information
x	BESALTP	Effective salinity
x	BPOLY	Polymer concentration
x	BPOLYVM	Polymer viscosity multiplier

Table 2.63: ECLIPSE 300 Polymer flood SUMMARY output controls

## Pseudo Steady-State (ECLIPSE 100 only)

The following keywords control output of data relevant to the calculation of a pseudo steady state solution, see keyword [PSTEADY](#). They will automatically be output from a steady-state run if the [PERFORMA](#) keyword is present in the summary section.

E100	Field	Description
x	PSSPR	Log of the pressure change per unit time, see <a href="#">PSTEADY</a>
x	PSSSO	Log of the oil saturation change per unit time, see <a href="#">PSTEADY</a>
x	PSSSW	Log of the water saturation change per unit time, see <a href="#">PSTEADY</a>
x	PSSSG	Log of the gas saturation change per unit time, see <a href="#">PSTEADY</a>

E100	Field	Description
x	PSSSC	Log of the salt concentration change per unit time, see PSTEADY

Table 2.64: Steady state SUMMARY output controls

## Reservoir coupling facility (ECLIPSE 100 only)

The following keywords control output of data relevant to the Reservoir Coupling facility:

E100	Group	Description
x	GOPRL	Group Oil Production Rate Target
x	GOIRL	Group Oil Injection Rate Target
x	GWPRL	Group Water Production Rate Target
x	GWIRL	Group Water Injection Rate Target
x	GGPRL	Group Gas Production Rate Target
x	GGIRL	Group Gas Injection Rate Target
x	GLPRL	Group Liquid Production Rate Target
x	GVPRL	Group reservoir Volume Production Rate Target
x	GVIRL	Group reservoir Volume Injection Rate Target

Table 2.65: Reservoir coupling SUMMARY output controls (ECLIPSE 100 only)

These keywords are intended for use with slave groups, in a slave reservoir being run on its own, when the rate limits of its slave groups are read from a Reservoir Coupling File. The keywords allow you to examine the rate targets in the file that are applied to the slave groups. These are the overall targets applied to the slave groups and represent the combination of the various limiting factors within the group tree. The reported value may therefore be less than the value reported with the same summary quantities for the master groups which report only the limits entered via the [GCONPROD](#), [GCONPRI](#) and [GCONINJE](#) keywords.

When no rate target is being applied, the value of the limit is normally set to 1.0E20. However, the automatic axis scaling in GRAF would make the y-axis extend to this value. To avoid this, infinite rate targets are reset to zero before writing to the Summary file.

## Solvent Model

ECLIPSE 100 only

The following keywords control output of data specific to the Solvent Model.

E100	Field	Group	Well	Connection	Region	Block	Information
x				CNFR			Solvent Flow Rate (+ or -)
x	FNPR	GNPR	WNPR				Solvent Production Rate
x	FNPT	GNPT	WNPT	CNPT			Solvent Production Total
x	FNIR	GNIR	WNIR				Solvent Injection Rate
x	FNIT	GNIT	WNIT	CNIT			Solvent Injection Total
x						BNSAT	Solvent SATuration
x	FNIP				RNIP	BNIP	Solvent In Place

E100	Field	Group	Well	Connection	Region	Block	Information
x					RNFT		Solvent inter-region Flow
x						BNKR	Solvent relative permeability

Table 2.66: Solvent SUMMARY output controls (ECLIPSE 100 only)

**Note:** ECLIPSE reports the field, group and well gas rates and totals for the **total** gas phase, including the solvent gas. The connection gas flow rates and totals are reported solely for the component gas phase, excluding the solvent gas.

## Surfactant Model

The following keywords control output of data specific to the Surfactant Model.

E100	E300	Field	Group	Well	Connection	Information
x					CTFRSUR	Flow Rate (+ or -)
x		FTPRSUR	GTPRSUR	WTPRSUR		Production Rate
x		FTPTSUR	GTPTSUR	WTPTSUR	CTPTSUR	Production Total
x		FTIRSUR	GTIRSUR	WTIRSUR		Injection Rate
x		FTITSUR	GTITSUR	WTITSUR	CTITSUR	Injection Total

Table 2.67: Surfactant SUMMARY field, group, well and connection output controls

E100	E300	Field	Region	Block	Information
x				BTCNFSUR	Concentration
	x			BSURF	Concentration in solution
x		FTIPTSUR	RTIPTSUR	BTIPTSUR	In Solution
x			RTFTTSUR		Inter-region Flow Total
x		FTADSUR	RTADSUR		Adsorption total
x				BTADSUR	Adsorption
x				BTCASUR	Log (Capillary Number)
	x			BSURFCNM	Log (Capillary Number)
x				BTSTSUR	Surface tension
	x			BSURFST	Surface tension
x				BEWV_SUR	Effective water viscosity due to surfactant concentration
	x			BSURFKR	Relative permeability interpolation factor
	x			BSURFCP	Capillary pressure multiplier
	x			BESALTS	Effective salinity

Table 2.68: Surfactant SUMMARY field, region and block output controls

## Alkaline model

The following keywords control output of data specific to the Alkaline Model.

E100	Field	Group	Well	Connection	Block	Information
x				CTFRALK		Flow Rate (+ or -)
x	FTPRALK	GTPRALK	WTPRALK			Production Rate
x	FTPTALK	GTPTALK	WTPTALK	CTPTALK		Production Total
x	FTIRALK	GTIRALK	WTIRALK			Injection Rate
x	FTITALK	GTITALK	WTITALK	CTITALK		Injection Total
x					BTCNFALK	Concentration
x					BTADSALK	Adsorption
x					BTSTMALK	Surface tension multiplier
x					BTSADALK	Surfactant adsorption multiplier
x					BTPADALK	Polymer adsorption multiplier

Table 2.69: Alkaline SUMMARY output controls (ECLIPSE 100 only)

**Note:** When requesting output of alkaline or surfactant (or any other active tracer) properties on an LGR, the corresponding SUMMARY mnemonics may exceed 8 characters in length, for example LBTCNFALK or LBTIPTSUR. In these special cases ECLIPSE will recognize the truncated forms of the mnemonics, that is LBTCNFSU and LBTIPTAL.

E300	Block	Information
x	BALSURF	Alkaline concentration
x	BALSTML	Surface tension multiplier

Table 2.70: Alkaline SUMMARY output block controls (ECLIPSE 300 only)

## Wellbore friction model

ECLIPSE 100 only

The following items are relevant to the Wellbore Friction Model:

E100	Connection	Information
x	COFRU	Sum of connection oil flow rates upstream of, and including, this connection
x	CWFRU	Sum of connection water flow rates upstream of, and including, this connection
x	CGFRU	Sum of connection gas flow rates upstream of, and including, this connection
x	LCOFRU	As COFRU but for local grids
x	LCWFRU	As CWFRU but for local grids
x	LCGFRU	As CGFRU but for local grids

Table 2.71: Wellbore friction SUMMARY output controls (ECLIPSE 100)

Use the local grid keywords if the well is situated in a local grid.

## Conductive Faults

The following items are relevant to the Conductive Fault model:

E300	Conductive Fault	Information
x	CFOWC	Oil-water contact depth in the fault
x	CFGOC	Gas-oil contact depth in the fault
x	CFPRES	Pressure in the fault
x	CFOSAT	Oil saturation in the fault
x	CFGSAT	Gas saturation in the fault
x	CFWSAT	Water saturation in the fault

Table 2.72: Conductive Fault SUMMARY output controls (ECLIPSE 300)

## User defined quantities

The user defined summary output options are:

E100	E300	User defined quantity	Information
x	x	CUxxxxxxx	User defined connection quantity
x	x	FUxxxxxxx	User defined field quantity
x	x	GUxxxxxxx	User defined group quantity
x	x	RUxxx	User defined region quantity
x	x	SUxxxxxxx	User defined segment quantity
x	x	WUxxxxxxx	User defined well quantity

Table 2.73: User defined quantities SUMMARY output controls

User defined summary quantities are constructed using the `UDQ` keyword in the `SCHEDULE` section. The facility allows the user to define quantities as either constants, or composed of ECLIPSE summary quantities in conjunction with a number of mathematical functions.

## ODD3P three-phase relative permeability and capillary pressure hysteresis model

The following items are specific to the `ODD3P` three-phase relative permeability and capillary pressure hysteresis model:

E300	Block	Information
x	BSONRM	Normalized oil saturation
x	BSGNRM	Normalized gas saturation
x	BSWNRM	Normalized water saturation
x	BSDROW	Oil phase saturation direction indicator for oil-water system
x	BSDRWO	Water phase saturation direction indicator for water-oil system
x	BSDROG	Oil phase saturation direction indicator for oil-gas system

<b>E300</b>	<b>Block</b>	<b>Information</b>
x	BSDRGO	Gas phase saturation direction indicator for gas-oil system
x	BSDRGW	Gas phase saturation direction indicator for gas-water system
x	BSDRWG	Water phase saturation direction indicator for water-gas system
x	BSOWNT	Normalized oil turning point saturation for oil-water system.
x	BSWONT	Normalized water turning point saturation for water-oil system
x	BSOGNT	Normalized oil turning point saturation for oil-gas system
x	BSGONT	Normalized gas turning point saturation for gas-oil system
x	BSGWNT	Normalized gas turning point saturation for gas-water system
x	BSWGNT	Normalized water turning point saturation for water-gas system
x	BSOWNH	Normalized oil hysteresis saturation for oil-water system
x	BSWONH	Normalized water hysteresis saturation for water-oil system
x	BSOGNH	Normalized oil hysteresis saturation for oil-gas system
x	BSGONH	Normalized gas hysteresis saturation for gas-oil system
x	BSGWNH	Normalized gas hysteresis saturation for gas-water system
x	BSWGNH	Normalized water hysteresis saturation for water-gas system
x	BSOWNE	Normalized oil equivalent opposite direction saturation for oil-water system
x	BSWONE	Normalized water equivalent opposite direction saturation for water-oil system
x	BSOGNE	Normalized oil equivalent opposite direction saturation for oil-gas system
x	BSGONE	Normalized gas equivalent opposite direction saturation for gas-oil system
x	BSGWNE	Normalized gas equivalent opposite direction saturation for gas-water system
x	BSWGNE	Normalized water equivalent opposite direction saturation for water-gas system
x	BSORWB	Residual oil saturation used to calculate normalized saturations in oil-water system
x	BSWROB	Residual water saturation used to calculate normalized saturations in water-oil system
x	BSORGB	Residual oil saturation used to calculate normalized saturations in oil-gas system
x	BSGROB	Residual gas saturation used to calculate normalized saturations in gas-oil system
x	BSGRWB	Residual gas saturation used to calculate normalized saturations in gas-water system
x	BSWRGB	Residual water saturation used to calculate normalized saturations in water-gas system
x	BSORWP	Process dependent residual oil saturation in oil-water system
x	BSWROP	Process dependent residual water saturation in water-oil system
x	BSORGP	Process dependent residual oil saturation in oil-gas system
x	BSGROP	Process dependent residual gas saturation in gas-oil system
x	BSGRWP	Process dependent residual gas saturation in gas-water system
x	BSWRGP	Process dependent residual water saturation in water-gas system
x	BKROWR	Representative oil-water relative permeability
x	BKRWOR	Representative water-oil relative permeability
x	BKROGR	Representative oil-gas relative permeability

<b>E300</b>	<b>Block</b>	<b>Information</b>
x	BKRGOR	Representative gas-oil relative permeability
x	BKRGWR	Representative gas-water relative permeability
x	BKRWGR	Representative water-gas relative permeability
x	BKROWH	Turning point relative permeability to oil for oil-water system
x	BKRWOH	Turning point relative permeability to water for water-oil system
x	BKROGH	Turning point relative permeability to oil for oil-gas system
x	BKRGOH	Turning point relative permeability to gas for gas-oil system
x	BKRGWH	Turning point relative permeability to gas for gas-water system
x	BKRWGH	Turning point relative permeability to water for water-gas system
x	BKROWE	Equivalent relative permeability to oil for oil-water system
x	BKRWOE	Equivalent relative permeability to water for water-oil system
x	BKROGE	Equivalent relative permeability to oil for oil-gas system
x	BKRGOE	Equivalent relative permeability to gas for gas-oil system
x	BKRGWE	Equivalent relative permeability to gas for gas-water system
x	BKRWGE	Equivalent relative permeability to water for water-gas system
x	BKROWT	Opposite saturation direction turning point relative permeability to oil for oil-water system
x	BKRWOT	Opposite saturation direction turning point relative permeability to water for water-oil system
x	BKROGT	Opposite saturation direction turning point relative permeability to oil for oil-gas system
x	BKRGOT	Opposite saturation direction turning point relative permeability to gas for gas-oil system
x	BKRGWT	Opposite saturation direction turning point relative permeability to gas for gas-water system
x	BKRWGT	Opposite saturation direction turning point relative permeability to water for water-gas system
x	BIFTOW	Oil-water interfacial tension
x	BIFTWO	Water-oil interfacial tension (alias for BIFTOW)
x	BIFTGO	Oil-gas interfacial tension (alias for BIFTGO)
x	BIFTGO	Gas-oil interfacial tension
x	BIFTGW	Gas-water interfacial tension
x	BIFTWG	Water-gas interfacial tension (alias for BIFTGW)
x	BPCOWR	Representative oil-water capillary pressure
x	BPCWOR	Representative water-oil capillary pressure
x	BPCOGR	Representative oil-gas capillary pressure
x	BPCGOR	Representative gas-oil capillary pressure
x	BPCGWR	Representative gas-water capillary pressure

E300	Block	Information
x	BPCWGR	Representative water-gas capillary pressure

Table 2.74: ODD3P SUMMARY output controls (ECLIPSE 300 only)

## Asphaltene model

The following outputs are specific to the Asphaltene model activated using the [ASPALTE](#) keyword in the RUNSPEC section. Please refer to "[Asphaltene Option](#)" in the *ECLIPSE Technical Description* for more details. See also the notes for this table:

1. See "[Format of SUMMARY keywords with a component index](#)".

E300	Block	Information
x	BAREAC	Asphaltene reaction rates (this keyword requires the I,J,K values for the cell as well as the reaction rate number M). See Note 1.
x	BASPADS	Asphaltene adsorption volume fraction (pre-2011.1 asphaltene model only)
x	BASPDOT	Asphaltene net deposition volume fraction (pre-2011.1 asphaltene model only)
x	BASPENT	Asphaltene entrainment volume fraction (pre-2011.1 asphaltene model only)
x	BASPFLT	Average oil flow rate at the previous timestep (2011.1 asphaltene model only)
x	BASPRD	Asphaltene fraction precipitated and dissolved
x	BASPKDM	Asphaltene permeability damage multiplier (pre-2011.1 asphaltene model only)
x	BASPLIM	Asphaltene precipitate fraction limit
x	BASPLUG	Asphaltene plugging volume fraction (pre-2011.1 asphaltene model only)
x	BASPRET	Asphaltene precipitation fraction including flocs
x	BASPREW	Asphaltene precipitation fraction
x	BASPVEL	Average oil velocity at the previous timestep (2011.1 asphaltene model only)
x	BASPVOM	Asphaltene oil viscosity multiplier

Table 2.75: Asphaltene SUMMARY output controls (ECLIPSE 300)

## Simulator performance keywords

The keywords are:

E100	E300	Keyword	Description
x	x	ELAPSED	Elapsed time in seconds.
x		HLINEARS	Number of linear iterations for each gradient calculation ( <i>Gradient Option</i> ).
x		HSUMLINS	Total number of linear iterations for each gradient pressure ( <i>Gradient Option</i> ).
	x	MAXCFL	Maximum explicit CFL value for each timestep.
	x	MAXDE	Maximum change in energy density for each timestep.
x	x	MAXDPR	Maximum change in pressure for each timestep.
x	x	MAXDSG	Maximum change in gas saturation for each timestep.

E100	E300	Keyword	Description
x	x	MAXDSO	Maximum change in oil saturation for each timestep.
x	x	MAXDSW	Maximum change in water saturation for each timestep.
	x	MAXDT	Maximum change in temperature for each timestep.
x	x	MEMORYTS	Maximum current memory usage across processors as reported by the operating system.
x	x	MLINEARP	Number of pressure iterations for each timestep (CPR or JALS solver only).
x	x	MLINEARS	Number linear iterations for each timestep.
x	x	MSUMLINP	Total number of pressure iterations since the start of the run (CPR or JALS solver only).
x	x	MSUMBUG	Total number of 'bug' messages since the start of the run.
x	x	MSUMCOMM	Total number of 'comment' messages since the start of the run.
x	x	MSUMERR	Total number of 'error' messages since the start of the run.
x	x	MSUMLINS	Total number of linear iterations since the start of the run.
x	x	MSUMMESS	Total number of 'message' messages since the start of the run.
x	x	MSUMNEWT	Total number of Newton iterations since the start of the run.
x	x	MSUMPROB	Total number of 'problem' messages since the start of the run.
x	x	MSUMWARN	Total number of 'warning' messages since the start of the run.
	x	NAIMFRAC	Fraction of implicit cells in AIM run.
	x	NBAKFL	Number of calls made to scalar fallback routines in the flash calculation for each timestep.
x	x	NBYTOT	Peak usage of dynamically allocated memory as reported the simulator internal memory allocator.  Note that some memory allocations are performed by other mechanisms and are not accounted for by this summary quantity. In parallel, this is the maximum across processors.
x	x	NCPRLINS	Average number of pressure iterations per linear iteration for each timestep (CPR or JALS solver only).
	x	NEWTFL	Cumulative average Newton iterations per cell in two phase flash calculations.
x	x	NEWTON	Number of Newton iterations used for each timestep
x	x	NLINEARP	Average number of pressure iterations per Newton iteration for each timestep (CPR or JALS solver only).
x	x	NLINEARS	Average number of linear iterations per Newton iteration for each timestep.
x	x	NLINSMIN	Actual minimum number of linear iterations in the Newton iterations within each timestep.
x	x	NLINSMAX	Actual maximum number of linear iterations in the Newton iterations within each timestep.

E100	E300	Keyword	Description
x	x	NMESSAGE	Requests a set of message data vectors for the run. The set of keywords implied by NMESSAGE is:  MSUMBUG, MSUMCOMM, MSUMERR, MSUMMESS, MSUMPROB and MSUMWARN
	x	NNUMFL	Total number of two phase flash calculations performed.
	x	NNUMST	Total number of stability tests performed.
	x	NLRESSUM	Sum of the non-linear residual.
	x	NLRESMAX	Maximum element of the non-linear residual.
	x	NTS	Number of timesteps taken.
	x	NTSPCL	Number of timesteps in which the pressure solution variable converged last.  The tolerance on the pressure solution change can be modified using item 1 of the <a href="#">CVCRT</a> keyword.
	x	NTSMCL	Number of timesteps in which the molar density solution variables converged last.  The tolerance on the pressure solution change can be modified using item 7 of the <a href="#">CVCRT</a> keyword.
	x	NTSECL	Number of timesteps in which the energy density solution variable converged last.  The tolerance on the pressure solution change can be modified using item 8 of the <a href="#">CVCRT</a> keyword (THERMAL option)
x		PERFORMA	Requests a set of performance data vectors for the run. The set of keywords implied by PERFORMA is:  TCPU, ELAPSED, NEWTON, NLINEARS, NLINSMIN, NLINSMAX, MLINEARS, MSUMLINS, MSUMNEWT, TIMESTEP, TCPUTS, TCPUDAY, STEPTYPE, and TELAPLIN. If a steady-state run, set with keyword <a href="#">PSTEADY</a> , then the PSS* keywords are also output.  If the CPR solver has been selected MLINEARP, MSUMLINP, NCPRLINS, NLINEARP are additionally output.
	x	PERFORMA	Requests a set of performance data vectors for the run. The set of keywords implied by PERFORMA is:  TCPU, ELAPSED, NEWTON, NLINEARS, NLINSMIN, NLINSMAX, MLINEARS, MSUMLINS, MSUMNEWT, TIMESTEP, NEWTFL, NNUMFL, NNUMST, NBAKFL, TCPUTS, TCPUDAY.  If the <a href="#">AIM</a> Solution option has been selected NAIMFRAC is additionally output.  If the CPR solver or the JALS solver has been selected MLINEARP, MSUMLINP, NCPRLINS, NLINEARP are additionally output.

E100	E300	Keyword	Description
x		STEPTYPE	<p>Outputs an integer representing the reason for selecting the timestep length (see "<a href="#">Convergence Reports</a>" in the <i>ECLIPSE Technical Description</i>):</p> <p>1=INIT 2=TRNC 3=MINF 4=MAXF 5=MINS 6=MAXS 7=REPT  8=HALF 9=CHOP 10=SATM 11=PCHP 12=DIFF 13=LGR C 14=SURF  15=NETW 16=THRP 17=EMTH 18=MAXP 19=WCYC 20=MAST  21=SLVR 22=SLVC 23=MAXW 24=EFF+ 25=EFF- 26=NLTR 27=EFFT  28=DLYA 29=ACTN 30=RAIN</p> <p>For initial time, the STEPTYPE will remain blank.</p> <p>When a neat tabulated output of the summary file data is printed in the Print file at the end of a run (see <a href="#">RUNSUM</a>) or in a separate RSM file (see <a href="#">SEPARATE</a>, <a href="#">EXCEL</a> and <a href="#">LOTUS</a>), then the output is rendered as mnemonics.</p>
x	x	TCPU	<p>Current CPU usage in seconds.</p> <p>This does not take into account the time taken by inter-process communications, whereas ELAPSED does. Consequently, in parallel, ELAPSED is the most relevant time measurement.</p>
x	x	TCPUDAY	CPU time per day (or hour in lab units).
x		TCPUH	Total CPU time for each gradient calculation ( <i>Gradient Option</i> ).
x		TCPUHT	Total CPU time for all gradient calculations ( <i>Gradient Option</i> ).
x		TCPUSCH	Total CPU time used in SCHEDULE section.
x	x	TCPUTS	CPU time per timestep in seconds.
x		TCPUTSH	CPU time per timestep for each gradient calculation ( <i>Gradient Option</i> ).
x		TCPUTSHT	CPU time per timestep for all gradient calculations ( <i>Gradient Option</i> ).
	x	TCPUTR	Total CPU time used in tracer calculations.
	x	TCPUTRSV	Total CPU time used in tracer calculations by the implicit solver.
	x	TCPULGTR	Total CPU time used in LAGTRAC streamline tracing.
	x	TCPULGSV	Total CPU time used in the LAGTRAC tracer solver.
x		TELAPDAY	Elapsed time per day (or hour in lab units).
x		TELAPLIN	Elapsed time per linear iteration in seconds.
x		TELAPTS	Elapsed time per timestep in seconds.
x	x	TIMESTEP	Timestep length.
x	x	TUNE	<p>Requests the following set of vectors for the run:</p> <p>NLRESSUM, NLRESMAX, NTS, NTSPCL, NTSMCL and NTSECL in a THERMAL simulation.</p>
x	x	WNEWTON	<p>Number of well Newton iterations taken in the last global Newton iteration.</p> <p>A negative value indicates that the well failed to converge.</p>
x		ZIPEFF	Predicted efficiency of the timestep (mainly for developer use).

E100	E300	Keyword	Description
x		ZIPEFFC	Predicted efficiency of the timestep divided by the actual efficiency (mainly for developer use).

Table 2.76: Simulator performance keywords

**Note:** When requesting output of total number of messages with the MSUMBUG, MSUMCOMM, MSUMERR, MSUMMESS, MSUMPROB, MSUMWARN or NMESSAGE for all message mnemonics, the count(s) reported by these mnemonics may be truncated by one count if the last type of message reported causes the run to stop.

## Other keywords

The other SUMMARY keywords are listed below.

ALL Requests a basic set of field, group and well keywords for all groups and wells present in the problem. The set of keywords implied by ALL is:

- FOPR GOPR WOPR FOPT GOPT WOPT
- FOIR GOIR WOIR FOIT GOIT WOIT These keywords are only valid in ECLIPSE 100.
- FWPR GWPR WWPR FWPT GWPT WWPT
- FWIR GWIR WWIR FWIT GWIT WWIT
- FGPR GGPR WGPR FGPT GGPT WGPT
- FGIR GGIR WGIR FGIT GGIT WGIT
- FVPR GVPR WVPR FVPT GVPT WVPT
- FVIR GVIR WVIR FVIT GVIT WVIT
- FWCT GWCT WWCT FGOR GGOR WGOR
- FWGR GWGR WWGR
- WBHP WTHP WPI
- FOIP FOIPL FOIPG
- FWIP
- FGIP FGIPL FGIPG FPR
- FAQR FAQRG AAQR AAQRG
- FAQT FAQTG AAQT AAQTG

E100	E300	Keyword	Description
x	x	DATE	Requests the date as three summary quantities DAY, MONTH, YEAR. In addition, the date is printed in place of the time in the RUNSUM output
x	x	EXCEL	Requests RUNSUM output to be in Microsoft Excel format.

E100	E300	Keyword	Description
x	x	GMWSET	Requests the set of keywords that counts the number of production and injection wells in various states and under various control modes. The set also includes counts of drilling queue and workover events in a timestep and the cumulative totals of such events. The wells included in the counts are limited to those that can be hierarchically traced to a named group.
x	x	FMWSET	Requests the set of mnemonics that counts the number of all production and injection wells in various states and under various control modes. The set also includes counts of drilling queue and workover events in a timestep and the cumulative totals of such events.
x		LOTUS	Requests RUNSUM output to be in Lotus 1-2-3 format.
x		MONITOR	Outputs information required by GRAF for run-time monitoring.
x	x	NOMONITO	Disables run-time monitoring.
x	x	NARROW	Increases the number of columns per page in the RUNSUM output by restoring the pre-97A (ECLIPSE 100) or pre-2000A (ECLIPSE 300) format with narrower columns.
x	x	RPTONLY	Requests that the summary data is only produced at report times. The default if RPTONLY is not present, is to write the summary information at every time.
x	x	RPTONLY	Requests summary data is written every timestep. This is the default situation and the keyword need only be used to turn off a previously entered RPTONLY instruction.
x		RPTSMRY	Requests printed output of keywords in the SUMMARY section
x		RUNSUM	Requests a neat tabulated output of the summary file data at the end of the normal ECLIPSE 100 printed output.
		RUNSUM	Requests a neat tabulated output of the summary file data at the end of the run, this output goes to a separate RSM file.
x		SEPARATE	Requests RUNSUM output to go to a separate RSM file.
x	x	SUMTHIN	Reduces the amount of summary data recorded. Data are only output once in each time period defined by this keyword, as well as every report timestep.

Table 2.77: Other SUMMARY keywords

## Deprecated keywords

The following SUMMARY keywords have been deprecated due to naming convention irregularities. The following replacements should be used:

E300	Deprecated Keyword	Replacement Keyword	Deprecation release
x	CCFR	CKFR	2011.1
x	CCFT	CKFT	2011.1
x	RCFR	RKFR	2011.1
x	RCFR+	RKFR+	2011.1
x	RCFR-	RKFR-	2011.1

E300	Deprecated Keyword	Replacement Keyword	Deprecation release
x	RCFT	RKFT	2011.1
x	RCFT+	RKFT+	2011.1
x	RCFT-	RKFT-	2011.1
x	BSWL	BPSWL	2011.1
x	BSWCR	BPSWCR	2011.1
x	BSWU	BPSWU	2011.1
x	BSGL	BPSGL	2011.1
x	BSGCR	BPSGCR	2011.1
x	BSGU	BPSGU	2011.1
x	BSOWC	BPSOWCR	2011.1
x	BSOGC	BPSOGCR	2011.1
x	BCFRI	BKFRI	2012.1
x	BCFRJ	BKFRJ	2012.1
x	BCFRK	BKFRK	2012.1
x	SCFRn	SCWGFR	2012.1
x	BPORVT	BRPV	2014.1
x	LBPORVT	LBRPV	2014.1

Table 2.78: Deprecated SUMMARY keywords

## Deleted keywords

The following SUMMARY keywords have been deleted. The following replacements must be used:

E300	Deleted Keyword	Replacement Keyword	Deprecation release	Deletion Release
x	BASPFL	BAREAC	2011.1	2011.1
x	WNPR	WNLPR	2008.1	2012.1
x	WNPT	WNLPT	2008.1	2012.1

x	RNPR	RNLPR	2008.1	2012.1
x	RNPT	RNLPT	2008.1	2012.1

Table 2.79: Deleted SUMMARY keywords

## SCHEDULE section

The SCHEDULE section specifies the operations to be simulated (production and injection controls and constraints) and the times at which output reports are required. Vertical flow performance curves and simulator tuning parameters may also be specified in the SCHEDULE section.

All keywords in this section are optional, except for those necessary to define the status of the wells, and the END keyword, which should mark the end of the scheduling data.

To define a well and its connection properties and controls, the following keywords should be used:

1. **WELSPECS** or **WELSPECL** (to introduce the well).

Having created a well specification you can now set its completion and control data.

2. **COMPDAT** or **COMPDATL** (to specify its completion data)
3. You can specify well controls using the following keywords:
  - WCONPROD** (production controls, if the well is a producer) or
  - WCONINJE** (injection controls, if the well is an injector) or
  - WCONHIST** (measured flows and pressures, if it is a history matching producer) or
  - WCONINJH** (measured flow and pressures, if it is a history matching injector) or
  - WCONINJP** (control of a pattern flood injector)
4. In ECLIPSE 300, separators should be defined with **SEPCOND** and allocated to wells with **WSEPCOND**. Injection gas composition should also be defined with **WINJGAS** or **GINJGAS**. Injection oil composition should be defined with the **WINJOIL** keyword.

The keywords **WELSPECL** and **COMPDATL** should be used in local grid refinement runs when the well is situated in a local grid. There are also some alternatives to the above keywords that are available only in ECLIPSE 300: **WELLSPEC**, **WELLCOMP**, **WELLPROD** and **WELLINJE**. These original keywords are retained for back compatibility, but you are encouraged to use the keywords that are compatible with both simulators.

Any other keywords that refer to a particular well must be positioned after the well and its connections have been defined.

Wells can be introduced at any time in the simulation, but once a well has been introduced using the keyword **WELSPECS** or **WELSPECL** its connection properties and operating status must be defined as shown above. Data concerning the well can be changed later in the simulation by repeating the appropriate keyword(s).

Certain keywords (for example **GCONPROD**, **GCONINJE**, **GECON**) refer to groups. A new group is automatically introduced immediately its name appears in either keyword **WELSPECS** or **GRUPTREE**. Any other keywords that refer to a particular group must be positioned after the group has been introduced.

Well and group names, and other character strings in the scheduling data, may be enclosed in quotes (' '), but generally this is not essential. Such quotes are only usually required if a name contains embedded blanks, starts with a number or contains non-alphanumeric characters. Quotes are also required for name roots and well list names (see below), which contain an asterisk (\*).

In most of the well scheduling keywords a well name root, ending with an asterisk (\*), can be used to refer to several wells in one record. The data is applied to all currently defined wells whose names begin with the sequence of characters preceding the asterisk in the name root. For example the root 'PR\*' applies to all

wells currently entered with names beginning with PR, including the name 'PR' itself. The root '\*' will refer to all wells currently entered. It is important to note that the data does **not** apply to any wells introduced later in the run. Therefore if you are going to use well name roots, it may be advisable to define all the wells at the beginning of the run with the keywords [WELSPECS](#), [COMPDAT](#) and [WCONPROD](#) or [WCONINJE](#) or [WCONHIST](#) or [WCONINJH](#) or [WCONINJP](#) and shut the wells that are not needed until later. Group name roots can similarly be used to refer to multiple groups. As with well name roots, group name roots only refer to groups that are currently defined. Well and group name roots must not have any characters following the asterisk.

An alternative method of referring to several wells in one record is to use a well list name. These begin with an asterisk, followed by at least one letter. A well list comprises a set of well names; there is no limit to the number or length of the well lists, and they may be changed at any time in the simulation. The keywords [WLIST](#) and [WLISTDYN](#) (ECLIPSE 300 only) provide a set of facilities for constructing and managing well lists.

All keywords must start in column 1 of the data file. The keywords may be up to 8 characters long, and all 8 characters (including blanks) are significant. Most of the keywords have a similar syntax: the keyword is followed by any number of records, each containing a number of data items, and each terminated by a slash character (/). The records can be terminated early using the slash character (/); the remaining items take their default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted. The set of records is ended by a blank record, containing only a slash. Some of the data items are character strings which select a particular option from a set of available options. In general, these may be truncated to the first one or two characters as necessary to avoid ambiguity. However, you are recommended to enter the complete character string as some sets of options may be extended in future releases and the number of characters necessary to avoid ambiguity may increase.

The order in which keywords are specified in the SCHEDULE section dictates the order in which the specified operations are simulated. A [TIME](#), [TSTEP](#) or [DATES](#) keyword advances the simulation to a specified time. A subsequent well control keyword alters the well status from the current time. A further [TIME](#), [TSTEP](#) or [DATES](#) keyword advances the simulation through another time period using the new well status. For example, if a [WELTARG](#) keyword is used to redefine a well production rate at a certain time, a subsequent [TIME](#), [TSTEP](#) or [DATES](#) keyword advances the simulation to the next report time with the well operating at its new rate.

A list of keywords available in the SCHEDULE section is given below, together with a brief description of their function. The list is grouped into functional categories. The list does not include old-style ECLIPSE 300 keywords which have been superseded by ECLIPSE 100 compatible keywords, although these keywords are generally retained for back compatibility. The list also does not include keywords specific to the special extensions (for example, local grid refinement); these are listed in the appropriate chapter of the *ECLIPSE Technical Description*. A more detailed description of all the keyword data may be found by looking up the keyword in this manual.

## Define wells, groups and well connections

Restriction	Keyword	Description
Required	<a href="#">WELSPECS</a>	Introduces new wells and specifies some of their general data, including the group to which they belong. A well must be introduced with this keyword before it can be referenced in any other keyword.

Restriction	Keyword	Description
	GRUPTREE	Defines a multi-level tree structure for groups. This keyword is only required if there is more than one level of groups in the field. Well-groups (that is groups containing wells) are introduced by naming them in WELSPECS. In a multi-level group structure there are node-groups, that is groups that have other groups as their immediate subordinates instead of wells. Node groups are introduced by naming them in GRUPTREE.

**Note:** If the GRUPTREE keyword is not used, all groups are assumed to be immediately subordinate to the FIELD, which is the name reserved for the top-most node in the structure. The FIELD cannot have wells of its own, and should not appear in WELSPECS. Apart from the FIELD, a group must have been introduced in WELSPECS or GRUPTREE before it can be referenced in any other keyword.

## Define well connections and set connection properties

### Common keywords

Restrictions	Keyword	Description
	COMPDAT	Defines connections between wells and grid blocks. This keyword is compulsory. All wells must have at least one connection defined. Connections are identified by their well name together with their grid block I,J,K locations. Connections must be defined in COMPDAT before they can be referenced in any other keyword.
Hysteresis option only	COMPIMB	Imbibition table numbers for well connections
	COMPMOBI	Sets a constant user-defined mobility in injection well connections. This enables the injectivity to be calculated more accurately in cases where, for example, gas is injected into a large grid block initially containing oil.
	COMPORD	Defines how the ordering of connections along the wellbore is determined. The default method uses the connection locations and penetration directions to trace the well track through the grid, but simpler ordering methods based on true depth or input order may be selected.
Cannot be used with the Vertical Equilibrium option.	COMPRP	Well connection saturation table end-point scaling data. This keyword may be used independently of any end-point scaling in the grid blocks, and it is typically applied to allow for the effects of partial penetration.
	COMPLUMP	Lumps connections into completions for automatic workovers. The lumped connections are opened or closed together in a workover, and their combined rates are examined when determining whether a workover should be performed.
	WDFAC	Sets the well D-factor (flow-dependent skin for free gas).
	WDFACCOR	Calculates well connection D-factors (flow-dependent skin for free gas).
	WELPI	Scales the connection transmissibility factors to give the well a specified steady-state productivity/injectivity index at the current reservoir conditions.

Restrictions	Keyword	Description
	WPIMULT	Multiplies the connection transmissibility factors by a specified value.
	PICOND	Controls the calculation of the generalized pseudo-pressure option for well inflow in gas condensate runs.
	WINJMULT	Specifies pressure-dependent injectivity multipliers. Sets a constant user-defined mobility in injection well connections. This enables the injectivity to be calculated more accurately in cases where, for example, gas is injected into a large grid block initially containing oil.

### ECLIPSE 100 only keywords

ECLIPSE 100 only keyword	Description
COMPINJK	Sets a constant user-defined relative permeability for injection well connections. This enables the injectivity to be calculated more accurately in cases where, for example, gas is injected into a large grid block initially containing oil.
COMPVE	Well connection depth data. This keyword may be used in vertical equilibrium runs only, to define where a connection penetrates only part of the thickness of a grid block.
WPITAB	Assigns PI multiplier tables (input with keyword PIMULTAB) to wells.
PIMULTAB	Inputs a set of PI multiplier tables, which scale well connection factors as a function of the well's maximum water cut.
WBOREVOL	Sets the wellbore volume, for modeling wellbore storage in well tests.

### ECLIPSE 300 only keywords

ECLIPSE 300 only keyword	Description
COMPKRI	Sets constant user-defined relative permeabilities for each phase in injection well connections. This enables the injectivity to be calculated more accurately in cases where, for example, gas is injected into a large grid block initially containing oil.
COMPAGH	Sets a constant density term used for the calculation of the connection gravity head, making the gravity head independent of the density of the fluid mixture in the well bore.
PSEUPRES	Activates the Generalized Pseudo Pressure option for all wells.

## Define multisegment wells

### Common keywords

Keyword	Description
COMPSEGL	Defines the location of multisegment well completions in a local grid.
COMPSEGS	Defines the location of completions in a multisegment well.
WELSEGS	Defines the segment structure of a multisegment well.
WSEGAICD	Defines segments to represent an 'autonomous' inflow control device.

Keyword	Description
WSEGDFIN	Inputs a table of inclination scaling factors versus deviation angle for the Drift Flux slip model
WSEGDFMD	Defines the Drift Flux slip model
WSEGDFPA	Changes parameter values in Drift Flux slip model.
WSEGEXSS	Specifies fluid import/removal through an external source/sink.
WSEGFLIM	Defines segments to represent a flow limiting valve.
WSEGFMOD	Specifies the multi-phase flow model and related parameters.
WSEGLABY	Defines segments to represent a 'labyrinth' inflow control device.
WSEGLINK	Defines the chord segment links for specifying looped flow paths.
WSEGMULT	Imposes constant or variable multipliers for segment frictional pressure drops.
WSEGPROP	Modifies the properties of individual well segments.
WSEGSICD	Defines segments to represent a 'spiral' inflow control device.
WSEGTABL	Designates segments to have their pressure drops calculated from a VFP table.
WSEGVALV	Defines segments to represent a sub-critical valve.

### ECLIPSE 100 only keywords

ECLIPSE 100 only keyword	Description
WFRICSEG	Converts WFRICTN keyword data for a friction well into data for a multisegment well.
WFRICSGL	Converts WFRICTNL keyword data for a friction well into data for a multisegment well.
WSEGINIT	Sets initial pressure and fluid contents of well segments.
WSEGITER	Activates the robust iteration scheme for solving multisegment wells.
WSEGPULL	Defines a pull through pump for a down-hole water separator.
WSEGSEP	Defines a segment to represent a down-hole separator.

### ECLIPSE 300 only keywords

Restrictions	ECLIPSE 300 only keyword	Description
	SCONINJE	Specifies secondary well injection controls.
	SCONPROD	Specifies secondary well production controls.
	STEST	Tests whether a closed secondary well should be reopened.
Thermal only	WSEGHEAT	Specifies heat loss from a segment.
	WSEGWELL	Associates a segment of a multisegment well with a secondary well name

## Define separators (ECLIPSE 300)

- `SEPCOND` Defines the conditions of a named separator, and assigns this as the default separator for all wells subordinate to a particular group.
- `WSEPCOND` Assigns named separators to wells, in place of their group's default separator specified in `SEPCOND`

The separator conditions associated with a well define the splitting of the well production in to stock tank oil and gas.

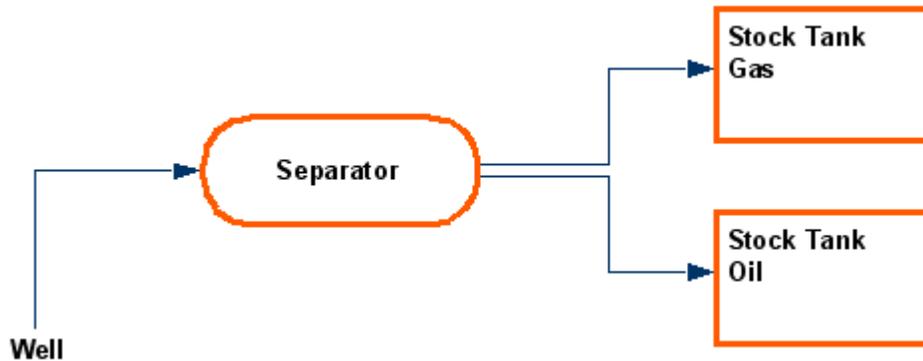

Figure 2.1. Splitting well production into stock tank oil and gas

Separator conditions are defined using the `SEPCOND` keyword. This sets the pressure and temperature for each separator stage, the method to be used to flash the stage, and the coupling to other stages. The last stage is always used to describe the stock tank. For a separator train consisting of two stages and a stock tank, the `SEPCOND` keyword required would be:

```

SEPCOND
SEP1 Field 1 65 815 /
SEP1 Field 2 65 65 /
SEP1 Field 3 45 14.7 /
/
  
```

Note that a final stock tank step is **not** supplied automatically. In this case the separator conditions are SEP1. The first stage has a temperature of 65 °F and a pressure of 815 psi, the second a temperature of 65 °F and a pressure of 65 psi, and the stock tank is at 45 °F and 14.7 psi. The coupling is the default: the liquid from stage 1 feeding stage 2, and the liquid from stage 2 feeding the stock tank. Note that all separators in a given group should have the same final stage (stock tank) conditions, in order that oil volumes are added consistently. A separator stage may be re-specified, or the whole separator condition re-specified. The separator stages must, however, be introduced in increasing order, in order to prevent missing stages when the simulation starts.

## Well controls and limits

Keyword	Description
<code>WEFAC</code>	Sets well efficiency factors, to take account of downtime when wells are taken down individually on a regular basis.
<code>WELOPEN</code>	Opens or closes wells or connections.
<code>WLIST</code>	Constructs well lists for use with other well keywords.

## Production well control data

### Common keywords

Restriction	Keyword	Description
Either WCONPROD or WCONHIST should be used to specify production wells once they have been introduced with WELSPECS and COMPDAT.	WCONPROD	Control data for production wells.
Either WCONPROD or WCONHIST should be used to specify production wells once they have been introduced with WELSPECS and COMPDAT.	WCONHIST	Observed production rates for history matching wells.
	WHISTCTL	Sets control mode instructions for all history matching wells.
	WELTARG	Resets an individual operating target or limit.
	WELCNTL	Resets the control mode and operating target on wells.
	WELDRAW	Sets a maximum allowable drawdown for production wells.
	WTADD	Adds to a well target or limit by a given amount.
	WTMULT	Multiplies a well target or limit by a given factor.
	WLISTARG	Resets individual operating targets or limits for a list of wells, constructed with the WLIST keyword.
	WREGROUP	Switches wells automatically between groups as certain limits are violated.
	LINCOM	Specifies coefficients for a linear combination of oil, water and gas.

### ECLIPSE 100 only keywords

- [WGORPEN](#) Sets data for the GOR Penalty option

## Injection well control data

### Common keywords

Restriction	Keyword	Description
	WCONINJE	Control data for injection wells. Either WCONINJE or WCONINJH should be used to specify injection wells once they have been introduced with WELSPECS and COMPDAT.
	WCONINJH	Observed injection rates for history matching wells. be used to specify injection wells once they have been introduced with WELSPECS and COMPDAT.

Restriction	Keyword	Description
	WCONINJP	Sets the rate of an injection well in terms of the voidage of the production wells that surround it.
	WHISTCTL	Sets control mode instructions for all history matching wells.
	WELTARG	Resets an individual operating target or limit.
	WELCNTL	Resets the control mode and operating target on wells
	WTMULT	Multiplies a well target or limit by a given factor.
	WLISTARG	Resets individual operating targets or limits for a list of wells, constructed with the <a href="#">WLIST</a> keyword.
Tracer option only	WTRACER	Defines the concentration of tracers in the well injection streams
Brine option only	WSALT	Defines the salt concentration in water injectors

### ECLIPSE 100 only keywords

Restriction	ECLIPSE 100 only keyword	Description
	WAPI	Defines the API of injected oil in API tracking cases.
Temperature option only	WTEMP	Defines the temperature of injected water

### ECLIPSE 300 only keywords

Restriction	ECLIPSE 300 only keyword	Description
	WINJGAS	Defines the composition of the fluid injected by wells.
	WINJOIL	Defines the composition of the fluid injected by wells.
Thermal	WINJTEMP	Defines the temperature of the fluid injected by wells
Water component model	WINJW	Defines the composition of the water injected by wells
	WELLSTRE	Sets the composition of a named wellstream for injection.
Water component model	WELLSTRW	Sets the composition of a named wellstream for water injection
	WINJEDET	Describes detailed composition of a lumped fluid for an injection well.
	WINJMIX	Defines an injection mixture by combining fluid from a set of sources according to specified fractions.
	WINJORD	Defines an injection mixture by combining fluid from a set of sources in a specified order.
	WELLWAG	Specifies WAG well injection targets.

## Vertical flow performance keywords

### Common keywords

Keyword	Description
<a href="#">VFPPROD</a>	Supplies a production well VFP table. VFP tables are required only if there are tubing head pressure targets or limits. The VFP table is also used to supply Tubing head temperature values (see the <a href="#">WHTEMP</a> keyword). A VFP table must be entered before it is referenced in <a href="#">WCONPROD</a> or <a href="#">WHTEMP</a> .
<a href="#">VFPINJ</a>	Supplies an injection well VFP table. VFP tables are required only if there are tubing head pressure targets or limits. A VFP table must be entered before it is referenced in <a href="#">WCONINJE</a> .
<a href="#">VFPCHK</a>	Turns off checks for crossing VFP curves when VFP tables are read in, or sets a threshold BHP value above which curve crossings will be ignored (for example to allow for supersonic flow conditions).
<a href="#">WVFPDP</a>	Adds a user-defined adjustment to a well's BHP obtained by interpolating the VFP tables (for example to help match a well's flow rate at a given THP).
<a href="#">WVFPEXP</a>	Instructs a well to use explicit water and gas fractions for VFP table look-up, or when using stabilized VFP tables, to be shut-in at the end of the timestep when it is operating in a part of the table that corresponds to the unstable region. Can also stop a well from hunting between THP and rate control when the rate limit forces the well to operate in the unstable part of the VFP curve.
<a href="#">WHTEMP</a>	This keyword is used to specify the VFP table reference number for Tubing Head Temperature calculations or to set the constant Tubing Head Temperature value. This option is supported only for production wells and not for injection wells.

### ECLIPSE 100 only keywords

ECLIPSE 100 only keyword	Description
<a href="#">VFPTABL</a>	Requests cubic spline interpolation for the artificial lift quantity. This may be useful when running the Gas Lift Optimization facility, by making the gradient of the wells' performance with reference to the lift gas injection rate vary more smoothly over the table.
<a href="#">WALQCALC</a>	Defines the well ALQ to be set equal to the surface density of the well's produced oil or gas.

### ECLIPSE 300 only keywords

ECLIPSE 300 only keyword	Description
<a href="#">VFPCHECK</a>	Contains data that ECLIPSE 300 uses to check for consistency between the simulator fluid model and that used in VFP <i>i</i> to generate the <a href="#">VFPPROD</a> and/or <a href="#">VFPINJ</a> keywords.

## Well economic limits and coning control

### Common keywords

Keyword	Description
WECON	Economic operating limits on well rates and production ratios.
CECON	Economic operating limits on individual well connections.
WCUTBACK	Instructions to cut back well rates to limit coning.
WLIMTOL	Tolerance fraction for economic limits. If the limit is broken by more than the specified tolerance, the timestep will be repeated after the remedial action has been taken.
WORKTHP	Instructions to perform a workover if the well is unable to produce at its THP limit.

### ECLIPSE 100 only keywords

ECLIPSE 100 only keyword	Description
WECONINJ	Sets a minimum economic rate for injection wells.
WTHPMAX	Sets a maximum THP design limit.
WBHGLR	Sets upper limits on the gas-liquid ratio at bottom hole conditions, which will trigger workovers or rate cutbacks.
CECONT	Economic limits on well connection tracer rates and concentrations.
WCUTBACT	Well rate cutbacks and reversals based on tracer rates and concentrations.
WECONT	Economic limits on well tracer rates and concentrations.

### ECLIPSE 300 only keywords

- [WECONCMF](#) Economic operating limits on component mole fractions.

## Group controls and limits

Keyword	Description
NUPCOL	Sets the number of iterations in each timestep for which well flow targets are recalculated for group control.
GCONTROL	Sets tolerance fractions and iteration limits for group control targets and (in ECLIPSE 300) gas injection calculations.
WLIMTOL	Tolerance fraction for workover limits.

## Group production control by guide rate

### Common keywords

Keyword	Description
GCONPROD	Group production rate targets and limits for control by guide rate.
GRUPTARG	Resets an individual production rate target or limit for a group.

Keyword	Description
GPMAINT	Sets group production or injection target to maintain the average pressure in a fluid-in-place region.
WGRUPCON	Sets or scales well guide rates for group control.
GUIDERAT	Coefficients for a general formula for variable well guide rates.
GTADD	Adds to a group rate target or limit by a given factor.
GTMULT	Multiplies a group rate target or limit by a given factor.

### ECLIPSE 100 keywords

- [PRORDER](#) Defines order of applying group production rules, a sequence of actions to maintain group production at its target rate.

### ECLIPSE 300 keywords

- [DGRDT](#) Limits the rate of change of guide rate calculated for wells under group control.
- [GQUALITY](#) Sets group gas quality target.

### Group production control by prioritization

- [PRIORITY](#) Activates prioritization option and sets priority coefficients
- [GCONPRI](#) Group production rate limits for prioritization option.
- [GRUPTARG](#) Resets an individual production rate limit for a group.
- [WELPRI](#) Sets priority numbers for wells.

### Group economic limits and coning control

#### Common keywords

- [GECON](#) Economic operating limits on group rates and production ratios.

### ECLIPSE 100 only keywords

ECLIPSE 100 only keyword	Description
<a href="#">GCUTBACK</a>	Instructions to cut back group rates to limit water/gas breakthrough.
<a href="#">GCUTBACT</a>	Instructions to cut back group rates based on tracer rates and concentrations.
<a href="#">GECONT</a>	Economic limits on group tracer rates and concentrations.

### Group injection control

#### Common keywords

Keyword	Description
<a href="#">GCONINJE</a>	Group injection rate targets and limits.

Keyword	Description
GPMAINT	Sets group production or injection target to maintain the average pressure in a fluid-in-place region.
WGRUPCON	Well guide rates for group control.

### ECLIPSE 100 only keywords

- [GCONSUMP](#) Gas consumption and import rates.

### ECLIPSE 300 only keywords

ECLIPSE 300 only keyword	Description
GINJGAS	Defines the composition of the fluid injected by groups.
WELLSTRE	Sets the composition of a named wellstream for injection.
WINJMIX	Defines an injection mixture by combining fluid from a set of sources according to specified fractions.
WINJORD	Defines an injection mixture by combining fluid from a set of sources in a specified order
GADVANCE	Assigns advance import gas to a group.
GRUPFUEL	Specifies fuel gas usage rate for a group.
GRUPSALE	Specifies gas sales rate for a group.
WTAKEGAS	Specifies the order in which fuel, sales and reinjection gas are extracted from the production gas stream of a source group.
WAVAILIM	Requests that gas reinjection rates should take account of the availability of gas supply.

### Group efficiency factor

- [GEFAC](#) Sets group efficiency factors, to take account of downtime when all the group's subordinate wells have their downtimes synchronized

### Sales gas control (ECLIPSE 100)

This facility provides a means of controlling the export of associated gas from an oil field, which may at the same time have controls on the oil production rate. The gas export rate is controlled by reinjecting the surplus gas not required for sale.

- [GCONSALE](#) Sales gas production targets and limits for groups and the field.
- [GCONSUMP](#) Gas consumption and import rates.
- [WGRUPCON](#) Well guide rates for group control.
- [WGASPROD](#) Defines wells as special gas producers for sales gas control.

## Satellite group flows

Satellite groups can be used to incorporate known production and injection flows from outside the simulation grid. They are groups that contain no wells or subordinate groups, and whose production and injection rates may be set periodically with the following keywords.

### Common keywords

- [GSATPROD](#) Production rate data for satellite groups
- [GSATINJE](#) Injection rate data for satellite groups.

### ECLIPSE 300 only keywords

- [GSATCOMP](#) Fluid composition for satellite groups.

## Sustainable capacity test

- [GSSCPTST](#) This allows the production rate which a group of wells is capable of maintaining for a period of time to be determined.

## Automatic drilling and workover controls

### Common keywords

Keyword	Description
<a href="#">WDRILTIM</a>	Time taken to drill each well. Limits the rate at which new wells can be drilled.
<a href="#">QDRILL</a>	Places wells in the sequential drilling queue. Wells are opened from this drilling queue in the sequence in which they were placed in the queue, whenever they are needed to maintain a group rate target under group control by guide rate ( <a href="#">GCONPROD</a> , <a href="#">GCONINJE</a> , <a href="#">GCONSALE</a> ) or when needed to maintain a group's production potential ( <a href="#">GDRILPOT</a> ).
<a href="#">WDRILPRI</a>	Places wells in the prioritized drilling queue. This operates in a similar way to the sequential drilling queue (keyword <a href="#">QDRILL</a> ) except that wells are opened in decreasing order of drilling priority. Well drilling priorities can either be set manually or calculated as a function of their potential rates according to a formula specified with the <a href="#">DRILPRI</a> keyword.
<a href="#">DRILPRI</a>	Defines the default priority formula for the prioritized drilling queue set up with keyword <a href="#">WDRILPRI</a>
<a href="#">GDRILPOT</a>	Causes wells to be drilled from the drilling queue when a group's production rate potential falls below a specified value.
<a href="#">WORKLIM</a>	Time taken to perform a workover. Limits the rate of doing workovers.
<a href="#">GRUPRIG</a>	Assigns workover rigs to groups. Together with <a href="#">WORKLIM</a> , it limits the rate at which workovers can be performed within particular groups.
<a href="#">COMPLUMP</a>	Lumps connections into completions for automatic workovers. The lumped connections will be opened or closed together in a workover, and their combined rates will be examined when determining whether a workover should be performed.

## ECLIPSE 100 only keywords

ECLIPSE 100 only keyword	Description
WDRILRES	Prevents two wells being drilled in the same grid block
WELSOMIN	Prevents new connections being opened in grid blocks having less than a specified minimum oil saturation.
PRORDER	Defines order of applying group production rules, including drilling and re-perforating, to maintain group production at its target rate.
WPLUG	Well plug-back lengths, for automatic plug-backs.

## Action keyword facility

Keyword	Description
ACTION	Initiates a set of actions (defined by SCHEDULE section keywords) to be executed when a specified field condition is satisfied.
ACTIONG	Defines actions to be triggered by group quantities.
ACTIONR	Defines actions to be triggered by region quantities.
ACTIONW	Defines actions to be triggered by well quantities.
ACTIONS	Defines actions to be triggered by well segment quantities.
ACTIONX	Defines actions to be triggered by a set of conditions on various quantities
DELAYACT	Defines actions to be triggered a given time after another action has been triggered.
ENDACTIO	Indicates the end of the set of actions initiated with the ACTION keyword family.

## Periodic testing and cycling wells

### Common keywords

- [WTEST](#) Instructions for periodic testing of closed wells, to see if they can operate again.

### ECLIPSE 100 only keywords

- [WCYCLE](#) Instructions for automatically cycling wells on and off.

### ECLIPSE 300 only keywords

- [WELLWAG](#) Specifies WAG well injection targets.

## Artificial lift operations (ECLIPSE 100)

ECLIPSE 100 only keyword	Description
WLIFT	Instructions for automatic retubing, lift switching and THP reduction, when a well or group production rate falls below a specified value.

<b>ECLIPSE 100 only keyword</b>	<b>Description</b>
GLIFTLIM	Limits on artificial lift capacity for groups. Prevents further automatic lift switching when group lift capacity would be exceeded.
WLIMTOL	Tolerance fraction for lift switching limits. If violated by more than the tolerance, the timestep will be repeated after retubing or lift switching.
WELTARG	Change VFP table number or artificial lift quantity, for manual retubing or lift switching.
PRORDER	Defines order of applying group production rules, including artificial lift operations, to maintain group production at its target rate.
VFPTABL	Requests cubic spline interpolation for the artificial lift quantity. This may be useful when running the Gas Lift Optimization facility, by making the gradient of the wells' performance with reference to the lift gas injection rate vary more smoothly over the table.

## Scale deposition model

<b>Keyword</b>	<b>Description</b>
SCDATAB	Defines scale damage tables which govern the reduction in the connection transmissibility factor caused by deposited scale.
SCDPTAB	Defines scale deposition tables which govern the rate of scale deposition (per unit water flow) at a well connection. This rate depends on the fraction of sea water present in the water flowing through the connection.
SCDPTRAC	Sets a passive water tracer to be associated with the sea water fraction.
WSCTAB	Specifies which scale deposition table and which scale damage table will be used to model scale effects for a well.
WSCCLEAN	Reduces the amount of scale deposited around well connections
WSCCLENL	Reduces the amount of scale deposited around local grid well connections

## Flash transformation and separator conditions

### Common keywords

<b>Keyword</b>	<b>Description</b>
COMPFLSH	Sets flash transformation ratios to apply to the well connection flows. They can be used to transform oil and gas production rates from differential liberation conditions to flash liberation conditions.

### ECLIPSE 100 only keywords

<b>Restriction</b>	<b>ECLIPSE 100 only keyword</b>	<b>Description</b>
	GSEPCOND	Assigns separators to groups, for use with SEPVALS

Restriction	ECLIPSE 100 only keyword	Description
Use of SEPVALS is not allowed in runs using the COMPFLSH keyword.	SEPVALS	Enters separator test results.  The keyword can be used firstly to define the initial separator conditions, and subsequently to change them. When the separator conditions have been changed, ECLIPSE will transform the oil and gas flow rates of the wells and groups that feed into the separator.

## Gas processing (ECLIPSE 300)

- [GPTABLE](#) Tables of gas plant recovery factors
- [GPTABLEN](#) Gas plant table with NGL recoveries
- [GPTABLE3](#) Gas plant table with oil, NGL and gas recoveries
- [RECOVERY](#) Recovery plant table.

## Aquifer controls

### Common keywords

Keyword	Description
<a href="#">AQUFLUX</a>	Modifies the water influx rate from a constant flux aquifer.
<a href="#">AQUCHGAS</a>	Modifies the gas head for a constant head gas aquifer.
<a href="#">AQUCHWAT</a>	Modifies the water head for a constant head water aquifer.
<a href="#">AQUCT</a>	Modifies the properties of a Carter-Tracy aquifer. <a href="#">AQUFETP</a> Modifies the properties of a Fetkovich aquifer.

### ECLIPSE 100 only keywords

ECLIPSE 100 only keyword	Description
<a href="#">RAINFALL</a>	Specifies a monthly flux rate for constant flux aquifers.
<a href="#">AQUCWFAC</a>	Modifies the properties of all <a href="#">AQUCHWAT</a> type aquifers.

### ECLIPSE 300 only keywords

ECLIPSE 300 only keyword	Description
<a href="#">AQSTREAM</a>	Sets composition of gas stream for <a href="#">AQUCHGAS</a> aquifer. For the <a href="#">GASWAT</a> and <a href="#">CO2STORE</a> options, sets composition of water <a href="#">AQUCHWAT</a> , <a href="#">AQUCT</a> , <a href="#">AQUFETP</a> and <a href="#">AQUFLUX</a> aquifers.
<a href="#">AQSTREAMW</a>	For the multi-component water option ( <a href="#">COMPW</a> ), sets composition of water <a href="#">AQUCHWAT</a> , <a href="#">AQUCT</a> , <a href="#">AQUFETP</a> and <a href="#">AQUFLUX</a> aquifers.

## Dissolved gas and vaporized oil constraints (ECLIPSE 100)

Restriction	ECLIPSE 100 only keyword	Description
If not specified, gas redissolves instantly in under-saturated oil	DRSDT	Gas re-solution rate.
If not specified, oil vaporizes instantly in under-saturated wet gas	DRVDT	Oil vaporization rate
Only for systems with both wet gas and live oil	VAPPARS	Parameters controlling vaporization of oil in under-saturated gas.

## Geomechanics option (ECLIPSE 300)

ECLIPSE 300 only keyword	Description
DISPBC	Permits the application of displacement (Dirichlet) or velocity boundary conditions.
GMDISBC	Permits the application of displacement (Dirichlet) boundary conditions.
GMPSTBC	Principal stresses can be applied as boundary conditions
GMTRABC	Permits application of traction (Neumann) boundary conditions.
PSTRBC	Principal stresses can be applied as boundary conditions.
STRESEBC	Permits the application of a load or a velocity (rigid) boundary condition on all external and internal surfaces of the simulation grid.
TRACTBC	Permits application of traction (Neumann) boundary conditions.
WSCTAB	Links a well to a scale damage table.

## Grid block property modifications

### Common keywords

Keyword	Description
BOX	Defines the current input box, for use with MULTX, MULTX-, MULTY, MULTY-, MULTZ, MULTZ- and MULTPV.
MULTFLT	Modifies the transmissibility across a named fault.
MULTPV	Multiplies the pore volumes of cells within the current input box.
MULTX	Multiplies X-direction transmissibilities of cells within the current input box
MULTX-	Multiplies negative X-direction transmissibilities of cells within the current input box.
MULTY	Multiplies Y-direction transmissibilities of cells within the current input box.
MULTY-	Multiplies negative Y-direction transmissibilities of cells within the current input box.
MULTZ	Multiplies Z-direction transmissibilities of cells within the current input box.

Keyword	Description
<a href="#">MULTZ-</a>	Multiplies negative Z-direction transmissibilities of cells within the current input box.
<a href="#">MULTR</a>	Multiplies R-direction transmissibilities of cells within the current input box.
<a href="#">MULTR-</a>	Multiplies negative R-direction transmissibilities of cells within the current input box.
<a href="#">MULTTHT</a>	Multiplies Theta-direction transmissibilities of cells within the current input box.
<a href="#">MULTTHT-</a>	Multiplies negative Theta-direction transmissibilities of cells within the current input box.

## ECLIPSE 100 only keywords

ECLIPSE 100 only keyword	Description
<a href="#">EXCAVATE</a>	Removes cells during a run.

## ECLIPSE 300 only keywords

ECLIPSE 300 only keyword	Description
<a href="#">OVERTR</a>	Overwrites R direction transmissibilities.
<a href="#">OVERTTHT</a>	Overwrites theta direction transmissibilities.
<a href="#">OVERTX</a>	Overwrites X direction transmissibilities.
<a href="#">OVERTY</a>	Overwrites Y direction transmissibilities.
<a href="#">OVERTZ</a>	Overwrites Z direction transmissibilities.

## Dynamic Regions Facility

Keyword	Description
<a href="#">DYNAMICR</a>	Defines regions based on when a set of conditions are satisfied. These regions may be static or allowed to change dynamically.
<a href="#">ENDDYN</a>	Indicates the end of a DYNAMICR keyword sequence

## Dual porosity

- [DIFFMMF](#) Diffusivity multipliers for matrix-fracture diffusive coupling.
- [MULSGGD](#) Specify dual porosity alternative oil-gas matrix-fracture transmissibility multiplier
- [MULSGGDV](#) Specify dual porosity alternative oil-gas matrix-fracture transmissibility multipliers
- [MULTSIG](#) Specify dual porosity matrix-fracture transmissibility multiplier
- [MULTSIGV](#) Specify dual porosity matrix-fracture transmissibility multipliers

## Lagrangian Tracer Solver (ECLIPSE 300)

ECLIPSE 300 only keyword	Description
LAGTRUPD	Defines the streamline update conditions and solver method for the Lagrangian tracer solver.
LTRACE	Forces a streamline trace at the end of the next timestep.
NOLTRACE	Prevents streamline tracing until the next LTRACE or LAGTRUPD.
RPTSLN	Controls the output of streamline data as SLN files.

## Simulator controls

The keywords are:

### Common keywords

Keyword	Description
NEXTSTEP (or NEXT)	Restricts the next timestep to a specified maximum size.
TUNING	Timestep and convergence controls.
SKIPREST	Makes ECLIPSE skip the subsequent keywords in a restart run until the restart time is reached.
NSTACK	Sets the linear solver stack size.
ZIPPY2	Experimental feature to automatically select timesteps in poorly converging runs.
ZIPP2OFF	Turns off ZIPPY2 feature.

### ECLIPSE 100 only keywords

ECLIPSE 100 only keyword	Description
TUNINGDP	Supplies a modified set of convergence parameters for some high throughput cases.
TIGHTEN	Enables convergence parameters to be tightened
TIGHTENP	Enables convergence parameters to be tightened.
DIMPES	Sets the <code>IMPES</code> solution procedure.
DIMPLICIT	Restores the fully implicit solution procedure.
MATCORR	Activates the material balance correction option, to reduce the accumulated material balance error.
READDATA	Reads files of SCHEDULE data that may be constructed externally during the course of the run.
OPTIONS	Activate special options within particular facilities in ECLIPSE 100.

## ECLIPSE 300 only keywords

ECLIPSE 300 only keyword	Description
TOPT	Preset tuning options.
TSCRIT	Timestep controls.
CVCRIT	Convergence criteria.
FCCRIT	Flash convergence criteria.
LSCRIT	Linear solution convergence criteria.
LSCRITS	Linear solution convergence criteria for each individual sub-grids.
AIMFRAC	Sets the target implicit fraction in AIM mode.
AIMPVI	Specifies the minimum pore volume for an explicit cell in AIM mode.
AIMCON	Controls implicit cells within an AIM run.
CHANDIMS	Increase well array dimensions.
OPTIONS3	Activate special options within particular facilities in ECLIPSE 300.
WCOMPRES	Reduce the memory requirements of a simulation that contains a large number of wells, some of which have many connections, but most have relatively few connections

## User defined values

- [UDQ](#) Specify user defined quantities.

## Output

### Common keywords

Keywords	Description
<a href="#">RPTSCHED</a>	Report switches to select which simulation results are to be printed at report times.
<a href="#">RPTRST</a>	Controls data written to the Restart file.
<a href="#">SAVE</a>	Controls solution output for plotting and flexible restarts.
<a href="#">OUTSOL</a>	Writes the current solution to a Save file for fast restarts.
<a href="#">BOUNDARY</a>	Defines section of grid for which output maps are required.
<a href="#">WPAVE</a>	Controls the calculation of well block average pressures that may be output to the Summary file.
<a href="#">WWPAVE</a>	Controls the calculation of well block average pressures for an individual well. Average pressures may be output to the Summary file.
<a href="#">WPAVEDEP</a>	Specifies a reference depth for the calculation of well block average pressures.
<a href="#">WRF'TPLT</a>	Requests output of RFT, PLT and segment data to the RFT file.
<a href="#">WELDEBUG</a>	Sets debug output switches for individual wells. (This is primarily intended as an aid to program development and debugging, and is not recommended for general use.)

Keywords	Description
WELEVNT	Sets SUMMARY keyword WPWEM output for individual wells.
WTEMPQ	Queries the well name and well list template matching algorithm
RPTONLY	Requests that the summary data is only produced at report times. The default, if RPTONLY is not present, is to write the summary information at every time.
RPTONLYO	Requests summary data is written every timestep. This is the default situation and the keyword need only be used to turn off a previously entered RPTONLY instruction.
RPRKPAME	Outputs the rock compaction
SUMTHIN	Reduces the number of data written to summary output files.

## ECLIPSE 100 only keywords

- [WRFT](#) Requests output of well block data to the RFT file.

## ECLIPSE 300 only keywords

ECLIPSE 300 only keyword	Description
DBGODD3P	Debug output for <a href="#">ODD3P</a> option.
RPTPRINT	Controls the output of printed simulation results.
AUTOSAVE	Writes the solution to a Save file every 'n' steps.
SAVEEND	Requests that the solution is written to a Save file whenever the run ends.
GSEPREPT	Specifies the separator chain used for sum-then-separate summary section keywords such as <a href="#">FGPRG</a>
ROCKPAME	pore volume and the permeability multipliers versus pressure for a given cell.

## Conductive Fractures (ECLIPSE 300)

- [WELLCF](#) Defines well behavior with conductive fractures.

## Adjoint gradient screening option (ECLIPSE 300)

- [AJGPARAM](#) Specify static parameters for the adjoint gradient screening option.
- [AJGWELLS](#) Specify objective functions for the adjoint gradient screening option.

## Advance simulation to new time/date

Keyword	Description
TSTEP	Advances the simulation over specified intervals between reporting times.
DATES	Advances the simulation to specified dates at which reports are required.
SIMULATE	Counteracts a NOSIM keyword and turns on the timestep simulation.

Keyword	Description
TIME	Advances the simulation to specified times at which reports are required, with respect to the START date in RUNSPEC.
NOSIM	Turns off simulation, but continues reading, processing and checking the subsequent keyword data.
SIMULATE	Counteracts a NOSIM keyword and turns on the timestep simulation.
END	Terminates the simulation.

## Instantaneous gradient option

- [GWRTWCV](#) Specify gradient parameters in terms of well collections.
- [GUPFREQ](#) Specify update frequency of the instantaneous gradient option.

## Polymer flood model

### ECLIPSE 100 only keywords

ECLIPSE 100 only keyword	Description
PLYADS	Polymer adsorption functions (tabulated).
PLYDHFLF	Polymer thermal degradation half life.
PLYMAX	Polymer/salt concentrations for mixing calculations.
PLYROCKM	Polymer-rock properties.
PLYSHEAR	Polymer shear thinning/thickening data.
PLYSHLOG	Activates a logarithm-based polymer shear thinning/thickening model that may be used as an alternative to PLYSHEAR. By default, this model is based on water velocity; if used in conjunction with keyword SHRATE then a switch to shear rate form is applied.
SHRATE	Activates the shear rate form of the alternative polymer shear thinning/thickening logarithmic model.

### ECLIPSE 300 only keywords

- [PLYVISC](#) Polymer solution viscosity function.
- [PLYVISCS](#) Polymer/salt solution viscosity function.

## OPTIMIZE section

**Note:** The OPTIMIZE section is for use with ECLIPSE 300 only.

The OPTIMIZE section header must **not** be specified in an included file.

The OPTIMIZE section is used to define the main components of an optimization loop:

- The objective function
- The parameters to vary to maximize the objective function
- Constraints to observe during the optimization
- Optimization tuning parameters, and reporting options.

The use of the above specifications is described in "[Optimization](#)" in the *ECLIPSE Technical Description*.

## OPTIMIZE section keywords

A list of all keywords that may occur in the OPTIMIZE section is given below, together with a brief description of their function. A more detailed description may be found by referring to the keyword description.

Keywords must start in column 1. All characters up to column 8 are significant.

Keyword	Description
<a href="#">OPTCONS</a>	Defines constraints for the reservoir optimization problem.
<a href="#">OPTDIMS</a>	Specifies dimensions for the reservoir optimization problem.
<a href="#">OPTFUNC</a>	Specifies the objective function for reservoir optimization.
OPTIMIZE	Defines the start of the optimization section.
<a href="#">OPTLOAD</a>	Hot-starts a reservoir optimization simulation.
<a href="#">OPTOPTS</a>	Specifies options that control the reservoir optimization.
<a href="#">OPTPARS</a>	Defines parameters for the reservoir optimization problem
<a href="#">OPTTUNE</a>	Defines tuning parameters for reservoir optimization.
<a href="#">RPTOPT</a>	Reservoir optimization report options.

Table 2.80: OPTIMIZE section keywords

## Acentric factor

In a run with  $N_c$  components, using an equation of state, this keyword defines the acentric factor for each component. The keyword should be followed by  $N_c$  values. The use of the acentric factor in the equation of state is discussed in "Equations of State" of the *ECLIPSE Technical Description*.

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of keyword `TABDIMS`. The use of multiple EoS regions is discussed in "Equations of State Regions" of the *ECLIPSE Technical Description*.

DEFAULT: There are no component-wise default values. The users are recommended not to default these to the internal default value.

## Examples

### Example 1

```
ACF
0.01 0.0 0.02 0.001 /
```

### Example 2

With three reservoir EoS regions and nine components:

```

## Acentric factor for detailed components

In a run with  $N_d$  detailed components, using an equation of state, this keyword defines the acentric factor for each detailed component. Lumped simulations are enabled with the [LUMPDIMS](#) keyword in the RUNSPEC section; further details can be found in "[Delumping and lumping](#)" in the *ECLIPSE Technical Description*. The keyword should be followed by  $N_d$  values. The use of the acentric factor in the equation of state is discussed in "[Equations of State](#)" in the *ECLIPSE Technical Description*.

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of State Regions](#)" in the *ECLIPSE Technical Description*.

### Examples

This keyword is used to specify the activity coefficient model for CO<sub>2</sub> which is used by the [CO2STORE](#) option (salting out effect).

This keyword has one item that specifies the activity coefficient model to be used.

1. An integer selecting the model:

0 No correction of the CO<sub>2</sub> activity due to salts.

1 This is the Rumpf et al. (1994) activity coefficient model with the modifications as detailed by Spycher and Pruess (2005) [[Ref. 102](#)]. It is applicable up to 160°C.

2 This is the activity coefficient model of Duan and Sun, as modified by Spycher and Pruess (2009) [[Ref. 103](#)]. It is applicable up to 250°C.

DEFAULT: 1

### Example

Selecting activity coefficient model 2 for CO<sub>2</sub>:

```
ACTCO2S
  2 /
```

## Dimensions for the ACTION facility

The data consists of some or all of the following items, specifying dimensions associated with the [ACTION](#) keyword family. The data must be terminated by a slash (/).

1. The maximum number of ACTION type keywords that may be defined.  
DEFAULT: 2
2. The maximum number of lines of SCHEDULE data (MNL PAC), including the [ENDACTIO](#) keyword, that can be defined in any one ACTION. (This number includes comment lines and blank lines, but excludes the lines defining the triggering condition for the action.)  
DEFAULT: 50
3. The maximum number of characters per line of ACTION data (NCPLIN). Note that ECLIPSE rounds this number up to a multiple of 8, with a limit of 128 characters per line.  
DEFAULT: 80
4. The maximum number of conditions in an [ACTIONX](#) keyword.  
DEFAULT: 3

See keywords [ACTION](#), [ACTIONG](#), [ACTIONR](#), [ACTIONW](#), [ACTIONS](#), [ACTIONX](#) and [ENDACTIO](#).

### Example

```
ACTDIMS
3 20 80 /
```

## ACTION

## Initiates a set of keywords to be processed when a specified field condition is satisfied

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The ACTION keyword is one of a group of keywords that trigger actions in the simulation when certain conditions are met. While the ACTION keyword will work as documented in simulation datasets, it is recommended that you use the ACTIONX keyword for new or updated datasets as it offers the greatest functionality and flexibility.

The ACTION (ACTIONG, ACTIONR, ACTIONW, ACTIONS) keyword marks the start of a set of SCHEDULE section keywords that are to be stored for later processing when a specified condition is satisfied. The ACTION keyword specifies a field condition for triggering an action. The ACTIONG, ACTIONR, ACTIONW and ACTIONS keywords offer greater flexibility, and specify actions triggered by group, region, well and segment conditions respectively. The set of keywords may be indented with one or more blank spaces for clarity and must be terminated with the ENDACTIO keyword. The keywords between the ACTION and ENDACTIO keywords are processed when the condition defined in the ACTION keyword is satisfied.

In ECLIPSE 100, almost any SCHEDULE section keyword may be placed between ACTION and ENDACTIO, with the exception of timestepping keywords (for example TIME, TSTEP, DATES and GASYEAR), the global keywords and the INCLUDE keyword. The RPTRST keyword can be used but any changes to the frequency of output will not be implemented until the report step following the satisfaction of the triggering condition.

In ECLIPSE 300, any keyword specifying data for wells, groups or separators may be placed between ACTION and ENDACTIO. The RPTRST keyword can also be used but any changes to the frequency of output will not be implemented until the report step following the satisfaction of the triggering condition.

The amount of storage space reserved for these keywords is controlled by the RUNSPEC section keyword ACTDIMS. The number of lines between an ACTION keyword and its corresponding ENDACTIO keyword (including the ENDACTIO keyword itself) is limited to MNLPAK in ACTDIMS item 2. The length of each line is limited to NCPLIN in ACTDIMS item 3.

Each action initiated with the ACTION keyword is executed only once, at the end of the timestep during which its triggering condition is first satisfied. However, any number of action keyword sets may be declared, each with its own triggering condition; the maximum number being limited to MAXACT in ACTDIMS item 1. Each action keyword set must be bracketed by a pair of ACTION (ACTIONG, ACTIONR, ACTIONW, ACTIONS) and ENDACTIO keywords, and is distinguished by its action name defined in item 1 of the keyword. If an ACTION family keyword is re-entered with the same action name as a previously declared action, the action keyword set is overwritten by the new data.

The ACTION keyword contains the following items of data, terminated with a slash (/):

1. The action name.

A name of up to 8 characters, to distinguish this action from any others.

2. The quantity to which the triggering condition applies.

This must be one of:

FOPR	Field oil production rate
FWPR	Field water production rate

	FGPR	Field gas production rate
	FGOR	Field gas oil ratio
	FWCT	Field water cut
	FPR	Field average pressure.
<i>ECLIPSE 100 only</i>	FOPT	Field oil production cumulative total
<i>ECLIPSE 100 only</i>	FWPT	Field water production cumulative total
<i>ECLIPSE 100 only</i>	FGPT	Field gas production cumulative total
<i>ECLIPSE 100 only</i>	FOIR	Field oil injection rate
<i>ECLIPSE 100 only</i>	FWIR	Field water injection rate
<i>ECLIPSE 100 only</i>	FGIR	Field gas injection rate
<i>ECLIPSE 100 only</i>	FOIT	Field oil injection cumulative total
<i>ECLIPSE 100 only</i>	FWIT	Field water injection cumulative total
<i>ECLIPSE 100 only</i>	FGIT	Field gas injection cumulative total
<i>ECLIPSE 100 only</i>	FCPR	Field polymer production rate
<i>ECLIPSE 100 only</i>	FCPC	Field polymer production concentration
<i>ECLIPSE 100 only</i>	FSPR	Field salt production rate
<i>ECLIPSE 100 only</i>	FSPC	Field salt production concentration
	FTPR	Field tracer production rate (the tracer name must be added)
	FTPC	Field tracer production concentration (the tracer name must be added).
<i>ECLIPSE 300 only</i>	FNLPR	Field NGL production rate
<i>ECLIPSE 300 only</i>	FCNMR	Field component molar rates in the NGL phase
	FUxxxxxx	User defined field quantity

3. The operator for the triggering condition.

This must be one of:

'>' Greater than

'<' Less than

4. The value of the triggering condition.

End the data record with a slash (/).

**CAUTION:** If you wish to define an action to be triggered when the field cannot meet its target flow rate, set the trigger value in item 4 to be slightly less than the target rate to allow for the fact that group/field control targets may not be met exactly (see keyword [NUPCOL](#)).

**Note:** Full checking of the keywords entered with an ACTION keyword cannot be performed until the ACTION is actually implemented, since it is possible to use wild cards in many of the keywords. However, before a simulation run is attempted the data can be run in [NOSIM](#) mode. This will then do what checks it can on the keywords within any ACTIONS that have been defined. All the most common types of ‘grammatical’ and typographical errors are found, but errors resulting from wild cards feeding inappropriate well/group names to keywords may not be found.

**CAUTION:** It is possible to nest actions by including the definition of the inner action within the keyword set of the ‘outer’ action (that is before its [ENDACTIO](#) keyword). This offers you great flexibility, but care should be exercised and the consequences of the nested actions should be thought through. For example: suppose that in the [ACTDIMS](#) keyword we have set `MAXACT=1` and have then defined an action `ACT1`. Suppose also that as part of this action we have defined another action, `ACT2`. ECLIPSE only issues an error when `ACT1` is actually implemented which may, of course, be well into the run. Alternatively we may call the inner action by the same name as the outer action, `ACT1`. This is perfectly allowable, but it must be remembered that each time an action of a given name is defined it overwrites the properties that the action may previously have had. Suppose that we have an outer action that can be repeated a number of times. Within this action is an inner one that can also be repeated and that also increments its triggering condition each time. No matter how many times the inner action has been called when the outer action is invoked again the inner action is redefined to its original specification.

## Example

This shows two action keyword sets. The first action (named `ACT1`) will open well `PROD5` when the field gas oil ratio is greater than 3.0 and change the well oil production rate limits to 2000. The second action (named `ACT2`) will end the run when the average pressure in the field falls below 3000 psia.

```

ACTION
ACT1 FGOR > 3.0 /
WELOPEN
PROD5 OPEN /
/
WELTARG
'P*' ORAT 2000 /
/
ENDACTIO

ACTION
ACT2 FPR < 3000.0 /
END
ENDACTIO

```

## ACTIONG

## Initiates a set of keywords to be processed when a group satisfies a specified condition

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The ACTIONG keyword is one of a group of keywords that trigger actions in the simulation when certain conditions are met. While the ACTIONG keyword will work as documented in simulation datasets, it is recommended that you use the ACTIONX keyword for new or updated datasets as it offers the greatest functionality and flexibility.

The ACTIONG keyword marks the start of a set of SCHEDULE section keywords that are to be stored for later processing when a nominated **group** satisfies a specified condition. The set of keywords may be indented with one or more blank spaces for clarity and must be terminated with the ENDACTIO keyword. The keywords between the ACTIONG and ENDACTIO keywords are processed at the end of the timestep when the condition defined in the ACTIONG keyword is satisfied by a group named in item 2. You can choose whether the action is to be performed only once, or repeatedly each timestep while the triggering condition is satisfied.

If a group keyword (for example GRUPTARG) is placed between ACTIONG and ENDACTIO, instead of entering the name of a specific group in the keyword you may enter a question mark. ECLIPSE then applies the keyword data to whichever group (or groups) triggered the action. For example, an action can be placed on a set of groups ( ' G\* ' in item 2 of ACTIONG) to change a group's rate limit when its water cut exceeds a certain value. The keyword GRUPTARG would be entered between ACTIONG and ENDACTIO, specifying the new rate limit and applying it to a group named '?' in item 1.

---

**Note:** Some keywords cannot have the group name entered as a question mark to be inherited from an ACTIONG keyword. These exceptions are those keywords where name roots are not allowed for the group name. These keywords, however, may still be used within an action if the group name is explicitly defined.

---

## ECLIPSE 100

Practically any SCHEDULE section keyword may be placed between ACTIONG and ENDACTIO, with the exception of timestepping keywords (for example TIME, TSTEP, DATES and GASYEAR), the global keywords and the INCLUDE keyword. The RPTRST keyword can be used but any changes to the frequency of output will not be implemented until the report step following the satisfaction of the triggering condition.

## ECLIPSE 300

Any keyword specifying data for wells, groups or separators may be placed between ACTION and ENDACTIO. The RPTRST keyword can also be used but any changes to the frequency of output will not be implemented until the report step following the satisfaction of the triggering condition.

The amount of storage space reserved for these keywords is controlled by the RUNSPEC section keyword ACTDIMS. The number of lines between an ACTIONG keyword and its corresponding ENDACTIO keyword (including the ENDACTIO keyword itself) is limited to MNLPAK in ACTDIMS item 2. The length of each line is limited to NCPLIN in ACTDIMS item 3.

Any number of action keyword sets may be declared, each with its own triggering condition; the maximum number being limited to MAXACT in ACTDIMS item 1. Each action keyword set must be bracketed by a pair of ACTION (ACTIONG, ACTIONR, ACTIONW, ACTIONS) and ENDACTIO keywords, and is distinguished by its action name defined in item 1. This name must be unique across all the action keyword family. If an ACTION (ACTIONG, ACTIONR, ACTIONW, ACTIONS) keyword is reentered with the same action name as a previously declared action, the previously declared action is deleted and replaced with the new action.

The ACTIONG keyword contains the following items of data, terminated with a slash (/):

1. The action name.

A name of up to 8 characters, to distinguish this action from any others.

If an action with this name has already been declared in any of the action keyword family ACTION (ACTIONG, ACTIONR, ACTIONW, ACTIONS), it is overwritten with the action data specified below.

2. Group name (or name root) of the group(s) that triggers this action,

or FIELD (for an action triggered by a field quantity).

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to make this action's triggering condition apply to more than one group. The action will then be performed if one or more groups having this name root satisfy the triggering condition. Note that the action is performed at most once per timestep, even if more than one group satisfies the triggering condition at the end of the timestep.

3. The quantity to which the triggering condition applies.

This must be one of:

GOPR	Group oil production rate
GPOT	Group oil production cumulative total
GOIR	Group oil injection rate
GOIT	Group oil injection cumulative total
GWPR	Group water production rate
GWPT	Group water production cumulative total
GWIR	Group water injection rate
GWIT	Group water injection cumulative total
GGPR	Group gas production rate
GGPT	Group gas production cumulative total
GGIR	Group gas injection rate
GGIT	Group gas injection cumulative total
GVPR	Group voidage production rate
GVPT	Group voidage production cumulative total
GVIR	Group voidage injection rate
GVIT	Group voidage injection cumulative total
GLPR	Group liquid production rate
GLPT	Group liquid production cumulative total

<i>ECLIPSE 300 only</i>	GWGPR	Group wet gas production rate
<i>ECLIPSE 300 only</i>	GWGPT	Group wet gas production cumulative total
<i>ECLIPSE 300 only</i>	GWGIR	Group wet gas injection rate
<i>ECLIPSE 300 only</i>	GWGIT	Group wet gas injection cumulative total
	GGOR	Group gas oil ratio
	GWCT	Group water cut
	GWGR	Group water gas ratio
	GGLR	Group gas liquid ratio
<i>ECLIPSE 100 only</i>	G CPR	Group polymer production rate
<i>ECLIPSE 100 only</i>	G CPC	Group polymer production concentration
<i>ECLIPSE 100 only</i>	G SPR	Group salt production rate
<i>ECLIPSE 100 only</i>	G SPC	Group salt production concentration
	G TPR	Group tracer production rate (the tracer name must be added)
	G TPC	Group tracer production concentration (the tracer name must be added)
<i>ECLIPSE 300 only</i>	G EXGR	Group excess gas rate
<i>ECLIPSE 300 only</i>	G NLPR	Group NGL Production rate
<i>ECLIPSE 300 only</i>	G CNMR	Group component molar rates in NGL phase
	GUxxxxxx	User defined group quantity

- The operator for the triggering condition.

This must be one of:

‘>’ Greater than

‘<’ Less than

- The value of the triggering condition.

The units depend upon the quantity selected in item 3.

- Number of times this action can be triggered.

The action is performed once at the end of each timestep while any group named in item 2 satisfies the triggering condition, until it has been performed the specified number of times. A number of 10,000 or greater is interpreted as ‘infinity’.

DEFAULT: 1

## 7. Increment to the triggering condition.

After each time the action is performed, the specified increment is added to the triggering condition value (initialized in item 5). The increment may be negative, if desired.

DEFAULT: 0.0

End the data record with a slash (/).

---

**CAUTION:** If you wish to define an action to be triggered when a group cannot meet its target flow rate, set the trigger value in item 5 to be slightly less than the target rate to allow for the fact that group control targets may not be met exactly (see keyword [NUPCOL](#)).

---

**CAUTION:** It is possible to nest actions by including the definition of the ‘inner’ action within the keyword set of the ‘outer’ action (that is before its [ENDACTIO](#) keyword). This offers great flexibility, but care should be exercised and the consequences of the nested actions should be thought through. For example: suppose that in the [ACTDIMS](#) keyword we have set `MAXACT=1` and have then defined an action `ACT1`. Suppose also that as part of this action we have defined another action, `ACT2`. ECLIPSE will only issue an error when `ACT1` is actually implemented, which may, of course, be well into the run. Alternatively we may call the inner action by the same name as the outer action, `ACT1`. This is perfectly allowable, but it must be remembered that each time an action of a given name is defined it overwrites the properties that the action may previously have had. Suppose that we have an outer action that can be repeated a number of times. Within this action is an inner one that can also be repeated and that also increments its triggering condition each time. No matter how many times the inner action has been called when the outer action is invoked again the inner action is redefined to its original specification.

---

**Note:** Full checking of the keywords entered with an action keyword cannot be performed until the action is actually implemented, since it is possible to use wild cards in many of the keywords. However, before a simulation run is attempted the data can be run in [NOSIM](#) mode. This then does whatever checks it can on the keywords within any action keyword blocks that have been defined. All the most common types of ‘grammatical’ and typographical errors will be found, but errors resulting from wild cards feeding inappropriate well/group names to keywords are not found.

---

## Example

This shows three action keyword sets. The first action (named `ACT1`) applies to all groups whose names begin with `G`, and reduces a group’s oil rate target by 20% whenever its gas oil ratio exceeds the value of 3.0. The second action (named `ACT2`) opens well `PROD5` when the oil production rate of group `GR3` falls below 5,000. The third action (named `ACT3`) increases the field’s water rate limit by 50% each time the cumulative oil production increases by 1.0E6, for a total of 3 times.

```

```

## ACTIONR

## Initiates a set of keywords to be processed when a region satisfies a specified condition

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The ACTIONR keyword is one of a group of keywords that trigger actions in the simulation when certain conditions are met. While the ACTIONR keyword will work as documented in simulation datasets, it is recommended that you use the ACTIONX keyword for new or updated datasets as it offers the greatest functionality and flexibility.

The ACTIONR keyword marks the start of a set of SCHEDULE section keywords that are to be stored for later processing when a nominated **fluid-in-place region** satisfies a specified condition. The set of keywords may be indented with one or more blank spaces for clarity and must be terminated with the ENDACTIO keyword. The keywords between the ACTIONR and ENDACTIO keywords are processed at the end of the timestep when the condition defined in the ACTIONR keyword is satisfied by a region identified in items 2 and 3. You can choose whether the action is to be performed only once, or repeatedly each timestep while the triggering condition is satisfied.

In ECLIPSE 100, practically any SCHEDULE section keyword may be placed between ACTIONR and ENDACTIO, with the exception of timestepping keywords (for example TIME, TSTEP, DATES and GASYEAR), the global keywords and the INCLUDE keyword. The RPTRST keyword can be used but any changes to the frequency of output will not be implemented until the report step following the satisfaction of the triggering condition.

In ECLIPSE 300 any keyword specifying data for wells, groups or separators may be placed between ACTIONR and ENDACTIO. The RPTRST keyword can also be used but any changes to the frequency of output will not be implemented until the report step following the satisfaction of the triggering condition.

The amount of storage space reserved for these keywords is controlled by the RUNSPEC section keyword ACTDIMS. The number of lines between an ACTIONR keyword and its corresponding ENDACTIO keyword (including the ENDACTIO keyword itself) is limited to MNL PAC in ACTDIMS item 2. The length of each line is limited to NCPLIN in ACTDIMS item 3.

Any number of action keyword sets may be declared, each with its own triggering condition; the maximum number being limited to MAXACT in ACTDIMS item 1. Each action keyword set must be bracketed by a pair of ACTION (ACTIONG, ACTIONR, ACTIONW, ACTIONS) and ENDACTIO keywords, and is distinguished by its action name defined in item 1. This name must be unique across all the ACTION keyword family. If an ACTION (ACTIONG, ACTIONR, ACTIONW, ACTIONS) keyword is reentered with the same action name as a previously declared action, the previously declared action is deleted and replaced with the new action.

The ACTIONR keyword contains the following items of data, terminated with a slash (/)

1. The action name.

A name of up to 8 characters, to distinguish this action from any others.

If an action with this name has already been declared in any of the action keyword family ACTION (ACTIONG, ACTIONR, ACTIONW, ACTIONS), it is overwritten with the action data specified below.

2. Fluid-in-place region number, whose conditions trigger this action.

This should be an integer between 0 and NTFIP (see keyword REGDIMS in the RUNSPEC section). Region 0 refers to the whole field.

Fluid-in-place regions are defined with the keyword FIPNUM in the REGIONS section (or, for ECLIPSE 100, the keyword FIP if a different family of regions is requested in item 3).

3. The fluid-in-place region family, to which the specified region belongs.

The family name should be up to 5 characters long.

A default (1\*) or blank ( ' ') entry refers to the standard set of fluid-in-place regions defined with the keyword FIPNUM.

Additional families of fluid-in-place regions may optionally be defined, using the keyword FIP. The family name is string of up to 5 characters that makes up the second part of the keyword name (characters 4 - 8). Each family can divide up the field in different ways. Thus, for example, the standard FIPNUM family may divide the field into layers, and an additional family can be defined to divide the field into areal sectors.

4. The quantity to which the triggering condition applies.

This must be one of:

- RPR Region pressure
- ROSAT Region oil saturation average value
- RWSAT Region water saturation average value
- RGSAT Region gas saturation average value
- ROIP Region oil in place
- RWIP Region water in place
- RGIP Region gas in place (in liquid and gas phases)
- ECLIPSE 100 only* RGIPG Region gas in place (in gas phase only)
- RUxxx User defined region quantity

5. The operator for the triggering condition.

This must be one of:

- '>' Greater than
- '<' Less than

6. The value of the triggering condition.

The units depend upon the quantity selected in item 4.

7. Number of times this action can be triggered.

The action is performed once at the end of each timestep while the triggering condition is satisfied, until it has been performed the specified number of times. A number of 10,000 or greater is interpreted as 'infinity'.

DEFAULT: 1

8. Increment to the triggering condition.

After each time the action is performed, the specified increment is added to the triggering condition value (initialized in item 6). The increment may be negative, if desired.

DEFAULT: 0.0

End the data record with a slash (/)

---

**CAUTION:** It is possible to nest actions by including the definition of the inner action within the keyword set of the outer action (that is before its `ENDACTIO` keyword). This offers great flexibility, but care should be exercised and the consequences of the nested actions should be thought through. For example: suppose that in the `ACTDIMS` keyword we have set `MAXACT=1` and have then defined an action `ACT1`. Suppose also that as part of this action we have defined another action, `ACT2`. ECLIPSE only issues an error when `ACT1` is actually implemented which may, of course, be well into the run. Alternatively we may call the inner action by the same name as the outer action, `ACT1`. This is perfectly allowable, but it must be remembered that each time an action of a given name is defined it overwrites the properties that the action may previously have had. Suppose that we have an outer action that can be repeated a number of times. Within this action is an inner one that can also be repeated and that also increments its triggering condition each time. No matter how many times the inner action has been called when the outer action is invoked again the inner action is redefined to its original specification.

---

**Note:** Full checking of the keywords entered with an action keyword cannot be performed until the action is actually implemented, since it is possible to use wildcards in many of the keywords. However, before a simulation run is attempted the data can be run in `NOSIM` mode. This then does whatever checks it can on the keywords within any action keyword blocks that have been defined. All the most common types of 'grammatical' and typographical errors will be found, but errors resulting from wildcards feeding inappropriate well/group names to keywords are not found.

---

## Example

This shows two action keyword sets. The first action (named `ACT6`) opens water injection well `WINJNEW` when the average pressure in the field (region 0) falls below 4000. The second action (named `ACT7`) reduces the oil rate target of well `PROD3` by 20% whenever the average gas saturation in region 3 of the family `WELRG` exceeds 0.05.

```

## ACTIONS

## Initiates a set of keywords to be processed when a well segment satisfies a specified condition

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The ACTIONS keyword is one of a group of keywords that trigger actions in the simulation when certain conditions are met. While the ACTIONS keyword will work as documented in simulation datasets, it is recommended that you use the [ACTIONX](#) keyword for new or updated datasets as it offers the greatest functionality and flexibility.

The ACTIONS keyword marks the start of a set of SCHEDULE section keywords that are to be stored for later processing when a nominated **segment** of a multisegment well (see "[Multisegment Wells](#)" in the *ECLIPSE Technical Description*) satisfies a specified condition. The set of keywords may be indented with one or more blank spaces for clarity and must be terminated with the [ENDACTIO](#) keyword. The keywords between the ACTIONS and ENDACTIO keywords are processed at the end of the timestep when the condition defined in the ACTIONS keyword is satisfied by the well segment. You can choose whether the action is to be performed only once, or repeatedly each timestep while the triggering condition is satisfied.

If a well keyword (for example [WELTARG](#)) is placed between ACTIONS and ENDACTIO, instead of entering the name of a specific multisegment well in the keyword you may enter a question mark. ECLIPSE then applies the keyword data to whichever multisegment well (or wells) triggered the action. For example, an action can be placed on a set of multisegment wells ('PROD\*' in item 2 of ACTIONS) to change their rate limit when a segment's water cut exceeds a certain value. The keyword WELTARG would be entered between ACTIONS and ENDACTIO, specifying the new rate limit and applying it to the well named '?' in item 1.

---

**Note:** Some keywords cannot have the well name entered as a question mark to be inherited from an ACTIONS keyword. These exceptions are those keywords where name roots are not allowed for the well name. These keywords may still be used within an action if the well name is explicitly defined. However, well names **can** be inherited in the [WELSPECS](#) / [WELSPECL](#) keyword for ECLIPSE 100.

---

## ECLIPSE 100

Practically any SCHEDULE section keyword may be placed between ACTIONS and ENDACTIO, with the exception of timestepping keywords (for example [TIME](#), [TSTEP](#), [DATES](#) and [GASYEAR](#)), the global keywords and the [INCLUDE](#) keyword. The [RPTRST](#) keyword can be used but any changes to the frequency of output will not be implemented until the report step following the satisfaction of the triggering condition.

## ECLIPSE 300

Any keyword specifying data for wells, groups or separators may be placed between ACTIONS and ENDACTIO. The [RPTRST](#) keyword can also be used but any changes to the frequency of output will not be implemented until the report step following the satisfaction of the triggering condition.

The amount of storage space reserved for these keywords is controlled by the RUNSPEC section keyword [ACTDIMS](#). The number of lines between an ACTIONS keyword and its corresponding ENDACTIO keyword (including the ENDACTIO keyword itself) is limited to MNLPAK in ACTDIMS item 2. The length of each line is limited to NCPLIN in ACTDIMS item 3.

Any number of action keyword sets may be declared, each with its own triggering condition; the maximum number being limited to MAXACT in ACTDIMS item 1. Each action keyword set must be bracketed by a pair of [ACTION](#) ([ACTIONG](#), [ACTIONR](#), [ACTIONW](#), [ACTIONS](#)) and ENDACTIO keywords, and is distinguished by its action name defined in item 1. This name must be unique across all the action keyword family. If an ACTION ([ACTIONG](#), [ACTIONR](#), [ACTIONW](#), [ACTIONS](#)) keyword is reentered with the same action name as a previously declared action, the previously declared action is deleted and replaced with the new action.

The ACTIONS keyword contains the following items of data, terminated with a slash (/):

1. The action name.

A name of up to 8 characters, to distinguish this action from any others.

If an action with this name has already been declared in any of the action keyword family ACTION (ACTIONG, ACTIONR, ACTIONW, ACTIONS), it will be overwritten with the action data specified below.

2. Well name (or name root) of the multisegment well(s) that triggers this action.

A well name root, enclosed in quotes and ending with an asterisk (\*), can be used to make this action's triggering condition apply to more than one well, although the segment number that is monitored must be the same in each well. The action will then be performed if one or more multisegment wells having this name root satisfy the triggering condition in the nominated segment. Wells that conform to the name root but are not multisegment wells is ignored. Note that the action will be performed at most once per timestep, even if more than one well satisfies the triggering condition at the end of the timestep.

3. The number of the well segment whose quantity may trigger the action.

An integer between 1 and NSEGMAX (set in the RUNSPEC section keyword [WSEGDIMS](#))

4. The quantity to which the triggering condition applies.

This must be one of:

SOFR	Segment oil flow rate
SWFR	Segment water flow rate
SGFR	Segment gas flow rate
SGOR	Segment gas oil ratio
SOGR	Segment oil gas ratio
SWCT	Segment water cut
SWGR	Segment water gas ratio
SPR	Segment pressure
SPRD	Segment pressure drop
SOHF	Segment oil holdup fraction
SWHF	Segment water holdup fraction
SGHF	Segment gas holdup fraction
SUxxxxxx	User defined segment quantity

5. The operator for the triggering condition.

This must be one of:

'>' Greater than

'<' Less than

6. The value of the triggering condition.

The units depend upon the quantity selected in item 4.

7. Number of times this action can be triggered.

The action is performed once at the end of each timestep while the segment set in item 3 of any multisegment well named in item 2 satisfies the triggering condition, until it has been performed the specified number of times. A number of 10,000 or greater is interpreted as 'infinity'.

DEFAULT: 1

8. Increment to the triggering condition.

After each time the action is performed, the specified increment will be added to the triggering condition value (initialized in item 6). The increment may be negative, if desired.

DEFAULT: 0.0

End the data record with a slash (/).

---

**CAUTION:** It is possible to nest actions by including the definition of the inner action within the keyword set of the outer action (that is before its **ENDACTIO** keyword). This offers great flexibility, but care should be exercised and the consequences of the nested actions should be thought through. For example: suppose that in the **ACTDIMs** keyword we have set **MAXACT=1** and have then defined an action **ACT1**. Suppose also that as part of this action we have defined another action, **ACT2**. ECLIPSE only issues an error when **ACT1** is actually implemented which may, of course, be well into the run. Alternatively we may call the inner action by the same name as the outer action, **ACT1**. This is perfectly allowable, but it must be remembered that each time an action of a given name is defined it overwrites the properties that the action may previously have had. Suppose that we have an outer action that can be repeated a number of times. Within this action is an inner one that can also be repeated and that also increments its triggering condition each time. No matter how many times the inner action has been called when the outer action is invoked again the inner action is redefined to its original specification.

---

**Note:** Full checking of the keywords entered with an action keyword cannot be performed until the action is actually implemented, since it is possible to use wild cards in many of the keywords. However, before a simulation run is attempted the data can be run in **NOSIM** mode. This then does whatever checks it can on the keywords within any action keyword blocks that have been defined. All the most common types of 'grammatical' and typographical errors will be found, but errors resulting from wild cards feeding inappropriate well/group names to keywords are not found.

---

## Example

This shows two action keyword sets. The first action (named **ACT5**) applies to segment 5 of all multisegment wells whose names begin with **PR**, and will reduce their liquid rate target by 20% whenever the segment pressure falls below the value of 3500. The second action (named **ACT6**) opens well **PR-A5** when the oil flow rate in segment 7 of any of the multisegment wells whose names begin with **PR-A** first falls below 1,000.

```

ACTIONS
ACT5 'PR*' 5 SPR < 3500 10000 /
WTMULT
'?' LRAT 0.8 /
/
ENDACTIO
ACTIONS
ACT6 'PR-A*' 7 SOFR < 1000.0 /
WELOPEN
PR-A5 OPEN /
/
ENDACTIO

```

## ACTIONW

## Initiates a set of keywords to be processed when a well satisfies a specified condition

x	ECLIPSE 100

	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The ACTIONW keyword is one of a group of keywords that trigger actions in the simulation when certain conditions are met. While the ACTIONW keyword will work as documented in simulation datasets, it is recommended that you use the ACTIONX keyword for new or updated datasets as it offers the greatest functionality and flexibility.

The ACTIONW keyword marks the start of a set of SCHEDULE section keywords that are to be stored for later processing when a nominated **well** satisfies a specified condition. The set of keywords may be indented with one or more blank spaces for clarity and must be terminated with the ENDACTIO keyword. The keywords between the ACTIONW and ENDACTIO keywords will be processed at the end of the timestep when the condition defined in the ACTIONW keyword is satisfied by a well named in item 2. You can choose whether the action is to be performed only once, or repeatedly each timestep while the triggering condition is satisfied.

If a well keyword (for example WELTARG) is placed between ACTIONW and ENDACTIO, instead of entering the name of a specific well in the keyword you may enter a question mark. ECLIPSE then applies the keyword data to whichever well (or wells) triggered the action. For example, an action can be placed on a set of wells ('PROD\*' in item 2 of ACTIONW) to change a well's rate limit when its water cut exceeds a certain value. The keyword WELTARG would be entered between ACTIONW and ENDACTIO, specifying the new rate limit and applying it to the well named '?' in item 1.

---

**Note:** Some keywords cannot have the well name entered as a question mark to be inherited from an ACTIONW keyword. These exceptions are those keywords where name roots are not allowed for the well name. These keywords may still be used within an action if the well name is explicitly defined. However, well names **can** be inherited in the WELSPECS / WELSPECL keyword for ECLIPSE 100.

---

## ECLIPSE 100

Practically any SCHEDULE section keyword may be placed between ACTIONW and ENDACTIO, with the exception of timestepping keywords (for example TIME, TSTEP, DATES and GASYEAR), the global keywords and the INCLUDE keyword. The RPTRST keyword can be used but any changes to the frequency of output will not be implemented until the report step following the satisfaction of the triggering condition.

## ECLIPSE 300

Any keyword specifying data for wells, groups or separators may be placed between ACTIONW and ENDACTIO. The RPTRST keyword can also be used but any changes to the frequency of output will not be implemented until the report step following the satisfaction of the triggering condition.

The amount of storage space reserved for these keywords is controlled by the RUNSPEC section keyword ACTDIMS. The number of lines between an ACTIONW keyword and its corresponding ENDACTIO keyword (including the ENDACTIO keyword itself) is limited to MNLPAK in ACTDIMS item 2. The length of each line is limited to NCPLIN in ACTDIMS item 3.

Any number of action keyword sets may be declared, each with its own triggering condition; the maximum number being limited to MAXACT in ACTDIMS item 1. Each action keyword set must be bracketed by a pair of ACTION (ACTIONG, ACTIONR, ACTIONS, ACTIONW) and ENDACTIO keywords, and is distinguished by its action name defined in item 1. This name must be unique across all the action keyword family. If an ACTION (ACTIONG, ACTIONR, ACTIONW, ACTIONS) keyword is re-entered with the same action name as a previously declared action, the previously declared action is deleted and replaced with the new action.

The ACTIONW keyword contains the following items of data, terminated with a slash (/):

## 1. The action name.

A name of up to 8 characters, to distinguish this action from any others.

If an action with this name has already been declared in any of the action keyword family ACTION (ACTIONG, ACTIONR, ACTIONW, ACTIONS), it is overwritten with the action data specified below.

## 2. Well name (or name root) of the well(s) that triggers this action.

A well name root, enclosed in quotes and ending with an asterisk (\*), can be used to make this action's triggering condition apply to more than one well. The action is then performed if one or more wells having this name root satisfy the triggering condition. Note that the action will be performed at most once per timestep, even if more than one well satisfies the triggering condition at the end of the timestep.

## 3. The quantity to which the triggering condition applies.

This must be one of:

WOPR	Well oil production rate
WOPT	Well oil production cumulative total
WOIR	Well oil injection rate
WOIT	Well oil injection cumulative total
WWPR	Well water production rate
WWPT	Well water production cumulative total
WWIR	Well water injection rate
WWIT	Well water injection cumulative total
WGPR	Well gas production rate
WGPT	Well gas production cumulative total
WGIR	Well gas injection rate
WGIT	Well gas injection cumulative total
WLPR	Well liquid production rate
WLPT	Well liquid production cumulative total
WVPR	Well voidage production rate
WVPT	Well voidage production cumulative total
WVIR	Well voidage injection rate
WVIT	Well voidage injection cumulative total
<i>ECLIPSE 300 only</i>	WWGPR Well wet gas production rate

<i>ECLIPSE 300 only</i>	WWGPT	Well wet gas production cumulative total
<i>ECLIPSE 300 only</i>	WWGIR	Well wet gas injection rate
<i>ECLIPSE 300 only</i>	WWGIT	Well wet gas injection cumulative total
	WGOR	Well gas oil ratio
	WWCT	Well water cut
	WWGR	Well water gas ratio
	WGLR	Well gas liquid ratio
	WBHP	Well bottom hole pressure
	WTHP	Well tubing head pressure
<i>ECLIPSE 100 only</i>	WBGLR	Well gas liquid ratio at bottom hole conditions
<i>ECLIPSE 300 only</i>	WXMF_nn	Well liquid mole fraction in component nn
<i>ECLIPSE 300 only</i>	WYMF_nn	Well vapor mole fraction in component nn
<i>ECLIPSE 300 only</i>	WZMF_nn	Well total mole fraction in component nn
<i>ECLIPSE 100 only</i>	WCPR	Well polymer production rate
<i>ECLIPSE 100 only</i>	WCPC	Well polymer production concentration
<i>ECLIPSE 100 only</i>	WSPR	Well salt production rate
<i>ECLIPSE 100 only</i>	WSPC	Well salt production concentration
	WTPR	Well tracer production rate (tracer name needs to be added)
	WTPC	Well tracer production concentration (tracer name needs to be added)
<i>ECLIPSE 300 only</i>	WNLPR	Well component molar rates in NGL phase
<i>ECLIPSE 300 only</i>	WCNMR	Well NGL Production rate
	WUxxxxxxx	User defined well quantity

4. The operator for the triggering condition.

This must be one of:

'>' Greater than

'<' Less than

5. The value of the triggering condition.

The units depend upon the quantity selected in item 3.

6. Number of times this action can be triggered.

The action will be performed once at the end of each timestep while any well named in item 2 satisfies the triggering condition, until it has been performed the specified number of times. A number of 10,000 or greater is interpreted as 'infinity'.

DEFAULT: 1

7. Increment to the triggering condition.

After each time the action is performed, the specified increment is added to the triggering condition value (initialized in item 5). The increment may be negative, if desired.

DEFAULT: 0.0

End the data record with a slash (/).

---

**CAUTION:** It is possible to nest actions by including the definition of the inner action within the keyword set of the outer action (that is before its `ENDACTIO` keyword). This offers great flexibility, but care should be exercised and the consequences of the nested actions should be thought through. For example: suppose that in the `ACTDIMS` keyword we have set `MAXACT=1` and have then defined an action `ACT1`. Suppose also that as part of this action we have defined another action, `ACT2`. ECLIPSE only issues an error when `ACT1` is actually implemented which may, of course, be well into the run. Alternatively we may call the inner action by the same name as the outer action, `ACT1`. This is perfectly allowable, but it must be remembered that each time an action of a given name is defined it overwrites the properties that the action may previously have had. Suppose that we have an outer action that can be repeated a number of times. Within this action is an inner one that can also be repeated and that also increments its triggering condition each time. No matter how many times the inner action has been called when the outer action is invoked again the inner action is redefined to its original specification.

---

**Note:** Full checking of the keywords entered with an action keyword cannot be performed until the action is actually implemented, since it is possible to use wild cards in many of the keywords. However, before a simulation run is attempted the data can be run in `NOSIM` mode. This then does whatever checks it can on the keywords within any action keyword blocks that have been defined. All the most common types of 'grammatical' and typographical errors will be found, but errors resulting from wild cards feeding inappropriate well/group names to keywords are not found.

---

## Example

This shows two action keyword sets. The first action (named `ACT5`) applies to all wells whose names begin with `PR`, and reduces their liquid rate target by 20% whenever their `BHP` falls below the value of 3500. The second action (named `ACT6`) opens well `PR-A5` when the oil production rate of any of the wells whose names begin with `PR-A` first falls below 1,000.

```

ACTIONW
ACT5 'PR*' WBHP < 3500 10000 /
WTMULT
 '?' LRAT 0.8 /
/
ENDACTIO
ACTIONW
ACT6 'PR-A*' WOPR < 1000.0 /
WELOPEN
PR-A5 OPEN /

```

/  
ENDACTIO

## ACTIONX

## Initiates a set of keywords to be processed when a set of conditions are satisfied

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The ACTIONX keyword is a more flexible version of the ACTION (ACTIONG, ACTIONR, ACTIONW, ACTIONS) type keywords. The keyword marks the start of a set of SCHEDULE section keywords that are to be stored for later processing when a set of conditions specified in this keyword are met. The set of keywords may be indented with one or more blank spaces for clarity and must be terminated with the ENDACTIO keyword. The keywords between the ACTIONX and ENDACTIO keywords will be processed at the end of the timestep when the set of conditions defined in the ACTIONX keyword is satisfied. You can choose whether the action is to be performed only once, or repeatedly each timestep while the triggering condition set is satisfied.

In ECLIPSE 100, practically any SCHEDULE section keyword may be placed between ACTIONX and ENDACTIO, with the exception of timestepping keywords (for example TIME, TSTEP, DATES and GASYEAR), the global keywords and the INCLUDE keyword. The RPTRST keyword can be used but any changes to the frequency of output will not be implemented until the report step following the satisfaction of the triggering condition.

## ECLIPSE 300

Practically any SCHEDULE section keyword may be placed between ACTIONX and ENDACTIO, with the exception of timestepping keywords (for example TIME, TSTEP, DATES and GASYEAR), the global keywords and the INCLUDE keyword, and SIMULATE, NOSIM, SKIPREST, PSEUPRES and PICOND. The RPTRST keyword can be used but any changes to the frequency of output will not be implemented until the report step following the satisfaction of the triggering condition.

In the ACTIONG (ACTIONR, ACTIONW, ACTIONS) keywords the single triggering condition compares the current value of a quantity against a constant value defined in the keyword. For example, in ACTIONW the condition might be that a well's GOR is greater than 3.0. In addition to this, the ACTIONX keyword also allows a comparison against the current value of another quantity. For example, a condition might be that a well's GOR is greater than the current value of its controlling group's GOR.

Multiple triggering conditions may be combined in the ACTIONX keyword using Boolean AND and OR operators to form the condition set. Conditions on quantities associated with well connections, well segments, wells, groups and regions may thus be combined in a single ACTIONX keyword.

Conditions may be set on the combined properties of a static (see WLIST keyword) or dynamic (see WLISTDYN keyword, ECLIPSE 300 only) list of wells. Grouping wells together using lists for the purposes of defining controlling conditions in an ACTIONX keyword offers more flexibility than conventional well groups. For example, a well in ECLIPSE 300 may belong to more than one list (see also WELLDIMS keyword item 11).

Conditions may be set on the day, month and year that the simulation has reached. Such a condition may be used to model the seasonal availability of workover and drilling rigs (see "Example 2"), or prevent the ACTION being triggered before a specific date (see "Example 4").

The amount of storage space reserved for these keywords is controlled by the RUNSPEC section keyword ACTDIMS. The number of lines between an ACTIONX keyword and its corresponding ENDACTIO keyword (including the ENDACTIO keyword itself) is limited to MNLPAC in ACTDIMS item 2. The length of each line is limited to NCPLIN in ACTDIMS item 3. The number of triggering conditions in an ACTIONX keyword is limited by item 4 in ACTDIMS.

Any number of action keyword sets may be declared, each with its own triggering condition(s); the maximum number being limited to MAXACT in ACTDIMS item 1. Each action keyword set must be bracketed by a pair of ACTIONG, ACTIONR, ACTIONW, ACTIONS and ENDACTIO keywords, and is

distinguished by its action name defined in item 1. This name must be unique across all the action keyword family. If an ACTIONG, ACTIONR, ACTIONW, ACTIONS keyword is reentered with the same action name as a previously declared action, the previously declared action is deleted and replaced with the new action.

The keyword is followed by a series of records each terminated by a slash (/) with the keyword terminated by a blank record containing only a slash (/):

The data items in each record are:

## Record 1

1. The action name.

A name of up to 8 characters, to distinguish this action from any others.

If an action with this name has already been declared in any of the action keyword family ACTION (ACTIONG, ACTIONR, ACTIONS, ACTIONW, ACTIONX), it is overwritten with the action data specified below.

2. Number of times this action can be triggered.

The action is performed once at the end of each timestep while the set of conditions is satisfied, until it has been performed the specified number of times.

DEFAULT: 1

3. Minimum time interval between action triggers.

If this item is set, the action will only be performed if the set of conditions have been satisfied and the simulation has advanced beyond the specified time interval since the last time this action was triggered.

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

DEFAULT: 0.0

## Each subsequent record

Each of these records defines a condition on a region, group or well quantity.

A condition consists of the following elements:

1. A left hand quantity.

The quantity types and the items needed to define them, are described below.

If a well or group type quantity contains a root name followed by an asterisk (\*), then this condition will be evaluated for more than one well or group. The condition will be deemed true if it is satisfied by at least one well or group. Similarly, in ECLIPSE 300, if a well connection quantity contains defaulted I, J or K locations, then the condition will be evaluated for more than one connection and deemed true if it is satisfied by at least one connection.

2. The operator for the triggering condition.

This must be one of:

'>' or '.GT.' Greater than

'<' or '.LT.' Less than

'>=' or '.GE.' Greater than or equals

'<=' or '.LE.' Less than or equals

'=' or '.EQ.' Equals

'!=' or '.NE.' Not equals

3. A right hand quantity

The quantity types and the items needed to define them, are described below.

The use of well or group root names or defaulted I, J or K connection locations is not permitted in right hand quantities.

4. The Boolean operator that links this condition with those in subsequent records.

This must be one of:

AND applies a logical 'and' to this condition with the following

OR applies a logical 'or' to this condition with the following

If there are no subsequent conditions, leave this item defaulted.

End the data record with a slash (/) and end the keyword with a blank record containing only a slash (/).

Brackets may be placed before the left hand quantity and after the right quantity of a subsequent condition to allow greater flexibility in how conditions may be logically combined with the AND and OR boolean operators (see "Example 2"). Note that nesting brackets is not permitted. In the absence of brackets conditions are evaluated left to right.

The "ALWAYS" condition

This is an exception to the above format. This condition has no operators and no quantities; it consists of the single word "ALWAYS" (including the double quotes). The record and keyword are terminated as for all other conditions.

"ALWAYS" cannot be linked with conditions in subsequent records, as it has the effect that the keywords will be processed at the end of every timestep unconditionally. It is particularly intended for use with the [DYNAMICR](#) keyword, but is not restricted to it.

## Quantity types and definitions

### Constant quantity

This is defined by the following items:

1. Triggering condition value.
2. Increment to the triggering condition value defined in item 1.

After each time the action is performed, the specified increment is added to the triggering condition value. The increment may be negative, if desired.

DEFAULT: 0.0

## Time quantity

1. This is defined by a single keyword. The following keywords can be used in both ECLIPSE 100 and ECLIPSE 300:

DAY Current simulation day of the month

MNTH Current simulation month

YEAR Current simulation year

These quantities will be compared against the nearest integer values of a constant quantity on the other side of the operator in a condition. The MNTH keyword may also be compared against three letter abbreviations for calendar months (JAN, FEB ... DEC). See "Example 3" and "Example 4" for usage of this quantity type.

## Region quantity

This is defined by the following items:

1. Region keyword. The following keywords can be used in both ECLIPSE 100 and ECLIPSE 300 unless other stated.

This must be one of:

RPR Region pressure

ROSAT Region oil saturation average value

RWSAT Region water saturation average value

RGSAT Region gas saturation average value

ROIP Region oil in place

RWIP Region water in place

RGIP Region gas in place (in liquid and gas phases)

RGIGP Region gas in place (in gas phase only). This keyword can be used in ECLIPSE 100 only.

RUxxx User defined region quantity

2. Fluid-in-place region number.

This should be an integer between 0 and NTFIP (see keyword [REGDIMS](#) in the RUNSPEC section). Region 0 refers to the whole field.

Fluid-in-place regions are defined with the keyword [FIPNUM](#) in the REGIONS section.

3. The fluid-in-place region family, to which the specified region belongs.

The family name should be up to 5 characters long.

A default (1\*) or blank (' ') entry refers to the standard set of fluid-in-place regions defined with the keyword [FIPNUM](#).

Additional families of fluid-in-place regions may optionally be defined, using the keyword [FIP](#). The family name is string of up to 5 characters that makes up the second part of the keyword name

(characters 4 - 8). Each family can divide up the field in different ways. Thus, for example, the standard FIPNUM family may divide the field into layers, and an additional family can be defined to divide the field into areal sectors.

### Field quantity

This is defined by the following item:

1. Field keyword. The allowed mnemonics are all field keyword listed in the [SUMMARY](#) section.

#### Keywords with a component index

ECLIPSE 300

Keywords that provide information at a component level must have the component number appended to the keyword with an underscore, see Examples 5 and 6.

### Group or well list quantity

This is defined by the following items:

1. Group keyword. The allowed mnemonics are all group keywords listed in the [SUMMARY](#) section.

#### Keywords with a component index

ECLIPSE 300

Keywords that provide information at a component level must have the component number appended to the keyword with an underscore, see Examples 5 and 6.

2. Group name (or name root, enclosed in quotes and ending with an asterisk - these are not permitted in a right hand quantity). A well list name may be specified for this item. The quantity defined in item 1, will then be calculated for the well grouping currently defined by this list.

### Well quantity

This is defined by the following items:

1. Well keyword. The allowed keywords are all well keywords listed in the [SUMMARY](#) section.
2. Well name (or name root, enclosed in quotes and ending with an asterisk - these are not permitted in a right hand quantity). The well name may be defaulted by using the character '\*' (this is not permitted in a right hand quantity).

#### Keywords with a component index

ECLIPSE 300. Keywords that provide information at a component level must have the component number appended to the keyword with an underscore, see Examples 5 and 6.

#### Keywords with a lumped completion index

Well keywords that need a lumped completion index must have this index appended to the keyword with underscores (two if the index is less than 10, one if it is less than 100, none otherwise).

### Well segment quantity

This is defined by the following items:

1. Well segment keyword. The allowed keywords are all those segment keywords listed in the [SUMMARY](#) section.
2. Multisegment well name (or name root, enclosed in quotes and ending with an asterisk - these are not permitted in a right hand quantity).

If a well name root is specified, then wells that conform to the name root but are not multisegment wells are ignored.

3. Well segment number.

An integer between 1 and NSEGMX (set in the RUNSPEC section keyword [WSEGDIMS](#))

### Well connection quantity

1. Well connection keyword. The allowed keywords are all those connection keywords listed in the [SUMMARY](#) section.
2. Well name (or name root, enclosed in quotes and ending with an asterisk - these are not permitted in a right hand quantity). The well name may be defaulted by using the character '\*' (this is not permitted in a right hand quantity).
3. I - location of connecting grid block(s)  
DEFAULT: Negative (allows any I-location)
4. J - location of connecting grid block(s)  
DEFAULT: Negative (allows any J-location)
5. K - location of connecting grid block(s)  
DEFAULT: Negative (allows any K-location)

If any of items 3, 4, or 5 are set negative, then a left hand quantity will be evaluated for more than one connection in the well. These connections are those with I,J,K locations matching the specified location indices in items 3, 4, or 5. If the well name is defaulted using the character '\*', the left hand quantity will be evaluated for **all** wells in the global model. Note that it is not permitted to default connection locations or well name if this is a right hand quantity.

### Well LGR connection quantity

This quantity refers to connections in a local grid refinement. It is defined by the following items:

1. Well connection keywords. The allowed keywords are all those connection keywords listed in the [SUMMARY](#) section. These keywords should be prefixed by an 'L' to indicate an LGR connection quantity (as is the case for summary mnemonics)
2. Well name (or name root, enclosed in quotes and ending with an asterisk - these are not permitted in a right hand quantity). The well name may be defaulted by using the character '\*' (this is not permitted in a right hand quantity).
3. Local grid name
4. I - location of connecting grid block(s) within the local grid  
DEFAULT: Negative (allows any I-location)
5. J - location of connecting grid block(s) within the local grid  
DEFAULT: Negative (allows any J-location)
6. K - location of connecting LGR grid block(s) within the local grid  
DEFAULT: Negative (allows any K-location)

If any of items 4, 5, or 6 are set negative, then a left hand quantity will be evaluated for more than one connection in the well. These connections are those with I,J,K locations matching the specified location

indices in items 4, 5, or 6 within the local grid. If the well name is defaulted using the character ‘\*’, the requested connection quantities are evaluated for **all** wells in the specified LGR. Note that it is not permitted to default connection locations or well name if this is a right hand quantity.

### Aquifer quantity

This is defined by the following items:

1. Aquifer keyword. The allowed keywords are all aquifer keywords listed in the [SUMMARY](#) section.
2. Aquifer number

### Block quantity

1. Block keyword. The allowed keywords are all block keywords listed in the [SUMMARY](#) section.
2. I - location of grid block
3. J - location of grid block
4. K - location of grid block

### Notes

- The order of the items in the quantities is similar to the way summary mnemonics are defined, that is the mnemonic is the first item and it is then followed by a well or group name for example. This is to be contrasted with the order of these items in the [ACTION](#) ([ACTIONG](#), [ACTIONR](#), [ACTIONW](#), [ACTIONS](#)) type keywords.
- A condition consisting of constant quantities on the left and right hand sides is not permitted. A condition may, however, consist of a constant quantity on the left hand side and a variable quantity on the right hand side.
- No checks are in place on the type of quantities that are compared in a condition. So for example, a condition on a region’s pressure being less than a connection’s water cut would be allowed.
- If sufficient conditions are met for the [ACTIONX](#) keyword to trigger the processing of its set of [SCHEDULE](#) section keywords, then details of those conditions that are true will be written to the print file.

*ECLIPSE 300 only*

- Combined rates, totals and ratios for all the wells in a well list may be written to the summary file using an appropriate group [SUMMARY](#) keyword followed by the well list name.
- If a well keyword (for example [WELTARG](#)) is placed between [ACTIONX](#) and [ENDACTIO](#), instead of entering the name of a specific well in the keyword you may enter a question mark (?). ECLIPSE then applies the keyword data to whichever well (or wells) are involved in triggering the action. See ["Examples"](#).

If there is more than one condition in the action that concerns wells, different sets of wells may trigger different conditions. These set of triggering wells are combined logically in the same manner as the conditions themselves. The question mark in the well keywords will then apply to this combined set of wells. Note that if conditions are combined with logical [AND](#) operators, there may be no wells that trigger every condition and thus the well keywords will not have any effect, even though the overall action has been triggered.

- Full checking of the keywords entered with an action keyword cannot be performed until the action is actually implemented, since it is possible to use wild cards in many of the keywords. However, before a simulation run is attempted the data can be run in [NOSIM](#) mode. This then does whatever checks it

can on the keywords within any action keyword blocks that have been defined. All the most common types of 'grammatical' and typographical errors will be found, but errors resulting from wild cards feeding inappropriate well/group names to keywords are not found.

- An action may be triggered on a grid block quantity by defining a region to consist of one grid block (keyword `FIPNUM`) and selecting a region quantity in a condition.

## Examples

### Example 1

The action named ACT1 reduces the liquid rate target by 20% of all wells starting with 'PR' whose GOR exceeds that of the FIELD when the gas production rate of the FIELD exceeds 50000 Mscf/day. The action will be repeated at the end of each timestep whilst the condition set is true.

```

ACTIONX
ACT1 100000 /
GGPR FIELD > 50000 AND /
WGOR 'PR*' > GGOR FIELD /
/

WTMULT
'?' LRAT 0.8 /
/

ENDACTIO

```

### Example 2

The action named ACT2 opens well PR-A5 when the combined water cut of all the wells in list \*LIST1 exceeds 0.7 and when the water production rate of list \*LIST1 exceeds the water production rate of either list \*LIST2 or \*LIST3. Action ACT2 is performed once only.

```

ACTIONX
ACT2 1 /
GWCT '*LIST1' > 0.7 AND /
( GWPR '*LIST1' > GWPR '*LIST2' OR /
  GWPR '*LIST1' > GWPR '*LIST3' ) /
/

WELOPEN
PR-A5 OPEN /
/

ENDACTIO

```

### Example 3

The dynamic well list \*HIGHWCT contains all wells that have a water cut exceeding 0.8. In any year between March and October, the action WORKOVER will be triggered if the list \*HIGHWCT contains more than 4 wells. This action will set an economic limit on the wells in the \*HIGHWCT list such that they will be worked over. The WORKOVER action also contains a nested action WECONOFF that is triggered when the simulation advances past October. WECONOFF stops any further workovers in the winter by re-specifying the WECON keyword with a high water cut limit.

```

WLISTDYN
'*HIGHWCT' '*' WWCT > 0.8 /
/

ACTIONX
WORKOVER 10000 /

```

ECLIPSE 300 only

```

MNTH .GE. MAR AND /
MNTH .LE. OCT AND /
GMWL '*HIGHWCT' .GE. 4 /
/
WECON
 '*HIGHWCT' 2* 0.75 2* CON /
/
ACTIONX
 WECONOFF 1 /
 MNTH .GT. OCT /
/
WECON
 '* ' 2* 1.0 2* CON /
/
ENDACTIO
ENDACTIO

```

### Example 4

The action named DELAY opens well PR-A5 when the simulation has advanced past the 1st June 2021 and the FIELD's water cut exceeds 0.8.

```

ACTIONX
 DELAY 1 /
 GWCT 'FIELD' > 0.8 AND /
 DAY > 1 AND /
 MNTH > JUN AND /
 YEAR >= 2021 /
/
WELOPEN
 PR-A5 OPEN /
/
ENDACTIO

```

### Example 5

ECLIPSE 300 only

The action named ACT5 reduces the liquid rate target by 20% of all wells starting with 'PR' when the 2nd component molar rate in the gas phase of the well 'PROD1' exceeds 5th component molar rate in the gas phase of the well 'PROD2' and when the 3rd component molar rate in the gas phase of the group 'G1' exceeds 7th component molar rate in the gas phase of the group 'G2' or when the 1st component molar rate in the gas phase of the FIELD exceeds the 7th component molar rate in the gas phase of the FIELD. That is, the first two conditions must be true, or the third. The action will be repeated at the end of each timestep whilst the condition set is true.

```

## ACTNUM

## Active grid block identification

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by one integer for every grid block in the current box.

A value of 1 indicates that the corresponding grid block is active, whilst a 0 indicates that it is inactive. If the ECLIPSE 300 Thermal option (keyword [THERMAL](#) in the RUNSPEC section) is requested, a value of 2 indicates that the grid block has rock volume only, and a value of 3 indicates that the grid block has pore volume only.

The data must be terminated by a slash(/).

It should be noted that this is only one of a number of ways of identifying inactive grid blocks. Other possibilities include setting the porosity ([PORO](#)), or net to gross thickness ratio ([NTG](#)), to zero in the GRID section.

Indeed, any method which results in zero pore volume will cause a grid block to be treated as inactive. For example, the [MINPV](#) keyword can be used to set a minimum threshold pore volume, so that any grid blocks having a pore volume smaller than this, will be treated as inactive.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 12\*0). Note that spaces must not be inserted on either side of the asterisk.

## ECLIPSE 300

For runs with the Thermal option and with Dual or Multi Porosity, the combination of available ACTNUM values can cause inconsistencies in how the data is used. A wholly inactive (ACTNUM=0) matrix or fracture cell will deactivate the corresponding fracture or matrix, but other values will affect only the selected porosity and leave the other porosities unaltered. However, the meaning of, for example, a rock-only fracture cell, or a fluid-only matrix cell, is ill-defined, and the user should take care in using these options. The issue is discussed further in "[Dual porosity](#)" in the *ECLIPSE Technical Description*.

## ECLIPSE 300

For runs with the Thermal option and with Dual or Multi Porosity, also note that ACTNUM=3, that is, pore volume only, means that the porosity will be set to 1.0, regardless of the input porosity values. Some control over the fraction of cell volume which is pore volume is still available with this option by use of the net to gross values (NTG).

## ECLIPSE 300

The ACTNUM values set using this keyword can be output by setting item 5 of the [DEBUG3](#) keyword to a non-zero positive value. The active cell indicator information is output to both the GRID and EGRID files. Please refer to the description provided in the *ECLIPSE File Formats Reference Manual*. This array of information is further updated internally to provide a natural cell to active cell mapping (refer to additional output given by this DEBUG3 switch as well as the IOCN argument for use with the [RPTGRID](#) and [RPTGRIDL](#) keywords).

## Example

With NDIVIX=8, NDIVIY=6, NDIVIZ=3 in RUNSPEC keyword [DIMENS](#):

```

ACTNUM
0 0 0 1 1 1 0 0
0 1 1 1 1 1 0 0
1 1 1 1 1 0 0 0
0 1 1 1 1 1 1 1
0 0 1 1 0 1 1 1
0 0 1 0 0 1 1 0
0 0 0 1 1 1 0 0
0 0 0 1 1 1 0 0
1 1 0 0 1 0 0 0
0 1 1 1 1 1 1 1
0 0 1 1 0 1 0 1
0 0 1 0 0 0 0 0

```

```
0 0 0 1 1 1 0 0
0 0 0 0 0 1 0 1
1 1 0 0 0 0 0 1
1 1 1 1 1 1 1 1
1 1 1 1 1 1 1 1
0 0 1 0 0 1 1 1 /
```

## ACTPARAM Parameters for the ACTION facility

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data consists of the following items, specifying control parameters associated with the ACTION keyword family. The data must be terminated by a slash (/).

1. The (target) maximum percentage violation of an ACTIONX type condition.

DEFAULT: 100.0% (Target not applied)

---

**Note:** When using this item there is no guarantee that the condition will not be violated by more than the percentage set here; a timestep cannot be repeated just because a condition has been violated by more than the target percentage. If the values on both sides of a condition are smoothly varying (in time) then item 1 will usually perform well. If one side of the condition changes abruptly, for example a group rate may change discontinuously due to wells shutting in, then this item may not help.

---

2. The default fractional equality tolerance used in deciding whether quantities are equal in an ACTIONX condition that contains an equals type comparator.

DEFAULT: 1.0E-4

See keywords [ACTION](#), [ACTIONG](#), [ACTIONR](#), [ACTIONW](#), [ACTIONS](#), [ACTIONX](#) and [ENDACTIO](#).

### Example

This example shows that the condition will be violated by not more than 3 percentage set in ACTPARAM keyword. Note that the number of times this condition can be triggered must be greater than 2.

```
ACTPARAM
3.0 /
```

## ADD

## Adds a constant to the specified array in current box

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
x	EDIT
x	PROPS
x	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

The keyword may be followed by any number of records, each of which is terminated by a slash (/). The data is terminated by a blank record, containing only a slash.

Each record consists of at least 2 items of data:

1. The name of the array to be modified
2. The constant to be added to the array specified by item 1

The constant must be an integer if the array contains integer region numbers (for example, [FIPNUM](#)). The constant may be real if the array contains real data (for example, [TOPS](#) or [TRANX](#)). This item should not be defaulted.

The following data items define the limits of a box within the grid over which the value is to be added.

These items may be used to redefine the input box for this and subsequent operations within the current keyword. The values are used until reset or until the end of the keyword.

If these items are not defined (a slash is inserted after item 2), they default to the values which were used for the previous operation within the current keyword.

For the first operation in the keyword, the box defaults to the values set by the most recent [BOX](#) or [ENDBOX](#) keyword. If there is no preceding [BOX](#) or [ENDBOX](#) in the current section, the box is taken to include the entire reservoir.

3. First block to be modified on the X axis (IX1)
4. Last block to be modified on the X axis (IX2)
5. First block to be modified on the Y axis (JY1)
6. Last block to be modified on the Y axis (JY2)
7. First block to be modified on the Z axis (KZ1)
8. Last block to be modified on the Z axis (KZ2)

The data must satisfy:

$$1 \leq IX1 \leq IX2 \leq NDX$$

$$1 \leq JY1 \leq JY2 \leq NDY$$

$$1 \leq KZ1 \leq KZ2 \leq NDZ$$

where NDX, NDY, and NDZ are the limits in the current BOX.

ECLIPSE 100

If the ADD keyword is used in the PROPS section to modify the end-point scaling arrays, the addition is only made to the end points that have been previously defined. If a cell in the input box has **not** been assigned a scaled end point, ADD does **not** operate on this cell, and its end point still defaults to the table value.

[TNUM](#) arrays can also be used with the ADD keyword.

**Notes**

- The above list is not exhaustive, but includes the most common examples.
- Keywords in brackets are for radial geometry runs.
- In the REGIONS section only integer values should be used.
- The added quantity may be negative, in order to subtract.
- The use of the ADD keyword assumes that a value has already been assigned to the array, either explicitly, or using the [EQUALS](#) keyword (except in the EDIT section, where the array has already been calculated after processing the GRID section).
- The ADD, [COPY](#), [EQUALS](#) and [MULTIPLY](#) keywords are processed as they are read, so that repeated operations are possible.

See also the keywords [BOX](#), [ENDBOX](#), [EQUALS](#), [MULTIPLY](#) and [COPY](#).

**Item 2 should not be defaulted.** However, this facility is retained for back-compatibility. If this item is defaulted, this will be treated differently by ECLIPSE 100 and ECLIPSE 300. For ECLIPSE 100, the defaulted value is assumed to be undefined, whereas for ECLIPSE 300, the defaulted value is assumed to be zero. The subsequent processing will depend, therefore, both upon the specific keyword to which the operation is being applied and which simulator is being used.

## Examples

### Example 1

In the REGIONS section:

```
----- ARRAY      CONSTANT      ----- BOX -----  
ADD  
    SATNUM      3          1 11 1 19 2 2 /  
    PVTNUM      1          / defaults to last specified box  
    EQLNUM      1          / defaults to last specified box  
    FIPNUM      8          / defaults to last specified box  
/
```

### Example 2

In the EDIT section:

```
----- ARRAY      CONSTANT      ----- BOX -----  
ADD  
    PORV        350.      0 1 11 1 19 2 2 /  
    DEPTH       1          / defaults to last specified box  
    TRANX       1          / defaults to last specified box  
/
```

## ADDREG

## Adds a constant to the specified array in either a flux region, MULTNUM region or OPERNUM region

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
x	EDIT
x	PROPS
x	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

ADDREG is similar to the [ADD](#) keyword, but uses either [FLUXNUM](#) regions, [MULTNUM](#) regions or [OPERNUM](#) regions, rather than boxes of cells.

For the [FLUXNUM](#) case, there is no requirement to use the Flux option.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated by a slash (/).

The records can be terminated early using the slash character (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

Each record consists of the following items of data:

- The name of the array to be modified
- The constant to be added to the array, specified by item 1  
The constant may be positive or negative, and, for the [REGIONS](#) section, should be integer.  
DEFAULT: 0.0
- The flux region number, [MULTNUM](#) region or [OPERNUM](#) region number (with choice of region determined using item 4)  
The flux region number refers to the region defined using the [FLUXNUM](#) keyword in the [GRID](#) section. It is not necessary to use the Flux Boundary option.  
The [MULTNUM](#) region number refers to the region defined using the [MULTNUM](#) keyword in the [GRID](#) section.  
The [OPERNUM](#) region number refers to the region defined using the [OPERNUM](#) keyword in the [GRID](#) or [REGIONS](#) section.
- Choice of region: [MULTNUM](#) (M), [FLUXNUM](#) (F) or [OPERNUM](#) (O).  
DEFAULT: M

The set of records is ended by a blank record, containing only a slash (/).

---

**Note:** The [FLUXNUM](#), [MULTNUM](#) or [OPERNUM](#) keyword must be input before the [ADDREG](#) keyword.

---

## ECLIPSE 100

This keyword may not be used to modify the [PBUB](#) or [PDEW](#) arrays.

---

**Note:** If item 4 is defaulted, then the [MULTNUM](#) keyword is used.

---

## ECLIPSE 300

This keyword may be used in the [SCHEDULE](#) section. However, this is a specialist facility.

---

**Note:** In the SCHEDULE section, regions (pre-defined by the `FIPxxxx` keyword in the REGIONS section) can be used in item 4.

---

- The use of the ADDRREG keyword assumes that a value has already been assigned to the array.

- Each record must refer to the same region. It is not possible to choose a different region for each data record.
- The ADDREG keyword is not available for use with local grid systems.

ECLIPSE 100 only

See also keywords [EQUALREG](#), [FLUXNUM](#), [MULTNUM](#), [OPERNUM](#), [MULTIREG](#) and [COPYREG](#).

### Additional notes

ECLIPSE 300 only

Additional notes for the use of this keyword in the SCHEDULE section. Again, this is a specialist facility. In the SCHEDULE section, the effect of this keyword will be as follows:

Keyword	Description
<a href="#">DIFFMMF</a>	Modifies the matrix-fracture diffusivity in dual-porosity runs. If output is required for flexible restart in the model, these multiplier values will be output as DIFFMMFS.
<a href="#">MULSGGD</a> <a href="#">MULSGGDV</a>	Modifies the matrix-fracture coupling transmissibility for oil-gas gravity drainage in dual-porosity runs. If output is required for flexible restart in the model, these multiplier values will be output as MULSGGDS.
<a href="#">MULTSIG</a> <a href="#">MULTSIGV</a>	Modifies the matrix-fracture coupling transmissibility in dual-porosity runs. If output is required for flexible restart in the model, these multiplier values will be output as MULTSIGS.
<a href="#">MULTX</a> <a href="#">MULTY</a> <a href="#">MULTZ</a>	Modifies transmissibility in the X/Y/Z-direction. If output is required for flexible restart in the model, the multiplier values will be output as MULTXS/MULTYS/MULTZS.
<a href="#">PERMX</a> <a href="#">PERMY</a> <a href="#">PERMZ</a>	Modifies permeability in the X/Y/Z-direction. Also approximates the corresponding transmissibility multiplier MULTX/Y/Z determined from the ratio of the new permeability value to the old one. If output is required for flexible restart in the model, the permeability values will be output as MODPERMX/Y/Z.
<a href="#">PORO</a>	Modifies porosity. Modifies the corresponding pore volume by a multiplier MULTPV determined from the ratio of the new porosity value to the old one. If output is required for flexible restart in the model, the porosity values will be output as MODPORO, and the pore volume multipliers will be output as MULTPVs.
<a href="#">SIGMA</a> <a href="#">SIGMAV</a>	Modifies the matrix-fracture coupling transmissibility in dual-porosity runs. If output is required for flexible restart in the model, these multiplier values will be output as SIGMA.
WORK (1 / 2)	These are work arrays to be stored for subsequent use. If output is required for flexible restart in the model, these values will be output as WORK (1 / 2).

Table 3.1: Additional notes for ADDREG in the SCHEDULE section

## ADDZCORN Adds a constant to the corner point depth array

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword may be followed by any number of records, each of which is terminated by a slash (/). The data is terminated by a null record (that is a record with no data before the terminating slash). Each record consists of at least one item of data.

Items 2-7 are used to redefine the input box for the modification to the corner depths. The constant specified in item 1 is added to all the corners within this box, with the possible exception of the bottom corners of the bottom layer ( $KZ = KZ2$ ), or the top corners of the top layer ( $KZ = KZ1$ ), see item 12 below.

The modification is either continuous with the surrounding cells or discontinuous, depending on the settings of data items 8 to 11.

1. The constant to be added to the corner point (**ZCORN**) array. The constant may be positive or negative; a positive constant increases the depths of the cell corner points.

A record can also contain the following data items.

If items 2-7 are not defined (a slash is inserted after item 1), they default to the values which were used for the previous operation within the current keyword. For the first operation in the keyword, the box defaults to the values set by the most recent **BOX** or **ENDBOX** keyword. If there is no preceding **BOX** or **ENDBOX** in the current section, the box is taken to include the entire reservoir.

2. **IX1** First block to be modified on the X axis.
3. **IX2** Last block to be modified on the X axis.
4. **JY1** First block to be modified on the Y axis.
5. **JY2** Last block to be modified on the Y axis.
6. **KZ1** First block to be modified on the Z axis.
7. **KZ2** Last block to be modified on the Z axis.

The data must satisfy

$$0 \leq IX1 \leq IX2 \leq NDIVIX$$

$$0 \leq JY1 \leq JY2 \leq NDIVIY$$

$$0 \leq KZ1 \leq KZ2 \leq NDIVIZ$$

Where **NDIVIX**, **NDIVIY** and **NDIVIZ** are specified in **RUNSPEC** keyword **DIMENS**.

However, if only certain corners within a block are to be modified, any of **IX1**, **IX2**, **JY1** or **JY2** may be zero (consider the [Examples](#)).

Items 8-11 are used to specify whether the modification should be continuous with the surrounding cells.

8.  $IX1A = IX1 - 1$  or  $IX1$   
DEFAULT:  $IX1 - 1$  if  $IX1 > 1$
9.  $IX2A = IX2 + 1$  or  $IX2$   
DEFAULT:  $IX2 + 1$  if  $IX2 < NDIVIX$
10.  $JY1A = JY1 - 1$  or  $JY1$

DEFAULT: JY1 -1 if JY1 >1

11. JY2A = JY2 +1 or JY2

DEFAULT: JY2 +1 if JY2 <NDIVIY

The data must satisfy

$$0 \leq IX1A \leq NDIVIX \quad 0 \leq IX2A \leq NDIVIX$$

$$0 \leq JY1A \leq NDIVIY, \quad 0 \leq JY2A \leq NDIVIY$$

If, for example,  $IX2A = IX2$ , then blocks with  $I = IX2 + 1$  are not modified and a discontinuity (or fault) is added to the surface. However, if  $IX2A = IX2 + 1$ , then the corner points in blocks at  $I = IX2 + 1$  adjacent to the blocks at  $I = IX2$  have the constant added, so preserving a continuous surface.

If the surface is discontinuous between  $I = IX2$  and  $I = IX2 + 1$  prior to the action of the ADDZCORN keyword, then no action is taken with the blocks at  $I = IX2 + 1$ .

By default items 8-11 are set to give a continuous surface.

12. Action required:

ALL      Modify both top and bottom corner points of all cells.

TOP      Modify both top and bottom corner points of all cells, except for the bottom layer, in which the top cells only are modified.

BOTTOM   Modify both top and bottom corner points of all cells, except for the top layer, in which the bottom corners, only are modified.

The word may be abbreviated as only the first character is significant.

DEFAULT: ALL

See also the [BOX](#), [ENDBOX](#), [ADD](#) and [EQLZCORN](#) keywords.

## Modifying selected corner point depths within a grid block

It is possible to modify selected corner depths within a grid block by specifying a zero in either the IX1, IX2 or JY1, JY2 box limits (or both). In this case only the corner depth on the appropriate side of the cell will be modified.

If data items 8-11 are defaulted or set to a box outside the box defined in data items 2-7, then the adjacent cell depths are modified to give a continuous surface. Note that if the surface was discontinuous prior to the ADDZCORN keyword, the adjacent cells are not modified. See [Example 2](#).

## Examples

### Example 1

With NDIVIZ=5 in RUNSPEC keyword DIMENS:

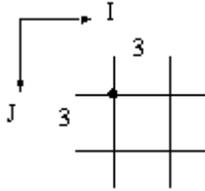

```

ADDZCORN
 10.0  3  4  3  4  1  5           / Add 10ft to all layers
-20.0  7  9  6  9  1  5  7  9  6  9 / Raise a fault block 20ft
-15.0 10 13 15 15  1  1  4* TOP   / Raise the top surface only
/

```

### Example 2

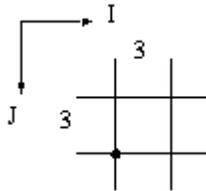

Add 10 ft. to the top-left corner of cells (3,3,1) to (3,3,5):

```
ADDZCORN

## ADSALNOD Salt concentration nodes for polymer solution adsorption

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTSFUN (see RUNSPEC keyword [TABDIMS](#)) tables of salt concentration values, each terminated by a slash (/), describing the nodal values for salt concentration to be used in the calculation of the polymer solution adsorption.

Note that this differs from the [SALTNODE](#) keyword in being specified by saturation function region rather than by PVT region.

Each table consists of up to NSSFUN (see RUNSPEC keyword [TABDIMS](#)) values of the salt concentration. Within each table the values should be positive and strictly increasing.

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB)

The number of entries in each table must correspond to the number of polymer solution adsorption entries used in the [PLYADSS](#) keyword.

Note that if keyword [ECLMC](#) is selected, the [BRINE](#) keyword activates the multi-component brine model (ECLIPSE 100 only) and functionality such as the polymer salt-sensitivity option (keywords [POLYMER](#), [BRINE](#), [SALTNODE](#) and [ADSALNOD](#)) cannot be used.

### Example

With NTSFUN=2 and NSSFUN ≥ 4:

```

ADSALNOD
  1.0
  5.0
 10.0
 30.0 /
  5.0
 30.0 /

```

## ADSORP

## Generic adsorption functions

This keyword supplies coefficients for analytical adsorption functions which can be used together with the polymer, surfactant, alkaline, foam and environmental tracer options (see the RUNSPEC keywords [POLYMER](#), [SURFACT](#), [ALKALINE](#), [FOAM](#) and [TRACERS](#), respectively). The keyword can be used in place of [PLYADS](#), [SURFADS](#), [ALKADS](#), [FOAMADS](#) and [TRADS](#). The analytical adsorption function allows for dependencies of adsorption on rock permeability as well as brine salinity in the case of polymer and surfactant (see "[Brine tracking](#)" in the *ECLIPSE Technical Description* for information on the calculation of standard and **effective** salinities for polymer and surfactant).

Currently a generalized Langmuir adsorption function is available in the ADSORP keyword:

$$C_{ads} = \frac{aC^m}{1+bC} \quad a = (a_1 + a_2 C_{SE}) \left( \frac{K_{ref}}{K} \right)^n,$$

where

$C_{ads}$  denotes the rock adsorbed concentration

$C$  denotes the concentration in the solution surrounding the rock

$m$  denotes an exponent for concentration dependence

$C_{SE}$  denotes the (effective) salinity for polymer/surfactant

$K$  denotes the grid block permeability  $K = \sqrt[3]{K_x K_y K_z}$

$K_{ref}$  denotes the reference permeability

$a_1$  denotes an adsorption coefficient

$a_2$  denotes an adsorption coefficient for salinity dependence

$b$  denotes an adsorption coefficient

$n$  denotes an exponent for permeability dependence

The data comprises NTSFUN+1 (see item 1 in the RUNSPEC keyword [TABDIMS](#)) records of data, each terminated by a slash (/).

### First record

The first record holds the name of the adsorbing component. Valid options are: [POLYMER](#), [SURFACT](#), [ALKALINE](#), [FOAM](#) or the three-character name of an environmental tracer.

### Remaining records

The following NTSFUN records hold adsorption coefficients for each region:

1. Name of adsorption isotherm. This item must be set to LANGMUIR which is currently the only adsorption function available.

DEFAULT: LANGMUIR.

2. Adsorption coefficient  $a_1$ .

DEFAULT: no default.

UNITS:  $(\text{sm}^3/\text{kg})^m$  (METRIC),  $(\text{stb}/\text{lb})^m$  (FIELD),  $(\text{scc}/\text{gm})^m$  (LAB)

If ADSORP is used with an environmental tracer and a unit has been specified for this tracer in keyword TRACER, the units employed here are:

UNITS:  $(\text{sm}^3)^m/(\text{TR}^{m-1} \text{ kg})$  (METRIC),  $(\text{stb})^m/(\text{TR}^{m-1} \text{ lb})$  (FIELD),  $(\text{scc})^m/(\text{TR}^{m-1} \text{ gm})$  (LAB)

where TR is the unit supplied for the tracer.

3. Adsorption coefficient for salinity dependence  $a_2$ . This item is only relevant when the ADSORP keyword is used in conjunction with the polymer or surfactant option. In all other cases the item is ignored.

For surfactant the effective salinity for surfactant is applied in the adsorption calculation (see keyword SURFESAL as well as the "Brine tracking" section in the *ECLIPSE Technical Description*). For polymer the salinity applied in the adsorption calculation depends on the type of brine model. When used with the Multi-Component Brine model the effective salinity for polymer (see keyword PLYESAL) will be used. Otherwise the standard brine concentration will be applied. Surfactant adsorption only allows a dependence on the effective salinity for surfactant, as activated by the SURFESAL keyword, and not the standard salinity.

DEFAULT: 0.0

When used with an effective salinity, as measured in moles equivalent per unit standard volume, the units of  $a_2$  are

UNITS:  $(\text{sm}^3)^{m+1}/(\text{kg}^m \text{ kg-M})$  (METRIC),  $(\text{stb}^{m+1})/(\text{lb}^m \text{ lb-M})$  (FIELD),  $(\text{scc})^{m+1}/(\text{gm}^m \text{ gm-M})$  (LAB)

When used with the standard brine concentration, as measured in mass per unit standard volume, the units of  $a_2$  are

UNITS:  $(\text{sm}^3/\text{kg})^{m+1}$  (METRIC),  $(\text{stb}/\text{lb})^{m+1}$  (FIELD),  $(\text{scc}/\text{gm})^{m+1}$  (LAB)

---

**Note:** Adsorption is always reversible with salinity, even when it is irreversible in concentration.

---

4. Adsorption coefficient  $b$ .

DEFAULT: no default

UNITS:  $\text{sm}^3/\text{kg}$  (METRIC),  $\text{stb}/\text{lb}$  (FIELD),  $\text{scc}/\text{gm}$  (LAB)

If ADSORP is used with an environmental tracer and a unit has been specified for this tracer in keyword TRACER, the units employed here are:

UNITS:  $\text{sm}^3/\text{TR}$  (METRIC),  $\text{stb}/\text{TR}$  (FIELD),  $\text{scc}/\text{TR}$  (LAB)

where TR is the unit supplied for the tracer.

5. Exponent,  $m$ , for concentration dependence.

DEFAULT: 1

UNITS: dimensionless

6. Exponent,  $n$ , for permeability dependence.  
 DEFAULT: 0.5  
 UNITS: dimensionless
7. Reference permeability  $k_{ref}$ . This is the permeability at which the adsorption coefficients are specified. Permeability dependencies can be ignored by setting item 6 to 0.  
 DEFAULT: no default  
 UNITS: mD (METRIC), mD (FIELD), mD (LAB)

---

**Note:** The adsorption function relates the solution concentration of a component per unit volume of host phase to the rock adsorbed concentration per unit mass of rock. The rock mass density as well as the adsorption index must be supplied in the respective rock keyword, that is [PLYROCK](#) for polymer adsorption and [TRROCK](#) for tracer adsorption for example.

---

---

**Note:** The ADSORP keyword with POLYMER as an item and the [PLYADS](#) keyword are mutually exclusive and similarly for ADSORP with SURFACT, ALKALINE, FOAM or an environmental tracer as an item and the [SURFADS](#), [ALKADS](#), [FOAMADS](#) and [TRADS](#) keywords.

---

## Example

Surfactant/polymer run with one environmental tracer ET1 and NTSFUN =2:

```

ADSORP
POLYMER /
-- isotherm      a1      a2      b      m      n      k_ref
  LANGMUIR 0.0012  0.7    0.4    1.1    0.5    100 /
  LANGMUIR 0.0009  0.5    0.1    1.2    0.3    50  /

ADSORP
SURFACT /
-- isotherm      a1      a2      b      m      n      k_ref
  LANGMUIR 0.0012  0.7    0.4    1*     0.5    100 /
/ -- default second table to first table

ADSORP
ET1 /
-- isotherm      a1      a2      b      m      n      k_ref
  LANGMUIR 0.001   1*     0.2    1*     0.5    250 /
  LANGMUIR 0.005   1*     1.1    1*     0.0    50  /

## Use the AIM solution option

This keyword selects the AIM (Adaptive IMplicit) solution option for ECLIPSE 300. This is the recommended option for most studies, and is the default. Alternative options are [FULLIMP](#) (fully implicit), [IMPSTAT](#) and [IMPES](#) (IMplicit Pressures, EXplicit Saturations). Generally AIM avoids the timestep restrictions imposed by small blocks, particularly those containing wells, whilst not suffering the much greater computational expense of a fully implicit solution.

For Thermal simulations the FULLIMP method is the default.

For [BLACKOIL](#) simulations the FULLIMP method is the default.

See "[Formulation of the equations](#)" in the *ECLIPSE Technical Description*.

---

**Note:** For ECLIPSE 300, the maximum rate of change of capillary pressure in explicit cells specified by the [DPCDT](#) keyword, which is assumed to be active by default for the AIM solution method, should be reviewed and checked for compatibility with the magnitudes of the oil-water and gas-oil capillary pressures specified via the saturation functions.

---

## Controls for AIM

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The data consists of some or all of the following data items, which control the implicit cell choice within an [AIM](#) run. The data must be terminated by a slash (/).

- An integer which controls the implicit treatment of the wells.
  - Wells are not given any special treatment.
    - All the inner solver direction lines of cells containing the completions of open wells are set to be implicit.
    - All the cells containing the completions of open wells are set to be implicit.
    - All the cells containing the completions of open wells and their neighbors are set to be implicit.

DEFAULT: 2

Thermal DEFAULT: 3

- An integer which controls the implicit treatment of LGRs (this item does not override the [NOAIMLGR](#) keyword).
  - All cells in LGRs are set implicit
  - LGRs are not given any special treatment.

DEFAULT: 1

- All cells below the specified pore volume threshold are made implicit. A negative value indicates that no pore volume limit is enforced.

UNITS:  $\text{rm}^3$  (METRIC), rb (FIELD), rcc (LAB),  $\text{rm}^3$  (PVT-M)

DEFAULT: -1.0

- An integer specifying the number of timesteps taken before reevaluating the AIM state.

The AIM state is always reevaluated at the beginning of a new report step.

If this item is negative (and item 5 is greater than zero), the AIM state is always reevaluated if throughput or solution change is limiting the current step.

DEFAULT: 5

- The fractional throughput target threshold.

The AIM state is always reevaluated at the beginning of a new report step.

All cells (up to the maximum % specified in item 6) with a throughput above the specified fraction of the current throughput target ratio (see item 8 of [TSCRIT](#)) are set to implicit.

A negative value indicates that this selection method is not used; instead the pre-2000A AIM selection criteria are activated.

DEFAULT: 0.5

*Thermal option*

DEFAULT: 0.1

*CO2STORE option*

DEFAULT: 0.01

6. The maximum percentage of cells that can be set to implicit when the throughput change is greater than the target set in item 5. This value must be between 0.0 and 100.0, and can be altered using the [AIMFRAC](#) keyword.

If the criterion specified in item 5 produces more than the specified limit, then all these cells are sorted by throughput change, and the top percentage (specified by this item) are chosen.

DEFAULT: 5.0

*Thermal option*

DEFAULT: 100.0

*CO2STORE option*

DEFAULT: 100.0

7. The fractional solution change target threshold.

All cells (up to the maximum % specified in item 8) with a normalized solution change above the specified fraction of the current solution change target ratio (see item 10 of [TSCRIT](#)) are set to implicit. A negative value turns off this selection criterion.

DEFAULT: 0.125

*Thermal option*

DEFAULT: -1.0

8. The maximum percentage of cells that can be set to implicit when the solution change is greater than the target set in item 7. This value must be between 0.0 and 100.0.

If the criterion specified in item 7 produces more than the specified limit, then all these cells are sorted by solution change, and the top percentage (specified by this item) are chosen.

DEFAULT: 5.0

*Thermal option*

DEFAULT: 100.0

9. An integer specifying the number of AIM state evaluations that an implicit cell remains implicit after being set, regardless of the selection criteria.

This option is only activated when item 5 is greater than 0.

DEFAULT: 5

*Thermal option*

DEFAULT: (Maximum number of non-linears allowed)/2, for instance [NEWTMX](#) /2 where [NEWTMX](#) is defined via item 1, record 3 of the [TUNING](#) keyword.

10. The extrapolation factor to be applied to the solution change before applying the selection criteria controlled by items 5 and 7.

DEFAULT: 1.0

*Thermal only*

11. The fractional temperature change target threshold.

All cells (up to the maximum% specified in item 12) with a temperature change above the specified fraction of the current temperature change target (see item 17 of [TSCRIT](#)) are set to implicit. A negative value turns off this selection criterion.

DEFAULT: -1.0

*Thermal only*

12. The maximum percentage of cells that can be set to implicit when the temperature change is greater than the target set in item 11. This value must be between 0.0 and 100.0.

If the criterion specified in item 11 produces more than the specified limit, then all these cells are sorted by solution change, and the top percentage (specified by this item) are chosen.

DEFAULT: 100.0

Thermal only

13. Threshold for gas saturation above which a cell will be designated as implicit. A negative value turns this option off.

DEFAULT: -1.0

Thermal only

14. Threshold for temperature difference above which a cell will be designated as implicit. A negative value turns this option off.

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

DEFAULT: 1°C

If item 5 is less than zero, then the selection criteria for Implicit cells with an AIM run are compatible with pre-2000A releases.

The basic premise with these selection criteria is to extrapolate a vector of timestep controlling values  $s$  to the next time-level:

$$S^{(n+*)} = S^{(n)} + \delta \times \Delta t^{(n)} \max \left( \left[ \frac{(S^{(n)} - S^{(n-1)})}{\Delta t^{(n-1)}} \right], 0 \right) \quad \text{Eq. 3.1}$$

Three criteria can be used in selecting AIM cells,  $S$  can be either the throughput (used with items 5 and 6), the solution change (used with items 7 and 8) or the temperature change (used with items 11 and 12).  $\delta$  is the extrapolation factor (specified in item 10). A cell  $i$  is set implicit if  $S_i > \beta \times \text{target}$  where  $\beta$  is the fraction specified in items 5, 7 or 11 and target is the timestepping target specified by items 8, 10 or 17 of the TSCRIT keyword. If the number of cells selected is above that specified by the limits imposed in items 6, 8 or 12, then the selected cells are sorted and only the largest values, up to the limit on the number of implicit cells, are chosen.

Note that if item 6 is set to 7% and item 8 is set to 3%, then up to 10% of the reservoir could be made implicit at any time (ignoring any well cells, that is item 1 is zero). As implicit cells will persist for a number of AIM state evaluations (item 9), then it is possible (although unlikely) that 100% of the reservoir could be made implicit after 10 AIM state evaluations.

## Example

In this example up to 5% (item 6) of the reservoir could be made implicit if the time extrapolated throughput of a cell is greater than a half (item 5) of the target, and up to 5% (item 7) of the reservoir could be made implicit if the time extrapolated solution change is within an eighth (item 6) of the target. All cells made implicit remain implicit for 5 (item 9) AIM state evaluations, and the AIM states are evaluated after every timestep (item 3). The items specified in the example have been shown to give good performance over a wide range of simulations.

```

AIMCON
--wells--lgr--minpV--#eval--TPT(thres)--TPT(max)--SCT(thres)--
SCT(max)--hist--extrap
   2   1*   1*   1   0.5           5           0.125           5           5           1
/

## AIMFRAC

### Set target implicit fraction in AIM mode

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword allows the user to modify the target fraction of cells which are implicit in an AIM (Adaptive Implicit Method) run. The default is 0.01, which is reasonable for most runs. Decreasing the target fraction will reduce the memory required and the CPU time per step, although it may reduce the size of each step. Increasing the target fraction has the opposite effect. Large AIMFRAC values should be avoided - [FULLIMP](#) may be preferable in this case.

This can also be altered using item 6 of keyword [AIMCON](#). An additional default value for the Thermal option can be chosen.

DEFAULT: 0.01

---

**Note:** In the absence of the AIMFRAC keyword the default AIM fraction is 0.05 (5%) or as specified by the AIMCON keyword.

---

#### Example

Set a target of 10 per cent of cells to be implicit:

```
AIMFRAC
0.1 /
```

	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE
	OPTIMIZE

**Note:** This keyword can only be used if the adjoint gradient option for sensitivities has been requested in the RUNSPEC section using the [AJGRADNT](#) keyword.

This keyword is used to specify a list of static grid properties for which the sensitivities of objective functions (specified using the [AJGWELLS](#) keyword) will be calculated at the end of the simulation run using the adjoint method (see "[Adjoint gradient screening](#)" in the *ECLIPSE Technical Description*). These sensitivities are calculated with respect to the specified static properties on every simulation grid cell at every report time, and they are output to the restart files. (Note that the sensitivities output to the restart file will be encoded unless the [UNCODHMD](#) keyword is present in the RUNSPEC section.)

This keyword should only appear once in the data file.

The keyword must be followed by a set of mnemonics, each specifying a parameter for which sensitivity calculations are required. The list should be terminated with a slash (/). An empty list is not permitted.

The available mnemonics are:

PORV Pore volume

PORO Porosity

TRANX Transmissibility in the x-direction

TRANX Transmissibility in the y-direction

TRANZ Transmissibility in the z-direction

TRANXY Transmissibility in the x- and y-directions (horizontal)

PERMX Permeability in the x-direction

PERMY Permeability in the y-direction

PERMZ Permeability in the z-direction

PERMXY Permeability in the x- and y-directions (horizontal)

### Example

This example shows how to request sensitivities with respect to the pore volume and x-permeability in every simulation grid cell at each report time.

```
AJGPARAM
'PORV' 'PERMX' /
```

## AJGRADNT Request sensitivities with respect to grid properties using the adjoint method

	SCHEDULE
	OPTIMIZE

This keyword activates the option to perform calculations of sensitivities using the adjoint method. It requires no data.

These sensitivities are the response of objective functions (such as the flowing bottom-hole pressure in a particular well) to changes in static grid properties (such as pore volume in each simulation grid cell). The objective functions and static grid properties are defined in the SCHEDULE section using the [AJGWELLS](#) and [AJGPARAM](#) keywords respectively.

These sensitivities are output to the restart files; the values will be encoded unless the [UNCODHMD](#) keyword is present in the RUNSPEC section.

---

**Note:** This option is not currently available with the parallel option. See "[Adjoint gradient screening](#)" in the *ECLIPSE Technical Description* for a complete list of the requirements and limitations of this option.

---

## AJGWELLS Specify objective functions for adjoint gradient calculation

x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE
	OPTIMIZE

**Note:** This keyword can only be used if the adjoint gradient option for sensitivities has been requested in the RUNSPEC section using the [AJGRADNT](#) keyword.

This keyword is used to specify the objective functions for which sensitivities will be calculated at the end of the simulation run using the adjoint method (see "[Adjoint gradient screening](#)" in the *ECLIPSE Technical Description*). These sensitivities are calculated with respect to static properties (specified using the [AJGPARAM](#) keyword) on every simulation grid cell at every report time, and they are output to the restart files. (Note that the sensitivities output to the restart file will be encoded unless the [UNCODHMD](#) keyword is present in the RUNSPEC section.)

The keyword must be followed by a set of records, each specifying a parameter to be used in the optimization. Each record should be terminated with a slash (/) and the set of records must end with a slash. At least one record is required for the calculation of sensitivities; an empty record is not allowed. (The total number of records should not exceed 200.)

### 1. Well name.

This should be the name of a well that has already been, or will be, defined in the SCHEDULE section. It is not possible to use wildcard characters to specify more than one well.

### 2. Objective function mnemonic.

The list of available keywords is:

WBHP Flowing bottom hole pressure

WOPR Oil production rate

WGPR Gas production rate

WGIR Gas injection rate

WWPR Water production rate

WWIR Water injection rate

WLPR Liquid production rate

## Example

This example shows how to request sensitivities for a selection of objective functions on a selection of wells.

```
AJGWELLS

	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTSFUN (see item 1 of keyword [TABDIMS](#)) tables of alkaline adsorption functions, each terminated by a slash (/), describing the adsorption of alkaline by the rock formation. Each table consists of the following columns of data:

- The local alkaline concentration in the solution surrounding the rock.  
The values should increase monotonically down the column.  
UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB)
- The corresponding saturated concentration of alkaline adsorbed by the rock formation.  
These values should increase monotonically down the column.  
UNITS: kg/kg (METRIC), lb/lb (FIELD), gm/gm (LAB)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (see item 3 of keyword [TABDIMS](#)). If any table after the first is defaulted, then that table is copied from the previous table.

---

**CAUTION:** The first row in the adsorption tables should consist of a pair of zeroes.

---

See "[Alkaline model](#)" in the *ECLIPSE Technical Description* for further information.

### Example

With NTSFUN=2 and NSSFUN≥5

```

ALKADS
.0000 .00000
.0003 .00005
.0005 .00007
.0008 .00008
.0010 .00008 /
.0000 .00000

	SCHEDULE

This indicates that the Alkaline Model is required (see "[Alkaline model](#)" in the *ECLIPSE Technical Description*).

The keyword has no associated data.

---

**Note:** In the current version of ECLIPSE this feature is targeted at ASP scenarios and would often be referred to as a high pH model.

---

## ALKROCK Specifies the alkaline-rock properties

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTSFUN (see item 1 of keyword [TABDIMS](#)) records specifying the rock adsorption index for alkaline adsorption. Each record should be terminated by a slash (/).

Possible values for the adsorption index are 1 or 2.

If a value of 1 is selected, then the alkaline adsorption isotherm is retraced whenever the local alkaline concentration in the solution decreases.

If a value of 2 is selected, then no alkaline desorption may occur and the alkaline effect on Polymer or Surfactant adsorption is assumed to be permanent: The multiplier tables in [ALSURFAD](#) or [ALPOLADS](#) are not retraced when the alkaline concentration decreases.

If any record after the first is defaulted, then that record is copied from the previous record.

---

**Note:** If the Polymer Flood Model is being used, the rock mass density required in the adsorption calculation is taken from the [PLYROCK](#) keyword. Otherwise, if the Surfactant Flood Model is used, the rock mass density is taken from the [SURFROCK](#) keyword.

---

See "[Alkaline model](#)" in the *ECLIPSE Technical Description* for further information.

### Example

With NTSFUN=2

```

ALKROCK
  2 /
  1 /

```

## ALPHA

## Transport coefficient tables

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The ALPHA keyword should provide NTALPHA tables of transport coefficients for oil and gas component flows as functions of one of the total mole fractions (see item 16 of keyword [TABDIMS](#) and also "[Transport coefficients](#)" in the *ECLIPSE Technical Description*). The component mole fraction to be used is identified separately with the [TRCOEF](#) keyword.

Each line of each table contains the mole fraction, then  $N_c$  oil transport coefficients, followed by  $N_c$  gas transport coefficients.

## Example

Example with 5 components and NTALPHA=2:

```

ALPHA
--      Oil coefficients      Gas coefficients
  0      1.5 1.2  1 1 1      2.5 1 1 1 1
  1      1   1   1 1 1      1   1 1 1 1
/
  0      1.4 1.1  1 1 1      2.4 1 1 1 1
  1      1   1   1 1 1      1   1 1 1 1
/

```

## ALPHAD

## Drainage transport coefficient tables

	ECLIPSE 100

	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The ALPHAD keyword is used to modify component mobilities for drainage (decreasing wetting phase saturation) processes only when hysteresis is occurring. Hysteresis should be specified using [SATOPTS](#) keyword with [HYSTER](#) option and also the keyword [EHYSTR](#).

The ALPHAD tables are input for drainage processes as functions of one of the component mole fractions. This component mole fraction is identified separately with the [TRCOEF](#) keyword.

The ALPHAD keyword should provide NTALPHA tables of transport coefficients (see item 16 of keyword [TABDIMS](#) and also "[Transport coefficients](#)" in the *ECLIPSE Technical Description*). Each line of each table contains the mole fraction, then  $N_c$  oil transport coefficients, followed by  $N_c$  gas transport coefficients.

It is also possible to modify the component mobilities for imbibition processes with the keyword [ALPHAI](#).

## Example

Example with 5 components, NTALPHA=2 and component number 3 specified by [TRCOEF](#):

```
ALPHAD
--Z3 Oil coefficients   Gas coefficients
  0  1.5 1.2 1 1 1     2.5 1 1 1 1
  1  1  1  1 1 1     1  1 1 1 1
/
  0  1.4 1.1 1 1 1     2.4 1 1 1 1
  1  1  1  1 1 1     1  1 1 1 1
/
```

## AMALGAM Specify LGR amalgamations

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The AMALGAM keyword is used to define groups of LGRs which are to be amalgamated.

This keyword can be followed by any number of records. Each record is of arbitrary length and is terminated by a slash (/). The set of records must be terminated with a blank record containing just a slash.

Each record defines one amalgamation, and should consist of the names of all the LGRs in the amalgamation (up to 8 characters). An LGR name root, ending with an asterisk (\*) and enclosed in quotes, can be used to refer to several LGRs at once.

LGRs within the same amalgamation are allowed to touch, but must not overlap and may not be nested within each other. ECLIPSE treats an amalgamation as a single entity, with non-neighbor connections between any LGRs which touch.

---

**Note:** Additional non-neighbor connections may arise owing to domain decomposition in parallel runs and may require the inclusion of additional LGRs in an amalgamation.

---

---

**Note:** Non-neighbor connections must **not** be disabled by the keyword `NONNC` in the RUNSPEC section.

---

This facility allows you to refine the grid more efficiently around deviated wells. Wells may be completed in several local grids, as long as they belong to the same amalgamation.

For these wells, it is necessary to use the keywords `COMPLMPL`, `WELOPENL` and `WFRICTNL` in place of `COMPLUMP`, `WELOPEN` and `WFRICTN`. (`COMPLMPL` lumps connections into completions; `WELOPENL` shuts or reopens well connections; and `WFRICTNL` permits the modeling of friction wells completed across several local grids if the Wellbore Friction Option is active.)

If LGRs that do not touch are amalgamated, ECLIPSE still lumps them together as a single entity in the solution process. Thus, their local timesteps are synchronized.

---

**Note:** Only Cartesian LGRs may be amalgamated.

---

VE and dispersed flow models must be used in all or none of the LGRs in an amalgamation. The options under keyword `QMOBIL` must be the same for all LGRs within an amalgamation.

The maximum number of wells allowed in any amalgamation is the sum of the maxima specified in item 11 of keyword `CARFIN` for all the local grids in the amalgamation.

Since an amalgamation of local grids is solved as a single entity in ECLIPSE, `LGRON` and `LGROFF` actions for any local grid in an amalgamation apply to the whole amalgamation.

ECLIPSE 300

This keyword is not required by ECLIPSE 300. Connections are generated between nested and adjoining local grids in ECLIPSE 300 in all runs.

See "Amalgamating Cartesian local grids (ECLIPSE 100)" in the *ECLIPSE Technical Description*.

See also keywords `COMPDATL`, `WELOPENL`, `COMPLMPL`, `WPIMULTL` and `WFRICTNL`.

ECLIPSE 100

---

**Note:** When using the Flux Boundary Conditions option (see keyword `USEFLUX`) all local grid refinements within an amalgamation must be in the same flux region (see keyword `FLUXNUM`).

---

ECLIPSE 100

---

**Note:** When using the flux boundary conditions option (see keyword USEFLUX) in parallel, amalgamations may not be used outside of the USEFLUX region.

---

## Example

Two local grid amalgamations:

```
AMALGAM
'NORTH*' /
LGR1 LGR2 LGR3 LGR4 /
/
```

## AMF

## Specifies cell initial aqueous composition explicitly

	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used to specify the initial aqueous phase composition values for each cell in runs with the [GASWAT](#), [CO2SOL](#), [H2SSOL](#), [GASSOL](#) or the thermal [KWTABTn](#) option active.

In the [GASWAT](#) case, the syntax follows that of [XMF](#) and [YMF](#) with the data entered as  $N_x \cdot N_y \cdot N_z \cdot N_c$  values in normal order.

In the [THERMAL](#) case the input follows the syntax of [XMF](#) and [YMF](#) with data entered as  $N_x \cdot N_y \cdot N_z \cdot (N_c + 1)$ . Please note that when using the [KWTABTn](#) option or using the [CO2STORE](#) option together with [THERMAL](#) it is possible to specify H<sub>2</sub>O in the list of components set by [COMPS](#), using the name H<sub>2</sub>O, in this case  $N_x \cdot N_y \cdot N_z \cdot N_c$  values are entered.

In the [CO2SOL](#) case only two components, CO<sub>2</sub> and water, are present in the aqueous phase; hence only  $N_x \cdot N_y \cdot N_z \cdot 2$  values are required with the CO<sub>2</sub> data followed by the water fraction. Usually it is preferable to use the [RSW](#) keyword to input the CO<sub>2</sub> concentration in the aqueous phase.

In the [H2SSOL](#) case only two components, H<sub>2</sub>S and water, are present in the aqueous phase; hence only  $N_x \cdot N_y \cdot N_z \cdot 2$  values are required with the H<sub>2</sub>S data followed by the water fraction.

If both [CO2SOL](#) and [H2SSOL](#) are present three components, CO<sub>2</sub>, H<sub>2</sub>S and water, are present in the aqueous phase; hence only  $N_x \cdot N_y \cdot N_z \cdot 3$  values are required with the CO<sub>2</sub> data followed by H<sub>2</sub>S data followed by the water fraction.

If [GASSOL](#) is present, [NCMPHW](#) components and water are present in the aqueous phase; hence only  $N_x \cdot N_y \cdot N_z \cdot NCMPHW$  values are required with the [NCMPHW](#) data followed by the water fraction.

## Aqueous mole fractions versus depth

This keyword can be used in a [THERMAL](#) run together with the [CO2STORE](#) option and/or when water  $K_w$  values are defined using [KWTABTn](#).

The data comprises a table of aqueous mole fractions (for example,  $\text{CO}_2$ ,  $\text{H}_2\text{S}$  and  $\text{H}_2\text{O}$ ) versus depth. Each table consists of the number of components plus 1 columns of data and must be terminated by a slash (/). Note that in a thermal run the  $\text{H}_2\text{O}$  component also should be specified.

When water-oil contact and gas-oil contact is above reservoir top then [COMPVD](#) and [ZMFVD](#) are not needed, AMFVD would be enough for initialization.

Column 1                      Depth values.

Values should increase monotonically.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

Columns 2 to  $N_c + 1$  Corresponding mole fraction for each component including water ( $\text{H}_2\text{O}$ ).

If AMFVD is not used in equilibrated cases ([EQUIL](#) keyword present) then water will be entirely composed of  $\text{H}_2\text{O}$ .

The initial aqueous mole fractions will be set from this keyword, unless the concentration exceeds the saturated value in which case the saturated value will be taken. Note, however, that the aqueous concentration may not be in equilibrium with the gaseous concentration. The concentration reported at initialization is the concentration after flashing the system, and hence dissolved gases (for example,  $\text{CO}_2$  or  $\text{H}_2\text{S}$ ) may be redistributed between the phases in each grid block.

### Example

Aqua mole fractions versus depth, one component and water.

```
AMFVD
----- gas   water
100    0.001 0.999
10000 0.002 0.998/
```

## API

### API tracking option is enabled

This indicates that the API Tracking option is required (see "[API tracking](#)" in the *ECLIPSE Technical Description*).

This option can be used in both live and dead oil systems. The keyword `RSCONSTT` cannot be used in API Tracking problems.

The keyword has no associated data.

## APIGROUP **Allows grouping of oil PVT tables for API tracking**

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by a single integer, terminated by a slash. The integer represents the maximum number of groups of oil PVT tables available when the API Tracking option is active. The default is 1.

The PVT tables are input in the usual way. Either the surface densities are set with keyword **DENSITY**, or the gravities are set with keyword **GRAVITY**. Normally the oil surface densities should increase monotonically with the table number (or the oil API gravities should decrease monotonically) when the API tracking option is in use. However, if keyword **APIGROUP** is present, a break in the required monotonicity is taken to indicate that the subsequent tables belong to the next API group. Thus the set of oil PVT tables can be arranged into API groups by breaking the monotonicity of the oil surface density or gravity. Within each API group, the densities increase (or gravities decrease) monotonically. An error is flagged if the total number of API groups exceeds the maximum number specified in this keyword.

The separate groups of oil PVT tables can then be used in different areas of the reservoir. The **REGIONS** section keyword **PVTNUM** is used to specify which API group is to be used for each grid block. For example, a cell in **PVTNUM** region 2 will use the second API group to obtain the oil properties. For water and gas PVT properties, the **PVTNUM** regions correspond to the actual table numbers, as in runs that do not use API tracking. So a cell in **PVTNUM** region 2 still uses table number 2 for its water and gas properties.

### Example

```
APIGROUP

## API limiting

This keyword can be used to monitor the numbers of grid blocks with API values outside the expected range when the API Tracking option has been selected (see "API tracking" in the *ECLIPSE Technical Description*). In addition, the API values may optionally be constrained to lie within a specified range. This keyword consists of the following items:

1. Type of limiting to be applied.

NONE Deselects any previously specified API value monitoring or limiting.

WARN Provides a summary of the numbers of grid blocks with API values outside the specified range at each timestep and a more detailed tabulated summary at each report step.

LIMIT Constrains the API values of grid blocks outside the specified range to the lower or upper limit as appropriate.

BOTH Provides a summary of the numbers of grid blocks with API values outside the specified range before limiting at each timestep and a more detailed tabulated summary at each report step. It also constrains the API values to the lower or upper limit as appropriate at each timestep.

DEFAULT: NONE

Items 2 to 5 inclusive, which are defined below, are ignored and need not be specified if the first data item is set to NONE.

2. Scope of limiting to be applied.

LOWER Applies monitoring and/or limiting to the lower API limit only.

UPPER Applies monitoring and/or limiting to the upper API limit only.

BOTH Applies monitoring and/or limiting to the both the lower and upper API limits.

DEFAULT: BOTH

3. Lower API limit.

UNITS: °API

DEFAULT: The minimum API value inferred from initialization via equilibration or enumeration.

4. Upper API limit.

UNITS: °API

DEFAULT: The maximum API value inferred from initialization via equilibration or enumeration.

5. Number of rows of tabular output in the more detailed tabulated summary at each report step.

DEFAULT: 10

This facility may be used both to monitor the values of grid blocks which are outside the expected API limits and to constrain the API values to these limits. If monitoring is specified, brief summaries of the numbers of grid blocks whose values are below the lower limit and above the upper limit are provided at each timestep together with the associated lowest and highest API values respectively. If API limiting is specified, these summaries pertain to the values before limiting is applied. More information is provided at

each report step where tabulated lists are provided for grid blocks with API values which are below the lower limit or above the upper limit. The lower and upper values are tabulated in increasing and decreasing order respectively with the number of rows in each table specified by item 5.

---

**Note:** The detailed tabulated summary at each report step is only available for parallel runs if item 8 of the `PARAOPTS` keyword is set to a value greater than zero.

---

**Note:** Care should be exercised in selecting the API limits when applying limiting. In general, these should not be within the expected range of API values which might reasonably be expected to occur during the simulation.

---

## Example

This keyword connects analytic aquifers, declared using [AQUCT](#), [AQUFETP](#), [AQUFLUX](#), [AQUCHWAT](#) and [AQUCHGAS](#), to one or more reservoir cells located within local grid refinements.

The connection to the reservoir is set up by an arbitrary box defined by lower and upper I, J and K indices within the local grid refinement (refer to items 3-8 below). For each active grid block within the box, an aquifer connection is made to the face specified in item 9 if either of the following conditions is met:

- the face is on the outside of the reservoir, or
- the face adjoins an inactive cell.

Any number of records may be entered, each terminated with a slash (/). The set of records must be terminated with a blank record containing just a slash.

The items in each record are:

1. Aquifer identification number  
This should be a number between 1 and the maximum number of aquifers, set in the keyword [AQUDIM5](#).
2. Local grid refinement name (up to 8 characters)
3. Lower I-location of connecting grid blocks
4. Upper I-location of connecting grid blocks
5. Lower J-location of connecting grid blocks
6. Upper J-location of connecting grid blocks
7. Lower K-location of connecting grid blocks
8. Upper K-location of connecting grid blocks
9. Index defining the face of the reservoir to which the aquifer connects (where `NDIVIX`, `NDIVIY` and `NDIVIZ` are specified in RUNSPEC keyword [DIMENS](#)):

I- I = 1 face

I+ I = `NDIVIX` of LGR face

J- J = 1 face

J+ J = `NDIVIY` of LGR face

K- K = 1 face (top)

K+ K = `NDIVIZ` of LGR face (bottom)

10. The aquifer influx coefficient.

This determines the fraction of the total communication between the reservoir and the aquifer for each cell defined in the box above.

The default for each cell in the box is its face area. If a non-default value is entered, the value is assigned to each cell within the box.

If a reservoir cell is defined more than once, its previous value for the aquifer influx coefficient is added to the present value. The exception is the case where you enter a zero value, which then sets the influx coefficient for all the cells in the box to zero.

The aquifer influx coefficient is not used if the aquifer is a constant flux aquifer (keyword `AQUFLUX`). A negative value is not accepted.

UNITS: m<sup>2</sup> (`METRIC`), ft<sup>2</sup> (`FIELD`), cm<sup>2</sup> (`LAB`), m<sup>2</sup> (`PVT-M`)

11. Aquifer influx coefficient multiplier.

The multiplier is applied to the influx coefficients of the aquifer - cell connections within the box.

For constant flux aquifers (keyword `AQUFLUX`) the multiplier is applied to the cell areas.

DEFAULT: 1.0

12. Allow aquifer connections to cell faces adjoining active cells?

either: YES or NO

If this data item is set to YES, the restriction that a connected face must not adjoin an active cell is lifted, allowing aquifer connections into the middle of the reservoir. This option should be used with care and is not recommended for general use.

DEFAULT: NO

ECLIPSE 100

The total number of grid blocks connected to any single aquifer must not exceed the value set by item 6 in the `AQUDIMS` keyword in the `RUNSPEC` section. In addition, this keyword cannot be used with the keyword `AQUFET`.

---

**Note:** Each aquifer can only have one connection in any given grid block. When more than one connection in a grid block is specified for a single aquifer only the first will be connected.

---

ECLIPSE 100

The aquifer connections can be listed by setting item 12 in the `RPTSOL` keyword to 2 (mnemonic `AQUFET`, `AQUCT` or `AQUANCON`).

For both simulators, an array with the name `AQUIFERA` is written to the `INIT` file to illustrate which cells are connected to each aquifer. If a cell is connected to aquifer N then the number  $2^{(N-1)}$  appears in the `AQUIFERA` array. If a cell is connected to multiple aquifers then the appropriate output numbers are summed. Similarly, for gas aquifers, an array `AQUIFERG` is written to the `INIT` file.

ECLIPSE 300

The aquifer connections can be listed by specifying the argument `AQANCONL` in the `RPTSOL` keyword.

---

**Note:** Each unique aquifer can only be connected to one grid. That is, an aquifer can only be connected to either the global grid or to a single local grid refinement.

---

**Note:** The keyword `AQANCONL` must not be used in restarted runs, as the aquifer specification data cannot be changed.

---

ECLIPSE 100

**Note:** This keyword cannot be used if the `PARALLEL` keyword is present.

---

## Example

One Carter-Tracy aquifer, connected to one side of a 10 x 10 x 2 local grid refinement called LGR with one face where the aquifer influx coefficient is set to 1000.

```
AQUCT
1 7000.0 4000.0 200.0 .3 1.0E-5 500.0 50.0 10.0 1 1 /
/
AQANCONL
1 LGR 1 1 1 10 1 2 'I+' 1000 /
/
```

## AQANNC

## Set connection values explicitly for analytic aquifers

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword enables a specified connection to be set up between grid cells and an analytic aquifer which is defined using the [AQUCT](#), [AQUFETP](#) or [AQUFLUX](#) keyword. Normally ECLIPSE will calculate the aquifer connections from the data given in the [AQUANCON](#) or [AQUFET](#) keywords, but the AQANNC keyword allows for more generality in defining the connections.

The keyword consists of a line of data for each required analytic aquifer connection, specifying the cells to be linked and the required area for communication. The cell coordinates are specified in natural order.

Each line of data must be terminated by a slash (/). After the last connection is defined, an additional slash on a new line terminates the list.

The values in each data record are:

1. Aquifer number
2. I-index of first cell joined to the non-neighbor connection (IX)
3. J-index of first cell joined to the non-neighbor connection (IY)
4. K-index of first cell joined to the non-neighbor connection (IZ)
5. Connecting area value for the grid cell (AREA)

UNITS: m<sup>2</sup> (METRIC), ft<sup>2</sup> (FIELD), cm<sup>2</sup> (LAB), m<sup>2</sup> (PVT-M)

DEFAULT: 0.0

Each line of data must be terminated by a slash (/). After the last connection is defined, an additional slash on a new line terminates the list. It is possible to specify this keyword more than once.

### Example

```
AQANNC
-- IA IX IY IZ AREA
   1  2  3  5  2.0 /
   1  2  3  6  4.5 /
/
```

## AQANTRC

## Sets initial tracer concentrations for analytic aquifers

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is used to specify the value of the initial tracer concentration in each of the analytic aquifers in the run.

To specify the value of the initial concentration of either a water phase tracer or hydrocarbon component tracer in each of the analytic aquifers, refer to the keywords [AQUCT](#), [AQUFETP](#), [AQUFLUX](#), [AQUCHWAT](#), and [AQUFET](#) (ECLIPSE 100 only).

For an [AQUCHGAS](#) aquifer, only the initial concentration value of a hydrocarbon component tracer should be specified.

The AQANTRC keyword can only appear after any of the keywords [AQUFET](#), [AQUFETP](#), [AQUCT](#), [AQUFLUX](#), [AQUCHWAT](#) or [AQUCHGAS](#) have been used to define the aquifer types.

If a tracer is not specified in the list of tracer names, a default concentration value of 0.0 is assumed.

The keyword is followed by any number of records, each containing the following items of data:

1. Aquifer identification number.

This should be a number between 1 and the maximum number of aquifers, entered using the [AQUDIMs](#) keyword.

2. Name of the tracer.

The tracer must have been previously defined to exist in the water phase (see keyword [TRACER](#) in the PROPS section).

3. Value of the initial tracer concentration in the aquifer.

This item should not be less than 0.

Each data record ends with a slash (/), and the set of records with a blank record, containing just a slash (/).

ECLIPSE 100

---

**Note:** Referring to items 1 and 2 described above, if the keyword [AQUFET](#) has been used to specify Fetkovich aquifer data, the aquifer identification number refers to the order in which the aquifers are defined.

---

---

**Note:** If the aquifer is specified with keyword [AQUFET](#), [AQUFETP](#), [AQUCT](#), [AQUFLUX](#), [AQUCHWAT](#) or [AQUCHGAS](#), the aquifer identification number refers to the identification number entered in the 1<sup>st</sup> item of the keyword. In addition, the name of the tracer should be specified in 1 to 3 characters.

---

See also "[Tracer tracking](#)" in the *ECLIPSE Technical Description* for further information.

### Examples

#### Example 1

With 2 aquifers specified in the keyword [AQUDIMs](#):

```
AQANTRC
 1 WT1 1.0 /
 1 WT2 0.0 /
```

```
2 WT1 0.0 /  
2 WT2 1.0 /  
/
```

## Example 2

Set 60% concentration of TR6 in the first aquifer.

```
AQANTRC  
1 TR6 0.6 /  
/
```

## AQCOEF

**A-coefficient terms for water component**

	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

In [GASWAT](#) mode the normal temperature dependence of the Peng-Robinson equation for the water component is modified to take the form:

$$\alpha^{1/2} = A_1 + A_2 T + A_3 T^{-3} \quad \text{Eq. 3.2}$$

The defaults for  $A_1$ ,  $A_2$  and  $A_3$  are described in detail in "[GASWAT option](#)" in the *ECLIPSE Technical Description*. The `AQCOEF` keyword allows these to be modified.

`AQCOEF` contains a data item for each value. If any are defaulted they take the precalculated values.

**Example**

```
AQCOEF
.4530      1.0   .34E-02 /
```

## AQSTREAM Set composition of the injected gas stream or water analytic aquifer

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
x	SCHEDULE

For compositional runs, this keyword should be used to specify the gas composition of the injected gas stream in an [AQUCHGAS](#) aquifer. This keyword must be placed after the [AQUCHGAS](#) aquifer definition for a gas aquifer.

For the [GASWAT](#) and [CO2STORE](#) options, this keyword can be used to specify the water composition of an [AQUCHWAT](#), [AQUCT](#), [AQUFETP](#) or [AQUFLUX](#) water analytic aquifer. This keyword must be placed after the [AQUCHWAT](#), [AQUCT](#), [AQUFETP](#) or [AQUFLUX](#) definition for a water aquifer.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash, the remaining items taking default values. Defaults of value 0 can also be specified by a null repeat count of the form  $n^*$ , where  $n$  is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. Aquifer identification number. This should be a number between 1 and the maximum number of aquifers, entered using the keyword [AQUDIMs](#).
2.  $a_1$ , the mole fraction of the first component.
3.  $a_2$ , the mole fraction of the second component.
- ...
- $N_c + 1$ .  $a_{N_c}$ , the mole fraction of the  $N_c^{\text{th}}$  component.

$N_c$  mole fractions should be specified, where  $N_c$  is the number of components in the run. The values are checked using the condition that the sum of the mole fractions must be 1.0

Once the gas stream is defined, it should be used together with the [AQUCHGAS](#) keyword.

---

**Note:** For Black Oil runs, there is no need to use the [AQSTREAM](#) keyword. It will be assumed that there are two components, oil and gas. ECLIPSE 300 will set up the necessary default values.

---

### Example

```
AQSTREAM
1 0.5 0.3 0.1 0.05 0.05 /
/
```

## AQSTREAW Set composition of multi-component water analytic aquifer

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
x	SCHEDULE

For the multi-component water option ([COMPW](#)), this keyword must be used to specify the water composition of an [AQUCHWAT](#), [AQUCT](#), [AQUFETP](#) or [AQUFLUX](#) aquifer. This keyword must be placed after the [AQUCHWAT](#), [AQUCT](#), [AQUFETP](#) or [AQUFLUX](#) definition for a water aquifer.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash, the remaining items taking default values. Defaults of value 0 can also be specified by a null repeat count of the form  $n^*$ , where  $n$  is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. Aquifer identification number. This should be a number between 1 and the maximum number of aquifers, entered using the keyword [AQUDIMS](#).
2.  $a_1$ , the mole fraction of the first component.
3.  $a_2$ , the mole fraction of the second component.
- ...
- ...
- $N_w + 1$ .  $a_{N_w}$ , the mole fraction of the  $N_w^{\text{th}}$  component.

$N_w$  mole fractions should be specified, where  $N_w$  is the number of water components in the run. The values are checked using the condition that the sum of the mole fractions must be 1.0

See "[Water components](#)" in the *ECLIPSE Technical Description* for further details of the water component option.

### Notes

- The keyword [AQSTREAM](#) must be used instead of [AQSTREAW](#) in a [GASWAT](#) or [CO2STORE](#) run.
- If the keyword [AQSTREAW](#) is not used in a multi-component water run, then an error will be emitted to the [PRINT](#) file and by default the water composition of an analytic water aquifer will be made up entirely of the last water component. However if the last water component is a surfactant, polymer or alkaline component (see [CWTYPE](#)), then the default aquifer water composition will be the preceding water component.

### Example

```
AQSTREAW
1 0.5 0.3 0.1 0.05 0.05 /
/
```

## AQUALIST Sets up lists of aquifers for output

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

The keyword AQUALIST may be used to construct lists of analytic aquifers, which are lists of aquifer numbers. A name should be given for the aquifer list. Output can be obtained for the sum of all the aquifers in the list, that is the aquifer lists act similarly to groups for the summary keywords associated with aquifers. Also AQUIFERL is output to the INIT file if one of the aquifer keywords has been used in RPTSOL. If a cell is connected to aquifer list  $N$  then the number  $2^{(N-1)}$  appears in the AQUIFERL array. If a cell is connected to multiple aquifers contained in aquifer lists, the appropriate output numbers are summed.

The maximum number of aquifer lists and the maximum number of aquifers to be associated with any one list are defined with items 7 and 8 of AQUUDIMS.

Each list should have a unique name, consisting of up to eight characters. If a list name is repeated those aquifers are appended to the original list

1. The aquifer list name.

This should consist of up to 8 characters, enclosed in quotes.

2. MXAAQL+1

A list of aquifer identification numbers up to a maximum of MXAAQL (item 8 of AQUUDIMS).

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

### Example

```
AQUALIST
  'NORTHEAS' 1 2 3/
  'SOTHWEST' 4 5 /
/
```

## AQUANCON Specifies connection data for analytic aquifers

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

AQUANCON connects analytic aquifers, declared using [AQUCT](#), [AQUFETP](#), [AQUFLUX](#), [AQUCHWAT](#) or [AQUCHGAS](#), and [AQUFET](#) in ECLIPSE 100, to one or more reservoir cells.

The connection to the reservoir is set up by an arbitrary box defined by lower and upper I, J and K indices (refer to items 2-7 below). For each active grid block within the box, an aquifer connection is made to the face specified in item 8 if either of the following conditions is met:

- the face is on the outside of the reservoir, or
- the face adjoins an inactive cell.

---

**Note:** Care must be taken while considering the IJK box extents. Multiple thin layers of cells on the reservoir boundary are strongly recommended over bulky boxes covering inner regions. ECLIPSE does not check for aquifer connections inside the reservoir. As a result, any cell within the prescribed box may be attached an aquifer as long as its adjacent cell is inactive. There are various situations when cells may be inactive inside the reservoir, for example due to their small pore volume (see [MINPV](#)) or when a sector model (see [USEFLUX](#)) is surrounded by inactive cells of the full-field model.

---

Any number of records may be entered, each terminated with a slash (/). The set of records must be terminated with a blank record containing just a slash.

ECLIPSE 100

The keyword can be specified in the SOLUTION section.

ECLIPSE 300

The keyword can be specified in the GRID and SOLUTION sections.

The items in each record are:

1. Aquifer identification number  
This should be a number between 1 and the maximum number of aquifers, set in the keyword [AQUDIMs](#).
2. Lower I-location of connecting grid blocks
3. Upper I-location of connecting grid blocks
4. Lower J-location of connecting grid blocks
5. Upper J-location of connecting grid blocks
6. Lower K-location of connecting grid blocks
7. Upper K-location of connecting grid blocks
8. Index defining the face of the reservoir to which the aquifer connects (where `NDIVIX`, `NDIVIY` and `NDIVIZ` are specified in RUNSPEC keyword [DIMENS](#)):
  - I- or X-    I or X = 1 face
  - I+ or X+   I or X = `NDIVIX` face
  - J- or Y-    J or Y = 1 face
  - J+ or Y+   J or Y = `NDIVIY` face
  - K- or Z-    K or Z = 1 face (top)

$K+$  or  $Z+$   $K$  or  $Z = \text{NDIVIZ}$  face (bottom)

9. The aquifer influx coefficient.

This determines the fraction of the total communication between the reservoir and the aquifer for each cell defined in the box above.

The default for each cell in the box is its face area. If a non-default value is entered, the value is assigned to each cell within the box.

If a reservoir cell is defined more than once, its previous value for the aquifer influx coefficient is added to the present value. The exception is the case where you enter a zero value, which then sets the influx coefficient for all the cells in the box to zero

The aquifer influx coefficient is not used if the aquifer is a constant flux aquifer (keyword `AQUFLUX`). A negative value is not accepted.

UNITS:  $\text{m}^2$  (`METRIC`),  $\text{ft}^2$  (`FIELD`),  $\text{cm}^2$  (`LAB`),  $\text{m}^2$  (`PVT-M`)

10. Aquifer influx coefficient multiplier.

The multiplier is applied to the influx coefficients of the aquifer - cell connections within the box.

For constant flux aquifers (keyword `AQUFLUX`) the multiplier is applied to the cell areas.

DEFAULT: 1.0

11. Allow aquifer connections to cell faces adjoining active cells?

either: YES or NO

If this data item is set to YES, the restriction that a connected face must not adjoin an active cell is lifted, allowing aquifer connections into the middle of the reservoir. This option should be used with care and is not recommended for general use.

DEFAULT: NO

ECLIPSE 100

The total number of grid blocks connected to any single aquifer must not exceed the value set by item 6 in the `AQUDIMS` keyword in the `RUNSPEC` section. In addition, this keyword cannot be used with the keyword `AQUFET`.

---

**Note:** Each aquifer can only have one connection in any given grid block. When more than one connection in a grid block is specified for a single aquifer only the first will be connected.

---

ECLIPSE 100

The aquifer connections can be listed by setting the argument `AQUFET`, `AQUCT` or `AQUANCON` in the `RPTSOL` keyword to 2.

ECLIPSE 300

The aquifer connections can be listed by specifying the mnemonic `AQUANCON` in the `RPTSOL` keyword.

For both simulators, an array with the name `AQUIFERA` is written to the `INIT` file to illustrate which cells are connected to each aquifer. If a cell is connected to aquifer  $N$  then the number  $2^{(N-1)}$  appears in the `AQUIFERA` array. If a cell is connected to multiple aquifers then the appropriate output numbers are summed. Similarly, for gas aquifers, an array `AQUIFERG` is written to the `INIT` file.

---

**Note:** Each unique aquifer can only be connected to one grid. That is, an aquifer can only be connected to either the global grid or to a single local grid refinement.

---

**Note:** The keyword AQUANCON must not be used in restarted runs, as the aquifer specification data cannot be changed.

---

See also "[Aquifer modeling facilities](#)" in the *ECLIPSE Technical Description*.

## Example

One Carter-Tracy aquifer, connected to two vertical sides of a 10 x 10 x 2 grid with one face where the aquifer influx coefficient is set to 1000.

```
AQUCT
1 7000.0 4000.0 200.0 .3 1.0E-5 500.0 50.0 10.0 1 1 /
/
AQUANCON
1 1 10 10 10 1 2 'J+' /
1 10 10 1 10 1 2 'I+' 1000. /
/
```

## AQUCHGAS Specifies the property data for constant head/pressure gas aquifers

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
x	SCHEDULE

The number of analytic aquifers is specified using the [AQUDIMs](#) keyword in the RUNSPEC section.

Each record specifies the properties of a separate constant head/pressure gas ‘aquifer’ (ranging from 1 to the number of analytic aquifers), and contains the following items of data:

1. Aquifer identification number  
This should be a number between 1 and the maximum number of aquifers, entered using the keyword [AQUDIMs](#).
  2. Datum depth  
UNITS: m ([METRIC](#)), ft ([FIELD](#)), cm ([LAB](#)), m ([PVT-M](#))
  3. Gas pressure in the aquifer at the datum depth  
UNITS: barsa ([METRIC](#)), psia ([FIELD](#)), atma ([LAB](#)), atma ([PVT-M](#))
  4. Aquifer productivity index  
(Total influx rate per unit pressure difference.)  
UNITS: sm<sup>3</sup>/day/bars ([METRIC](#)), Mscf/day/psi ([FIELD](#)), scc/hr/atm ([LAB](#)), sm<sup>3</sup>/day/atm ([PVT-M](#))
  5. Table number for gas pressure properties (for example see keyword [PVTG](#)).  
DEFAULT: 1
- ECLIPSE 300* For compositional runs, this item refers to an EoS region number. In such a case, the gas properties are calculated using the equation of state for the given region.
- ECLIPSE 300*
6. Temperature in aquifer  
This item is ignored unless either the thermal or temperature option has been activated (see keywords [THERMAL](#) and [TEMP](#)).  
UNITS: °C ([METRIC](#)), °F ([FIELD](#)), °C ([LAB](#)), °C ([PVT-M](#))

Each record should be terminated with a slash (/). The set of records should be terminated with a blank record containing just a slash.

*ECLIPSE 100*

---

**Note:** The slash could be omitted for ECLIPSE 100, especially if the number of records entered using the [AQUCHGAS](#) keyword is the same as the number specified in [AQUDIMs](#). If not, a warning message regarding “spurious data” will be output, but the run will carry on as before.

---

Connections to a constant head/pressure gas ‘aquifer’ defined by this keyword are read in by either the [AQUANCON](#) or [AQANCONL](#) keyword, which allows more than one face of the reservoir to be connected to an aquifer.

The aquifer properties can be modified at any time during the simulation by reentering the [AQUCHGAS](#) keyword in the [SCHEDULE](#) section.

ECLIPSE 300 only

**Note:** For compositional runs, the `AQSTREAM` keyword must be used together with the `AQUCHGAS` keyword.

The aquifer inflow is given by the equation:

$$Q_{ai} = \frac{d}{dt} (G_{ai}) = J\alpha_i [p_a + p_c - p_i + \rho g (d_i - d_a)] \quad \text{Eq. 3.3}$$

where

$Q_{ai}$  is the inflow rate from the aquifer to the connecting grid block i

$G_{ai}$  is the cumulative influx from the aquifer to grid block i

$J$  is the specified Productivity Index of the aquifer

$\alpha_i$  is the area fraction for the connection to grid block i

$p_a$  is the pressure in the aquifer

$p_i$  is the gas pressure in a connecting grid block i

$\rho$  is gas density in the aquifer

$d_i$  is the grid block depth

$d_a$  is the datum depth of the aquifer.

$p_c$  is the capillary pressure

## Example

One constant head gas 'aquifer', connected to two vertical sides of a 10 x 10 x 2 grid:

```

AQUCHGAS
 1 0.0 1.0 2.0E9 1 /
/
AQUANCON
 1 1 10 10 10 1 2 'J+' /
 1 10 10 1 10 1 2 'I+' /
/

```

## AQUCHWAT Specifies the property data for constant head/pressure water aquifers

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
x	SCHEDULE

The number of analytic aquifers is specified using the keyword in the RUNSPEC section.

Each record specifies the properties of a separate constant head aquifer (ranging from 1 to the number of analytic aquifers), and contains the following items of data:

1. Aquifer identification number.

This should be a number between 1 and the maximum number of aquifers, entered using the keyword AQU DIMS.

2. Datum depth

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

3. Describes the input to item 4

PRESSURE

HEAD

DEFAULT: PRESSURE

4. Pressure in the aquifer at the datum depth if item 3 is PRESSURE

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

or

Head in the aquifer at the datum depth if item 3 is HEAD

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

If this quantity is defaulted or given a negative value, the initial pressure is calculated to place the aquifer as nearly as possible in equilibrium with the reservoir.

---

**Note:** If using the head option the head, H, is immediately converted by ECLIPSE to a pressure using the formula  $p_a = \rho g (H - d_a) + 1$  atmosphere. ECLIPSE 300 calculates the density,  $\rho$ , from the table given in item 6. ECLIPSE 100 uses the water density specified with the [DENSITY](#) keyword.

---

5. Aquifer productivity index

(total influx rate per unit pressure difference)

UNITS:  $\text{sm}^3/\text{day}/\text{bars}$  (METRIC),  $\text{stb}/\text{day}/\text{psi}$  (FIELD),  $\text{scc}/\text{hr}/\text{atm}$  (LAB),  $\text{sm}^3/\text{day}/\text{atm}$  (PVT-M)

6. Table number for water pressure properties (see keyword [PVTW](#)).

DEFAULT: 1

ECLIPSE 300

For the [GASWAT](#), [CO2STORE](#), [CO2SOL](#), [GASSOL](#) or [COMPW](#) options this item refers to an EoS region number. In such a case, the water properties are calculated using the equation of state for the given region for GASWAT or CO2STORE and the water properties data for COMPW or CO2SOL or GASSOL. If [item 119](#) of [OPTIONS3](#) is set to 1, this reverts to a table number.

7. Initial salt concentration in the aquifer

This item is ignored unless either the Brine option, or the Salt-sensitivity option in the Polymer Flood Model, has been activated (keyword `BRINE` in `RUNSPEC`).

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB), kg/sm<sup>3</sup> (PVT-M)

DEFAULT: 0.0

---

**Note:** If items 8 and 9 are defined, if one is defined they must both be defined, then the pressure,  $p_i$ , in the formula for the flux is replaced with  $\min(\max(p_{min}, p_i), p_{max})$ . If heads are being used ECLIPSE immediately converts them to the appropriate pressure using the formula given above.

---

8. Minimum pressure if item 3 is PRESSURE

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: -infinity

or

Minimum head if item 3 is HEAD

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: -infinity

9. Maximum pressure if item 3 is PRESSURE

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: infinity

or

Maximum head if item 3 is HEAD

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: infinity

10. Do you want to ignore the capillary pressure term in the equation 3.4?

(The alternative way of regarding this question is, do you want the aquifer pressure given in item 4 to account for all pressure effects?) YES or NO?.

DEFAULT: 'NO'

11. Minimum allowed flow per aquifer connection

UNITS: sm<sup>3</sup>/day (METRIC), stb/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: -infinity

12. Maximum allowed flow per aquifer connection

UNITS: sm<sup>3</sup>/day (METRIC), stb/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: infinity

13. Do you want to remove the depth term,  $J\alpha_i \rho g (d_i - d_a)$ , in equation 3.4? 'YES' or 'NO'

DEFAULT: 'NO'

14. Do you want to impose minimum and maximum flow rates (items 11 and 12) before or after the flow rate has been scaled by the grid block saturation in cases when water is flowing into aquifer from grid. This number should be zero if before and non-zero if after.

DEFAULT: 0

ECLIPSE 300

15. Temperature in aquifer

This item is ignored unless either the thermal or temperature option has been activated (see keywords [THERMAL](#) and [TEMP](#)).

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

Each record should be terminated with a slash (/). The set of records should be terminated with a blank record containing just a slash (/).

ECLIPSE 100

**Note:** The slash could be omitted for ECLIPSE 100, especially if the number of records entered using the [AQUCHWAT](#) keyword is the same as the number specified in [AQUDIMS](#). If not, a warning message regarding “spurious data” will be output, but the run will carry on as before.

Connections to a constant head aquifer defined by this keyword are read in by either the [AQUANCON](#) or the [AQUANCONL](#) keyword, which allows more than one face of the reservoir to be connected to an aquifer.

The aquifer properties can be modified at any time during the simulation by entering the [AQUCHWAT](#) keyword again in the [SCHEDULE](#) section.

ECLIPSE 300 only

**Note:** For the [GASWAT](#) and [CO2STORE](#) options, the [AQSTREAM](#) keyword may be used to give the composition of a specified aquifer. By default, the aquifer contains only the component “H2O”. Any water component is allowed to leave the reservoir or enter it, depending on the aquifer composition. If [item 131](#) of [OPTIONS3](#) is set to 1, this reverts to the pre-2007.2 behavior where the water entering / leaving the reservoir is made up entirely of the “H2O” component.

For the multi-component water option ([COMPW](#)), the [AQSTREAW](#) keyword may be used to give the composition of a specified aquifer. By default, the aquifer contains only the last water component. Any water component is allowed to leave the reservoir or enter it, depending on the aquifer composition. If [item 131](#) of [OPTIONS3](#) is set to 1, this reverts to the pre-2008.1 behavior where the water entering / leaving the reservoir is made up entirely of the last water component.

For the [CO2SOL](#) and [GASSOL](#) options, any water aquifer is made up entirely of the “WATER” component. Any water component is allowed to leave the reservoir. If [item 131](#) of [OPTIONS3](#) is set to 1, this reverts to the pre-2008.1 behavior where the water entering / leaving the reservoir is made up entirely of the “WATER” component.

The aquifer inflow is given by the equation:

$$Q_{ai} = \frac{d}{dt} (G_{ai}) = J\alpha_i [p_a + p_c - p_i + \rho g (d_i - d_a)] \quad \text{Eq. 3.4}$$

where

$Q_{ai}$  is the inflow rate from the aquifer to the connecting grid block  $i$

$G_{ai}$  is the cumulative influx from the aquifer to grid block  $i$

- $J$  is the specified productivity index of the aquifer
- $\alpha_i$  is the area fraction for the connection to grid block  $i$
- $p_a$  is the pressure in the aquifer
- $p_i$  is the pressure in a connecting grid block  $i$
- $\rho$  is water density in the aquifer
- $d_i$  is the grid block depth
- $d_a$  is the datum depth of the aquifer.
- $p_c$  is the capillary pressure.

## Example

One constant head aquifer, connected to two vertical sides of a 10 x 10 x 2 grid:

```
AQUCHWAT
 1 0.0 'PRESSURE' 1.0 2.0E9 1 /
/
AQUANCON
 1 1 10 10 10 1 2 'J+' /
 1 10 10 1 10 1 2 'I+' /
/
```

## AQUCON

## Specifies connection data for numerical aquifers

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

AQUCON connects a numerical aquifer (declared using the [AQUNUM](#) keyword) to one or more reservoir cells. The connection to the reservoir is set up by an arbitrary box defined by lower and upper I, J and K indices.

For each active grid block within the box, an aquifer connection is made to the face specified in item 8 if either of the following conditions are met:

- The face is on the outside of the reservoir, or
- The face adjoins an inactive cell.

---

**Note:** Care must be taken while considering the IJK box extents. Multiple thin layers of cells on the reservoir boundary are strongly recommended over bulky boxes covering inner regions. ECLIPSE does not check for aquifer connections inside the reservoir. As a result, any cell within the prescribed box may be attached an aquifer as long as its adjacent cell is inactive. There are various situations when cells may be inactive inside the reservoir, for example due to their small pore volume (see [MINPV](#)) or when a sector model (see [USEFLUX](#)) is surrounded by inactive cells of the full-field model.

---

Any number of records may be entered, each terminated with a slash (/). The set of records must be terminated with a blank record containing just a slash.

The total number of lines of AQUCON data must be less than or equal to MXNAQC set in item 2 of keyword [AQUDIMS](#) in the RUNSPEC section.

ECLIPSE 100

The keyword can be specified in the GRID section.

ECLIPSE 300

The keyword can be specified in the GRID and SOLUTION sections.

The items in each record are:

1. Aquifer identification number  
This should be a number between 1 and the maximum number of aquifers, set in the keyword [AQUDIMS](#).
2. Lower I-coordinate of cells to be connected
3. Upper I-coordinate of cells to be connected
4. Lower J-coordinate of cells to be connected
5. Upper J-coordinate of cells to be connected
6. Lower K-coordinate of cells to be connected
7. Upper K-coordinate of cells to be connected
8. Face of the cell to be connected to the aquifer.  
This should be one of I+, I-, J+, J-, K+ or K-, where K+ for instance means the bottom face. Alternatively, X+, X-, Y+, Y-, Z+ or Z- could be chosen where Z+ for instance means the bottom face.
9. The transmissibility multiplier  
The multiplier enables the calculated transmissibility value to be multiplied by a user defined factor, for example in history matching.

DEFAULT: 1.0

ECLIPSE 100 only

10. Transmissibility option

The option enables the aquifer connection transmissibility to be calculated based on either the aquifer cross-sectional area (specified in item 5 of AQUNUM) or the aquifer connection cell area. A value of 0 uses the cross-sectional area specified in item 5 of AQUNUM, whereas a value of 1 uses the cross-sectional area calculated from the aquifer connection cell. Note: the second option is only used for non-radial grids.

An integer, either 0 or 1

DEFAULT: 0

11. Allow aquifer connections to cell faces adjoining active cells?

Either YES or NO

If this data item is set to YES, the restriction that a connected face must not adjoin an active cell is lifted, allowing aquifer connections into the middle of the reservoir. This option should be used with care and is not recommended for general use.

DEFAULT: NO

ECLIPSE 100

12. VE option only. VE fraction (VEFRAC) for relative permeability calculations for aquifer-to-grid connections.

A value of 1.0 gives pure VE relative permeabilities with the whole face available for flow; while a value of 0.0 gives pure rock curves.

DEFAULT: 1.0

ECLIPSE 100

13. VE option only. VE fraction (VEFRACP) for capillary pressure calculation for aquifer-to-grid connections.

A value of 1.0 gives pure VE pseudo capillary pressures, while a value of 0.0 gives pure rock curves.

DEFAULT: 1.0

The transmissibility between the numerical aquifer and grid block is calculated as follows:

$$T = \frac{CDARCY}{(1/T_a) + (1/T_c)} \tag{Eq. 3.5}$$

where

$T_c$  = Component of transmissibility from the grid block

$T_a$  = Component of transmissibility from the aquifer

In the Cartesian case:

$$T_c = \frac{K_c \cdot A_c \cdot NTG}{D_c} \tag{Eq. 3.6}$$

where

$K_c$  = Cell permeability in the appropriate direction

$A_c$  = Cell face area

NTG = The cell net-to-gross ratio if the cell face X or Y

$D_c$  = Distance from the cell center the face

If transmissibility option 0 (item 10) is used:

$$T_a = \frac{K_a \cdot A_a}{D_a} \quad \text{Eq. 3.7}$$

where

$K_a$  = Aquifer permeability from AQUNUM

$A_a$  = Aquifer area from AQUNUM

$D_a$  = Half the aquifer length from AQUNUM

If transmissibility option 1 (item 10) is used:

$$T_a = \frac{K_a \cdot A_c}{D_a} \quad \text{Eq. 3.8}$$

ECLIPSE 100

The NNCs that both connect the aquifer cells and connect the aquifer to the reservoir can be listed by using the ALLNNC mnemonic (24<sup>th</sup> control) in the RPTGRID keyword.

ECLIPSE 300

For this simulator, the NNCs can be output using the NNC mnemonic in the RPTGRID keyword.

In addition, an array with the name AQUIFERN is written to the INIT file to illustrate which cells are connected to each aquifer. If a cell is connected to aquifer N, then the number  $2^{(N-1)}$  will appear in the AQUIFERN array. If a cell is connected to multiple aquifers, then the appropriate output numbers are summed. Cells representing the aquifer itself are given a negative number.

See also "[Aquifer modeling facilities](#)" in the *ECLIPSE Technical Description*.

## Examples

### Example 1

An example is the connection of aquifer number 2 to all the cells in the first three J-K planes with a free face in the I- direction. This attaches the aquifer to the reservoir face, even if there are inactive cells between the grid edge and the reservoir. It is assumed the grid has NX=20, NY=20, NZ=10.

```
AQUCON
 2 1 3 1 20 1 10 'I-' 1.0 /
/
```

### Example 2

In the following, aquifer 1 is connected to cells in the first three layers of the fifth column of an X-Z cross-section. The I+ face is used, so connections are only made if the corresponding cells of column 6 are inactive, or if NDIVIX (specified in RUNSPEC keyword [DIMENS](#)) is 5.

```
AQUCON  
1 5 5 1 1 1 3 'I+' 1.0 /  
/
```

## AQUCT

## Specifies the property data for Carter-Tracy aquifers

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
	EDIT
x	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies Carter-Tracy aquifers.

In ECLIPSE 100, the keyword can be specified in the SOLUTION and SCHEDULE sections.

In ECLIPSE 300, the keyword can be specified in the GRID, PROPS, SOLUTION and SCHEDULE sections.

The number of analytic aquifers is entered using the [AQUDIMS](#) keyword in the RUNSPEC section.

Each record refers to a separate Carter-Tracy aquifer and contains the following items of data:

1. Aquifer identification number

This should be a number between 1 and the maximum number of aquifers, entered using the [AQUDIMS](#) keyword.

2. Datum depth

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

3. Initial aquifer pressure at the datum depth

If this quantity is defaulted, the initial pressure is calculated to place the aquifer as nearly as possible in equilibrium with the reservoir.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

4. Permeability of the aquifer

UNITS: mD (METRIC), mD (FIELD), mD (LAB), mD (PVT-M)

5. Porosity of the aquifer

UNITS: m<sup>3</sup>/m<sup>3</sup> (METRIC), ft<sup>3</sup>/ft<sup>3</sup> (FIELD), cc/cc (LAB), m<sup>3</sup>m<sup>3</sup> (PVT-M)

DEFAULT: 1.0

6. Total (rock + water) compressibility of the aquifer

UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB), 1/atm (PVT-M)

7. External radius of reservoir or the inner radius of the aquifer

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

8. Thickness of the aquifer

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

9. Angle of influence (the angle subtended by the boundary between the reservoir and the aquifer)

UNITS: degrees (METRIC), degrees (FIELD), degrees (LAB), degrees (PVT-M)

DEFAULT: 360.0 degrees

10. Table number for water pressure properties

(see keyword [WATERTAB](#) (ECLIPSE 300 only), or [PVTW](#))

ECLIPSE 300

ECLIPSE 300

For the [GASWAT](#), [CO2STORE](#), [CO2SOL](#), [GASSOL](#) or [COMPW](#) options this item refers to an EoS region number. In such a case, the water properties are calculated using the equation of state for the given region for [GASWAT](#) or [CO2STORE](#) and the water properties data for [COMPW](#) or [CO2SOL](#) or [GASSOL](#). Note that, for [CO2SOL](#), the “viscosibility” term of the first water PVT table defined using [PVTW](#) is used during the calculation of the aquifer water viscosity. If [item 119](#) of [OPTIONS3](#) is set to 1, this reverts to a table number.

DEFAULT: Table 1

11. Table number for influence functions, which are the dimensionless time and pressure values (see the [AQUTAB](#) keyword)

DEFAULT: Table 1

Table 1 is the constant terminal rate case for an infinite aquifer as given by Van Everdingen and Hurst. This table is automatically supplied by the simulator.

12. Initial salt concentration in the aquifer

This item is ignored unless either the Brine option, or the Salt-sensitivity option in the Polymer Flood Model, has been activated (keyword [BRINE](#) in [RUNSPEC](#)).

UNITS: kg/sm<sup>3</sup> ([METRIC](#)), lb/stb ([FIELD](#)), gm/scc ([LAB](#)), kg/sm<sup>3</sup> ([PVT-M](#))

DEFAULT: 0.0

ECLIPSE 300

13. Temperature in aquifer

This item is ignored unless either the thermal or temperature option has been activated (see keywords [THERMAL](#) and [TEMP](#)).

UNITS: °C ([METRIC](#)), °F ([FIELD](#)), °C ([LAB](#)), °C ([PVT-M](#))

Each record is terminated with a slash (/). The set of records should be terminated with a blank record containing just a slash.

ECLIPSE 100

---

**Note:** The slash could be omitted for ECLIPSE 100, especially if the number of records entered using the [AQUCT](#) keyword is the same as the number specified in [AQUDIMS](#). If not, a warning message regarding “spurious data” will be output, but the run will carry on as before.

---

Connections to a Carter-Tracy aquifer defined by this keyword are read in by either the [AQUANCON](#) or the [AQANCONL](#) keyword, which allows more than one face of the reservoir to be connected to a Carter-Tracy aquifer.

The aquifer properties can be modified at any time during the simulation by entering the [AQUCT](#) keyword again in the [SCHEDULE](#) section.

ECLIPSE 300

---

**Note:** For the [GASWAT](#) and [CO2STORE](#) options, the [AQSTREAM](#) keyword may be used to give the composition of a specified aquifer. By default, the aquifer contains only the component “H2O”. Any water component is allowed to leave the reservoir or enter it, depending on the aquifer composition. If [item 131](#) of [OPTIONS3](#) is set to 1, this reverts to the pre-2007.2 behavior where the water entering / leaving the reservoir is made up entirely of the “H2O” component.

For the multi-component water option ([COMPW](#)), the [AQSTREAW](#) keyword may be used to give the composition of a specified aquifer. By default, the aquifer contains only the last water component. Any

water component is allowed to leave the reservoir or enter it, depending on the aquifer composition. If item 131 of `OPTIONS3` is set to 1, this reverts to the pre-2008.1 behavior where the water entering / leaving the reservoir is made up entirely of the last water component.

For the `CO2SOL` and `GASSOL` options, any water aquifer is made up entirely of the “WATER” component. Any water component is allowed to leave the reservoir. If item 131 of `OPTIONS3` is set to 1, this reverts to the pre-2008.1 behavior where the water entering / leaving the reservoir is made up entirely of the “WATER” component.

ECLIPSE 100

The `AQUCT` keyword cannot be used with the keyword `AQUFET`. It is also possible to use the `AQUCT` keyword in the `GRID` and `PROPS` sections. See also "[Aquifer modeling facilities](#)" of the *ECLIPSE Technical Description*.

**Note:** `AQUCT` must not be used in the `SOLUTION` section of restarted runs, as the aquifer specification data cannot be changed.

## Example

One Carter-Tracy aquifer, connected to two vertical sides of a 10 x 10 x 2 grid:

```

AQUCT
1 7000.0 4000.0 200.0 .3 1.0E-5 500.0 50.0 10.0 1 1 /
/
AQUANCON
1 1 10 10 10 1 2 'J+' /
1 10 10 1 10 1 2 'I+' /
/

```

```

# AQUDIMS Dimensions for aquifers

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data consists of some or all of the following items which describe the aquifers employed during the run (see "Aquifer modeling facilities" in the *ECLIPSE Technical Description*). The data must be terminated by a slash (/).

1. MXNAQN The maximum number of lines of **numerical** aquifer data entered in keyword [AQUNUM](#) in the GRID section.  
DEFAULT: 1
2. MXNAQC The maximum number of lines of connection data for **numerical** aquifers entered in keyword [AQUCON](#) in the GRID section.  
DEFAULT: 1
3. NIFTBL The maximum number of influence tables for Carter-Tracy aquifers, entered by the keyword [AQUTAB](#) in the PROPS section. This should be greater than 1 if there are any user supplied tables, as table number 1 is a built-in default table.  
DEFAULT: 1
4. NRIFTB The maximum number of rows in a Carter-Tracy aquifer influence table. As table 1 contains 36 rows, a minimum value of 36 is always recorded.  
DEFAULT: 36
5. NANAQU The maximum number of **analytic** aquifers in the model.  
DEFAULT: 1
6. NCAMAX

ECLIPSE 100

The maximum number of grid blocks connected to any single **analytic** aquifer.

ECLIPSE 300

The maximum number of lines of **analytic** aquifer connection data.

DEFAULT: 1

ECLIPSE 300

---

**Note:** No distinction is made between MXNAQN, the maximum number of lines in the numerical aquifers, and NANAQU, the maximum number of analytic aquifers. This is the same between MXNAQC and NCAMAX, the number of connections to numerical and analytic aquifers. If two values are input then the maximum is used. Although there is a difference in the specification of item 6 of this keyword between the two simulators, ECLIPSE 300 will internally determine the maximum number of connections for any aquifer.

---

ECLIPSE 100 only

7. MXNALI The maximum number of aquifer lists.

DEFAULT: 0

ECLIPSE 100 only

8. MXAAQL The maximum number of **analytic** aquifers in any single aquifer list.

DEFAULT: 0

---

**Note:** Any aquifer identification number used in aquifer keywords must lie between 1 and the sum of MXNAQN and NANAQU.

---

## Example

Two analytic aquifers, up to 100 grid block connections each. Default influence table.

```
AQUUDIMS  
0 0 1 36 2 100 /
```

## AQUFET

## Specification data for Fetkovich aquifers

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used to supply both the aquifer properties and the cell connections to Fetkovich aquifers.

---

**Note:** This keyword can only be used in ECLIPSE 100.

---

The connection to the reservoir is set up by an arbitrary box defined by lower and upper I, J and K indices (refer to items 7-12 below). It allows only one reservoir face to be connected to any single aquifer. If an aquifer is required to connect to two or more faces, use the keywords [AQUFETP](#) and [AQUANCON](#) or [AQUANCONL](#), instead of [AQUFET](#).

The number of analytic aquifers is specified using the [AQUDIMs](#) keyword.

Each record refers to a separate Fetkovich aquifer (ranging from 1 to the number of analytic aquifers), and contains the following items of data:

- Datum depth  
UNITS: m (METRIC), ft (FIELD), cm (LAB)
- Initial aquifer pressure at the datum depth  
If this quantity is defaulted or given a negative value, the initial pressure is calculated to place the aquifer as nearly as possible in equilibrium with the reservoir.  
UNITS: barsa (METRIC), psia (FIELD), atma (LAB)
- Initial volume of water in the aquifer  
UNITS: sm<sup>3</sup> (METRIC), stb (FIELD), scc (LAB)
- Total (rock + water) compressibility of the aquifer  
UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB)
- Aquifer productivity index  
(total influx rate per unit pressure difference)  
UNITS: sm<sup>3</sup>/day/bars (METRIC), stb/day/psi (FIELD), scc/hr/atm (LAB)
- Table number for water pressure properties  
(See keyword [PVTW](#))
- Lower I-location of connecting grid blocks
- Upper I-location of connecting grid blocks
- Lower J-location of connecting grid blocks
- Upper J-location of connecting grid blocks
- Lower K-location of connecting grid blocks
- Upper K-location of connecting grid blocks
- Index defining the face of the reservoir to which the aquifer connects (where [NDIVIX](#), [NDIVIY](#) and [NDIVIZ](#) are specified in [RUNSPEC](#) keyword [DIMENS](#))

'I-' I = 1 face

'I+' I = NDIVIX face

'J-' J = 1 face

'J+' J = NDIVIY face

'K-' K = 1 face (top)

'K+' K = NDIVIZ face (bottom)

#### 14. Initial salt concentration in the aquifer

This item is ignored unless either the brine option, or the salt-sensitivity option in the polymer flood model, has been activated (see the [BRINE](#) keyword in the RUNSPEC section).

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB)

DEFAULT: 0.0

Each record should be terminated with a slash (/).

The aquifer connects with all the grid blocks that lie within the specified bounds and have no active neighboring block on the side facing the aquifer. The total number of connecting grid blocks must not exceed the value entered using item 6 in keyword [AQUDIMS](#) in the RUNSPEC section.

The aquifer productivity index is apportioned between the connecting grid blocks in proportion to the area of their connecting faces.

This keyword [AQUFET](#) cannot be used together with the keywords [AQUFETP](#), [AQUCT](#), [AQUANCON](#) or [AQANCONL](#)

This keyword must not be used in restarted runs, as the aquifer specification data cannot be changed.

See also "[Aquifer modeling facilities](#)" in the *ECLIPSE Technical Description* for further information.

## Example

One aquifer, on the bottom of a 10 x 10 x 5 grid:

```
AQUFET
7000 4000 2.0E9 1.0E-5 500.0 1 1 10 1 10 5 5 'K+' /
```

## AQUFETP

## Specifies the property data for Fetkovich aquifers

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY

The number of analytic aquifers is specified using the [AQUDIMs](#) keyword in the RUNSPEC section.

Each record specifies the properties of a separate Fetkovich aquifer (ranging from 1 to the number of analytic aquifers), and contains the following items of data:

1. Aquifer identification number

This should be a number between 1 and the maximum number of aquifers, entered using the keyword [AQUDIMs](#).

2. Datum depth

UNITS: m ([METRIC](#)), ft ([FIELD](#)), cm ([LAB](#)), m ([PVT-M](#))

3. Initial aquifer pressure at the datum depth

If this quantity is defaulted, the initial pressure is calculated to place the aquifer as nearly as possible in equilibrium with the reservoir.

UNITS: barsa ([METRIC](#)), psia ([FIELD](#)), atma ([LAB](#)), atma ([PVT-M](#))

4. Initial volume of water in the aquifer

UNITS: sm<sup>3</sup> ([METRIC](#)), stb ([FIELD](#)), scc ([LAB](#)), sm<sup>3</sup> ([PVT-M](#))

5. Total (rock + water) compressibility of the aquifer

UNITS: 1/bars ([METRIC](#)), 1/psi ([FIELD](#)), 1/atm ([LAB](#)), 1/atm ([PVT-M](#))

6. Aquifer productivity index

(total influx rate per unit pressure difference)

UNITS: sm<sup>3</sup>/day/bars ([METRIC](#)), stb/day/psi ([FIELD](#)), scc/hr/atm ([LAB](#)), sm<sup>3</sup>/day/atm ([PVT-M](#))

7. Table number for water pressure properties

(see keyword [PVTW](#)).

DEFAULT: 1

*ECLIPSE 300*

For the [GASWAT](#), [CO2STORE](#), [CO2SOL](#), [GASSOL](#) or [COMPW](#) options this item refers to an EoS region number. In such a case, the water properties are calculated using the equation of state for the given region for [GASWAT](#) or [CO2STORE](#) and the water properties data for [COMPW](#) or [CO2SOL](#), or [GASSOL](#). If [item 119](#) of [OPTIONS3](#) is set to 1, this reverts to a table number.

DEFAULT: 1

8. Initial salt concentration in the aquifer

This item is ignored unless either the Brine option, or the Salt-sensitivity option in the Polymer Flood Model, has been activated (keyword [BRINE](#) in RUNSPEC).

UNITS: kg/sm<sup>3</sup> ([METRIC](#)), lb/stb ([FIELD](#)), gm/scc ([LAB](#)), kg/sm<sup>3</sup> ([PVT-M](#))

DEFAULT: 0.0

*ECLIPSE 300*

9. Temperature in aquifer

This item is ignored unless either the thermal or temperature option has been activated (see keywords [THERMAL](#) and [TEMP](#)).

UNITS: °C ([METRIC](#)), °F ([FIELD](#)), °C ([LAB](#)), °C ([PVT-M](#))

Each record should be terminated with a slash (/). The set of records should be terminated with a blank record containing just a slash (/).

## ECLIPSE 100

**Note:** The slash could be omitted for ECLIPSE 100, especially if the number of records entered using the [AQUFETP](#) keyword is the same as the [NANAQU](#) number specified in [AQUDIMS](#). If not, a warning message regarding “spurious data” will be output, but the run will carry on as before.

Connections to a Fetkovich aquifer defined by this keyword are read in by either the [AQUANCON](#) or the [AQANCONL](#) keyword, which allows more than one face of the reservoir to be connected to a Fetkovich aquifer.

## ECLIPSE 100

This keyword [AQUFETP](#) cannot be used together with the keyword [AQUFET](#).

The aquifer properties can be modified at any time during the simulation by entering the [AQUFETP](#) keyword again in the [SCHEDULE](#) section.

## ECLIPSE 300 only

**Note:** For the [GASWAT](#) and [CO2STORE](#) options, the [AQSTREAM](#) keyword may be used to give the composition of a specified aquifer. By default, the aquifer contains only the component “H2O”. Any water component is allowed to leave the reservoir or enter it, depending on the aquifer composition. If [item 131](#) of [OPTIONS3](#) is set to 1, this reverts to the pre-2007.2 behavior where the water entering or leaving the reservoir is made up entirely of the “H2O” component.

For the multi-component water option ([COMPW](#)), the [AQSTREAW](#) keyword may be used to give the composition of a specified aquifer. By default, the aquifer contains only the last water component. Any water component is allowed to leave the reservoir or enter it, depending on the aquifer composition. If [item 131](#) of [OPTIONS3](#) is set to 1, this reverts to the pre-2008.1 behavior where the water entering / leaving the reservoir is made up entirely of the last water component.

For the [CO2SOL](#) and [GASSOL](#) options, any water aquifer is made up entirely of the “WATER” component. Any water component is allowed to leave the reservoir. If [item 131](#) of [OPTIONS3](#) is set to 1, this reverts to the pre-2008.1 behavior where the water entering / leaving the reservoir is made up entirely of the “WATER” component.

See also "[Aquifer modeling facilities](#)" in the *ECLIPSE Technical Description* for further information.

**Note:** [AQUFETP](#) must not be used in the [SOLUTION](#) section of restarted runs, as the aquifer specification data cannot be changed.

## Example

One Fetkovich aquifer, connected to two vertical sides of a 10 x 10 x 2 grid:

```

AQUFETP
 1 7000.0 4000.0 2.0E9 1.0E-5 500.0 1 /
/
AQUANCON
 1 1 10 10 10 1 2 'J+' /

```

```
1 10 10 1 10 1 2 'I+' /  
/
```

# AQUFLUX

## Specifies a constant flux aquifer

x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword should be followed by up to NANAQU records of data, each record terminated with a slash (/). NANAQU refers to the number of analytic aquifers, as entered under item 5 of the [AQUDIMs](#) keyword.

Each record specifies the properties of a separate aquifer (1 to NANAQU) and contains the following items of data:

1. Aquifer identification number  
 This should be a number between 1 and the maximum number of aquifers, set in the keyword [AQUDIMs](#).
2. Aquifer flux  
 This is the water inflow rate per unit area of connected cell face.  
 UNITS:  $\text{sm}^3/\text{day}/\text{m}^2$  (METRIC),  $\text{stb}/\text{day}/\text{ft}^2$  (FIELD),  $\text{scc}/\text{hr}/\text{cm}^2$  (LAB),  $\text{sm}^3/\text{day}/\text{m}^2$  (PVT-M)
3. Salt concentration in the aquifer  
 This item is ignored unless either the Brine option, or the salt sensitivity option in the Polymer Flood Model, has been activated (keyword [BRINE](#) in RUNSPEC).  
 UNITS:  $\text{kg}/\text{sm}^3$  (METRIC),  $\text{lb}/\text{stb}$  (FIELD),  $\text{gm}/\text{scc}$  (LAB),  $\text{kg}/\text{sm}^3$  (PVT-M)  
 DEFAULT: 0.0
4. Temperature in aquifer  
 This item is ignored unless either the thermal or temperature option has been activated (see keywords [THERMAL](#) and [TEMP](#)).  
 UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)
5. Pressure in aquifer at datum depth  
 This pressure is used along with the temperature in the aquifer to calculate the enthalpy of the aquifer and is ignored unless either the thermal or temperature option has been activated (see keywords [THERMAL](#) and [TEMP](#)).  
 UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

The set of records should be terminated with a blank record containing just a slash (/).

ECLIPSE 100 only

---

**Note:** The slash could be omitted for ECLIPSE 100, especially if the number of records entered using the [AQUFLUX](#) keyword is the same as the NANAQU number specified in [AQUDIMs](#). If not, a warning message regarding “spurious data” will be output, but the run will carry on as before.

---

The grid block connections to each constant flux aquifer defined by this keyword must be specified by either the [AQUANCON](#) or the [AQUANCONL](#) keyword.

ECLIPSE 300 only

---

**Note:** For the [GASWAT](#) and [CO2STORE](#) options, the [AQSTREAM](#) keyword may be used to give the composition of a specified aquifer. By default, the aquifer contains only the component “H2O”. Any water component is allowed to leave the reservoir or enter it, depending on the aquifer composition. If [item 131](#)

of `OPTIONS3` is set to 1, this reverts to the pre-2007.2 behavior where the water entering / leaving the reservoir is made up entirely of the “H2O” component.

For the multi-component water option (`COMPW`), the `AQSTREAW` keyword may be used to give the composition of a specified aquifer. By default, the aquifer contains only the last water component. Any water component is allowed to leave the reservoir or enter it, depending on the aquifer composition. If item 131 of `OPTIONS3` is set to 1, this reverts to the pre-2008.1 behavior where the water entering / leaving the reservoir is made up entirely of the last water component.

For the `CO2SOL` and `GASSOL` options, any water aquifer is made up entirely of the “WATER” component. Any water component is allowed to leave the reservoir. If item 131 of `OPTIONS3` is set to 1, this reverts to the pre-2008.1 behavior where the water entering or leaving the reservoir is made up entirely of the “WATER” component.

The water flow rate into a grid block from a constant flux aquifer is given by:

$$Q_w = F_w \cdot A \cdot M \quad \text{Eq. 3.9}$$

where

$F_w$  is the flux, entered in item 2

$A$  is the area of the connected cell face

$M$  is the aquifer influx multiplier (item 10 of the `AQUANCON` keyword or item 11 of the `AQUANCONL` keyword), which defaults to 1.0.

The area is calculated directly from the connected cell geometry, and is not affected by item 9 of the `AQUANCON` keyword or item 10 in the `AQUANCONL` keyword.

The aquifer flux can be modified at any time during the simulation by reentering the `AQUFLUX` keyword in the `SCHEDULE` section.

*ECLIPSE 100 only*

The keyword `AQUFLUX` cannot be used together with the keyword `AQUFET`.

See also "[Aquifer modeling facilities](#)" in the *ECLIPSE Technical Description* for further information.

## Example

Two constant flux aquifers, connected to two vertical sides of a 10 x 10 x 4 grid

```

AQUFLUX
1 0.0003 /
2 0.0004 /
/

AQUANCON
-- Aquifer 1
1 1 10 10 10 10 1 4 'J+' /
1 10 10 6 10 1 4 'I+' /
--Aquifer 2
2 10 10 6 10 1 4 'I+' /
/

```

## AQUNNC

## Set non-neighbor connection values explicitly for numerical aquifers

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword enables a specified transmissibility to be set up between grid cells and numerical aquifer cells which are defined using the [AQUNUM](#) keyword. Normally ECLIPSE will calculate the numerical aquifer connections from the data given in the [AQUCON](#) keyword, but the AQUNNC keyword allows for more generality in defining the connections.

The keyword consists of a line of data for each required aquifer non-neighbor connection, specifying the cells to be linked and the required transmissibility value. The cell coordinates are specified in natural order.

Each line of data must be terminated by a slash (/). After the last non-neighbor connection is defined, an additional slash on a new line terminates the list.

The values in each data record are:

1. Aquifer number
2. I-index of first cell joined to the non-neighbor connection (IX)
3. J-index of first cell joined to the non-neighbor connection (IY)
4. K-index of first cell joined to the non-neighbor connection (IZ)
5. I-index of second cell joined to the non-neighbor connection (JX)
6. J-index of second cell joined to the non-neighbor connection (JY)
7. K-index of second cell joined to the non-neighbor connection (JZ)
8. Transmissibility value of the non-neighbor connection (TRAN)
 

UNITS: cP.rm<sup>3</sup>/day/bars (METRIC), cP.rb/day/psi (FIELD), cP.rcc/hr/atm (LAB)

DEFAULT: 0.0
9. Saturation table number to be associated with flow from the first to the second cell (IST1)
10. Saturation table number to be associated with flow from the second to the first cell (IST2)
11. Pressure table number to be associated with flow from the first to the second cell (IPT1)
12. Pressure table number to be associated with flow from the second to the first cell (IPT2)
13. The face associated with flow from the first to the second cell (ZF1)
 

Choose either: X+, X-, Y+, Y-, Z+, Z-

This information is used only for the [VE](#) option.
14. The face associated with flow from the second to the first cell (ZF2)
 

Choose either: X+, X-, Y+, Y-, Z+, Z-

This information is used only for the [VE](#) option.
15. Diffusivity value of the non-neighbor connection (DIFF)

This item will be ignored unless the Molecular Diffusion option is activated (keyword [DIFFUSE](#) in RUNSPEC section).

UNITS: m (METRIC), ft (FIELD), cm (LAB)

DEFAULT: 0.0

Each line of data must be terminated by a slash (/). After the last non-neighbor connection is defined, an additional slash on a new line terminates the list. It is again possible to specify this keyword more than once in the grid data.

The last seven items are optional. Therefore, if the slash is placed after the TRAN item, the table numbers is defaulted to those for the cells joined.

## Example

```
AQUNNC
-- IA IX IY IZ JX JY JZ TRAN
   1  2  3  5  5  7  5  2.0 /
   1  2  3  6  8  6  5  4.5 /
/
```

	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

## Assigns a numerical aquifer to a block

This keyword specifies blocks representing one-dimensional numerical aquifers. One or more aquifers may be set up. Each line of AQUNUM declares that a given grid block is to represent a numerical aquifer. This enables its properties (such as initial pressure and volume) to be independent of its size and position in the grid. To complete the description of the aquifer, connections to other blocks may be made using the [AQUCON](#) keyword.

The total number of lines of data following the AQUNUM keyword must be less than or equal to the value set by the 1<sup>st</sup> item in the [AQUDIMS](#) keyword in the RUNSPEC section.

Each record must be terminated by a slash (/). The set of records must be terminated with a blank record containing just a slash.

The items in AQUNUM are as follows:

1. Aquifer identification number

This should be a number between 1 and the maximum number of aquifers, set in the keyword [AQUDIMS](#).

2. I-coordinate of grid block to represent aquifer
3. J-coordinate of grid block to represent aquifer
4. K-coordinate of grid block to represent aquifer.

For dual porosity cases, this should be in the fracture. Additionally, for dual porosity (single permeability) cases, the inactive grid block with these I,J,K coordinates should be set as dual porosity if the [DPNUM](#) keyword is used. It is possible to use [DPNUM](#) to set the inactive grid block as single porosity and then place the K-coordinate in the matrix, but this is not recommended as it does not use [DPNUM](#) default values.

5. Cross-sectional area

This may be larger than can be accommodated within the grid block I,J,K. However, the position of the grid block on graphical displays is unchanged.

UNITS: m<sup>2</sup> (METRIC), ft<sup>2</sup> (FIELD), cm<sup>2</sup> (LAB), m<sup>2</sup> (PVT-M)

6. Length

This may be larger than can be accommodated within the grid block I,J,K.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

7. Porosity

UNITS: m<sup>3</sup>/m<sup>3</sup> (METRIC), ft<sup>3</sup>/ft<sup>3</sup> (FIELD), cc/cc (LAB), m<sup>3</sup>/m<sup>3</sup> (PVT-M)

DEFAULT: Grid cell value

8. Permeability

UNITS: mD (METRIC), mD (FIELD), mD (LAB), mD (PVT-M)

9. Aquifer depth

This may differ from the geometric position in the reservoir. It may be defaulted, in which case the grid block depth is obtained.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

#### 10. Initial pressure

This may be specified explicitly or defaulted. If defaulted, the initial pressure is set by the equilibration procedure to be in hydrostatic equilibrium with the reservoir. The default procedure is recommended except in the case in which all initial pressures are entered by the user.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

ECLIPSE 100 only

#### 11. PVT table number for aquifer

DEFAULT: Block `PVTNUM` value.

ECLIPSE 100 only

#### 12. Saturation table number for aquifer

DEFAULT: Block value.

## Notes

- The length, cross-sectional area and porosity are used to calculate the aquifer volume. The length, cross-sectional area and permeability are used to calculate the aquifer transmissibility.
- The table number used for flow into the aquifer will be that used for normal grid flows.
- In dual porosity runs the aquifer should be placed in the lower half (that is the fracture part) of the grid.
- The aquifer pore volume is calculated from the data entered in the `AQUNUM` keyword in all cases using

$$PORV = Porosity \cdot Length \cdot Area \quad \text{Eq. 3.10}$$

where the porosity is taken from the grid block value if defaulted. Any values of `MULTPV` entered in the `GRID` or `EDIT` sections does **not** apply to numerical aquifer cells. Any edits to `PORV` in the `EDIT` section for numerical aquifer cells are ignored and the aquifer pore volume is always calculated from equation 3.10. See also "Aquifer modeling facilities" in the *ECLIPSE Technical Description*.

- In parallel runs, defining a numerical aquifer in one grid partition and connecting it to cells in other partitions leads to the so-called off-processor connections which can degrade the overall performance. The number of off-processor connections is reported as part of the warning when this situation occurs. It is recommended that the creation of off-processor connections is avoided, or at least that their number is reduced. If this is not possible, try to increase `NSTACK` and `LITMAX` but expect more linear iterations per timestep. Note that analytical aquifers do not require any off-processor connections at all.

## Example

In the following example a four cell aquifer is defined, with default porosity, depth and initial pressure. Aquifer-grid connections are made to the first cell specified with a given aquifer number.

```

AQUNUM
1 7 1 1 1.0E+5 20000 1* 200.0 2* 1 1 /
1 8 1 1 1.0E+5 20000 1* 200.0 2* 1 1 /
1 9 1 1 1.0E+5 20000 1* 200.0 2* 1 1 /
1 10 1 1 1.0E+5 20000 1* 200.0 2* 1 1 /
/

```

## Influence function tables for Carter-Tracy aquifers

The number of influence function tables is specified by the [AQUDIMS](#) keyword.

These tables are of dimensionless time and pressure, each terminated by a slash (/).

The first table is the default table that **cannot** be changed. Table one is defined and reserved for the constant terminal rate case for an infinite aquifer as given by Van Everdingen and Hurst.

The remaining tables entered using this keyword are numbered from 2 onwards.

Each table consists of 2 columns of data:

1. Dimensionless time

Values should be greater than 0 and should increase monotonically down the column.

2. The corresponding dimensionless pressure

Values should be greater than 0.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than the maximum value specified as the 4th item in the [AQUDIMS](#) keyword.

---

**Note:** The number of rows (specified in [AQUDIMS](#)) is always set to at least 36, to accommodate the first, default, table.

---

### Example

Example with two influence function tables set in [AQUDIMS](#). The first is the default table, and the second, is read in with [AQUTAB](#).

```

AQUTAB
0.01 0.112
0.05 0.229
0.1 0.315
0.15 0.376
0.2 0.424
0.25 0.469
0.3 0.503
0.4 0.564
0.5 0.616
0.6 0.659
/

```

See "[Aquifer modeling facilities](#)" in the *ECLIPSE Technical Description* for further information.

## ASPDEPO

This keyword is set to provide data for the asphaltene deposition process. The required data consists of:

1. A static deposition or adsorption coefficient  $\alpha$   
UNITS: 1/day (METRIC), 1/day (FIELD), 1/hr (LAB), 1/day (PVT-M)
2. A plugging coefficient  $\gamma_1$ , used in the pre-2011.1 deposition model  
UNITS: 1/m<sup>3</sup> (METRIC), 1/ft<sup>3</sup> (FIELD), 1/cc (LAB), 1/m<sup>3</sup> (PVT-M)
3. An entrainment coefficient  $\beta$   
UNITS: 1/m (METRIC), 1/ft (FIELD), 1/cm (LAB), 1/m (PVT-M)
4. A critical velocity  $U_{cr}$  above which entrainment takes place  
UNITS: m/day (METRIC), ft/day (FIELD), cm/hr (LAB), m/day (PVT-M)
5. A plugging coefficient  $\gamma_2$  used in the three-component deposition model  
UNITS: 1/m (METRIC), 1/ft (FIELD), 1/cm (LAB), 1/m (PVT-M)

All the above entries must be non-negative.

For more details please refer to the "[Asphaltene option](#)" in the *ECLIPSE Technical Description*.

## Example

```

ASPDEPO
-- adsorp      plug1      entrain      Vcr      plug2
   0.001        0          1.e-5        0.01     0.1/

## ASPFLOC

## Asphaltene flocculation components

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used to define the range of components that can precipitate as asphaltene, and the component number representing the flocs. Assuming that the list of components is enumerated as  $1, 2, \dots, i, i+1, \dots, j, \dots, k, \dots, N$ , this keyword should be followed by three integers corresponding to:

- the number of the first component that can precipitate, say  $i$
- the number of the last component that can precipitate, say  $j$
- the number of the component that represents the flocs, say  $k$

This keyword has to be used in conjunction with the [ASPFLRT](#) keyword, which specifies the kinetic rates for the flocculation/dissociation processes.

Keyword [CATYPE](#) can be used instead of this keyword, and must be used if the Three component asphaltene deposition model is required.

For more details please refer to "[Asphaltene option](#)" in the *ECLIPSE Technical Description*.

## Example

Run with 7 components, of which components 4 to 6 can precipitate and flocculate into component 7:

```

ASPFLOC
-- cplast  cplast  cpflocs
   4       6      7 /

```

## ASPFLRT

**Asphaltene flocculation/dissociation rates**

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is used to provide the kinetic reaction rates for the flocculation of fines into flocs and the dissociation of flocs into fines. The rates must be positive numbers.

Assuming that there are  $N$  components that can precipitate, then this keyword should be followed by  $2N$  numbers corresponding to the rates.

- The first  $N$  rates correspond to the flocculation process.
- The next  $N$  rates correspond to the inverse process, whereby the flocs component (partially) dissociates.

This keyword has to be used in conjunction with the [CATYPE](#) or [ASPFLOC](#) keyword, which specifies the components that can precipitate and the flocs component number.

For more details please refer to "[Asphaltene option](#)" in the *ECLIPSE Technical Description*.

UNITS: 1/day (METRIC), 1/day (FIELD), 1/hr (LAB), 1/day (PVT-M)

**Example**

For a run where 3 components can precipitate and flocculate:

```
ASPFLRT
-- floc rates      followed by dissociation rates
  0.010  0.05    0.10
  0.005  0.04    0.08 /
```

## ASPHALTE Asphaltene option

This keyword activates the asphaltene modeling option. The full asphaltene modeling facility is described in "Asphaltene option" in the *ECLIPSE Technical Description*.

This keyword contains data items that specify the asphaltene model options to be used.

1. A character string specifying the characterization criterion

WEIGHT percentage molar weight of asphaltene dissolved in the oil as a function of specified variable(s). The data are then specified using either the set of keywords [ASPP1P](#) and [ASPREWG](#) for one variable, or the set of keywords [ASPP2P](#) and [ASPPW2D](#) for 2 variables.

DEFAULT: WEIGHT

2. A character string specifying the permeability damage model ([ASPKDAM](#) keyword)

PORO permeability damage are correlated to porosity changes (power-law model)

TAB permeability damage is tabulated against asphaltene volume fraction deposit

NO no permeability change

DEFAULT: NO

If permeability damage is to be modeled, the [ASPKDAM](#) keyword must be specified in the [PROPS](#) section with the corresponding data.

This item is only used with the pre-2011.1 asphaltene deposition model. If the solid model is used for asphaltene deposition then this item is ignored. Permeability damage can be modeled using the [SOLIDMMS](#) keyword.

3. A character string specifying the viscosity model ([ASPVISO](#) keyword)

EI Einstein model (highly diluted solution): one parameter

KD Krieger-Dougherty model: two parameters

TAB oil viscosity multiplier is tabulated against the asphaltene precipitation fraction

NO no viscosity change

DEFAULT: NO

If oil viscosity change is to be modeled, the [ASPVISO](#) keyword must be specified in the [PROPS](#) section with the appropriate data.

## Examples

### Example 1

Asphaltene characterized by percentage weight of asphaltene component(s) in the oil, permeability damage defined by a solid saturation dependent mobility multiplier, and Krieger-Dougherty viscosity model.

```

ASPHALTE
-- charact. crit Perm damage Viscosity model
  WEIGHT      1*      KD/

```

## Example 2

Asphaltene default: weight, no permeability damage and no viscosity change:

```
ASPHALTE
-- charact. crit Perm damage Viscosity model
/
```

## ASPKDAM Asphaltene permeability damage

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

Setting this keyword provides data to model permeability damage due to asphaltene deposition. However, it can only be used with the pre-2011.1 asphaltene deposition model. If, instead of this model, the solid model is used for asphaltene deposition, then a solid dependent mobility multiplier should be used with keyword [SOLIDMMS](#) or [SOLIDMMC](#).

There are two possible ways to model this damage:

1. by correlating the permeability change to the porosity change. This is done by setting the second item of the [ASPHALTE](#) keyword to 'PORO'. Then this keyword provides the exponent in the power-law relationship between the permeability change and the porosity change.
2. by providing a look-up table giving the permeability multiplier as a function of the volume fraction of asphaltene deposit. This is done by setting the second item of the [ASPHALTE](#) keyword to 'TAB'. In this case, the first column is the volume fraction of the asphaltene deposit and the second column is the permeability multiplier. The number of rows for this table can be set in item 17 of [TABDIMS](#).

If the asphaltene volume fraction goes outside the specified range in the first column, the permeability multiplier is taken as the first or the last value specified in the table accordingly. No extrapolation is performed.

Depending on the model chosen, this keyword takes the appropriate number of data, as shown in the examples below. For more details please refer to "[Asphaltene option](#)" in the *ECLIPSE Technical Description*.

---

**Note:** The reported values using ASPKDM or BASKDM mnemonics should be interpreted as follows: a value of 1 means no damage whereas a value less than 1 means permeability damage.

---

### Examples

#### Example 1

Permeability change correlated to porosity changes

```
ASPKDAM
-- exponent
  3 /
```

#### Example 2

Permeability change as a function of volume fraction of asphaltene deposit (see item 17 of [TABDIMS](#) for the maximum number of rows).

```

-- deposit multiplier
  0.00  1.0
  0.01  0.9
  0.10  0.5 /
```

## ASPKROW

## Asphaltene relative permeability for wettability change

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used to provide the oil wet relative permeability values for  $k_{rw}$  and  $k_{ro}$ . The actual relative permeabilities are determined by interpolation between the oil wet values (provided by this keyword) and the water wet values (provided by standard keywords such as [SWFN](#), [SOF3](#) or [SWOF](#)). Interpolation depends on the wettability factor  $F$  which is given by the [ASPWETF](#) keyword.

The keyword is followed by a number of tables, each containing three columns of data:

1. The water saturation.
2. The corresponding water relative permeability.
3. The corresponding oil relative permeability.

The number of tables to be provided with this keyword is equal to the number of saturation tables (see item 1 of the [TABDIMS](#) keyword), and the maximum number of rows in each table is set by item 3 of the [TABDIMS](#) keyword.

For more details please refer to the "[Asphaltene option](#)" in the *ECLIPSE Technical Description*.

**Note:** This keyword is active only where the system is water wet, defined here by the oil-water capillary pressure  $P_{cow} > 0$

### Example

```

ASPKROW
-- Sw   krw   kro
  0.00  0.0   1.0
  0.50  0.31  0.7
  1.00  0.95  0.0/

```

## ASPLCRT

## Asphaltene plugging control

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used to control asphaltene plugging. The required data consist of:

1. A critical volume fraction of asphaltene deposit above which plugging can happen, either  $S_{cr}$  or  $\varepsilon_{cr}$ .

If the solid model is used for asphaltene deposition, the volume fraction is measured as a proportion of the pore volume, and the critical solid saturation  $S_{cr}$  is required here. However, if the pre-2011.1 asphaltene deposition model is used, the volume fraction of asphaltene deposit is measured as a proportion of the cell volume and  $\varepsilon_{cr} = \phi \cdot S_{cr}$  is required here.

2. A critical asphaltene flocs molar concentration above which plugging can happen.

UNITS: kg-M/rm<sup>3</sup> (METRIC), lb-M/rb (FIELD), gm-M/rcc (LAB), kg-M/rm<sup>3</sup> (PVT-M)

3. A character string equal to “AND” or “OR” that is used to combined the effects of the first two items.

DEFAULT: “AND”

The “OR” option is only used in the pre-2011.1 Asphaltene model. For the three-component (2011.1) model, plugging will only happen if both criteria are met. If a critical solid fraction is not required, set  $S_{cr} = 0$ .

All the numbers must be non-negative.

For more details please refer to the "[Asphaltene option](#)" in the *ECLIPSE Technical Description*.

## Example

```
ASPLCRT
-- vol frac.      conc
   0.001          1.e-4      /
```

## ASPP1P

## Asphaltene one parameter precipitation

This keyword provides data for the asphaltene precipitation in the case where the characterization is based on the percentage molar weight of specified component(s). The characterization is specified by the first item of the [ASPHALTE](#) keyword, and the component range is specified by the [ASPFLOC](#) keyword.

This keyword specifies the variable the percentage limit is set against. It can have the following data items. Valid items are:

- P (for pressure)
- T (for temperature)
- Z (for total molar fraction)

DEFAULT: 'P'

If the first item is Z (for total molar fraction) then a second item must be provided to set the component number for the concentration.

This keyword should be used in conjunction with [ASPREWG](#) keyword to specify the percentage molar weight limit set against the variable specified here by the ASPP1P keyword.

For more details please refer to the "[Asphaltene option](#)" in the *ECLIPSE Technical Description*.

---

**Note:** The temperature can only be used in thermal runs.

---

## Examples

### Example 1

The first item of the [ASPHALTE](#) keyword is WEIGHT, and precipitation set as a function of pressure:

```
ASPP1P
-- pressure
'P' /
```

### Example 2

The first item of the [ASPHALTE](#) keyword is WEIGHT, and precipitation set as a function of the molar fraction of the second component:

```
ASPP1P
-- concentration 2nd component
'Z' 2 /
```

## ASPP2P

This keyword provides data for the asphaltene precipitation in the case where the characterization is based on the percentage molar weight of specified component(s). The characterization is specified by the first item of the [ASPHALTE](#) keyword, and the component range is specified by the [ASPFLOC](#) keyword.

This keyword specifies the set of two variables that the percentage limit is set against. Valid items are:

- P T (for pressure and temperature)
- P Z xx (for pressure and total molar fraction of xx component)
- T Z xx (for temperature and total molar fraction of xx component)

If the total molar fraction is used as a variable, then a third item must be provided to set the component number for the concentration.

This keyword should be used in conjunction with the [ASPPW2D](#) keyword to specify the percentage molar weight limit set against the variable specified here by the [ASPP2P](#) keyword.

For more details please refer to the "[Asphaltene option](#)" in the *ECLIPSE Technical Description*.

---

**Note:** The temperature can only be used in thermal runs.

---

## Examples

### Example 1

The first item of the [ASPHALTE](#) keyword is `WEIGHT`, and precipitation set as a function of pressure and temperature.

```
ASPP2P
-- pressure temperature
  'P'   'T' /
```

### Example 2

The first item of the [ASPHALTE](#) keyword is `WEIGHT`, and precipitation set as a function of temperature and molar fraction of the 2nd component

```
ASPP2P
-- temperature concentration 2nd component
  'T'       'Z'       2 /
```

## ASPPW2D

## Asphaltene two parameters precipitation data

x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword provides data for the asphaltene precipitation in the case where the characterization is based on the percentage molar weight of specified component(s). The characterization is specified by the first item of the [ASPHALTE](#) keyword, and the component range is specified by the [ASPFLOC](#) keyword.

This keyword takes a 2D table where the first row is either the temperature or the molar fraction and the first column is either the pressure or the temperature depending on the couple of variables specified in the [ASPP2P](#) keyword. The other values in the table represent the percentage molar weight of asphaltene component(s) dissolved in the oil phase and should lie between 0 and 100. The table should be terminated by a slash (/).

The number of columns and rows for the table can be set using items 21 and 22 of the [TABDIMS](#) keyword respectively. If defaulted the table can take 5 columns and 5 rows.

For more details please refer to the "[Asphaltene option](#)" in the *ECLIPSE Technical Description*.

## Example

The first item of the [ASPHALTE](#) keyword is WEIGHT (for illustrative purposes):

```

ASPP2P
-- pressure temperature
  'P'   'T' /
ASPPW2D
----- temperature -----
                100    150    200    400 /
--pressure
  1000          10.0   30.0   50.0   60. /
  2000           5.0   20.0   30.0   50. /
  3000          10.0   25.0   45.0   80. /
  8000          80.0   80.0   90.0  100. /
/

```

## ASPREWG Asphaltene as percentage weight

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is set to provide data for the asphaltene precipitation in the case where the characterization is based on the percentage molar weight of specified component(s). The characterization is specified by the first item of the [ASPHALTE](#) keyword, and the component range is specified by the [ASPFLOC](#) keyword.

This keyword should be used in conjunction with [ASPP1P](#) keyword to specify the variable the molar weight percentage limit is set against. If the [ASPP1P](#) keyword is not specified, the default variable is set to pressure.

This keyword provides the percentage molar weight dissolved in solution as a function of a chosen variable (pressure, temperature or molar fraction). For more details please refer to the "[Asphaltene option](#)" in the *ECLIPSE Technical Description*.

Column:

1. Pressure (oil pressure), or temperature or molar fraction.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

UNITS: dimensionless

Values should increase monotonically down the column.

2. The corresponding percentage of “asphaltene” dissolved in the oil phase.

Values should be between 0 and 100. A value of 1.6 means that the oil phase can contain a maximum of 1.6% asphaltene by weight. The number of rows can be specified in item 18 of [TABDIMS](#).

No extrapolation is made if the pressure goes outside the range specified in the table. The lowest or highest percentage of asphaltene will be used accordingly.

### Examples

#### Example 1

The first item of the [ASPHALTE](#) keyword is WEIGHT, and precipitation set as a function of pressure:

```

ASPP1P
-- pressure
  'P' /
ASPREWG
-- pressure      % weight
   3000          30.0
   3500          70.0
   4000         100.0 /

```

#### Example 2

The first item of the [ASPHALTE](#) keyword is WEIGHT, and precipitation set as a function of the molar fraction of the 2nd component.

```

ASPP1P
-- molar fraction 2nd component
  'Z' 2 /
ASPREWG
-- Z2      % weight
  0.001    100.0

```

0.005	70.0
0.010	10.0 /

## ASPVISO

## Asphaltene oil viscosity change

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is set to provide data for the modeling of the oil viscosity change when asphaltene precipitation occurs (see item 3 in [ASPHALTE](#) keyword). There are 3 possible ways to model the oil viscosity change:

1. Generalized Einstein model (one parameter): slope of relative viscosity with respect to concentration.
2. Krieger and Dougherty model (two parameter): mass concentration at maximum packing, and intrinsic viscosity.
3. Look-up table given the oil viscosity multiplier as a function of the mass fraction of the asphaltene precipitate. The first column is the mass fraction and the second column is the viscosity multiplier. The number of rows can be set in item 19 of [TABDIMS](#).

No extrapolation is made if the mass fraction of precipitate goes outside the range specified in the table. The lowest or highest viscosity multiplier will be used accordingly.

Depending on the model chosen, this keyword takes the appropriate number of data, as shown in the examples below.

For more details please refer to the "[Asphaltene option](#)" in the *ECLIPSE Technical Description*.

## Examples

### Example 1

Generalized Einstein mode: EI in item 3 in the [ASPHALTE](#) keyword.

```
ASPVISO
-- slope
   2.5 /
```

### Example 2

Krieger and Dougherty model: KD in item 3 in the [ASPHALTE](#) keyword.

```
ASPVISO
-- Conc. max pack.   int. visco
   0.7              2 /
```

### Example 3

Look-up table: TAB string in item 3 in the [ASPHALTE](#) keyword.

```
ASPVISO
-- mass.frac multiplier
   0.00   1.0
   0.01   1.01
   0.05   1.06 /
```

## ASPWETF Asphaltene wettability factor data

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used to define a wettability factor  $F$  as a function of the asphaltene deposition. The wettability factor is used to interpolate relative permeability between the water wet relative permeabilities at  $F = 0$ , provided by standard keywords such as [SWFN](#), [SOF3](#) or [SWOF](#) and the oil wet relative permeabilities at  $F = 1$ , provided by the [ASPKROW](#) keyword.

The keyword is followed by a number of tables, each containing two columns of data:

1. The volume fraction of asphaltene deposit, either  $S_s$  or  $\varepsilon$ .

If the solid model is used for asphaltene deposition, the volume fraction is measured as a proportion of the pore volume, and the solid saturation  $S_s$  is required here. However, if the pre-2011.1 asphaltene deposition model is used, the volume fraction of asphaltene deposit is measured as a proportion of the cell volume and  $\varepsilon = \phi \cdot S_s$  is required here.

2. The wettability factor  $F$  which must be between 0 and 1.

The number of tables to be provided with this keyword is equal to the number of saturation tables (see item 1 of the [TABDIMS](#) keyword), and the maximum number of rows in each table is set by item 23 of the [TABDIMS](#) keyword.

For more details please refer to the "[Asphaltene option](#)" in the *ECLIPSE Technical Description*.

---

**Note:** This keyword is active only where the system is water wet, defined here by the oil-water capillary pressure  $P_{cow} > 0$

---

### Example

```

ASPWETF
-- deposit F factor
   0.00    0.0
   0.01    0.01
   0.10    0.20 /
  
```

## AUTOCOAR Specifies a box of cells for grid coarsening within an auto refinement

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is analogous to the [COARSEN](#) keyword and may be used in auto-refined grids (keyword [AUTOREF](#) specified in RUNSPEC). The AUTOCOAR keyword has two effects. Firstly it may be used to coarsen cells in the base grid, in a similar manner to COARSEN. Secondly, it prevents auto refinement from happening within the box of cells specified in items 1 - 6; the coarse cells in the base grid are retained.

The difference between the effects of the COARSEN and AUTOCOAR keywords is that any coarsened cell amalgamations constructed with COARSEN is then auto refined into the number of cells specified in AUTOREF, while those constructed with AUTOCOAR remain unrefined.

Note that it is possible to keep the original base cell structure within a box of cells by using AUTOCOAR to coarsen them into the same number of coarse cells. The effect of this is to keep them unaffected by the auto refinement process.

The AUTOCOAR keyword is followed by any number of records, each containing the following items and each terminated with a slash (/). The set of records must end with a blank record containing just a slash. Each record defines a box of grid cells for coarsening. The data items are:

1. I1 Lower I coordinate of the box.
2. I2 Upper I coordinate of the box.
3. J1 Lower J coordinate of the box.
4. J2 Upper J coordinate of the box.
5. K1 Lower K coordinate of the box.
6. K2 Upper K coordinate of the box.
7. NX Number of coarsened cells along the X direction in this box.  
NX must be an exact factor of I2-I1+1.
8. NY Number of coarsened cells along the Y direction in this box.  
NY must be an exact factor of J2-J1+1.
9. NZ Number of coarsened cells along the Z direction in this box.  
NZ must be an exact factor of K2-K1+1.

This divides the box I1-I2, J1-J2, K1-K2 into  $NX * NY * NZ$  coarse cells. Coarsening boxes specified using COARSEN or AUTOCOAR must not overlap one another, but they may join together.

The parameter MCOARS in keyword [LGR](#) in the RUNSPEC section must be set equal to or greater than the total number of coarse cells. Coarsening generates non-neighbor connections, and is disallowed if the keyword [NONNC](#) has been entered in RUNSPEC.

### Examples

#### Example 1

Keyword syntax

```
AUTOCOAR
-- I1-I2 J1-J2 K1-K2 NX NY NZ
   1 10  1  4  1  6  5  2  3 /
   1  4  5 10  1  6  2  3  3 /
/
```

**Example 2**

Consider a 6x6x1 grid with:

```
COARSEN
- I1 I2 J1 J2 K1 K2 NX NY NZ
  1  6  1  2  1  1  3  1  1 /
  1  2  3  4  1  1  1  1  1 /
  5  6  3  4  1  1  1  1  1 /
  1  6  5  6  1  1  3  1  1 /
/
```

With the original uncoarsened cells shown by dashed lines, this gives a grid like figure 3.1.

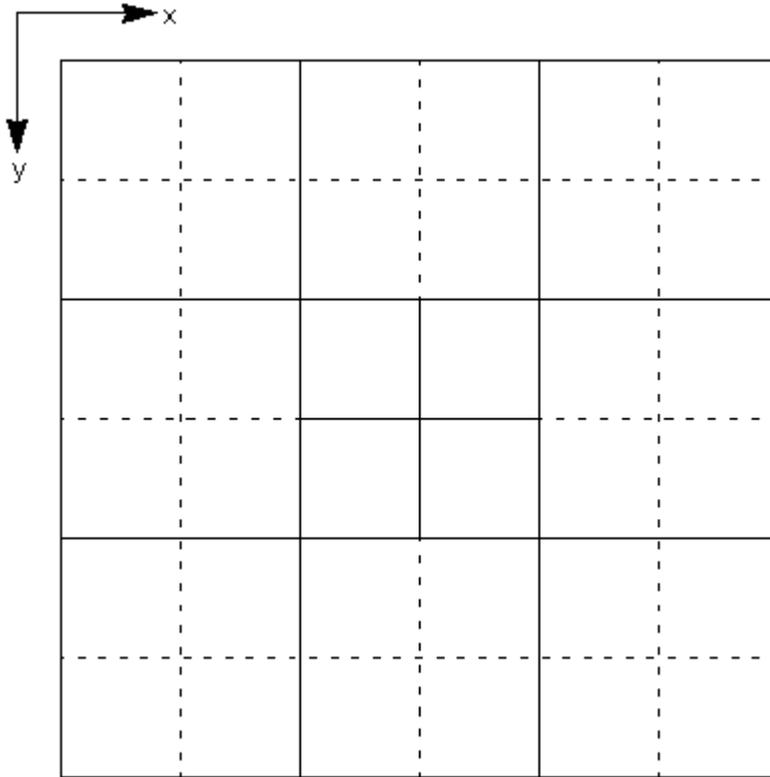

Figure 3.1. The effect of the COARSEN keyword

Now with

```
AUTOREF
3 3 1 /
```

the grid is refined as shown in figure 3.2.

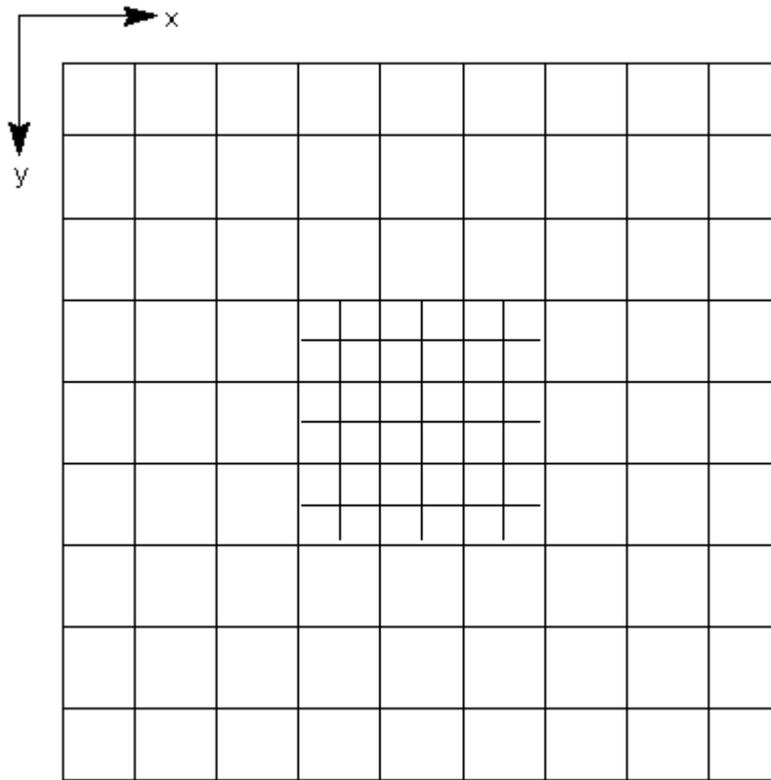

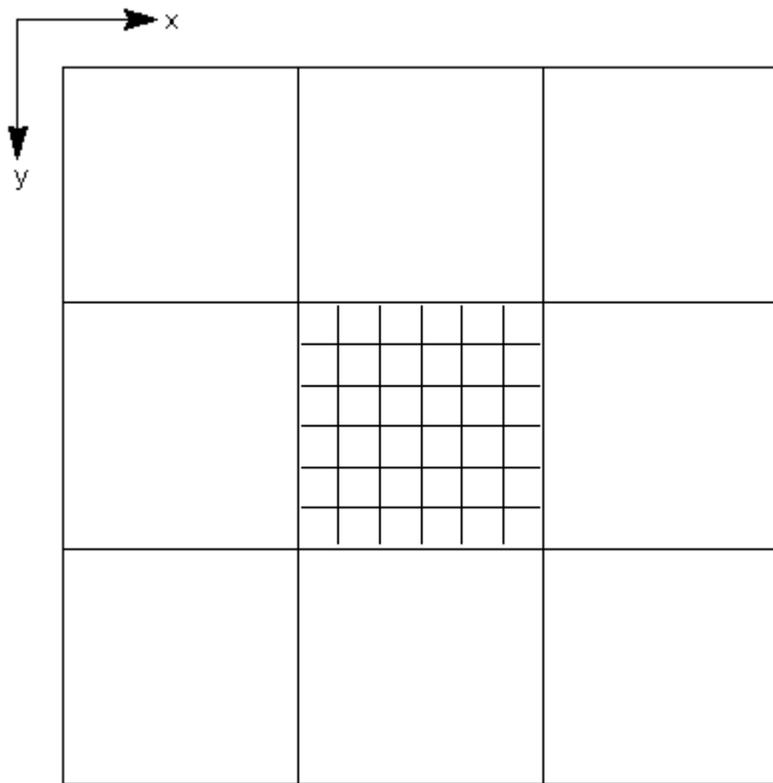

Figure 3.2. The effect of the AUTOREF keyword

But if the COARSEN keyword is replaced by AUTOCOAR, such as:

```

AUTOCOAR
- I1 I2 J1 J2 K1 K2 NX NY NY
  1 6 1 2 1 1 3 1 1 /
  1 2 3 4 1 1 1 1 1 /
  5 6 3 4 1 1 1 1 1 /
  1 6 5 6 1 1 3 1 1 /
/
    
```

then the coarsened cells are not auto refined and the resultant grid appears as shown in figure 3.3.

*Figure 3.3. The effect of the AUTO COAR keyword*

## AUTOREF Set options for auto refinement

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword sets options for auto refinement.

The data consists of the following items specifying the refinement factors to be applied to the grid in each direction. The data must be terminated by a slash (/).

1. Refinement factor in the X-direction; NX must be an odd number.

DEFAULT: 1

2. Refinement factor in the Y-direction; NY must be an odd number.

DEFAULT: 1

3. Refinement factor in the Z-direction; NZ must be an odd number.

DEFAULT: 1

4. Option for applying transmissibility multipliers.

0 Any transmissibility multipliers for example [MULTX](#) are inherited from host cells in the base grid.

1 Transmissibility multipliers, for example [MULTX](#), on the base grid are only applied on the auto-refined grid at boundaries of the base grid.

2 Allows additional transmissibility multipliers [SMULTX](#), [SMULTY](#) and [SMULTZ](#) which are applied only at boundaries of the base grid as in option 1. Any multipliers [MULTX](#), [MULTY](#) or [MULTZ](#) are inherited from the host cells in the base grid as in option 0 above.

DEFAULT: 0

The auto refinement facility is useful for automatic scaling of datasets for massively parallel computations, and for grid refinement sensitivity studies. (See "[Automatic refinement \(ECLIPSE 100\)](#)" of the *ECLIPSE Technical Description* for more details.)

If auto refinement is used, then neither [PETGRID](#) nor [GDFILE](#) can be specified.

### Example

Refine each cell into 3 x 3 areally:

```
AUTOREF
--NRX  NRY  NRZ  Option for MULTX/Y/Z
   3    3    1    1 /
```

## AUTOSAVE Specify automatic writing of SAVE files

	<b>ECLIPSE 100</b>
x	<b>ECLIPSE 300</b>
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies that SAVE files are to be written every N steps during the simulation. It may be entered more than once in the SCHEDULE section.

The effect depends on the [MULTSAVE](#) option specified in the RUNSPEC section:

- If MULTSAVE set to -1: No effect, as SAVE files suppressed
- If MULTSAVE set to 0 (default): Continuously overwrites SAVE files
- If MULTSAVE set to 1: Produce a new SAVE file each time.

### Example

```
AUTOSAVE
1 /
```

## **B**

This section contains an alphabetic listing of keywords starting with the letter B.

## BAKER1

## Request Baker three-phase relative permeability model (General)

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword, which is followed by a line containing up to three items terminated with a slash (/), is used to specify that the three-phase relative permeability values are to be calculated using Baker's general formulation. See "[Saturation functions](#)" in the *ECLIPSE Technical Description* for a description of three-phase relative permeability models available in ECLIPSE. The BAKER1 keyword should only be used in three-phase runs.

The possible item values are

OIL Baker oil relative permeability. Baker oil relative permeability with two-phase relative permeability hysteresis specified in [EHYSTR](#).

GAS Baker gas relative permeability. Baker gas relative permeability with two-phase relative permeability hysteresis specified in [EHYSTR](#).

WATER Baker water relative permeability. Baker water relative permeability with two-phase relative permeability hysteresis specified in [EHYSTR](#).

The options are used to determine whether or not to use Baker's calculation for each of the water, gas and oil phases, respectively providing independent control on a per phase basis. The items can appear in any order and are optional. At least one of the above values should be specified (see Examples 1, 2, and Example 3).

The BAKER1, [BAKER2](#), [IKU3P](#) and [ODD3P](#) relative permeability models are mutually exclusive. The BAKER1, BAKER2, [STONE](#), [STONE1](#) and [STONE2](#) relative permeability models are mutually exclusive for the oil phase. The use of BAKER1 requires the second family of saturation function keywords, that is, [SWFN](#) or [SWF3](#), [SGFN](#) or [SGF3](#) and [SOF3](#). If the Baker water model is specified the [SWF3](#) keyword must be used. If the Baker model is specified, but not for water, the [SWFN](#) keyword must be used. Similarly, if the Baker gas model is specified the [SGF3](#) keyword must be used. If the Baker model is specified, but not for gas, the [SGFN](#) keyword must be used.

---

**Note:** The hysteresis model selected according to the items on the [EHYSTR](#) keyword for the three-phase relative permeability will be used for omitted phases. See "[Saturation functions](#)" in the *ECLIPSE Technical Description* for a description of default three-phase relative permeability models available in ECLIPSE.

---

### Examples

#### Example 1

Example 1 implements the BAKER1 model for water and gas three-phase relative permeability.

```
BAKER1
WATER GAS/
```

#### Example 2

Example 2 shows how to use the BAKER1 model for gas and oil three-phase relative permeability.

```
BAKER1  
GAS OIL /
```

### Example 3

Example 3 uses the BAKER1 model for water, gas and oil three-phase relative permeability. Water, gas and oil hysteresis is deselected if hysteresis model was turned on.

```
BAKER1  
WATER GAS OIL/
```

## BAKER2

## Request Baker three-phase relative permeability model (Simplified)

## BDENSITY **Brine surface density**

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword may optionally be used in runs with the brine tracking option active (keyword [BRINE](#)). It enables the brine surface density to vary with the salt concentration. If the keyword is not present, the brine takes the surface density of water, as specified in the [DENSITY](#) (or [GRAVITY](#)) keyword.

The data comprises NTPVT (see keyword [TABDIMS](#)) records, each terminated by a slash (/). Each record consists of up to NPPVT values of water surface density. The density values in each record correspond with the salt concentration values tabulated in column 1 of each table in the [PVTWSALT](#) keyword.

UNITS: kg/m<sup>3</sup> (METRIC), lb/ft<sup>3</sup> (FIELD), gm/cc (LAB), kg/m<sup>3</sup> (PVT-M)

See also keywords [PVTWSALT](#) and [DENSITY](#).

### Example

With NTPVT =2 and NPPVT ≥ 4 in [TABDIMS](#):

```

BDENSITY
 64.0 65.0 67.0 69.0 /
 64.1 64.8 65.1 /
PVTWSALT

## BGGI

## Variation of saturated gas FVF with pressure and $G_i$

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTPVT (see keyword [TABDIMS](#)) tables of saturated gas FVF multiplier functions, each terminated by a slash (/), describing the variation of the saturated FVF of gas with pressure and  $G_i$  values. Each table consists of up to NPPVT sets of data records. Each set of records within a table consists of up to NPPVT records of data items to allow the specification of a two-dimensional (P,  $G_i$ ) function which multiplies the saturated gas FVF value at (P,  $G_i=0$ ) to give the true saturated gas FVF at (P,  $G_i$ ). The saturated gas FVF value at (P,  $G_i=0$ ) is obtained from the corresponding PVTG table.

The first record of each elementary set of records contains the following items of data:

1. The gas pressure value.  
The values should increase monotonically down the column.  
UNITS: barsa (METRIC), psia (FIELD), atma (LAB)
2. The factor by which the saturated gas FVF calculated from the [PVTG](#) keyword at a pressure corresponding to item 1 has to be multiplied to give the true saturated gas FVF at a pressure corresponding to item 1 and a  $G_i$  value given by item 1 in the corresponding [GINODE](#) table.

For record 2 and all subsequent records up to a maximum of NPPVT, there should be only 1 data item in the record. This item defines the corresponding factor by which the saturated gas FVF at (P,  $G_i=0$ ) (computed from the PVTG data) has to be multiplied to give the true saturated FVF for gas at a pressure value given in item 1 above and whose  $G_i$  value is specified in the corresponding record in the [GINODE](#) keyword.

See "[Gi pseudo-compositional model](#)" in the *ECLIPSE Technical Description* for further information.

### Example

With NTPVT =1 and NPPVT =2

```
BGGI
100.0  1.0
        0.99  /
200.0  1.0
        0.992 /

```

## BIC

## Binary interaction coefficients

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

In a run with  $N_c$  components, using an equation of state, this keyword defines the binary interaction coefficients between the components.

The keyword should be followed by  $N_c(N_c - 1)/2$  values, where  $N_c$  is the number of components specified in the RUNSPEC section with the [COMPS](#) keyword. The values are arranged in lower triangular form, the symmetry of the interaction coefficients being used to define the upper triangular part, and the self binary interaction coefficients being zero.

The use of the binary interaction coefficients in the equation of state is discussed in "[Equations of state](#)" in the *ECLIPSE Technical Description*.

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. This is entered as item 9 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

DEFAULT: 0 (for all values)

## Examples

## Example 1

For a five-component system with a binary interaction coefficient of 0.01 between component pairs 1-2 and 1-3; 0.02 between components 1-4; 0.005 between pairs 2-3 and 4-5; and 0.001 between pairs 1-5, 3-4 and 3-5.

In [GASWAT](#) mode the binary interaction coefficients for the Peng-Robinson equation of state are different from those used for the hydrocarbon phases, and may be temperature dependent. The default forms used are those suggested by Soreide and Whitson, and are described in "[GASWAT option](#)" in the *ECLIPSE Technical Description*. The general form is:

$$k_{jw}^a = bq_1 + bq_2T_{rj} + bq_3T_{rj}^2 \quad \text{Eq. 3.11}$$

The BICAQ1 keyword allows  $bq_1$  values to be entered directly. The form is the same as that for the [BIC](#) keyword.

$bq_2$  and  $bq_3$  default values may be overridden using the related [BICAQ2](#) and [BICAQ3](#) keywords.

## BICAQ2

# Second binary interaction coefficient for aqueous phase

This keyword allow you to enter a non-default aqueous phase binary interaction coefficient for use with the [GASWAT](#) option. See keyword [BICAQ1](#) for further details.

This keyword has no effect if **GEOMECH** is not specified in the RUNSPEC section.

The keyword should be followed by one non-negative real number for every grid block in the current input box, specifying the Biot constant. This parameter is dimensionless and must be greater than the porosity and less than or equal to 1. The data must be terminated by a slash (/).

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0.4). Note that spaces may not be inserted on either side of the asterisk.

The default is 1.0 for every block.

### Example

```
BIOTC
324*0.3 /
```

## BIOTCTAB

# Geomechanics Biot constant multiplier as a tabular function of rock stress

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

A multiplier for Biot’s constant may be specified in table form as a function of maximum and minimum principal stress. This keyword is only valid if the geomechanics option is chosen (see [GEOMECH](#) in the RUNSPEC section).

The data comprises NGMYRG (first item of keyword [GEODIMS](#) in the RUNSPEC section) tables, each terminated by a slash (/), where NGMYRG is the number of geomechanics regions in the model.

The first record sets the values of the maximum principal stress,  $\sigma_1$ . These must be monotonically increasing. This record must end with a slash (/).

Record 1       $\sigma_{1,1} \quad \sigma_{1,2} \quad \dots \quad \sigma_{1,NGMBTC}$

The next NGBMTR records set the values of the minimum principal stress,  $\sigma_3$ , followed by the table data for the Biot constant multipliers  $BM$ . A value of 1 for a multiplier means the Biot constant is unchanged. Values of the minimum principal stress must be monotonically increasing; that is subsequent records must have increasing  $\sigma_3$ . Repeat counts may be used with the multipliers, but not with the maximum/minimum principal stresses.

Record 2       $\sigma_{3,1} \quad BM_{1,1} \quad \dots \quad BM_{1,NGMBTC}$

Record 3       $\sigma_{3,2} \quad BM_{2,1} \quad \dots \quad BM_{2,NGMBTC}$

... ..

... ..

NGBMTR+1     $\sigma_{3,NGBMTR} \quad BM_{NGBMTR,1} \quad \dots \quad BM_{NGBMTR,NGMBTC}$

Records 2 through NGBMTR must end with a slash (/).

---

**Note:** If the Biot constant multiplier is only a function of the maximum principal stress, then set or default the number of rows, NGBMTR, to be 1. In this case, the first value in Record 2,  $\sigma_{3,1}$ , is ignored. Similarly, if the multiplier is only a function of the minimum principal stress, then set or default the number of columns, NGMBTC, to be 1. Again, in this case the first value in Record 1,  $\sigma_{1,1}$ , is ignored.

---

The set of records is ended by a blank record, containing only a slash.

The Biot constant multipliers are not checked for monotonicity. If an input maximum and minimum principal stress from the simulation model lies outside the range of the above table, constant slope extrapolation is used.

See "[Geomechanics](#)" in the *ECLIPSE Technical Description*.

### Example

With NGMYRG=1, NGMBTC=4, NGBMTR=3:

```
BIOTCTAB
-- Maximum principal stresses
   5000  7000  9000 11000 /
-- Minimum principal stress, Biot constant multipliers
5000  2*1      0.99 0.98 /
6000  1       0.99 0.97 0.94 /
8000  0.99 0.95 0.93 0.91 /
/
```

## BLACKOIL Requests black oil mode

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword activates the black oil mode, and is an alternative to [COMPS](#). Once BLACKOIL has been specified, keywords appropriate to compositional mode may not be entered. If neither COMPS nor BLACKOIL are specified, black oil mode will be assumed.

In ECLIPSE 300, if BLACKOIL is specified, the presence of all three phases (oil, water and gas) is assumed. A reduced phase black oil model (for example, oil and water only) can be selected by omitting the BLACKOIL keyword and specifying the phases which are present via the phase keywords ([WATER](#), [OIL](#) and [GAS](#)). However, it is strongly recommended that if a reduced phase black oil model is required, this is simulated instead by specifying BLACKOIL and selecting properties for the unrequired third phase such that it is not active in the simulation.

In ECLIPSE 100 the BLACKOIL keyword tries to reproduce the ECLIPSE 300 default BLACKOIL behavior by setting the following keywords: [GAS](#), [DISGAS](#), [VAPOIL](#) (if [PVTG](#) is entered).

In ECLIPSE 300, the default solution method for black oil simulations is [FULLIMP](#).

This keyword can be used with the Thermal option as an alternative to [LIVEOIL](#) and [DEADOIL](#). The simulation will be run using the Thermal code, but properties should be specified using black oil keywords.

## BOGI

## Variation of saturated oil FVF with pressure and $G_i$

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTPVT (see keyword [TABDIMS](#)) tables of saturated oil FVF multiplier functions, each terminated by a slash(/), describing the variation of saturated FVF of oil with pressure and  $G_i$  values. Each table consists of up to NPPVT sets of data records. Each set of records within a table consists of up to NPPVT records of data items to allow the specification of a two-dimensional (P,  $G_i$ ) function which multiplies the saturated oil FVF value at (P,  $G_i=0$ ) to give the true saturated oil FVF at (P,  $G_i$ ). The saturated oil FVF value at (P,  $G_i=0$ ) is obtained from the corresponding PVTO table.

The first record of each elementary set of records contains the following items of data:

1. The oil pressure value.

The values should increase monotonically down the column.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB)

2. The factor by which the saturated oil FVF calculated from the [PVTO](#) keyword at a pressure corresponding to item 1 has to be multiplied to give the true saturated oil FVF at a pressure corresponding to item 1 and a  $G_i$  value given by item 1 in the corresponding [GINODE](#) table.

For record 2 and all subsequent records up to a maximum of NPPVT, there should be only 1 data item in the record. This item defines the corresponding factor by which the saturated oil FVF at (P,  $G_i=0$ ) (computed from the PVTO data) has to be multiplied to give the true saturated FVF for oil at a pressure value given in item 1 above and whose  $G_i$  value is specified in the corresponding record in the GINODE keyword.

See "[Gi pseudo-compositional model](#)" in the *ECLIPSE Technical Description* for further information.

### Example

With NTPVT =1 and NPPVT =2

```
BOGI
100.0  1.0
        0.97  /
200.0  1.0
        0.952  /
/
```

## BOUNDARY Defines area of grid to be printed

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
x	EDIT
	PROPS
x	REGIONS
x	SOLUTION
	SUMMARY
x	SCHEDULE

The BOUNDARY keyword may be used to specify the rectangular area of the grid for which printed output of grid data or solution data (for example [TOPS](#), [PERMX](#), [PORV](#), [FIPNUM](#) and [SWAT](#)) is required.

The keyword should be followed by the data items described below. The initial values are also shown:

1. First cell on X axis to be included in output (IX1)  
INITIAL: 1
2. Last cell on X axis to be included in output (IX2)  
INITIAL: NDIVIX (which specified in RUNSPEC keyword [DIMENS](#))
3. First cell on Y axis to be included in output (JY1)  
INITIAL: 1
4. Last cell on Y axis to be included in output (JY2)  
INITIAL: NDIVIY (which specified in RUNSPEC keyword [DIMENS](#))
5. First cell on Z axis to be included in output (KZ1)  
INITIAL: 1
6. Last cell on Z axis to be included in output (KZ2)  
INITIAL: NDIVIZ (which specified in RUNSPEC keyword [DIMENS](#))
7. Orientation Index
  - 1 X across the page, Y down the page, for each Z (XYZ)
  - 2 X across the page, Z down the page, for each Y (XZY)
  - 3 Y across the page, X down the page, for each Z (YXZ)
  - 4 Y across the page, Z down the page, for each X (YZX)
  - 5 Z across the page, X down the page, for each Y (ZXY)
  - 6 Z across the page, Y down the page, for each X (ZYX)

If the orientation index is set negative (for example -1, -2 or -3), and the number of cells in the inner direction exceeds 15, then all the data for the inner directions are printed prior to moving to the next outer layer.

For example, setting the orientation index to -1 prints all the XY data for layer 1, followed by all the XY data for layer 2, and so on sequentially for the other layers.

DEFAULT: 1

- ECLIPSE 100 only*
8. Dual Porosity output flag (relevant in dual porosity runs only)
 

BOTH	Both matrix and fracture cells
MATRIX	Matrix cells only

FRACTURE Fracture cells only

The word may be abbreviated, as only the first character is significant.

DEFAULT: BOTH

The data must satisfy:

$$1 \leq IX1 \leq IX2 \leq NDIVIX$$

$$1 \leq JY1 \leq JY2 \leq NDIVIY$$

$$1 \leq KZ1 \leq KZ2 \leq NDIVIZ.$$

The data field should be terminated by a slash (/).

If fewer than eight items are read, the remainder are left unchanged.

ECLIPSE 100

In addition, this keyword controls the orientation of the output, and in dual porosity run enables you to print only the matrix or fracture cells.

ECLIPSE 300

This keyword can also be used in the RUNSPEC, PROPS and [SUMMARY](#) sections. Output to GRAF specified by [OUTSOL](#) and in the SUMMARY section is not affected.

## Example

```
----- IX1-IX2  JY1-JY2  KZ1-KZ2 Orientation Dual Poro
BOUNDARY      3   7    1   8    3   3 /
```

## Redefines the current input box

The keyword should be followed by six integers that redefine the current input box. Subsequent operations using [EQUALS](#), [ADD](#), [MULTIPLY](#) and [COPY](#) only alter grid blocks within the current input box. Similarly, data read into an array (for example, using [PERMX](#), [PORV](#) or [SATNUM](#)) are assigned to the grid blocks in the current input box.

The keyword should be followed by the data items described below, terminated with a slash.

1. First block on X axis of the new input box (IX1)
2. Last block on X axis of the new input box (IX2)
3. First block on Y axis of the new input box (JY1)
4. Last block on Y axis of the new input box (JY2)
5. First block on Z axis of the new input box (KZ1)
6. Last block on Z axis of the new input box (KZ2)

The data must satisfy:

$$1 \leq IX1 \leq IX2 \leq NDIVIX$$

$$1 \leq JY1 \leq JY2 \leq NDIVIY$$

$$1 \leq KZ1 \leq KZ2 \leq NDIVIZ \text{ (where NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword } \text{DIMENS})$$

The default cell limits are the current BOX values.

The data should be terminated by with a slash (/).

Note that at the end of each input section, the program effectively supplies an [ENDBOX](#) and resets the input box.

This keyword can be used in the RUNSPEC and [SUMMARY](#) sections.

See also keywords [ADD](#), [COPY](#), [ENDBOX](#), [EQUALS](#), [MULTIPLY](#), [MINVALUE](#) and [MAXVALUE](#).

### Example

```

-- IX1-IX2  JY1-JY2  KZ1-KZ2

## Block Parallel license

This keyword enables the Block Parallel license option.

This is an alternative license option for parallel simulations with up to eight parallel domains. In such cases, a single Block Parallel license can be used instead of the (up to) eight parallel licenses that would normally be required.

To use this option the parallel keyword ([PARALLEL](#)) must also be present, with item 1 (the number of domains) set to a value in the range 2 to 8.

The keyword BPARA contains no items of associated data.

---

### Note:

- The Block Parallel license feature is not compatible with multiple realization ([MULTREAL](#)) runs.
  - Only one Block Parallel license can be used in an ECLIPSE run. If more than eight domains are requested the simulation will stop with an error message and the simulation should then be run using the normal parallel licensing options.
  - The BPARA keyword cannot be used with the Reservoir Coupling option in ECLIPSE 100.
- 

See "[Block parallel license](#)" in the *ECLIPSE Technical Description* for more information.

### Example

```

BPARA
PARALLEL
--NDMAIN MACHINE TYPE
      8      DISTRIBUTED /

```

## BRANPROP Defines the extended network branches

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword must be used to define the structure of the network when the extended network model is employed (keyword [NETWORK](#) in the RUNSPEC section). The network structure can be different from the group control hierarchy defined by keyword [GRUPTREE](#). However, it must have a gathering tree structure, and the source nodes (the bottom nodes in the tree) must correspond to groups in the [GRUPTREE](#) hierarchy (usually well groups or satellite groups); in ECLIPSE 100 the corresponding nodes and groups must have the same name in both structures. The remaining network nodes and [GRUPTREE](#) groups need not coincide.

You cannot mix [BRANPROP](#) and [GRUPNET](#); the complete production network must be defined with either [BRANPROP](#) and [NODEPROP](#) (for an extended network) or [GRUPNET](#) (for a standard network).

In ECLIPSE 300, if an injection network is present as well, it must be of the same type as the production network. If the production network has been defined with [BRANPROP](#) and [NODEPROP](#) then the injection network must also be defined with these keywords.

In ECLIPSE 100 only production networks may use [BRANPROP](#) and [NODEPROP](#); injection networks must be defined using [GNETINJE](#).

The [BRANPROP](#) keyword is followed by any number of records, each containing the following items of data and terminated with a slash (/). The set of records must end with a blank record, containing only a slash.

1. Name of the branch's downtree node.

(up to 8 characters)

This is the node that is nearer to the wells and further from the terminal node at the top of the tree. In a production network it is the branch's inlet node; in an injection network it is the branch's outlet node.

2. Name of the branch's uptree node.

(up to 8 characters)

This is the node that is nearer to the terminal node at the top of the tree. In a production network it is the branch's outlet node; in an injection network it is the branch's inlet node.

3. VFP table number for the branch.

In a production network this should be the production VFP table number (keyword [VFPPROD](#)).

*ECLIPSE 300*

In an injection network this should be the injection VFP table number (keyword [VFPINJ](#)). The inlet and outlet nodes must both belong to the same type of network (Item 7 of keyword [NODEPROP](#)).

Two or more network pipelines may share the same VFP table if they have similar pressure loss characteristics.

A value of 9999 can be entered to indicate that there is no pressure loss in the network branch defined by items 1 and 2. Branches representing chokes (see item 3 of keyword [NODEPROP](#)) **must** have a value of 9999 input here.

*ECLIPSE 300*

Compositional production VFP tables (keyword [VFPPROD](#)) are not currently supported in the network model.

A value of 0 will close the branch, that is remove it from the network. The inlet node's production (or the outlet node's injection) is not added to the network flows.

4. Artificial Lift Quantity (ALQ) used in the pressure loss calculations for the branch.

This quantity is used as a look-up parameter for the VFP table in item 3. It may be regarded as the pump or compressor power, for example, according to the definition used in the construction of the table.

ECLIPSE 100

If the branch contains an automatic compressor (keyword [NETCOMPA](#)), the ALQ value entered here should correspond to the compressor's "off" state (which would normally be zero).

ECLIPSE 100

Default this item if the ALQ is equated to DENO or DENG in item 5.

UNITS: These depend on what the ALQ was meant to represent when the table was created. Refer to section "[Record 6:ALQ values](#)" in the description of keyword [VFPPROD](#).

DEFAULT: Zero

ECLIPSE 100 only

5. Equate the branch's ALQ to the surface density.

The branch's ALQ may optionally be equated to the average surface density of either the oil phase or the gas phase flowing along it. ECLIPSE will then automatically set it equal to this value when it looks up the VFP table. The VFP table must have been prepared using the same definition of the ALQ (see keyword [VFPPROD](#)), and should span the expected range of surface density values. This option is useful when a mixture of oil or gas with different surface densities flows into the network. Obviously the ALQ cannot then also be used to represent a pump or compressor, and the branch cannot contain an automatic compressor.

DENO Set the ALQ equal to the average surface density of the **oil** flowing along the branch.

DENG Set the ALQ equal to the average surface density of the **gas** flowing along the branch.

NONE Do not equate the ALQ to the oil or gas density. Leave it at the value entered in item 4 (or let it be reset by the automatic compressor facility).

DEFAULT: NONE

End the data record with a slash (/).

End the set of records with a blank record containing just a slash.

See also keyword [NODEPROP](#).

---

**Note:** It is possible to change the network topology during the run by adding new branches between the nodes. However, each node may only have one uptree branch (in the direction of the terminal node at the top of the tree). Hence if a node's uptree branch is redirected to a different uptree node, its original uptree branch must be removed by giving it a zero VFP table number in item 3.

---

## Example

```

BRANPROP
-- DnTre   UpTre   VFP   ALQ   ALQ=
-- node   node   table  value  dens?
  GB2     N4         3 /
  GA2     N3         2 /
  GB1     N2         1 /
  GA1     N1       9999 /
  N4      N3         4 /
  N3      N2         4 /
  N2      N1         5 /
  N1      FIELD    6   100 /
/

```

## BRINE

### Brine tracking is required

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This indicates that the brine tracking option is required, to allow the modeling of waters with different salinities. (See "Brine tracking" in the *ECLIPSE Technical Description*).

For runs using the ECLIPSE polymer flood option (enabled with keyword `POLYMER`), BRINE switches on the polymer salt-sensitivity option instead.

The keyword has no associated data for the standard brine tracking option.

When used in conjunction with keyword `ECLMC` the BRINE keyword activates the multi-component brine model (ECLIPSE 100 only). In this case the keyword should be followed by a list of salts specified by their chemical formulae. At least one salt must be specified. The salts available are listed in Table 3.2. The data must be terminated by a slash (/)

The Multi-component Brine Model is currently not compatible with the polymer salt-sensitivity option, and will invalidate its keywords.

Salt name	Chemical formula
Sodium Chloride	NaCl
Potassium Chloride	KCl
Calcium Chloride	CaCl <sub>2</sub>
Magnesium Chloride	MgCl <sub>2</sub>
Sodium Carbonate	Na <sub>2</sub> CO <sub>3</sub>
Potassium Carbonate	K <sub>2</sub> CO <sub>3</sub>
Calcium Carbonate	CaCO <sub>3</sub>
Magnesium Carbonate	MgCO <sub>3</sub>
Sodium Sulfate	Na <sub>2</sub> SO <sub>4</sub>
Potassium Sulfate	K <sub>2</sub> SO <sub>4</sub>
Calcium Sulfate	CaSO <sub>4</sub>
Magnesium Sulfate	MgSO <sub>4</sub>

Table 3.2: List of available salts in the Multi-Component Brine model

### Example

ECLIPSE 100 only

Multi-component brine model with three salts.

```

## BTOBALFA Dual porosity block to block matrix-fracture coupling multiplier

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
X	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

If the Dual Porosity option is being used (keyword [DUALPORO](#) in the `RUNSPEC` section), and the matrix-fracture coupling transmissibilities have been specified in the grid section through the [SIGMA](#) or [SIGMAV](#) keywords, then this keyword activates additional matrix fracture connections between every active fracture grid block and an active matrix grid block immediately below it. The value specified with this keyword is the multiplier for all these new vertical block-to-block connections equivalent to the value specified by the [SIGMA](#) keyword for the conventional dual porosity connections, and represents the fractional contact between the upper fracture and the lower matrix. However, because it is multiplying a directional transmissibility, unlike [SIGMA](#), it is dimensionless.

For further information, see the section on "[Block to block transmissibility calculations](#)" in the *ECLIPSE Technical Description*.

Note that block-to-block connections cannot be made if a multi porosity gridding is specified (using [NMATRIX](#) for multi porosity or [TRPLPORO](#) for triple porosity).

The keyword should be followed by a single positive real number which will be applied to every grid block in the current grid.

To specify different values for different cells, use the [BTOBALFV](#) keyword.

UNITS: dimensionless

### Example

```
BTOBALFA
0.01 /
```

This keyword is used to specify the tracer whose concentration represents the calorific value of the gas, when the Gas Calorific Value Control option is being used (see "Gas calorific value control" in the *ECLIPSE Technical Description*).

The tracer must be already defined as a gas phase passive tracer (keyword `TRACER` in the PROPS section), and initialized to equal the calorific value in units of  $\text{kJ}/\text{sm}^3$  (METRIC),  $\text{Btu}/\text{Mscf}$  (FIELD),  $\text{J}/\text{scc}$  (LAB). (See "Tracer tracking" in the *ECLIPSE Technical Description* for an account of how to define tracers.)

The keyword is followed by a single record, terminated with a slash (/).

1. Name of the tracer  
(Up to 3 characters)

End data record with a slash (/).

### Example

```
CALTRAC
CAL /
```

## Component calorific values

This keyword associates a molar calorific value with each component. Either the keyword CALVAL or CALVALR is required if calorific value production rate constraints are to be set for wells (see keyword WCONPROD) or groups (see keyword GCONPROD). It is also required in a GASWAT run if a gas quality calculation is to be performed. (See "GASWAT option" in the *ECLIPSE Technical Description* for further information.)

The keyword should be followed by  $N_c$  values.

UNITS: kJ/kg-M (METRIC), Btu/lb-M (FIELD), J/gm-M (LAB), kJ/kg-M (PVT-M)

### Example

```
--Calorific values in kJ/kg-M
CALVAL
10 20 0.0 0.0 /
```

## CALVALR **Component calorific values for multiple equation of state regions**

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword associates a molar calorific value with each component in each equation of state region. Equation of state regions are defined using the [EOSNUM](#) keyword. The CALVALR keyword enables the calorific value production rate for wells completed in multiple equations of state regions to be computed. Note, if crossflow occurs in a production well the calorific value of the injected fluid will be taken as a wellbore or segment average, computed per component as a flow rate weighted average of the producing completions. For injecting wells the calorific values are those of the equation of state associated with the wellbore.

Either of the keywords [CALVAL](#) or CALVALR is required if calorific value production rate constraints are to be set for wells (see keyword [WCONPROD](#)) or groups (see keyword [GCONPROD](#)). It is also required in a [GASWAT](#) run if a gas quality calculation is to be performed. (See "[GASWAT option](#)" in the *ECLIPSE Technical Description* for further information.)

The keyword should be followed by  $N_c$  values for each equation of state region.

UNITS: kJ/kg-M (METRIC), Btu/lb-M (FIELD), J/gm-M (LAB), kJ/kg-M (PVT-M)

### Example

```
--Calorific values in kJ/kg-M
CALVALR
10 20 0.0 0.0 /
12 22 0.0 0.0 /
```

## CARFIN

## Specifies a Cartesian local grid refinement

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The CARFIN keyword is used to set up a Cartesian local grid refinement. It specifies a cell or a box of cells identified by its global grid coordinates I1-I2, J1-J2, K1-K2 to be replaced by refined cells. The dimensions of the refined grid within this box are specified as NX, NY, NZ.

Local grid refinement is described in "[Local grid refinement and coarsening](#)" in the *ECLIPSE Technical Description*.

The CARFIN keyword is followed by the following items of data, terminated by a slash (/):

1. Name of the local grid refinement (up to 8 characters).
2. I1 Lower I-coordinate of the box in the parent grid.
3. I2 Upper I-coordinate of the box in the parent grid.
4. J1 Lower J-coordinate of the box in the parent grid.
5. J2 Upper J-coordinate of the box in the parent grid.
6. K1 Lower K-coordinate of the box in the parent grid.
7. K2 Upper K-coordinate of the box in the parent grid.
8. NX Number of refined cells along the X-direction.
9. NY Number of refined cells along the Y-direction.
10. NZ Number of refined cells along the Z-direction.
11. NWMAX Maximum number of wells this local refined grid will contain.
12. Name of parent LGR - up to 8 characters. This item may be set to either a null string or to the string 'GLOBAL' to indicate that the parent grid is global (that is, this is not a nested refinement).

Nested refinements may be used in ECLIPSE 300 and ECLIPSE 100. If the parent grid is already an LGR then the name of the parent LGR should be specified. The range of I-, J- and K- indices should then refer to the parent grid. If the parent grid is the global grid, then the range of I-, J- and K- indices refers to the global grid.

*ECLIPSE 100 only*

*ECLIPSE 100*

Nested refinements cannot be used in ECLIPSE 100 if the parent or child is part of an amalgamated local grid. They also cannot be used with the Parallel or Gradient options.

DEFAULT: 'GLOBAL'

## Notes

- In ECLIPSE 100, and when using the WARP linear solver in ECLIPSE 300, LGRs can only be positioned at a boundary of their parent grid if that boundary is also the boundary of the global grid.
- When the grid is a dual or (in ECLIPSE 300) a multi-porosity grid, then the box of the parent grid is specified in the matrix only. The number of refined cells in the Z-direction is specified in the same way as for the [DIMENS](#) keyword in RUNSPEC - namely that NZ (item 10) gives the total number of Z-direction cells in all porosities, so that NZ must be a multiple of the number of porosities. An error will be posted if this is not the case. For example, for a dual porosity case, Z should be a multiple of 2 and NZ /2 should give the number of Z-direction refined cells in the matrix.

## Examples

### Example 1

```

CARFIN
--Name  I1 I2 J1 J2 K1 K2  NX NY  NZ
  REF1  19 19  3  3  1  2    3  1   6  /
--Enter data for this local grid
PORO
0.25 0.28 0.21 0.225 0.23 0.18
0.17 0.15 0.22 0.165 0.17 0.16
0.20 0.21 0.19 0.120 0.15 0.17 /
ENDFIN

```

### Example 2

Nested refinement, located at the boundary (K1=1) of both REF1 and the global grid.

```

--Define a local grid REF1
CARFIN
--Name  I1 I2 J1 J2 K1 K2  NX NY  NZ NWMAX PARENT
  REF1  16 19  3  3  1  4    8  4  16   1* GLOBAL /
ENDFIN
--Define a local grid REF2 contained within REF1
CARFIN
--Name  I1 I2 J1 J2 K1 K2  NX NY  NZ NWMAX PARENT
  REF2   2 3  2  3  1  8    4  4  16   1* REF1 /
--Enter data for this local grid here if required
ENDFIN

```

## CART

### Specify Cartesian geometry

The keyword indicates Cartesian (X, Y, Z), rather than radial geometry is to be used for the simulation. Note that as this is the default geometry convention, it is not normally necessary to specify this keyword.

The CART keyword takes no associated data.

## Component type for Asphaltene model

This keyword can be used with the Asphaltene option ([ASPHALTE](#)) to identify special components in the asphaltene model. It is an alternative to the [ASPFLOC](#) keyword. The keyword should be followed by one value for each component. The value should be one of the following:

NONE for an ordinary component

PREC for a component that can precipitate as asphaltene

FLOC for the component that represents the flocculated asphaltene

DEPO for the component that represents deposited asphaltene

DEFAULT: NONE

The following restrictions apply when using this keyword:

- Exactly one component should be identified as the precipitate.
- Exactly one component should be identified as the flocculate.
- If the asphaltene deposition model ([ASPDEPO](#)) is not used, then there should be no deposition component.
- If the three component asphaltene deposition model is required, then exactly one component should be identified as deposited asphaltene. This component must also be a solid component (using keywords [SOLID](#) and [CVTYPE](#)).
- If the pre-2011.1 asphaltene deposition model is required, then there should be no deposition component.

If this keyword is used the [ASPFLOC](#) keyword will be ignored.

### Example

```
CATYPE
3* PREC FLOC DEPO/

CVTYPE
5* SOLID
```

## CBMOPTS Options for the Coal Bed Methane Model

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword is used to control options associated with the Coal Bed Methane Model. A Coal Bed Methane Model must be activated by including the [COAL](#) keyword in the RUNSPEC section.

The CBMOPTS keyword is optional and should be followed by some or all of the following data items, terminated by a slash (/).

1. The adsorption model used. (ECLIPSE 300 only.)

The TIMEDEP model requires that the run is a [DUALPORO](#) (or multi-porosity) run while the INSTANT model can also be used for single porosity models.

The model is either INSTANT or TIMEDEP.

DEFAULT: TIMEDEP

2. Specify if water flow in/out of a coal cell is allowed. (ECLIPSE 300 only.)

A coal cell is a cell with a non-zero coal region number as set by the [COALNUM](#) keyword. This will only have an effect on runs using the INSTANT adsorption model.

The value is either YES or NO.

DEFAULT: YES

3. Specify if interpolation of oil gas relative permeabilities is allowed. (ECLIPSE 300 only.)

The value is either NOKRMIX or KRMIX.

DEFAULT: NOKRMIX which corresponds to using the keyword [NOMIX](#).

4. Specify that the passes through the rebound region, when the Palmer-Mansoori rock model is used ([ROCKPAMA](#) or [ROCKPAME](#)), are counted.

The rebound region is where the pressure derivative of the pore volume model changes sign. Warnings are issued for the first detections. Note that this includes passes done within each Newton iteration. The total number of passes through the rebound region can be viewed by the array NPMREB output by RPTSCHED or RPTRST.

NOPMREB or PMREB

DEFAULT: NOPMREB.

5. Specify the method to be used for the Palmer-Mansoori rock model (ROCKPAMA):

PMSTD    Invoke the standard Palmer-Mansoori method.

PMADTN    Use the adsorbed gas in the matrix for the sorption-induced swelling/shrinkage strain term. The gas concentrations at the current timestep, given by the Newton iteration, is used. However, derivatives with respect to the gas concentrations are not included in the Jacobian matrix. For ECLIPSE 300 this method requires [TPAMEPS](#).

PMADIMP    Use the adsorbed gas in the matrix for the sorption-induced swelling/shrinkage strain term and solve for this implicitly. The derivatives with respect to the matrix gas concentrations are included in the Jacobian matrix during the Newton iterations. For ECLIPSE 300 this method requires [TPAMEPS](#).

PMADTT Use the adsorbed gas in the matrix, at the previous timestep, for the sorption-induced swelling/shrinkage strain term. For ECLIPSE 300 this method requires TPAMEPS.

Note that PMADTN, PMADIMP or PMADTT are compatible with using the keyword TPAMEPS and TPAMEPSS.

DEFAULT: PMSTD.

Pre-2013.1 calculations can be obtained by using [item 295](#) in OPTIONS3 for ECLIPSE 300, or [item 200](#) in OPTIONS for ECLIPSE 100.

- Use the Langmuir scaling value for the volumetric strain term in the Palmer-Mansoori model ([ROCKPAMA](#) or [ROCKPAME](#)).

NOPMSCAL or PMSCAL

DEFAULT: PMSCAL

- Select if the Palmer Mansoori model should be applied to the pore volume and/or to the permeability. This enables a subset of the model to be activated ([ROCKPAMA](#) or [ROCKPAME](#)).

PMPVK Both pore volume and permeability

PMCPVK Compressibility term for pore volume, but full method for permeability

PMK Only for the permeability

PMPV Only for the pore volume

DEFAULT: PMPVK

*ECLIPSE 100 only*

- Pressure chop if passing through the rebound pressure.

PMPCHP or NOPMPCHP

DEFAULT: NOPMPCHP

- Minimum pore volume of the Palmer-Mansoori method ([ROCKPAMA](#) or [ROCKPAME](#)).

DEFAULT: 5.0D-6

## Example

```
CBMOPTS
-- model water-flow
INSTANT NO/
```

## CCTYPE

## Component compressibility type

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used with the Thermal option to specify the formula used for the liquid phase compressibility of a hydrocarbon component.

By default the volume of a component in the liquid phase is given by:

$$V_c = [1 - c_{P_c} (P - P_{ref_c})] \cdot [1 + C_{T1_c} (T - T_{ref_c})] \cdot MW_c / \rho_{ref_c} \quad \text{Eq. 3.12}$$

where the constants used in this equation are described further in keywords [CREF](#), [DREF](#), [PREF](#), [TREF](#) or [THERMEX1](#).

However, when modeling foamy oil, it is convenient to model the gas trapped in the oil as a component in the liquid phase, but with a gas-like compressibility. Keyword CCTYPE allows the component liquid phase volume to be modeled using a gas law:

$$V_c = Z_c RT / P \quad \text{Eq. 3.13}$$

See keyword [ZFACTOR](#) for more details.

The keyword should be followed by one value for each component. The value should be one of the following

OIL for standard liquid phase compressibility shown in equation [3.12](#)

GAS for gas-like liquid phase compressibility shown in equation [3.13](#)

These values may be enclosed in quotes. Only the first character is significant.

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "Equations of state regions" in the *ECLIPSE Technical Description*.

## Example

```
CCTYPE
OIL OIL GAS /
```

## CCTYPES

## Component compressibility type for surface conditions

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used with the [THERMAL](#) option to specify the component oil phase compressibility type (OIL or GAS) at surface conditions. If this keyword is not used, the surface compressibility type will be the same as the reservoir compressibility type, set using the [CCTYPE](#) keyword.

The keyword is used in the same way as the [CCTYPE](#) keyword.

If multiple equations of state are being used, a set of data should be entered for each surface EoS. The number of surface equation of state regions is entered as item 10 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

## CECON

**Economic limits for production well connections**

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

CECON is used to set economic limits for production well connections. If an individual connection violates one of its economic limits it will be automatically closed. The well connections must already be defined before this keyword can be used.

CECON is followed by any number of records, described below, each record terminated by a slash (/). A record may be terminated early at any item; the remaining items assume their default values. Default values can be specified before the slash by a null repeat count of the form  $n^*$ , where  $n$  is the number of consecutive items to be defaulted.

The set of records must end with a blank record, containing only a slash (/).

Each record can contain some or all of the following items:

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. I - location of connecting grid block(s)

DEFAULT: 0 (allows any I-value)

3. J - location of connecting grid block(s)

DEFAULT: 0 (allows any I-value)

4. K - location of upper connecting block in this set of data

DEFAULT: (corresponds to top connection of well)

5. K - location of lower connecting block in this set of data

DEFAULT: (corresponds to bottom connection of well)

The following economic limits will be applied to all the connections in the well that match the location indices specified in items 2 - 5. But if a location index is defaulted to zero, it plays no part in selecting which connections have these limits. Thus if the I and J location indices are defaulted to zero, the economic limits are applied to all connections in the well that are located between layers K1 and K2 specified in items 4 and 5. If all four location indices are defaulted, the limits are applied to all the connections in the well.

6. Maximum water cut (water-liquid ratio). User defined arguments can be set with keywords UDQ and UDADIMS.

A value of 0.0 switches off this limit

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: No limit

7. Maximum gas-oil ratio. User defined arguments can be set with keywords UDQ and UDADIMS.

A value of 0.0 switches off this limit

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), Mscf/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: No limit

8. Maximum water-gas ratio. User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

A value of 0.0 switches off this limit

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/Mscf (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: No limit

9. Workover procedure when a limit is violated

CON Shut the connection

+CON Shut the connection and all below it (see keyword [COMPORD](#))

WELL Shut or stop the well (Item 9 in keyword [WELSPECS](#))

PLUG Plug back the well (see keyword [WPLUG](#))

DEFAULT: CON

10. Continue checking stopped wells?

YES The connection economic limits continue to be checked even if the well is stopped (as crossflow may still occur).

NO Connection economic limits are not checked in stopped wells.

DEFAULT: NO

11. Minimum oil production rate. User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

If its oil production rate falls below this value, the connection is shut (and all below it, if item 9 requests).

UNITS:  $\text{sm}^3/\text{day}$  (METRIC), stb/day (FIELD), scc/hr (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

DEFAULT: - infinity (-1.0E20)

12. Minimum gas production rate. User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

If its gas production rate falls below this value, the connection is shut (and all below it, if item 9 requests).

UNITS:  $\text{sm}^3/\text{day}$  (METRIC), Mscf/day (FIELD), scc/hr (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

DEFAULT: - infinity (-1.0E20)

13. Name of well to be opened when this well is shut (the follow-on well)

If a well name is entered here, the named well is opened when the well specified in item 1 is closed automatically for any reason (for example on violating an economic limit). The named well must be fully specified as a SHUT producer or injector. Manual closure of the well in item 1 (for example using [WCONPROD](#) or [WELOPEN](#)) does not cause the named well to be opened.

This option can be used, for example, to open an injector when a producer closes after becoming uneconomic. If the injector has the same completions as the producer, the effect is equivalent to converting the producer into an injector, although in this case they are regarded as two separate wells.

ECLIPSE 100

If the well to be opened is given a non-zero drilling time in keyword [WDRILTIM](#), the opening is subject to constraints on drilling rig availability (see keyword [GRUPRIG](#)).

DEFAULT: ''

## Notes

- If keyword [COMPLUMP](#) is used to lump connections into completions, the connection economic limits are applied to whole completions (that is a whole completion is closed if its total water cut, GOR or WGR exceeds the limit set for its connections, or if its total oil or gas production rate falls below the minimum value set for its connections). All connections in the same completion must be given the same limits.
- Crossflowing (injecting) connections have a negative production rate. Thus setting item 11 or 12 to a small negative value causes the connection to be shut if it attempts to crossflow. The default of  $-1.0E20$  allows the connection to remain open if it crossflows.
- Only one UDA may be defined for each item per well at any one time. For any particular item, if two UDAs are defined for different connections on the same well then that the corresponding value will be calculated for all UDA-controlled connections using the most recently requested UDA.

See also keyword [WLIMTOL](#) and the ECLIPSE 100 keyword [WORKLIM](#).

## Example

```
CECON
  PROD1  4*    0.7 / Water cut limit for all connections in well
  'P*'   2*  2  2  1* 3.5 / GOR limit for layer-2 connections
  /                               in all wells with names beginning with P
```

## CECONT

## Tracer economic limits for production well connections

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

CECONT is used to set tracer economic limits for production well connections, including polymer and brine. If an individual connection violates one of its economic limits it will be automatically closed. The well connections must already be defined before this keyword can be used.

CECONT is followed by any number of records, described below, each record terminated by a slash (/). A record may be terminated early at any item; the remaining items assume their default values. Default values can be specified before the slash by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted. There are two types of record; one describes the connection and the second lists the tracers and their limits.

The set of records must end with a blank record, containing only a slash (/).

Records of the first kind can contain some or all of the following items:

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. I - location of connecting grid block(s)

DEFAULT: 0 (allows any I-value)

3. J - location of connecting grid block(s)

DEFAULT: 0 (allows any J-value)

4. K - location of upper connecting block in this set of data

DEFAULT: 0 (corresponds to top connection of well)

5. K - location of lower connecting block in this set of data

DEFAULT: 0 (corresponds to bottom connection of well)

The following economic limits will be applied to all the connections in the well that match the location indices specified in items 2 - 5. However, if a location index is defaulted to zero, it plays no part in selecting which connections have these limits. Thus if the I and J location indices are defaulted to zero, the economic limits are applied to all connections in the well that are located between layers K1 and K2 specified in items 4 and 5. If all four location indices are defaulted, the limits are applied to all the connections in the well.

6. Workover procedure when a limit is violated

CON Shut the connection

+CON Shut the connection and all below it (see keyword [COMPORD](#))

DEFAULT: CON

7. Continue checking stopped wells?

YES The connection economic limits continue to be checked even if the well is stopped (as crossflow may still occur).

NO Connection economic limits are not checked in stopped wells.

DEFAULT: NO

End the record with a slash (/)

A maximum of three subsequent records can follow, for each well connection or range of connections. These records can contain some or all of the following items.

1. Tracer name (Use PLY for a polymer and BRI for brine)
2. Maximum total tracer rate  
DEFAULT: No limit
3. Maximum total tracer concentration (not available for partitioned tracers)  
DEFAULT: No limit.

The following are only available for two-phase tracers

4. Maximum free tracer rate  
DEFAULT: No limit
5. Maximum free tracer concentration  
DEFAULT: No limit
6. Maximum solution tracer rate  
DEFAULT: No limit
7. Maximum solution tracer concentration  
DEFAULT: No limit.

End the record with a slash (/).

End the data for this well connection with a blank line containing just a slash(/).

Note that this means that the keyword will end with two blank lines containing just slashes.

## Notes

- If keyword **COMPLUMP** is used to lump connections into completions, the connection economic limits are applied to whole completions (that is a whole completion is closed if its total rate or concentration exceeds the limit set for its connections). All connections in the same completion must be given the same limits.
- Crossflowing (injecting) connections have a negative production rate. Thus setting item 11 or 12 to a small negative value causes the connection to be shut if it attempts to crossflow. The default of  $-1.0E20$  allows the connection to remain open if it crossflows.
- No units are given for the tracer rates. The rates are those of the carrier flow rate.

- Since the tracers are solved after the main reservoir simulation if it is subsequently discovered that a limit is violated, the timestep is always repeated with the action being enforced from the start of the timestep. Even with doing this it may be that the 'action' lags the violation by a timestep.
- This keyword needs to end with two lines containing only slashes. See the examples below.

## Examples

## CFLLIMIT

## Stable timestepping

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The data consists of some or all of the following items, which control the implicit cell choice within an [AIM](#) run or the timestep choice within an [IMPES](#) run. The data must be terminated by a slash (/).

- Turns on (or off) the stable timestepping option.  
ON Stable timestepping turned on.  
OFF Stable timestepping turned off.  
DEFAULT: OFF
- The target maximum CFL value for any explicit cell.  
DEFAULT: 1.0

---

**CAUTION:** Whilst many cases will run faster, and with no apparent ill effect, with a maximum CFL greater than 1 this is strongly discouraged unless the user is confident of being able to spot when problems have arisen.

---

- In AIM runs only, the CFL value above which cells will be made implicit (subject to item 5)  
DEFAULT: 0.75
- At the end of the timestep the CFL numbers are recalculated with the new solution. If any cell has a CFL above the value given here the timestep is chopped and repeated.  
DEFAULT: 2.0
- The fraction of cells that can be made implicit in an AIM run.  
DEFAULT: 0.05 (=5%)

---

**Note:** If the predominant reason given for timestep choice in the run is 'CFL' then it is usually the case that the run is more efficient if a larger value is given here, that is, more cells are allowed to be implicit.

---

- An integer specifying the number of AIM state evaluations that an implicit cell remains implicit after being set, regardless of the selection criteria.  
This option is only activated when item 5 is greater than 0.  
DEFAULT: 1.0
- An integer which controls the implicit treatment of the wells.
  - Wells are not given any special treatment.
  - All the inner solver direction lines of cells containing the completions of open wells are set to be implicit.
  - All the cells containing the completions of open wells are set to be implicit.
 DEFAULT: 1

8. Turn off limiting of change due to capillary pressure, that is, the keyword `DPCDT` is ignored. If set to 'NO' then the value given to `DPCDT` in the `RUNSPEC` section is honored.

DEFAULT: YES

9. An integer specifying the number of timesteps taken before reevaluating the AIM state.

The AIM state is always reevaluated at the beginning of a new report step.

If this item is negative (and item 5 is greater than zero), the AIM state is always reevaluated if throughput or solution change is limiting the current step.

DEFAULT: 1

## Example

In this example up to 5% (item 5) of the reservoir could be made implicit if needed, the run is assumed to be AIM. A more conservative choice has been taken for item 4.

```
CFLLIMIT  
'ON' 2* 1.5 0.05 1*/

## CGDTYPE

## Component gas density type

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used with the [THERMAL](#) option to specify how the gas phase molar density is computed. With the keyword present an equation of state (EoS) can be used. The default equation of state is Peng-Robinson (PR). If the [EOS](#) keyword is used, the equations of state are the ones defined in the item in EOS. All of the keyword necessary for the EoS, such as BIC, need to be added in the PROPS section when using the CGDTYPE keyword (even when all items are NO).

The keyword should be followed by one value for each component. The value should be one of the following:

Type	Component
NO	Not used. The molar volume for this component is computed as if this keyword were not present.
EMIX	An equation of state is used for the EMIX components. The vapor root of the cubic equation of state is always used.
EGFE	An equation of state is used for the EGFE components. The molar volume is chosen to be the volume with the lowest Gibbs free energy. Thus a liquid molar volume would be used if the stable phase at the given pressure and composition corresponds to a liquid.

Table 3.3: CGDTYPE component values

If the keyword is present the default is EMIX.

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

**Note:** If only a subset of the mixture is modeled by an EoS and many of the heavy components are included, and the light components are not, the mixture could yield a molar volume similar to that of an OIL or give an unphysical molar volume.

For more information see [Thermal option](#) in the *ECLIPSE Technical Description*.

## Example

In a thermal run with 4 hydrocarbon components:

```
CGDTYPE
EMIX EMIX EMIX EMIX /
```

## CGVTYPE

x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used with the [THERMAL](#) option to specify how the gas viscosity is computed, such as using the Lorentz-Bray-Clark viscosities. With the keyword present an equation of state (EoS) can be used.

The keyword should be followed by one value for each component. The value should be one of the following:

Type	Component
NO	Not used. The viscosity for this component is computed as if this keyword was not present.
LMIX	The LBC viscosity model is applied with these components' gas phase molar density.
LEMIX	The LBC viscosity model is applied on the LEMIX components densities where an EoS is used to compute the phase molar density.

Table 3.4: CGVTYPE component values

If the keyword is present the default is LMIX.

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

**Note:** If only a subset of the mixture is modeled by an EoS and many of the heavy components are included, and the light components are not, the mixture could yield a molar volume similar to that of an OIL and consequently the viscosity will be similar to that of an oil.

For more information see the [Thermal option](#)" in the *ECLIPSE Technical Description*.

## CHANDIMS **Increase well dimensions**

	<b>ECLIPSE 100</b>
x	<b>ECLIPSE 300</b>
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword allows the well dimensioning information, initially entered using [WELLDIMS](#), to be increased in the Schedule section. This might be done if one of the well dimension limits is exceeded, particularly during a “fast restart” run.

The format of the keyword is similar to [WELLDIMS](#). The data consisting of the following integers which describe the dimensions of the well data to be used in the run.

Items may be defaulted, in which case they will retain their original values. No action will be taken if none of the dimensions is increased.

In order to increase the size of the well arrays concerned, the existing arrays are written to a scratch file, the space used compressed out, the arrays reallocated and read back. This is a fairly expensive process, and it is always preferable to set up sufficiently large [WELLDIMS](#) dimensions initially. In fact the use of [CHANDIMS](#) may be avoided altogether by using “flexible restarts”, which allow the well dimensions to be increased at each restart (see keyword [RESTART](#)).

The data items entered are:

- The maximum number of wells  
DEFAULT: Same as the value set in [WELLDIMS](#)
- The maximum number of completions per well.  
DEFAULT: Same as the value set in [WELLDIMS](#)
- The maximum number of groups.  
DEFAULT: Same as the value set in [WELLDIMS](#)
- The maximum number of wells in a group, or child groups in a group.  
DEFAULT: Same as the value set in [WELLDIMS](#)
- The maximum number of stages per separator including the last, which represents the stock tank.  
DEFAULT: Same as the value set in [WELLDIMS](#)
- The maximum number of wellstreams.  
DEFAULT: Same as the value set in [WELLDIMS](#)
- The maximum number of mixtures.  
DEFAULT: Same as the value set in [WELLDIMS](#)
- The maximum number of separator conditions.  
DEFAULT: Same as the value set in [WELLDIMS](#)
- The maximum number of mixture items.  
DEFAULT: Same as the value set in [WELLDIMS](#)
- Item not used.
- The maximum number of well lists that a well may belong to at any one time.  
DEFAULT: Same as the value set in [WELLDIMS](#)

12. The maximum number of dynamic well lists in the simulation.

DEFAULT: Same as the value set in WELLDIMS

---

**CAUTION:** CHANDIMS must not be used to change any well dimensions if the run contains any multisegment wells. Well dimensions may still be changed, however, in flexible restarts using the RESTART keyword.

---

## Example

```
CHANDIMS  
20 40 4* 10 4 /
```

## Requests completion of the circle

This keyword requests that non-neighbor connections be generated to complete the circle in radial geometry. These connections act between the last cell in the azimuthal,  $\theta$ , direction, and the first cell, for each layer and ring of cells in the R-direction.

Such connections are only generated if the grid subtends 360 degrees, so that the first and last cells are in contact.

This keyword has no items, and only has an effect if the [RADIAL](#) keyword is specified in the RUNSPEC section.

### Example

```
CIRCLE

	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword turns on the CO<sub>2</sub> Solution option. The CO<sub>2</sub> component is then allowed to exist in all three phases. This keyword cannot be used if directional saturation table end-point scaling is used (switched on by setting the first item of keyword [ENDSCALE](#) to DIRECT).

CO2SOL is the only keyword required for this option. There are several optional keywords which can be used to modify the solubility and define initial conditions.

If the CO2SOL keyword is used on its own, default formulae will be used to create solubility tables. The default formulae depend on the salinity, which is taken to be zero, unless specified by one of the following keywords:

[SALINITY](#) Define the salinity.

[SALINITR](#) Define the salinity on a regional basis.

Alternatively, user specified solubility tables can be entered using one of the following keywords:

[SOLUBILI](#) This allows values in the default solubility table to be entered by the user.

[SOLUBILS](#) This allows the user to enter a solubility table with salt dependencies.

[SOLUBILT](#) This allows the user to enter a solubility table with temperature dependencies.

The following keywords can optionally be used to set initial conditions:

[RSWVD](#) This specifies the initial variation of aqueous CO<sub>2</sub> gas-water ratio versus depth.

[RSW](#) This specifies the initial variation of aqueous CO<sub>2</sub> gas-water ratio by enumeration.

[AMF](#) This specifies the initial composition of aqueous CO<sub>2</sub> system.

For further information see "[CO<sub>2</sub>/H<sub>2</sub>S solution in the aqueous phase](#)" in the *ECLIPSE Technical Description*.

## COALADS

## Gas/solvent relative adsorption data

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

Either the COALADS keyword or the COALPP keyword should be used to specify the relative adsorption data in runs containing solvent. The COALADS keyword tabulates simple relative adsorption factors for the gas (methane) and solvent. See "Coal bed methane model" in the *ECLIPSE Technical Description* for further information.

The data comprises NTCREG (see keyword REGDIMS, item 6) tables of gas/solvent relative adsorption functions, each terminated by a slash (/).

The tables consist of 3 columns of data. The first column is the phase fraction of gas,  $S_{\text{gas}} / (S_{\text{gas}} + S_{\text{solvent}})$ . The next two columns are respectively the relative adsorption of gas ( $F_g$ ) and the relative adsorption of solvent ( $F_s$ ).

Column:

1. The gas phase fraction ( $f_g$ ). Values should span the range 0 to 1 and increase monotonically down the column.
2. The corresponding gas relative adsorption ( $F_g$ ). Values should be between 0 and 1 and should be level or increasing down the column.
3. The corresponding solvent relative adsorption ( $F_s$ ). Values should be between 0 and 1 and should be level or decreasing down the column.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (see keyword TABDIMS).

The surface concentration of gas and solvent at a given pressure and composition are given by:

$$\text{Surface concentration of gas} = C_g(P) \cdot F_g(f_g)$$

$$\text{Surface concentration of solvent} = C_s(P) \cdot F_s(f_g)$$

where

$C_g(P)$  is the adsorption of pure gas at pressure  $P$  (LANGMUIR keyword)

$C_s(P)$  is the adsorption of pure solvent at pressure  $P$  (LANGSOLV keyword)

$F_g$  is the gas relative adsorption

$F_s$  is the solvent relative adsorption

$f_g$  is the fraction of gas in the fracture ( $= S_g / (S_g + S_{\text{solv}})$ )

The coal region number COALNUM is used to look up the table.

If item 180 of the OPTIONS keyword is activated, the number of tables should equal NTSFUN (see keyword TABDIMS) and the region keyword SATNUM is used to look up the table.

## Example

Where NTCREG is 2 and NSSFUN is  $\geq 4$ .

COALADS	Fg	Fs
--		
0.0	0.0	1.0
1.0	1.0	0.0

## COALNUM Coal regions

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The COALNUM keyword is used with the coal bed methane option to define regions with coal. The region number entered with this keyword is used to determine the sorption of the coal. See keyword [LANGMEXT](#) (ECLIPSE 300) or keyword [LANGMUIR](#). A zero value implies there is no coal and that the standard dual porosity fluid flow equations should be solved. The keyword should be followed by one integer for each grid cell in the matrix. The data entries should not exceed NTCREG entered using keyword [REGDIMS](#) in the RUNSPEC section (item 6). The data must be terminated by a slash (/).

Any matrix cell not explicitly assigned a COALNUM value will be defaulted to a value of unity (ECLIPSE 300).

If the keyword is not present all matrix cells are assigned a value of unity.

---

**Note:** If a non-coal region is specified, the usual matrix porosities and permeabilities must be entered for the region.

---

### Examples

A 11\*11\*2 dual porosity grid with a coal matrix. Top layer is matrix, bottom layer is fracture.

```
COALNUM
121*1
121*0 /
```

A 4\*4\*3 single porosity grid with two layers of coal and one layer without coal. This example is based on the use of the E300 instantaneous desorption model.

```
COALNUM
16*1
16*2
16*0 /
```

## COALNUMR Redefine coal region numbers for matrix subcells

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The COALNUMR keyword is used with the Coal Bed Methane option to define variation in the adsorbed gas behavior of subgrid matrix cells when the multi porosity option is used. For more information, see "Multi porosity" in the *ECLIPSE Technical Description*. This keyword redefines the coal region numbers for subgrid matrix cells. This keyword is optional. By default all subgrid matrix cells will be assigned the coal region number assigned to the grid cell with keyword COALNUM. Please note that if COALNUM is not present all matrix cells will be assigned coal region number 1 by default.

The keyword requires one record for each COALNUM region to be provided with subgrid coal region number variation. Each record starts with the identifier coal region number. The following region numbers represent the 'new' coal region number of all matrix cells, first the outermost cell followed by the nested subcell's coal region numbers. The first entry acts therefore as an identification number followed by NMATRIX entries. The maximum number of records is limited by REGDIMS item 6. The diffusion data for the coal regions are specified with DIFFCBM, while the adsorption characteristics are specified with the keyword LANGMEXT.

The first item of each record must be in increasing order.

Default values:

- The first item must not be defaulted and correspond to a coal region number already specified for the outermost primary matrix grid cells.
- The following numbers can be defaulted.
  - The outermost primary matrix cells and intermediate subgrid matrix cells will not be assigned any coal region number and no adsorbed gas is associated with these cells.
  - The inner subgrid matrix cells will be assigned the coal region number as specified in the primary matrix grid cells (same as the first item).

If a record is missing, the innermost subgrid matrix cells will be assigned the coal region number from the primary matrix grid cell and the other subgrid matrix cells will be conventional pore volume cells.

---

**Note:** Using this keyword with default values alter the coal region numbers so only the innermost subgrid matrix cells are assigned a coal region number.

---

For further information see "Coal bed methane model" in the *ECLIPSE Technical Description*.

Each record must be terminated by a slash(/) and the keyword is terminated by a second slash (/).

### Examples

#### Example 1

This example assumes that the user has specified two matrix cells using the NMATRIX keyword and that two coal region numbers are set with COALNUM. The primary matrix grid cells with region number 1 are redefined to have no coal region number, the next subgrid matrix cell uses the Langmuir /diffusion data for region number 1. Next record is for cells with region number 2. These are also set to conventional pore volume cells while the inner subgrid matrix cells uses coal region number 3.

```
COALNUMR
1 0 1 /
2 0 3 /
/
```

## Example 2

In this example we assume that the instant desorption model is used, see [CBMOPTS](#). A coal region can then be defined for each of the subgrid matrix cells, while the time dependent method requires coal connections to be with pore volume grid cells or to cells with the same coal region numbers. Recall that for the instant desorption model coal cells also have pore volume.

Coal region number 1 in the primary matrix grid cells is set to 1. For the submatrix grid cells we get coal region number 2. The next record tells that coal region number 2 in the primary matrix grid cells is set to 1, while the following subgrid matrix cells get coal region number 3.

```
COALNUMR  
1 1 2/  
2 1 3/  
/
```

## COALPP

## Gas/solvent partial pressure data

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

Either the COALPP or the COALADS keyword should be used to specify the relative adsorption data in runs containing solvent. The COALPP keyword tabulates the pressure factor used in a partial pressure model of the relative adsorption. See "Coal bed methane model" in the *ECLIPSE Technical Description* for further information.

The data comprises NTCREG (see keyword REGDIMS, item 6) tables of gas/solvent relative adsorption functions, each terminated by a slash (/).

The tables consist of 3 columns of data. The first column is the phase fraction of gas,  $S_{\text{gas}} / (S_{\text{gas}} + S_{\text{solvent}})$ . The next two columns are respectively the relative adsorption of gas ( $F_g$ ) and the relative adsorption of solvent ( $F_s$ ).

Column:

1. The gas phase fraction ( $f_g$ ). Values should span the range 0 to 1 and increase monotonically down the column.
2. The corresponding gas relative adsorption ( $F_g$ ). Values should be between 0 and 1 and should be level or increasing down the column.
3. The corresponding solvent relative adsorption ( $F_s$ ). Values should be between 0 and 1 and should be level or decreasing down the column.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (see keyword TABDIMS).

The surface concentration of gas and solvent at a given pressure and composition are given by:

$$\text{Surface concentration of gas} = C_g(P \cdot F_g(f_g))$$

$$\text{Surface concentration of solvent} = C_s(P \cdot F_s(f_g))$$

where

$C_g(P \cdot F_g(f_g))$  is the adsorption of gas at partial pressure  $P \cdot F_g(f_g)$  (LANGMUIR keyword)

$C_s(P \cdot F_s(f_g))$  is the adsorption of solvent at partial pressure  $P \cdot F_s(f_g)$  (LANGSOLV keyword)

$F_g$  is the gas pressure multiplier

$F_s$  is the solvent pressure multiplier

$f_g$  is the fraction of gas in the fracture ( $= S_g / (S_g + S_{\text{solv}})$ )

The coal region number COALNUM is used to look up the table.

If item 180 in OPTIONS is activated, the number of tables should equal NTSFUN (see keyword TABDIMS) and the region keyword SATNUM is used to look up the table.

### Example

With NTCREG=1 and NSSFUN≥4. Unmodified partial pressure model.

```
COALPP
--      Fg   Fs
   0.0  0.0  1.0
   1.0  1.0  0.0
/
```

## COARSEN Specifies a box of cells for grid coarsening

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword is followed by any number of records, each containing the following items of data, and each terminated by a slash (/).

Each record describes a box of grid cells for coarsening.

The data items are as follows:

1. Lower I-coordinate of the box (I1)
2. Upper I-coordinate of the box (I2)
3. Lower J-coordinate of the box (J1)
4. Upper J-coordinate of the box (J2)
5. Lower K-coordinate of the box (K1)
6. Upper K-coordinate of the box (K2)
7. Number of coarsened cells along the X-direction in this box (NX)

NX must be an exact factor of  $I2 - I1 + 1$ .

DEFAULT: 1

8. Number of coarsened cells along the Y-direction in this box (NY)

NY must be an exact factor of  $J2 - J1 + 1$ .

DEFAULT: 1

9. Number of coarsened cells along the Z-direction in this box (NZ)

NZ must be an exact factor of  $K2 - K1 + 1$ .

DEFAULT: 1

The set of records must end with a blank record containing just a slash.

The Grid Coarsening option is described in further detail in "[Local grid coarsening](#)" in the *ECLIPSE Technical Description*.

### Notes

In addition, the following conditions must be satisfied:

$$1 \leq I1 \leq I2 \leq NX$$

$$1 \leq J1 \leq J2 \leq NY$$

$$1 \leq K1 \leq K2 \leq NZ.$$

The data items specified above divides the box  $I1 - I2$ ,  $J1 - J2$ ,  $K1 - K2$  into  $NX * NY * NZ$  coarse cells.

Grid coarsening automatically generates non-neighbor connections. Transmissibilities and diffusivities across the cells are modified accordingly. If the [NONNC](#) keyword has been entered in RUNSPEC section, an error message is issued, and this option is disallowed.

It is important to note that coarsening boxes must not overlap one another, although they may join together. Furthermore, coarsening boxes should not overlap any local grid refinement.

ECLIPSE 100

The parameter specified as the 3rd item (MCOARS) in keyword [LGR](#) in the RUNSPEC section must be set equal to or greater than the total number of coarse cells. See also the keyword [AUTOCOAR](#).

## Example

An example using a 6 x 6 x 1 grid.

```
COARSEN
- I1 I2 J1 J2 K1 K2 NX NY NZ
  1  6  1  2  1  1  3  1  1  /
  1  2  3  4  1  1  1  1  1  /
  5  6  3  4  1  1  1  1  1  /
  1  6  5  6  1  1  3  1  1  /
/
```

## CODTYPE

## Component oil density type

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used with the [THERMAL](#) option to specify how the oil phase molar density is computed. With the keyword present an equation of state (EoS) can be used. The default equation of state is Peng-Robinson (PR). If the [EOS](#) keyword is used, the equations of state are the ones defined in the item of EOS. All of the keyword necessary for the EoS, such as BIC, need to be added in the PROPS section when using the CODTYPE keyword (even when all items are NO).

The keyword should be followed by one value for each component. The value should be one of the following:

Type	Component
NO	Not used. The molar volume for this component is computed as if this keyword was not present.
EMIX	An equation of state is used for the EMIX components. The liquid root of the cubic equation of state is always used.
EGFE	An equation of state is used for the EGFE components. The molar volume is chosen to be the volume with the lowest Gibbs free energy. Thus a vapor molar volume would be used if the stable phase at the given pressure and composition corresponds to a vapor.

Table 3.5: CODTYPE component values

If the keyword is present the default is EMIX.

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

**Note:** If only a subset of the mixture is modeled by an EoS and many of the light components are included, and the heavy components are not, the mixture could yield a molar volume similar to that of a GAS.

For more information see [Thermal option](#) in the *ECLIPSE Technical Description*.

## Example

In a thermal run with 4 hydrocarbon components:

```
CODTYPE
EMIX EMIX EMIX EMIX /
```

## COLLAPSE Identifies collapsible cells in the compressed VE option

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The COLLAPSE keyword may optionally be used in compressed VE runs (keyword [VE](#) in the RUNSPEC section). It specifies which cells can be collapsed, or merged with other cells in the same column, to form the larger compressed VE cells.

The keyword should be followed by one integer for each grid cell in the model. The integers should be equal to either 0 or 1:

0 Implies that a cell will not be merged with its lower neighbor.

1 Implies that a cell is available to be merged with its lower neighbor.

DEFAULT: 1 (throughout the grid.)

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*1). Note that spaces must not be inserted on either side of the asterisk.

A cell merges with the next active cell below, provided that **none** of the following situations occur:

- COLLAPSE = 0 for that cell
- TRANZ = 0.0
- $PERMZ \leq$  critical value entered in [CRITPERM](#), if this keyword is present
- There is an inactive cell with  $DZ > 0.0$  between the two active cells
- Either cell has been refined using [RADFIN](#) or [CARFIN](#) (see "[Local grid refinement and coarsening](#)" in the *ECLIPSE Technical Description*).

See also keyword [CRITPERM](#) and "[Compressed vertical equilibrium option](#)" in the *ECLIPSE Technical Description*.

### Examples

#### Example 1

To keep the top layer as original cells. (NDIVIX =10, NDIVIY =10 and NDIVIZ =4 as specified in RUNSPEC keyword [DIMENS](#).)

```
COLLAPSE
100*0
100*1
100*1
100*1
100*1 /
```

#### Example 2

To return the model to a full 3D VE model. (NDIVIX =10, NDIVIY =10, NDIVIZ =4)

```
COLLAPSE
400*0 /
```

## COLUMNS

**Sets the left and right margins for the input data file**

x	ECLIPSE 100
	ECLIPSE 300
	<b>SPECIAL</b>
x	RUNSPEC
x	GRID
x	EDIT
x	PROPS
x	REGIONS
x	SOLUTION
x	SUMMARY
x	SCHEDULE

Sets the left and right margins of an input data file. Only the data within the margins and at the margins is read and processed by the free format input parser.

The keyword should be followed by a line containing two integers (the left and right margin settings respectively), terminated with a slash (/). Their values must lie between 1 and 132, and the right margin setting must be greater than the left margin setting.

The default settings of the margins are 1 and 132 for the left and right margins respectively.

Suppose an input data file contained line numbers on the right side at columns 72-80, by setting the right margin to 71 these line numbers are ignored and not read in. Also an input data file may contain a carriage control character at column 1, then to prevent reading in column 1 the user may set the left margin to 2.

**Example**

```
COLUMNS
 1 71 / Sets left margin at 1 and right margin at 71
COLUMNS
 2 80 / Sets left margin at 2 and right margin at 80
```

## COMPAGH Completion gravity head

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

COMPAGH is used to set the gravity head for a completion. The pressure at each completion,  $P_{comp}$ , is calculated by:

$$P_{comp} = P_{BH} + AGH \cdot (D_{comp} - D_{BH}) \quad \text{Eq. 3.14}$$

where:

$P_{BH}$  Pressure at bottom hole reference depth

$AGH$  Average gravity head between  $D_{comp}$  and  $D_{BH}$

$$AGH = \left( \int_{D_{comp}}^{D_{BH}} \rho(\delta) g d\delta \right) / \left( \int_{D_{comp}}^{D_{BH}} d\delta \right) \quad \text{Eq. 3.15}$$

$D_{comp}$  Depth of completion

$D_{BH}$  Depth at which bottom hole pressure is defined

Each completion's pressure head is calculated using the average gravity head value specified in this keyword and the difference in depth between the completion and the reference depth. The average gravity head values specified here overrides those values calculated internally by ECLIPSE 300, based on completion inflows (see item 12 of keyword [WELSPECS](#)).

The keyword is followed by any number of records, each containing the items of data described below, and each terminated by a / character.

The records can be terminated early using the / character, the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. I - location of connecting grid block(s)  
DEFAULT: 0 (allows any I-value)
3. J - location of connecting grid block(s)  
DEFAULT: 0 (allows any J-value)
4. K - location of upper connecting block in this set of data  
DEFAULT: 0 (corresponds to top connection of well)
5. K - location of lower connecting block in this set of data  
DEFAULT: 0 (corresponds bottom top connection of well)

6. *AGH*, the average gravity head

UNITS: bars/m (METRIC), psi/ft (FIELD), atm/cm (LAB), atm/m (PVT-M)

DEFAULT: 0.0

### Example

```
COMPAGH  
WELL1 18 6 8 23 0.04 /  
/
```

## COMPAGHL Completion gravity head in local refined grids

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

COMPAGHL is used to set the gravity head for a completion in a local refined grid (LGR) cell. The keyword data is similar to that for [COMPAGH](#), except that there is an additional item at position 2 which gives the name of the LGR in which the completion is located.

The pressure at each completion,  $P_{comp}$ , is calculated by:

$$P_{comp} = P_{BH} + AGH \cdot (D_{comp} - D_{BH}) \quad \text{Eq. 3.16}$$

where

$P_{BH}$  Pressure at bottom hole reference depth

$AGH$  Average gravity head between  $D_{comp}$  and  $D_{BH}$ ,

$$AGH = \left( \int_{D_{comp}}^{D_{BH}} \rho(\delta) g d\delta \right) / \left( \int_{D_{comp}}^{D_{BH}} d\delta \right) \quad \text{Eq. 3.17}$$

$D_{comp}$  Depth of completion

$D_{BH}$  Depth at which bottom hole pressure is defined

Each completion's pressure head is calculated using the average gravity head value specified in this keyword and the difference in depth between the completion and the reference depth. The average gravity head values specified here will override those values calculated internally by ECLIPSE 300, based on completion inflows (see item 13 of keyword [WELSPECL](#)).

The keyword is followed by any number of records, each containing the items of data described below, and each terminated by a / character.

The records can be terminated early using the / character, the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Local grid name
3. I - location of connecting grid block(s) within the local grid  
DEFAULT: 0 (allows any I-value)
4. J - location of connecting grid block(s) within the local grid  
DEFAULT: 0 (allows any J-value)
5. K - location of upper connecting block within the local grid in this set of data  
DEFAULT: 0 (corresponds to top connection of well)

6. K - location of lower connecting block within the local grid in this set of data  
DEFAULT: 0 (corresponds to bottom connection of well)
7. AGH, the average gravity head  
UNITS: bars/m (METRIC), psi/ft (FIELD), atm/cm (LAB), atm/m (PVT-M)  
DEFAULT: 0.0

### Example

## COMPDAT Well completion specification data

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

COMPDAT specifies the position and properties of one or more well completions. This must be entered after the [WELSPECS](#) keyword defining the appropriate well.

The keyword is followed by any number of records, described below, each record terminated by a slash (/). A record may be terminated at any item after item 9; the remaining items will assume their default values. If the well bore diameter is not required (see item 9), the record can be terminated after item 8.

A single record can be used to assign the properties of several connections of a well, as long as they are situated in the same vertical column of grid blocks. A deviated well can be completed in more than one column, but each column requires a separate record.

The set of records must end with a blank record, containing only a slash (/).

### 1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

### 2. I - location of connecting grid block(s)

If set to 0 or defaulted, the I - location of the well head (entered in keyword [WELSPECS](#)) will be used.

### 3. J - location of connecting grid block(s)

If set to 0 or defaulted, the J - location of the well head (entered in keyword [WELSPECS](#)) will be used.

### 4. K - location of upper connecting block in this set of data

### 5. K - location of lower connecting block in this set of data

The following data then applies to each layer (or connection) with K - locations between the upper and lower values given above.

### 6. Open/shut flag of connection

OPEN Connection open to flow

SHUT Connection closed off

*ECLIPSE 100 only*

AUTO Connection initially closed, but will be opened automatically when another connection in the well is closed during an automatic workover. A connection on AUTO is opened each time the well is worked over, in the order in which the connections are first defined in COMPDAT. Connections on AUTO are also opened when necessary to maintain group production rate targets if the [REPERF](#) action is selected in keyword [PRORDER](#).

*ECLIPSE 300 Thermal*

HEAT Connection is defined to model heat transfer to the formation when using the multisegment well model. Heat connections cannot be opened to fluid flow during the simulation.

*ECLIPSE 300 only*

In pre-2012.1 releases, any input other than SHUT would result in an OPEN connection. This behavior has been changed in subsequent releases so that only OPEN, SHUT or HEAT can be entered.

DEFAULT: OPEN

### 7. Saturation table number for connection relative permeabilities

If a default, zero or negative value is entered, the relative permeabilities are calculated using the same saturation table as the grid block containing the connection, selected with keyword `SATNUM`.

In runs using the Hysteresis option (keyword `SATOPTS` in `RUNSPEC`), the saturation table number entered here apply to both imbibition and drainage processes. If a different table number is required for imbibition, it should be set using `COMPIMB` after the `COMPDAT` keyword. If a default, zero or negative value is entered, the respective tables for the grid block containing the connection (defined using `SATNUM` for the drainage table and `IMBNUM` for the imbibition table) is used.

ECLIPSE 100

In runs using the Vertical Equilibrium option (keyword `VE` in `RUNSPEC`) the end-points of the saturation table are used to calculate the contact depths and relative permeabilities at the well connection.

ECLIPSE 300

If the `ODD3P` relative permeability and capillary pressure hysteresis model has been selected and a non-default saturation table number is specified, this will be ignored.

#### 8. Transmissibility factor for the connection

If defaulted or set to zero, the connection transmissibility factor is calculated using the remaining items of data in this record. See "[The connection transmissibility factor](#)" in the *ECLIPSE Technical Description* for an account of the methods used in Cartesian and radial geometries. The well bore diameter must be set in item 9.

UNITS: cP.rm<sup>3</sup>/day/bars (`METRIC`), cP.rb/day/psi (`FIELD`), cP.rcc/hr/atm (`LAB`), cP.rm<sup>3</sup>/day/atm (`PVT-M`)

- If the well is situated on an edge (or a corner) of a Cartesian grid, for example in a sector model or symmetry element, use keyword `WPIMULT` after `COMPDAT` to scale the resulting connection factors by 0.5 (or 0.25).
- A well connection in an outer-most block of a radial grid (`I = NDIVIX`, which is specified in `RUNSPEC` keyword `DIMENS`) is assumed to occupy the entire outer boundary of the block for the purpose of applying boundary conditions. If you wish to model a real well in an outer block of a radial grid, the calculated connection factor will be much too large. In this case, you should either supply an appropriate connection factor value yourself, or add an extra ring of inactive cells so that the well is no longer in an outer block.

If a value > 0.0 is entered, the connection transmissibility factor is set to this value. The value will also be used to calculate either the connection's effective Kh or the denominator term  $\ln(r_o/r_w) + S$  according to the following rules:

- If the Kh value in item 10 is defaulted or set negative, and the well bore diameter set in item 9, the Kh value is calculated from the connection transmissibility factor and the denominator term. In this case, however, the Kh is only used for output (if Schedule data output is requested in `RPTSCHED`). The denominator term will be calculated from the grid block dimensions, as described in the "[The connection transmissibility factor](#)" in the *ECLIPSE Technical Description*.
- If the Kh value is set > 0.0, the denominator term is calculated from the connection transmissibility factor and the given Kh value, instead of the well bore radius and the grid block dimensions.
- If the Kh value is set = 0.0, it is replaced by the effective Kh of the grid block, then used to calculate the denominator term in the same way as if it had been set > 0.0.
- In ECLIPSE 100, the recalculation of Kh or the denominator term may be turned off by setting [item 45](#) in the `OPTIONS` keyword > 0. The denominator term is then always calculated from the

grid block dimensions and the well bore radius. This option can be used to achieve back-compatibility with pre-95A datasets, if required.

The denominator term is used when calculating the well's productivity/injectivity index and when calculating the effects of a D-factor (see "[Well Inflow Performance](#)" in the *ECLIPSE Technical Description*). Thus, when the connection factor is set to a positive value, the results of these calculations depend on the setting of the Kh value in item 10.

---

**Note:** If a positive value is entered for the connection transmissibility factor, this should include the effect of any skin entered in item 11, but exclude the effect of any D-factor. The effect of a D-factor is modeled separately by adjusting the mobility (see "[The flow-dependent skin factor](#)" in the *ECLIPSE Technical Description*).

---

#### 9. Well bore diameter at the connection

This quantity is required for:

- Calculating the connection transmissibility factor
- (If a zero or negative value was supplied for item 8)
- Calculating the well's productivity/injectivity index
- (If a positive value was supplied for the drainage radius in item 7 of keyword [WELSPEC3](#))
- Calculating the effects of a D-factor

The quantity is ignored if not required.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

ECLIPSE 300

DEFAULT: 1 ft = 0.3048 m

ECLIPSE 100

DEFAULT: Undefined.

#### 10. Effective Kh (permeability x thickness) value of the connection

If a default, zero or negative value is entered, the Kh value is calculated from the grid block data.

If a positive value for the connection transmissibility factor is entered in item 8, the calculation of the denominator term depends on whether the Kh value is set or defaulted. See item 8.

This quantity is required for calculating the connection transmissibility factor (if a default or zero value was supplied for item 8). It is ignored if not required.

UNITS: mD.m (METRIC), mD.ft (FIELD), mD.cm (LAB), mD.m (PVT-M)

DEFAULT: Negative

#### 11. Skin factor

This quantity is used for the same purposes as listed for item 9. It is ignored if not required.

Large negative skin factors can cause problems if they increase the effective wellbore radius to approach the pressure equivalent radius of the grid block. Very high values of the connection transmissibility factor may result, which could cause convergence problems. In these circumstances, it may be preferable to change the grid block data near the well to model the physical cause of the negative skin (for example enhance the permeability out to a certain distance from the well). If the effective wellbore radius is increased beyond the pressure equivalent radius, the connection factor becomes negative and an error message is issued.

ECLIPSE 100

A warning message will be issued if the effective wellbore radius increases beyond half the pressure equivalent radius, or extends outside the grid block.

DEFAULT: 0.0

12. D-factor, for handling the effects of non-Darcy flow of free gas

A D-factor measured for the well should preferably be entered with keyword `WDFAC`, and this item should be left defaulted. But it may be entered here instead, for back-compatibility with old ECLIPSE 100 datasets. ECLIPSE converts the well D-factor into D-factors for the connections. See the `WDFAC` keyword for information on how the conversion is performed. Note that the well D-factor must reflect the current number of open connections at the time it is specified.

If you wish to enter the connection's D-factor directly, you can enter it here with a negative sign. A negative sign tells ECLIPSE to regard it as the connection's D-factor rather than the well's D-factor. ECLIPSE simply reverses its sign without applying any conversion.

UNITS: day/sm<sup>3</sup> (METRIC), day/Mscf (FIELD), hr/scc (LAB), day/sm<sup>3</sup> (PVT-M)

DEFAULT: "Keep the current value of the connection's D-factor"

13. Direction in which the well penetrates the grid block

X the well penetrates the grid block in the X direction

Y the well penetrates the grid block in the Y direction

Z the well penetrates the grid block in the Z direction

ECLIPSE 300 only

FX the well is completed in a fracture in the X direction

ECLIPSE 300 only

FY the well is completed in a fracture in the Y direction

DEFAULT: z

In radial grids, only penetration in the Z direction is allowed.

ECLIPSE 300

For Cartesian grids in ECLIPSE 300, if a direction other than Z is specified, the `HWELLS` keyword must be included in the RUNSPEC section. If FX or FY is specified, the keyword `FWELLS` must be included in the RUNSPEC section.

This item is used in calculating the transmissibility factor of the connection if it was not supplied in item 8. In Cartesian grids the Peaceman formula is used, taking the components of permeability and grid block dimensions appropriate to the direction of penetration (see "[The connection transmissibility factor](#)" in the *ECLIPSE Technical Description*). Note that the formula assumes that the well completely penetrates a rectangular block through its center in a direction perpendicular to two of its faces.

This item also influences the way ECLIPSE orders the connections in the well (except for friction and multisegment wells) if the default TRACK method is used. See keyword `COMPORD` for further details.

14. Pressure equivalent radius,  $r_o$

If a value > 0.0 is entered,  $r_o$  is set to this value instead of being calculated from the grid block dimensions according to Peaceman's formula (see "[The connection transmissibility factor](#)" in the *ECLIPSE Technical Description*). Note that the pressure equivalent radius is not used for connections in the innermost or outermost cells of a radial grid or, in ECLIPSE 300, for wells completed in fractured cells.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: Calculate  $r_o$  from Peaceman's formula

## Notes

ECLIPSE 100

- The calculated values of the connection transmissibility factor and Kh (if defaulted) can be examined by requesting a printout of the SCHEDULE section keyword data (argument WELSPECS in keyword [RPTSCHED](#)). The connection transmissibility factor can also be written to the SUMMARY file with the SUMMARY section keyword CTFAC.
- If you wish to prevent inter-block flow (for example due to shale breaks or faults), use keywords [MULTZ](#) and [MULTX](#) for example to set a zero transmissibility multiplier. Don't set the rock permeability to zero instead, as it is needed to calculate the connection transmissibility factor.
- There is a choice of methods for determining the ordering of the connections along the wellbore. See keyword [COMPORD](#) for further details.

ECLIPSE 300

- If non-Darcy Forchheimer effects for gas flow have been enabled using item 4 of the [VELDEP](#) keyword, then a D-factor for each production well connection will be calculated. These calculated, Forchheimer parameter based D-Factors will override any set in this keyword. See "[Forchheimer parameter based well D-factors](#)" in the *ECLIPSE Technical Description* for further details.

## COMPDATL Completion data for wells in local grids

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

COMPDATL must be used in place of [COMPDAT](#) to specify the connection data for wells in local refined grids, after the wells have been introduced with keyword [WELSPECL](#).

The keyword data for COMPDATL is the same as for COMPDAT, except for an extra item (item 2) which names the local grid containing the connections specified in the record. The well may be completed in more than one local grid, but in ECLIPSE 100 these local grids must be amalgamated using the keyword [AMALGAM](#).

---

**Note:** In ECLIPSE 100, the format of this keyword was altered in the 2000A release, with the addition of the local grid name in item 2. This makes it compatible with the ECLIPSE 300 form of the keyword. It is now the same as the [COMPDATM](#) keyword in ECLIPSE 100, which is treated as an alias for COMPDATL. For back compatibility, ECLIPSE 100 still recognizes and reads the old form of COMPDATL if this is entered. The form of the keyword (as in 2000A and after) is distinguished by item 6 being an integer (it must not be defaulted), or alternatively item 2 being a character string which is not a pure integer, or item 7 being a character string beginning with a letter. If any of these conditions is true ECLIPSE 100 recognizes the keyword as the new form, otherwise it reads it as an old form of the keyword.

---

The keyword is followed by any number of records, described below, each record terminated by a slash (/). A record can be terminated early using a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Local grid name

*ECLIPSE 100*

The local grids that the well is completed in must belong to the same amalgamation (see keyword [AMALGAM](#)).

3. I - location of the connecting grid block(s) within the local grid

This item can be set to 0 or defaulted if the local grid named in item 2 is the same as the well's local grid entered in [WELSPECL](#); the I - location of the well head (entered in keyword [WELSPECL](#)) will then be used.

4. J - location of the connecting grid block(s) within the local grid This item can be set to 0 or defaulted if the local grid named in item 2 is the same as the well's local grid entered in [WELSPECL](#); the J- location of the well head (entered in keyword [WELSPECL](#)) will then be used.

5. K - location of upper connecting block in this set of data within the local grid

This item cannot be defaulted.

6. K - location of lower connecting block in this set of data within the local grid

This item cannot be defaulted.

The following data then applies to each layer (or connection) with K - locations between the upper and lower values given above.

7. Open/shut flag of connection

OPEN Connection open to flow

SHUT Connection closed off

*ECLIPSE 100 only*

AUTO Connection initially closed, but is opened automatically when another connection in the well is closed during an automatic workover. A connection on AUTO is opened each time the well is worked over, in the order in which the connections are first defined in COMPDATL. Connections on AUTO is also opened when necessary to maintain group production rate targets if the REPERF action is selected in keyword [PRORDER](#).

*ECLIPSE 300 Thermal*

HEAT Connection is defined to model heat transfer to the formation when using the multisegment well model. Heat connections cannot be opened to fluid flow during the simulation.

*ECLIPSE 300 only*

In pre-2012.1 releases, any input other than SHUT would result in an OPEN connection. This behavior has now been changed so that only OPEN, SHUT or HEAT may be input.

DEFAULT: OPEN

8. Saturation table number for connection relative permeabilities

If a default, zero or negative value is entered, the relative permeabilities are calculated using the same saturation table as the grid block containing the connection, selected with keyword [SATNUM](#).

In runs using the hysteresis option (keyword [SATOPTS](#) in the RUNSPEC section), the saturation table number entered here will apply to both imbibition and drainage processes. If a different table number is required for imbibition, it should be set using [COMPIMB](#) after the COMPDATL keyword. If a default, zero or negative value is entered, the respective tables for the grid block containing the connection (defined using [SATNUM](#) for the drainage table and [IMBNUM](#) for the imbibition table) will be used.

*ECLIPSE 100*

In runs using the vertical equilibrium option (keyword [VE](#) in the RUNSPEC section) the end-points of the saturation table are used to calculate the contact depths and relative permeabilities at the well connection.

*ECLIPSE 300*

If the [ODD3P](#) relative permeability and capillary pressure hysteresis model has been selected and a non-default saturation table number is specified, this will be ignored.

9. Transmissibility factor for the connection

If defaulted or set to zero, the connection transmissibility factor are calculated using the remaining items of data in this record. See "[Well inflow performance](#)" in the *ECLIPSE Technical Description* for an account of the methods used in Cartesian and radial geometries. The well bore diameter must be set in item 10.

UNITS: cP.rm<sup>3</sup>/day/bars (METRIC), cP.rb/day/psi (FIELD), cP.rcc/hr/atm (LAB), cP.rm<sup>3</sup>/day/atm (PVT-M)

Note the following two points:

- If the well is situated on an edge (or a corner) of a Cartesian grid, for example in a sector model or symmetry element, use keyword [WPIMULTL](#) after COMPDATL to scale the resulting connection factors by 0.5 (or 0.25).

- A well connection in an outermost block of a radial grid ( $I = \text{NDIVIX}$  , which is specified in RUNSPEC keyword [DIMENS](#)) is assumed to occupy the entire outer boundary of the block for the purpose of applying boundary conditions. If you wish to model a real well in an outer block of a radial grid, the calculated connection factor is much too large. In this case, you should either supply an appropriate connection factor value yourself, or add an extra ring of inactive cells so that the well is no longer in an outer block.

If a value  $> 0.0$  is entered, the connection transmissibility factor is set to this value. The value is also used to calculate either the connection's effective Kh or the denominator term  $\ln(r_o/r_w) + S$  according to the following rules:

- If the Kh value in item 11 is defaulted or set negative, and the well bore diameter set in item 10, the Kh value is calculated from the connection transmissibility factor and the denominator term. In this case, however, the Kh is only used for output (if the mnemonic [WELSPEDS](#) is entered in [RPTSCHED](#)). The denominator term is calculated from the grid block dimensions, as described in the "[Well inflow performance](#)" in the *ECLIPSE Technical Description*.
- If the Kh value is set  $> 0.0$ , the denominator term will be calculated from the connection transmissibility factor and the given Kh value, instead of the well bore radius and the grid block dimensions.
- If the Kh value is set  $= 0.0$ , it is replaced by the effective Kh of the grid block, then used to calculate the denominator term in the same way as if it had been set  $> 0.0$ .
- The recalculation of Kh or the denominator term may be turned off by setting [item 45](#) of the [OPTIONS](#) keyword  $> 0$ . The denominator term is then always be calculated from the grid block dimensions and the well bore radius. This option can be used to achieve back-compatibility with pre-95A datasets, if required.

ECLIPSE 100

The denominator term is used when calculating the well's productivity/injectivity index and when calculating the effects of a D-factor (see "[Well inflow performance](#)" in the *ECLIPSE Technical Description*). Thus, when the connection factor is set to a positive value, the results of these calculations will depend on the setting of the Kh value in item 11.

---

**Note:** If a positive value is entered for the connection transmissibility factor, this should include the effect of any skin entered in item 12, but exclude the effect of any D-factor. The effect of a D-factor is modeled separately by adjusting the mobility (see "[The flow-dependent skin factor](#)" in the *ECLIPSE Technical Description*).

---

#### 10. Well bore diameter at the connection

This quantity is required for:

- Calculating the connection transmissibility factor  
(If a zero or negative value was supplied for item 9)
- Calculating the Well's Productivity/Injectivity Index  
(If a positive value was supplied for the drainage radius in item 8 of keyword [WELSPECL](#))
- Calculating the effects of a D-factor
- Calculating the equivalent global well's connection transmissibility factor.

ECLIPSE 100

UNITS: m ([METRIC](#)), ft ([FIELD](#)), cm ([LAB](#)), m ([PVT-M](#))

ECLIPSE 300

DEFAULT: 1 ft = 0.3048 m

ECLIPSE 100

DEFAULT: Undefined.

## 11. Effective Kh (permeability x thickness) value of the connection

If a default, zero or negative value is entered, the Kh value will be calculated from the grid block data.

If a positive value for the connection transmissibility factor is entered in item 9, the calculation of the denominator term depends on whether the Kh value is set or defaulted. See item 9.

This quantity is required for calculating the connection transmissibility factor (if a default or zero value was supplied for item 9). It is ignored if not required.

UNITS: mD.m (METRIC), mD.ft (FIELD), mD.cm (LAB), mD.m (PVT-M)

DEFAULT: Negative

## 12. Skin factor

This quantity is used for the same purposes as listed for item 10. It will be ignored if not required.

Large negative skin factors can cause problems if they increase the effective wellbore radius to approach the pressure equivalent radius of the grid block. Very high values of the connection transmissibility factor may result, which could cause convergence problems. In these circumstances, it may be preferable to change the grid block data near the well to model the physical cause of the negative skin (for example enhance the permeability out to a certain distance from the well). If the effective wellbore radius is increased beyond the pressure equivalent radius, the connection factor becomes negative and an error message is issued.

ECLIPSE 100

A warning message is issued if the effective wellbore radius increases beyond half the pressure equivalent radius, or extends outside the grid block.

DEFAULT: 0.0

## 13. D-factor, for handling the effects of non-Darcy flow of free gas

A D-factor measured for the well should preferably be entered with keyword `WDFAC`, and this item should be left defaulted. But it may be entered here instead, for back-compatibility with old ECLIPSE 100 datasets. ECLIPSE converts the well D-factor into D-factors for the connections. See the `WDFAC` keyword for information on how the conversion is performed. Note that the well D-factor must reflect the current number of open connections at the time it is specified.

If you wish to enter the connection's D-factor directly, you can enter it here with a negative sign. A negative sign tells ECLIPSE to regard it as the connection's D-factor rather than the well's D-factor. ECLIPSE simply reverses its sign without applying any conversion.

UNITS: day/sm<sup>3</sup> (METRIC), day/Mscf (FIELD), hr/scc (LAB), day/sm<sup>3</sup> (PVT-M)

DEFAULT: "Keep the current value of the connection's D-factor"

## 14. Direction in which the well penetrates the grid block

X the well penetrates the grid block in the X direction

Y the well penetrates the grid block in the Y direction

Z the well penetrates the grid block in the Z direction

ECLIPSE 300 only

FX the well is completed in a fracture in the X direction

ECLIPSE 300 only

FY the well is completed in a fracture in the Y direction

DEFAULT: z

In radial grids, only penetration in the Z direction is allowed.

ECLIPSE 300

For Cartesian grids in ECLIPSE 300, if a direction other than Z is specified, the [HWELLS](#) keyword must be included in the RUNSPEC section. If FX or FY is specified, the keyword [FWELLS](#) must be included in the RUNSPEC section.

This item is used in calculating the transmissibility factor of the connection if it was not supplied in item 9. In Cartesian grids the Peaceman formula is used, taking the components of permeability and grid block dimensions appropriate to the direction of penetration (see "[Well inflow performance](#)" in the *ECLIPSE Technical Description*). Note that the formula assumes that the well completely penetrates a rectangular block through its center in a direction perpendicular to two of its faces.

This item also influences the way ECLIPSE orders the connections in the well (except for friction and multisegment wells) if the default TRACK method is used. See keyword [COMPORD](#) for further details.

#### 15. Pressure equivalent radius, $r_o$

If a value  $> 0.0$  is entered,  $r_o$  is set to this value instead of being calculated from the grid block dimensions according to Peaceman's formula (see "[Well inflow performance](#)" in the *ECLIPSE Technical Description*). Note that the pressure equivalent radius is not used for connections in the innermost or outermost cells of a radial grid or, in ECLIPSE 300, for wells completed in fractured cells.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: Calculate  $r_o$  from Peaceman's formula

## Notes

ECLIPSE 100

- The calculated values of the connection transmissibility factor and Kh (if defaulted) can be examined by requesting a printout of the SCHEDULE section keyword data (argument WELSPECS in keyword [RPTSCHED](#)). The connection transmissibility factor can also be written to the SUMMARY file with the SUMMARY section keyword [LCTFAC](#).
- If you wish to prevent inter-block flow (for example due to shale breaks or faults), use keywords [MULTZ](#) and [MULTX](#) for example to set a zero transmissibility multiplier. Do not set the rock permeability to zero instead, as it is needed to calculate the connection transmissibility factor.
- There is a choice of methods for determining the ordering of the connections along the wellbore. See keyword [COMPORD](#) for further details.

## Example

```

COMPDATL
PROD1  CARF1  6  4  1  3  OPEN  0  0.0  0.333  500  3.5  1E-3  Z  /
PROD2  CARF2  3  5  3  3  OPEN  3  0.0  0.333  /
PROD3  CARF3  3  5  2  2  OPEN  0  1*  0.333  3*  X  /
PROD3  CARF3  4  5  2  3  OPEN  0  1*  0.333  3*  X  /
/

```

## COMPDATM **Completion data for wells in amalgamated local refined grids**

COMPDATM is an alias for [COMPDATL](#).

x	<b>ECLIPSE 100</b>
	<b>ECLIPSE 300</b>
x	<b>SPECIAL</b>

## COMPFLSH Flash transformation ratios for well connections

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

COMPFLSH may be used to specify transformation ratios, to transform well oil and gas production flows from differential liberation conditions to flash liberation conditions. For flexibility, the transformation ratios can be set independently for different well connections (ECLIPSE 100 only). The well connections must already have been defined with the keyword [COMPDAT](#).

COMPFLSH is followed by any number of records, described below, each terminated by a slash (/). The set of records must end with a blank record, containing only a slash (/).

Each record can contain some or all of the following items:

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. I - location of connecting grid block(s)

This item is not used in ECLIPSE 300 and must be defaulted.

DEFAULT: 0 (Allows any I-value)

3. J - location of connecting grid block(s)

This item is not used in ECLIPSE 300 and must be defaulted.

DEFAULT: 0 (Allows any J-value)

4. K - location of upper connecting block in this set of data

This item is not used in ECLIPSE 300 and must be defaulted.

DEFAULT: 0 (Corresponds to top connection of well)

5. K - location of lower connecting block in this set of data

This item is not used in ECLIPSE 300 and must be defaulted.

DEFAULT: 0 (Corresponds to bottom connection of well)

The following flash transformation ratios are applied to the currently defined connections in the well which match the location indices specified in items 2 - 5. But if a location index is defaulted to zero, it plays no part in selecting which connections use these ratios. Thus if the I and J location indices are defaulted to zero, the transformation ratios are applied to all connections in the well that are located between layers K1 and K2 specified in items 4 and 5. If all four location indices are defaulted, as required in ECLIPSE 300, the transformation ratios are applied to all the connections in the well.

6. Transformation ratio ( $F_1$ ) for oil formation volume factor at the bubble point, where

$$F_1 = \frac{B_{ob}(\text{flash}) - 1}{B_{ob}(\text{diff}) - 1} \quad \text{Eq. 3.18}$$

DEFAULT: 1.0

7. Transformation ratio ( $F_2$ ) for solution gas - oil ratio, where

$$F_2 = \frac{R_s(\text{flash})}{R_s(\text{diff})} \quad \text{Eq. 3.19}$$

DEFAULT: 1.0

8. Flash PVT table number.

If a number > 0 is entered, the transformation ratios entered in items 6 and 7 will be ignored, and instead the ratios are calculated at the beginning of each timestep from the respective equations using the properties of bubble point oil.  $B_{ob}(\text{diff})$  and  $R_s(\text{diff})$  are obtained from the PVT table of the grid block containing the connection (see keyword `PVTNUM`) at its bubble point pressure.  $B_{ob}(\text{flash})$  and  $R_s(\text{flash})$  are the properties of saturated oil, at the same bubble point pressure, obtained from the nominated flash PVT table.

A flash PVT table cannot be used in API tracking runs.

DEFAULT: 0

**Note:** Only the saturated oil properties in this table (keyword `PVCO` or `PVTO`) will be used in the calculation. The other PVT property keywords (for example `PVTW`, `PVTG`, `DENSITY`, `ROCK`) must also have a table corresponding to this table number, but these tables will not be used. They could be defaulted, or contain copies of the table number `PVTNUM`.

## Example

```

COMPFLSH
-- well   I  J  K1  K2  F1  F2  flash
-- name                    table
  PROD1   4*                1.2  1.15 / all connections use these ratios
  PROD2   2*      1    3    1*  1*  2 / only layers 1-3 use this table
/

```

## Treatment of flash transformation ratios in ECLIPSE

Within an oil reservoir, the release of dissolved gas from the oil as the pressure decreases resembles a differential liberation process, in which the gas is removed from the oil as it is released. By contrast, the continuing release of dissolved gas from the oil in its passage up the wellbore and through the separator resembles a flash liberation process, in which released gas remains in contact with the oil. Often it is possible to account for these different processes by devising a suitable composite PVT table to use in both the well and the reservoir. But this cannot be done if the bubble point pressure varies significantly within the reservoir.

The flash transformation facility provides an alternative solution to this problem. The oil PVT tables for the reservoir are constructed to model a differential liberation and a transformation is applied to the well rates to account for the effects of flashing the fluid from local reservoir conditions. The transformation parameters are specified in the form of two ratios:

$$F_1 = \frac{B_{ob}(\text{flash}) - 1}{B_{ob}(\text{diff}) - 1} \quad F_2 = \frac{R_s(\text{flash})}{R_s(\text{diff})} \quad \text{Eq. 3.20}$$

where

$B_{ob}$  is the formation volume factor of oil at bubble point pressure, and

$R_G$  is the solution gas oil ratio.

Using these ratios will ensure that  $B_{ob}$  (flash) approaches 1.0 and  $R_s$  (flash) approaches zero as their differential counterparts do when the pressure approaches stock tank conditions. At pressures above the bubble point, the ratio of oil formation volume factors is maintained the same as that for bubble point oil:

$$\frac{B_o \text{ (flash)}}{B_o \text{ (diff)}} = \frac{B_{ob} \text{ (flash)}}{B_{ob} \text{ (diff)}} = F_1 + \frac{1-F_1}{B_{ob} \text{ (diff)}} \quad \text{Eq. 3.21}$$

This leaves the compressibility of undersaturated oil unaltered by the transformation.

### Transforming the oil and gas flows

The oil and gas flow rates entering the well through the connections are calculated as if  $B_o$ (flash) and  $R_s$ (flash) were used to determine the phase mobilities. The flows within the reservoir, and the flows leaving the reservoir through the well connections, are calculated using  $B_o$ (diff) and  $R_s$ (diff), as given in the oil PVT table. ECLIPSE does this by transforming the oil and gas flows that have entered the well ( $Q_o$ ,  $Q_g$ ) to  $Q_o^*$  and  $Q_g^*$ ,

where

$$Q_o^* = T_{\text{oil-oil}} Q_o$$

$$Q_g^* = T_{\text{gas-oil}} Q_o + Q_g$$

with the transformation coefficients

$$T_{\text{(oil-oil)}} = \frac{1}{F_1 + \left( \frac{1-F_1}{B_{ob} \text{ (diff)}} \right)} \quad \text{Eq. 3.22}$$

$$T_{\text{(gas-oil)}} = (T_{\text{(oil-oil)}} F_2 - 1) R_s \text{ (diff)} \quad \text{Eq. 3.23}$$

The transformation coefficients for each well connection are calculated at the start of each timestep from the values of  $B_{ob}$  and  $R_s$  in the connecting grid blocks. They are then held constant for the duration of the timestep. The use of explicit  $B_{ob}$  and  $R_s$  values in the transformation coefficients is not expected to cause serious oscillations; however, if these do occur, they may be damped out by specifying a time-average weighting for these quantities with [item 42](#) in the OPTIONS keyword (ECLIPSE 100 only).

### Reporting

The flow transformations are applied inside the well bore. Thus the well flows reported in the Print and Summary files have been transformed to flash conditions, while the connection flows reported are the original differential values. The group and field flows, being the sum of the well flows, are also reported at flash conditions. All well, group and field rate constraints are applied to the flows transformed to flash conditions.

Reporting the connection flows at their original differential values has a number of advantages. They, and their derived quantities such as layer and region production, can be directly compared with the fluids in place, which are reported at differential liberation conditions. Also, in the absence of free gas flow, the reported connection GOR is equal to the  $R_s$  of the oil in the grid block. Note, however, that the reported well flow is no longer the exact sum of the reported connection flows, the difference being the amount of fluid lost or gained by the transformation to flash conditions.

In the fluid-in-place reports, the fluids in place and all flows are reported at differential liberation conditions.

## Comparison with SEPVALS

The `SEPVALS` keyword, which changes the separator conditions, provides an alternative means of transforming the oil and gas flows. The two options are incompatible, and should not be used in the same run.

There are a number of differences between the `SEPVALS` and `COMPFLSH` facilities:

- `SEPVALS` applies the same transformation to the well flow and all the well's connection flows. `COMPFLSH` can apply different transformations to individual connections (useful when a well is completed in two regions with different types of oil).
- `SEPVALS` transforms the flows by applying a constant ratio to  $B_o$  and a constant increment to  $R_s$ . If the bubble point pressure falls significantly during the simulation, the transformation will become less accurate, because the transformed values of  $B_{ob}$  and  $R_s$  do not approach 1.0 and 0.0 respectively as the pressure reduces to surface conditions. The `COMPFLSH` transformation, on the other hand, applies constant ratios to  $B_{ob} - 1$  and  $R_s$ , so their transformed values will approach the correct values as the pressure reduces to surface conditions.
- With `SEPVALS`, both the well and connection flows are reported at the transformed rates. With `COMPFLSH`, the connection flows are reported at the untransformed rates.
- With `SEPVALS`, the VFP tables are interpolated using the untransformed well rates (at original separator conditions), as it is assumed that the tables were prepared at the original separator conditions. With `COMPFLSH` the tables are interpolated using the well rates transformed to flash conditions, as it is assumed that they were prepared using flash liberation PVT properties.

## Restrictions and limitations

- The flash transformation facility should only be used in black oil runs having both live oil (containing dissolved gas) and dry gas as active phases.
- The facility may not be used in gas condensate runs, nor in conjunction with the miscible flood and solvent options.
- A flash PVT table (see item 8) cannot be used in API tracking runs, but it is still possible to specify transformation ratios in items 6 and 7.
- It is strongly recommended that the flash transformation facility is not used on connections of multisegment wells in ECLIPSE 100 (this option is not permitted in ECLIPSE 300).

In both the conventional well and the multisegment well models the inflowing fluid is transformed to flash conditions when it enters the wellbore through the connections to the reservoir grid. To calculate the fluid properties (for example, for the hydrostatic head) a back transformation is applied based on the overall inflow; this is consistent with the treatment of the well as a "mixing tank" and is thus appropriate for the conventional well model. With a multisegment well, this back transformation (based on the overall inflow) is still applied, even though the local fluid properties may vary with position in the well. Thus the local fluid properties are not as accurately represented as they should be for a discretized wellbore model such as a multisegment well. These fluid properties influence the hydrostatic and frictional pressure gradients, the out flowing mixture properties when crossflow occurs, and slip (when using the drift-flux model).

## COMPIMB

## Imbibition table numbers for well connections

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

COMPIMB is used to set the imbibition saturation table number for well connections, in runs using the Hysteresis option (keyword [SATOPTS](#) in the RUNSPEC section). The table number specified in item 7 of keyword [COMPDAT](#) applies to both the imbibition and drainage processes. If a different table number is required for imbibition, it should be set using COMPIMB after the COMPDAT keyword.

If the [ODD3P](#) relative permeability and capillary pressure hysteresis model has been specified this keyword will be ignored.

COMPIMB is followed by any number of records, described below, each record terminated by a slash (/). A record may be terminated early at any item; the remaining items will assume their default values. The set of records must end with a blank record, containing only a slash (/).

Each record can contain some or all of the following items:

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. I - location of connecting grid block(s)

DEFAULT: 0 (allows any I-value)

3. J - location of connecting grid block(s)

DEFAULT: 0 (allows any J-value)

4. K - location of upper connecting block in this set of data

DEFAULT: 0 (corresponds to top connection of well)

5. K - location of lower connecting block in this set of data

DEFAULT: 0 (corresponds bottom top connection of well)

The table number in item 6 is applied to all the connections in the well which match the location indices specified in items 2 - 5. But if a location index is defaulted to zero, it plays no part in selecting the connections to which the table number applies. Thus if the I and J location indices are defaulted to zero, the table number is applied to all connections in the well that are located between layers K1 and K2 specified in items 4 and 5. If all four location indices are defaulted, the table number is applied to all the connections in the well.

6. Imbibition saturation table number for the connection(s)

If the table number is zero, the imbibition table for the grid block containing the connection (set using keyword [IMBNUM](#)) will be used.

DEFAULT: 0

### Example

The first line of data sets the imbibition table number to 3 for all the connections belonging to well PROD1. The second line of data sets the imbibition table number to 2 for the layer-3 connection of well PROD2.

```
COMPIMB
PROD1 4*      3 /
```

```
PROD2 2* 3 3 2 /  
/
```

## COMPINJK User-defined injection well relative permeabilities

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

In well connections where fluid is being injected into the formation, the mobility of the injected phase is made to vary as the total fluid mobility in the grid block (see "Injecting connections" in the *ECLIPSE Technical Description*),

$$M(p, j) = \frac{\left[ \frac{k_r(o, j)}{\mu(o, j)} + \frac{k_r(w, j)}{\mu(w, j)} + \frac{k_r(g, j)}{\mu(g, j)} \right]}{B(p, j)} \quad \text{Eq. 3.24}$$

If gas or water is injected into a grid block initially containing oil, this relationship will cause the well's injectivity to vary until the grid block is completely flooded out with the injected phase. In reality however, most of the pressure drop occurs over a region close to the well, and when this region has flooded out the injectivity stays approximately constant. If the grid block size is much larger than this region, the calculated injectivity is incorrect until the whole grid block has flooded out.

The COMPINJK keyword provides an alternative approach, which is more accurate in cases where:

- The well injects fluid having a mobility significantly different to that of the fluid initially in the grid block, and
- The grid blocks containing the well connections are large, and
- The well is not subject to crossflow.

The relative permeability of the injected phase is given a constant value  $k_r(p,*)$ , representing its value in the region that has been flooded out by the injected phase. The relative permeabilities of the other phases are set to zero. The relationship for the injected phase mobility thus becomes

$$M(p, j) = \frac{k_r(p, *)}{B(p, j)\mu(p, j)} \quad \text{Eq. 3.25}$$

COMPINJK is followed by any number of records, each containing some or all of the following items of data and terminated by a slash (/). The set of records must end with a blank record, containing only a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "Well name and well list template matching" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword `WLIST`.

2. I - location of connecting grid block(s)  
DEFAULT: 0 (allows any I-value)
3. J - location of connecting grid block(s)  
DEFAULT: 0 (allows any J-value)
4. K - location of upper connecting block in this set of data  
DEFAULT: 0 (corresponds to top connection of well)
5. K - location of lower connecting block in this set of data  
DEFAULT: 0 (corresponds to bottom connection of well)
6. Relative permeability of the injected phase

The relative permeability in item 6 is applied to all the connections in the well which match the location indices specified in items 2 - 5. But if a location index is defaulted to zero, it plays no part in selecting which connections use the relative permeability value. Thus if the I and J location indices are defaulted to zero, the relative permeability value is applied to all connections in the well that are located between layers K1 and K2 specified in items 4 and 5. If all four location indices are defaulted, the relative permeability value is applied to all the connections currently defined in the well.

A positive value is applied as the relative permeability of the injected phase.

A default or negative value causes the relative permeability of the injected phase to be set to a suitable value in the saturation table used by the well connection, depending on the phase of the injector:

$k_{rw}(S_w = 1 - S_{owcr} - S_{gco})$  for water injectors

$k_{rg}(S_g = 1 - S_{ogcr} - S_{wco})$  for gas injectors

$k_{ro}(S_w = S_{wco}, S_g = S_{gco})$  for oil injectors.

If a default or negative value is supplied, the well must already have been declared an injector with keyword `WCONINJE` in order to know what phase it injects.

A zero value will cause the injected phase mobility to vary as the total fluid mobility in the grid block, resorting to the standard relationship applied in the absence of keyword `COMPINJK`.

---

**Note:** An injection well with a constant user-defined value of the injected phase relative permeability must not be allowed to crossflow, as this may result in multiphase injection. If a well has its crossflow flag set to YES (item 10 in keyword `WELSPECS`), its flag will be reset to NO and a warning message is printed.

---

## Example

This example causes all connections in well INJ1 to have a constant injected phase relative permeability set to the appropriate saturation table end point. The connection in layer 3 of well INJ2 has an injected phase relative permeability of 1.0.

```
COMPINJK
  INJ1      /
  INJ2  2* 3 3 1.0 /
  /
```

## COMPKRI

## Relative permeabilities for injector

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

COMPKRI is used to set the phase relative permeabilities for an injection well completion. The total mobility is

$$\frac{k_{rw}}{\mu_w} + \frac{k_{ro}}{\mu_o} + \frac{k_{rg}}{\mu_g} \quad \text{Eq. 3.26}$$

Setting the phase relative permeabilities will fix the relative permeabilities in the total mobility while allowing the viscosities to vary implicitly. Injection will then be the product of a mass or energy density times the total mobility times the connection factor times the drawdown (see "[Injecting connections](#)" in the *ECLIPSE Technical Description*).

The keyword is followed by any number of records, each containing the items of data described below, and each terminated by a / character.

The records can be terminated early using the / character, the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. I - location of connecting grid block(s)

DEFAULT: 0 (allows any I-value)

3. J - location of connecting grid block(s)

DEFAULT: 0 (allows any J-value)

4. K - location of upper connecting block in this set of data

DEFAULT: 0 (corresponds to top connection of well)

5. K - location of lower connecting block in this set of data

DEFAULT: 0 (corresponds to bottom connection of well)

6. Kro, the oil relative permeability.

A negative value will leave a previously defined value unaltered.

DEFAULT: 0.5

7. Krg, the gas relative permeability.

A negative value will leave a previously defined value unaltered.

DEFAULT: 0.5

8. Krw, the water relative permeability.

A negative value will leave a previously defined value unaltered.

DEFAULT: 0.5

9. Only use the relative permeability of the injected phase in the injection mobility calculation

YES The relative permeabilities of the phases not injected by the well will be set to zero in this calculation.

NO The values as entered in items 6, 7 and 8 will be used in this calculation.

DEFAULT: NO

To retrospectively set this item to YES for previously defined COMPKRI keywords, default the connection items appropriately and set the relative permeability items 6 to 8 negative to ensure your values are not overwritten with default values.

---

**Note:** This option can introduce non-linearities into the model. The problem is that if a phase is not present in a cell then it wouldn't contribute to the injection mobility (note that the phase viscosity is not known). However, if a minute amount of the phase is present then the injection mobility will increase to reflect the rel-perm input in COMPKRI. This non-linearity causes the simulator significant convergence problems. Hence it is recommended that only the phase relative permeability of either the injected phase and/or a phase likely to exist in the reservoir should be specified. So, for example, items 6 and 7 could be set to zero for water injectors. Alternatively, setting item 9 to YES would ensure that while the well injects water, items 6 and 7 are effectively zero, and while it injects gas, items 6 and 8 are effectively zero.

---

## Example

```
COMPKRI
'WINJ' 4* 0.0 0.0 0.8 /
'CYCLIC' 4* 0.4 0.0 0.2 /
/
```

## COMPKRIL Relative permeabilities for injector completions in local refined grids

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

COMPKRIL is used to set the phase relative permeabilities for an injection well completion in a local refined grid (LGR) cell. The keyword data is similar to that for [COMPKRI](#), except that there is an additional item at position 2 which gives the name of the LGR in which the completion is located.

The total mobility is

$$\frac{k_{rw}}{\mu_w} + \frac{k_{ro}}{\mu_o} + \frac{k_{rg}}{\mu_g} \quad \text{Eq. 3.27}$$

Setting the phase relative permeabilities will fix the relative permeabilities in the total mobility while allowing the viscosities to vary implicitly. Injection will then be the product of a mass or energy density times the total mobility times the connection factor times the drawdown (see "[Injecting connections](#)" in the *ECLIPSE Technical Description*).

The keyword is followed by any number of records, each containing the items of data described below, and each terminated by a / character.

The records can be terminated early using the / character, the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Local grid name
3. I - location of connecting grid block(s)  
DEFAULT: 0 (allows any I-value)
4. J - location of connecting grid block(s)  
DEFAULT: 0 (allows any J-value)
5. K - location of upper connecting block in this set of data  
DEFAULT: 0 (corresponds to top connection of well)
6. K - location of lower connecting block in this set of data  
DEFAULT: 0 (corresponds to bottom connection of well)
7. Kro, the oil relative permeability.  
A negative value will leave a previously defined value unaltered.  
DEFAULT: 0.5
8. Krg, the gas relative permeability.  
A negative value will leave a previously defined value unaltered.  
DEFAULT: 0.5

9. K<sub>rw</sub>, the water relative permeability.

A negative value will leave a previously defined value unaltered.

DEFAULT: 0.5

10. Only use the relative permeability of the injected phase in the injection mobility calculation

YES The relative permeabilities of the phases not injected by the well will be set to zero in this calculation.

NO The values as entered in items 7, 8 and 9 will be used in this calculation.

DEFAULT: NO

To retrospectively set this item to YES for previously defined COMPKR1 keywords, default the connection items appropriately and set the relative permeability items 7 to 9 negative to ensure your values are not overwritten with default values.

---

**Note:** This option can introduce non-linearities into the model. The problem is that if a phase is not present in a cell then it wouldn't contribute to the injection mobility (note that the phase viscosity is not known). However, if a minute amount of the phase is present then the injection mobility will increase to reflect the relative permeability input in COMPKR1. This non-linearity causes the simulator significant convergence problems. Hence it is recommended that only the phase relative permeability of either the injected phase and/or a phase likely to exist in the reservoir should be specified. So, for example, items 7 and 8 could be set to zero for water injectors. Alternatively, setting item 10 to YES would ensure that while the well injects water, items 7 and 8 are effectively zero, and while it injects gas, items 7 and 9 are effectively zero.

---

## Example

```
COMPKR1L
CYCLIC LGR1 4* 0.4 0.2 0.1 /
/
```

## COMPLMPL Lumps connections in local grids for automatic workovers

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

COMPLMPL is used to lump well connections together into completions for simultaneous closure in automatic workovers, when the connections are located in local grid refinements. The connections must first have been defined with the keyword [COMPDATL](#). COMPLMPL performs the same role as [COMPLUMP](#) does, but the name of the local grid containing the connections specified in the record should be entered in item 2 of COMPLMPL.

Wells may be worked over after violating limits set in keywords [WECON](#), [CECON](#), [GECON](#), [GCONPROD](#), [GCONPRI](#) and, for ECLIPSE 100, [GCONSALE](#), when for example the worst offending connection will be shut. If the connections have been lumped into completions, then the worst-offending completion will be identified (by summing the production rates of its connections) and all the connections belonging to it will be shut together. The connection economic limits in keyword [CECON](#) will also be applied to completions, that is a whole completion will be closed if its total water cut, [GOR](#) or [WGR](#) exceeds the limit set for its connections.

### ECLIPSE 100

If a worked-over well has any connections left in the [AUTO](#) queue for automatic opening (see keyword [COMPDATL](#). [COMPDATM](#) is just an alias for [COMPDATL](#).), then the completions are examined in increasing order of their completion number, and the first one found with connections in the [AUTO](#) queue will have all its connections opened together.

When a connection is first defined with keyword [COMPDATL](#), it is given a completion number equal to its order of introduction in the well. For example, the third connection defined in the well is put in completion number three. When several connections are defined in one record (items 4 and 5 define the upper and lower layers), the connections are introduced in layer order from top to bottom. So if the keyword [COMPLMPL](#) is not used, each connection is in its own separate completion, and the terms completion and connection are equivalent.

---

**Note:** When the [COMPLMPL](#) keyword is used, the named connections will be added to any existing connections in the completion specified. For this reason, it is advisable that the completion numbers of all connections in the well are re-specified at the same time.

---

### ECLIPSE 100

---

**Note:** If a well is completed in several amalgamated local grids, then connections in different local grids may **not** be lumped together. Only connections within the same local grid may be lumped.

---

Completion numbers can also be used in the [WELOPENL](#), [WPIMULTL](#) and [WSCCLENL](#) keywords to refer to a range of connections. Also, they can be used in the [SUMMARY](#) section with the keywords beginning with the letter [W](#) and ending with the letter [L](#) to output completion quantities. Keywords beginning with the letters [LC](#) and ending with the letter [L](#) output the corresponding connection quantity totaled over all the connections that belong to the same lumped completion located in local grid refinements. Any connection within the lumped completion can be specified to define the completion. For example, [WOFRL](#) and [LCOFRL](#) give the oil flow rate for the entire completion, though note that, in the latter case, the completion is identified by specifying a connection within the completion and not by specifying the completion number itself. See the [SUMMARY](#) section documentation for a full list of completion keywords.

[COMPLMPL](#) is followed by any number of records, described below, each record terminated by a slash (/). The set of records must end with a blank record, containing only a slash.

Each record contains the following items

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Name of local grid containing the completions to be lumped

If this item is defaulted or set to a blank string, the local grid name defaults to the well's local grid named in keyword [WELSPECL](#).

ECLIPSE 100

This item may not be defaulted, however, if the local grid containing the well is amalgamated (using keyword [AMALGAM](#)).

The connection locations in items 3 - 6 refer to their coordinates within this local grid.

3. I - location of connecting grid block(s)

DEFAULT: 0 (allows any I-value)

4. J - location of connecting grid block(s)

DEFAULT: 0 (allows any J-value)

5. K - location of upper connecting block in this completion

DEFAULT: 0 (corresponds to top connection of the well in the local grid specified in item 2)

6. K - location of lower connecting block in this completion

DEFAULT: 0 (corresponds to bottom connection of the well in the local grid specified in item 2)

7. Completion number of the connections

This must lie between 1 and NCWMAX (set by item 2 of keyword [WELLDIMS](#) in RUNSPEC).

The set of connections in the well which match the location indices specified in items 3 to 6 will be given the completion number specified in item 7. All connections having the same completion number are treated as belonging to the same completion, and will be closed together in an automatic workover.

If a location index is defaulted to zero, it plays no part in selecting the set of connections. Thus if the I and J location indices are defaulted to zero, all connections in the well that are located between layers K1 and K2 specified in items 5 and 6 will be given the completion number specified in item 7. If all four location indices are defaulted, all the well's connections will be given this completion number.

ECLIPSE 100

---

**Note:** It is still possible to use keyword [COMPLUMP](#) for wells completed in a single, unamalgamated local grid.

---

## Example

```

COMPLMPL
-- Connections in layers 1 and 2 for local grid CARF1
-- are in completion 1 for well PROD1
  PROD1  CARF1  2*  1  2  1 /
-- Connections in layers 3 and 4 for local grid CARF2
-- are in completion 2 for well PROD1
  PROD1  CARF2  2*  3  4  2 /
-- Connections in layer 5 for local grid CARF3
-- are in completion 3 for well PROD2

```

PROD2 CARF3 2\* 5 5 3 /  
/

## COMPLUMP Lumps connections for automatic workovers

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

COMPLUMP is used to lump well connections together into completions for simultaneous closure in automatic workovers. The connections must first have been defined with the keyword [COMPDAT](#).

Wells may be worked over after violating limits set in keywords [WECON](#), [CECON](#), [GECON](#), [GCONPROD](#), [GCONPRI](#) and, for ECLIPSE 100, [GCONSALE](#), when for example the worst offending connection will be shut. If the connections have been lumped into completions, then the worst-offending completion will be identified (by summing the production rates of its connections) and all the connections belonging to it will be shut together. The connection economic limits in keyword [CECON](#) will also be applied to completions, that is a whole completion will be closed if its total water cut, [GOR](#) or [WGR](#) exceeds the limit set for its connections.

In ECLIPSE 100, if a worked-over well has any connections left in the [AUTO](#) queue for automatic opening (see keyword [COMPDAT](#)), then the completions are examined in increasing order of their completion number, and the first one found with connections in the [AUTO](#) queue will have all its connections opened together.

When a connection is first defined with keyword [COMPDAT](#), it is given a completion number equal to its order of introduction in the well. For example, the third connection defined in the well is put in completion number three. When several connections are defined in one record (items 4 and 5 define the upper and lower layers), the connections are introduced in layer order from top to bottom. So if the keyword [COMPLUMP](#) is not used, each connection is in its own separate completion, and the terms completion and connection are equivalent.

---

**Note:** When the [COMPLUMP](#) keyword is used, the named connections will be added to any existing connections in the completion specified. For this reason, it is advisable that the completion numbers of all connections in the well are re-specified at the same time.

---

Completion numbers can also be used in the [WELOPEN](#), [WPIMULT](#) and [WSCCLEAN](#) keywords to refer to a range of connections. Also, they can be used in the [SUMMARY](#) section with the keywords beginning with the letter [W](#) and ending with the letter [L](#) to output completion quantities. Keywords beginning with the letter [C](#) and ending with the letter [L](#) output the corresponding connection quantity totaled over all the connections that belong to the same lumped completion. Any connection within the lumped completion can be specified to define the completion. For example, [WOFRL](#) and [COFRL](#) give the oil flow rate for the entire completion, though note that, in the latter case, the completion is identified by specifying a connection within the completion and not by specifying the completion number itself. See the [SUMMARY](#) section documentation for a full list of completion keywords.

[COMPLUMP](#) is followed by any number of records, described below, each record terminated by a slash (/). The set of records must end with a blank record, containing only a slash.

Each record contains the following items:

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. I - location of connecting grid block(s)

DEFAULT: 0 (allows any I-value)

3. J - location of connecting grid block(s)  
DEFAULT: 0 (allows any J-value)
4. K - location of upper connecting block in this completion  
DEFAULT: 0
5. K - location of lower connecting block in this completion  
DEFAULT: 0
6. Completion number of the connections

This must lie between 1 and NCWMAX (set by item 2 of keyword `WELLDIMS` in `RUNSPEC`).

The set of connections in the well which match the location indices specified in items 2 to 5 will be given the completion number specified in item 6. All connections having the same completion number are treated as belonging to the same completion, and will be closed together in an automatic workover (see example).

If a location index is defaulted to zero, it plays no part in selecting the set of connections. Thus if the I and J location indices are defaulted to zero, all connections in the well that are located between layers K1 and K2 specified in items 4 and 5 will be given the completion number specified in item 6. If all four location indices are defaulted, all the well's connections will be given this completion number.

ECLIPSE 100

---

**Note:** It is still possible to use keyword `COMPLUMP` for wells completed in a single, non-amalgamated local grid.

---

## Example

```

COMPLUMP
-- connections in layers 1 and 2 are lumped with connection 1 in
-- completion 1
  PROD1  2* 1 2 1  /
-- connections in layers 3 and 4 are lumped with /connection 2 in
-- completion 2
  PROD1  2* 3 4 2  /
--the connection in layer 5 is lumped with connection 3 in completion3
  PROD1  2* 5 5 3  /
/

```

## COMPMBIL Voidage mobility for injector completions in local refined grids

	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The COMPOFF keyword switches off all automatic compressors defined by the [GASFCOMP](#) keyword in the Gas Field Operations Model, or the [NETCOMPA](#) keyword in the Extended Network Model, except those defined to stay on permanently (PERM in item 9 of NETCOMPA). The compressors will be turned on again automatically as soon as they are needed.

This keyword has no effect on compressors defined with the [GNETPUMP](#) keyword.

See "[Gas field operations model](#)" and "[Network option](#)" in the *ECLIPSE Technical Description* for further details.

The keyword has no associated data.

## COMPORD Defines the ordering of well connections

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Method for ordering the connections in the well

**DEPTH** The connections will be ordered according to their vertical depth, from the top downwards. For connections at the same vertical depth, they will be ordered in the sequence they are first declared in [COMPDAT](#) or [COMPDATL](#).

**INPUT** The connections will be ordered in the sequence that they are first declared in [COMPDAT](#) or [COMPDATL](#). If you use this option, you must declare the connections in their correct sequence, starting with the connection nearest the wellhead then working along the wellbore towards the bottom or toe of the well.

**TRACK** ECLIPSE will determine the order of the connections by attempting to trace the well track through the grid from the grid blocks in which the connections are located. If this fails, or if all the connections in the well are vertical (according to [COMPDAT](#) item 13 or [COMPDATL](#) item 14), **DEPTH** ordering will be used. See the second note below for further explanation.

DEFAULT: TRACK

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

### Notes

- ECLIPSE uses the connection ordering when outputting RFT/PLT data (see [WRFPTPLT](#)) and when calculating the wellbore hydrostatic head with the segmented density calculation ([WELSPECS](#) item 12 set to SEG). The connection ordering also determines which additional connections are closed in a +CON workover (see for example [WECON](#) item 7). In these workovers, all connections below the offending one are also closed. Here, "below" is interpreted as "further from the wellhead according to the connection ordering". However, if you set [item 53](#) in the [OPTIONS](#) to > 0 in ECLIPSE 100 "below" will be interpreted literally and all connections with a greater depth will be closed. For back compatibility in ECLIPSE 300, setting item 2 in this keyword to **DEPTH** will revert both the +CON workover calculation and the segmented density calculation to their pre-2002A state.
- When the **TRACK** method is selected, ECLIPSE determines the connection ordering as described below. If all connections in the well penetrate vertically (Z-direction in [COMPDAT](#) item 13 or [COMPDATL](#) item 14), the connections are ordered according to their depth. But if any connection is declared to be horizontal (X- or Y-direction), ECLIPSE will attempt to order the connections in heel-to-toe fashion. It takes the heel to be the connection whose I,J coordinates are nearest the wellhead I,J (set in [WELSPECS](#) items 3 and 4, or [WELSPECL](#) items 4 and 5). If more than one connection can be a candidate for the heel, ECLIPSE selects the one with the minimum depth. The rest of the ordering is

determined from the location and orientation of the connections. If ECLIPSE cannot find a unique sensible ordering (for example with a multilateral well), it will issue a warning message and resort to ordering the connections by depth.

- For wells with complex trajectories, and in particular multilateral wells, you are recommended to define these as **multisegment** wells ([WELSEGS](#)) or, in ECLIPSE 100, **friction** wells ([WFRICTN](#)). The connection ordering for these wells is determined more precisely by the additional information supplied in their associated keywords. Note that the setting of COMPORD item 2 is **ignored** for these types of well; their connection ordering will **always** be determined by a more precise equivalent of the TRACK method.
- The COMPORD keyword is optional. If it is not entered, all wells will use the TRACK method.

## Example

```
COMPORD  
HWELL1    INPUT /  
HWELL2    INPUT /  
/
```

## COMPRIV

**Specifies which grid blocks connect to a river**

x	ECLIPSE 100

	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

COMPRIV specifies which grid blocks will be allowed to connect to the river bed. This must be entered after the [RIVERSYS](#) keyword defining the appropriate river. It must also be defined before the [GRDREACH](#) keyword is used for the river.

The keyword is followed by any number of records, described below, each record terminated by a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. River name or river name root
2. I - location of connecting grid block
3. J - location of connecting grid block
4. K - location of connecting grid block

**Example**

```

COMPRIV
'MYRIVER' 35 1 1 /
'MYRIVER' 35 2 1 /
'MYRIVER' 35 3 1 /
'MYRIVER' 35 4 1 /

```

## COMPRP

## Data for rescaling saturations at well connections

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

COMPRP is used to rescale the fluid saturations at the well connections, to take account of the position of the perforations and the distribution of the phases within large grid blocks. The well connections must already be defined with the keyword [COMPDAT](#) (or [WELLCOMP](#)).

COMPRP is followed by any number of records, described below, each record terminated by a slash (/). A record may be terminated early at any item; the remaining items will assume their default values. Defaults can also be specified by a null repeat count of the form  $n^*$ , where  $n$  is the number of consecutive items to be defaulted.

The set of records must end with a blank record, containing only a slash (/).

---

**Note:** The `COMPRP` keyword cannot be used with the Hysteresis option active if the imbibition and drainage table numbers are different for any connection (see item 6).

---

Each record can contain some or all of the following items:

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. I - location of connecting grid block(s)

DEFAULT: 0 (allows any I-value)

3. J - location of connecting grid block(s)

DEFAULT: 0 (allows any J-value)

4. K - location of upper connecting block in this set of data

DEFAULT: 0 (corresponds to top connection of well)

5. K - location of lower connecting block in this set of data

DEFAULT: 0 (corresponds to bottom connection of well)

The following rescaling quantities are applied to all the connections in the well which match the location indices specified in items 2 - 5. But if a location index is defaulted to zero, it plays no part in selecting which connections use the rescaling data. Thus if the I and J location indices are defaulted to zero, the rescaling data is applied to all connections in the well that are located between layers K1 and K2 specified in items 4 and 5. If all four location indices are defaulted, the rescaling data is applied to all the connections in the well.

6. Saturation table number for connection relative permeabilities

If the number is zero or positive, it will override the saturation table number specified in item 7 of keyword `COMPDAT`. If the number is zero, the relative permeabilities will be calculated using the same saturation table as the grid block containing the connection.

If the number is negative, the saturation table number will not be altered.

In runs using the hysteresis option (keyword `SATOPTS` in `RUNSPEC`), the saturation table number entered here will apply to both imbibition and drainage processes. Rescaling is not allowed if the imbibition and drainage table numbers for the connection are different.

DEFAULT: Negative

7. `SWMIN` Scaled value of the connate water saturation

The value is ignored in problems not containing water.

DEFAULT:  $S_{wco}$

8. `SWMAX` Scaled value of the maximum water saturation

The value is ignored in problems not containing water.

DEFAULT:  $1 - S_{owcr}$  in three-phase or oil-water problems, or  $1 - S_{gcr}$  in gas-water problems.

9. `SGMIN` Scaled value of the critical gas saturation

The value is ignored in problems not containing both gas and oil.

DEFAULT:  $S_{gcr}$

10. `SGMAX` Scaled value of the maximum gas saturation

The value is ignored in problems not containing both gas and oil.

DEFAULT:  $1 - S_{ogcr} - S_{wco}$

## Example

```

.....
COMPRP
PROD1 4*      3 .39 .63 .15 .29 / scales all connections in well PROD1
'P*'  2*  2 2 1* .39 .63 .15 .29 / scales layer-2 connections in all
/                                     wells with names beginning with P.
.....

```

## The saturation rescaling equations

$S_{gcr}$  = Critical gas saturation

$S_{owcr}$  = Critical oil saturation in water

$S_{ogcr}$  = Critical oil saturation in gas and connate water

$S_{wco}$  = Connate water saturation

(See "[Saturation functions](#)" in the *ECLIPSE Technical Description* for a full definition of these quantities)

The relative permeabilities at the well connections are calculated using the scaled values of the water and gas saturations,  $SS_w$  and  $SS_g$ ,

$$k_{rw} = k_{rw}(SS_w) \quad \text{Eq. 3.30}$$

$$k_{rg} = k_{rg}(SS_g) \quad \text{Eq. 3.31}$$

$$k_{ro} = k_{ro}(SS_w, SS_g) \quad \text{Eq. 3.32}$$

**Water saturation scaling**

In three-phase and oil-water problems, the water saturation is scaled as follows:

If

$$SWMIN < S_w < SWMAX \quad \text{Eq. 3.33}$$

Then

$$SS_w = (1-f_w)S_{wco} + f_w(1-S_{owcr})$$

where

$$f_w = (S_w - SWMIN) / (SWMAX - SWMIN)$$

If

$$S_w < SWMIN \quad \text{Eq. 3.34}$$

If

$$S_w > S_{wco},$$

$$\text{Then } SS_w = S_{wco}$$

$$\text{If } S_w < S_{wco},$$

$$\text{Then } SS_w = \frac{(S_w S_{wco})}{\text{MIN}(S_{wco}, SWMIN)}$$

If

$$S_w > SWMAX \quad \text{Eq. 3.35}$$

$$\text{If } S_w < 1 - S_{owcr},$$

$$\text{Then } SS_w = 1 - S_{owcr}$$

$$\text{If } S_w > 1 - S_{owcr},$$

$$\text{Then } 1 - SS_w = \frac{(1 - S_w) S_{owcr}}{\text{MIN}(S_{owcr}, \{1 - SWMAX\})}$$

ECLIPSE 100

In gas-water problems, the water saturation is scaled as follows:

If

$$SWMIN < S_w < SWMAX \quad \text{Eq. 3.36}$$

$$\text{Then } SS_w = (1-f_w)S_{wco} + f_w(1-S_{gcr})$$

$$\text{Where } f_w = \frac{S_w - SWMIN}{SWMAX - SWMIN}$$

If

$$S_w < SWMIN \quad \text{Eq. 3.37}$$

$$\begin{aligned}
&\text{If } S_w > S_{wco}, \\
&\text{Then } SS_w = S_{wco} \\
&\text{If } S_w < S_{wco}, \\
&\text{Then } SS_w = \frac{S_w S_{wco}}{\text{MIN}(S_{wco}, \text{SWMIN})} \\
&\text{If} \\
&S_w > \text{SWMAX} \tag{Eq. 3.38} \\
&\text{If } S_w < 1 - S_{gcr}, \\
&\text{Then } SS_w = 1 - S_{gcr} \\
&\text{If } S_w > 1 - S_{gcr}, \\
&\text{Then } 1 - SS_w = \frac{(1 - S_w) S_{gcr}}{\text{MIN}(S_{gcr}, \{1 - \text{SWMAX}\})}
\end{aligned}$$

### Gas saturation scaling

In three-phase and oil-gas problems, the gas saturation is scaled as follows:

$$\begin{aligned}
&\text{If} \\
&\text{SGMIN} < S_g < \text{SGMAX} \tag{Eq. 3.39} \\
&\text{Then } SS_g = (1 - f_g) S_{gcr} + f_g (1 - S_{ogcr} - S_{wco}) \\
&\text{Where } f_g = \frac{(S_g - \text{SGMIN})}{\text{SGMAX} - \text{SGMIN}}
\end{aligned}$$

$$\begin{aligned}
&\text{If} \\
&S_g < \text{SGMIN} \tag{Eq. 3.40} \\
&\text{If } S_g > S_{gcr}, \\
&\text{Then } SS_g = S_{gcr} \\
&\text{If } S_g < S_{gcr}, \\
&\text{Then } SS_g = \frac{S_g S_{gcr}}{\text{MIN}(S_{gcr}, \text{SGMIN})}
\end{aligned}$$

$$\begin{aligned}
&\text{If} \\
&S_g > \text{SGMAX} \tag{Eq. 3.41} \\
&\text{If } S_g < 1 - S_{ogcr} - S_{wco}, \\
&\text{Then } SS_g = 1 - S_{ogcr} - S_{wco} \\
&\text{If } S_g > 1 - S_{ogcr} - S_{wco},
\end{aligned}$$

$$\text{Then } 1-SS_g = \frac{(1-S_g)(S_{ogcr} + S_{wco})}{\text{MIN}(\{S_{ogcr} + S_{wco}\}, \{1-SGMAX\})}$$

In gas-water problems, the scaled gas saturation is given by

$$SS_g = 1-SS_w \quad \text{Eq. 3.42}$$

## Notes

- If the default values are used for the items SWMIN, SWMAX, SGMIN and SGMAX, then the saturations are unchanged by the COMPRP keyword.
- If the end point scaling option for grid blocks is being used (keyword [ENDSCALE](#) in RUNSPEC), the end-points used for calculating the default values will be chosen according to the following rules:
  - If the saturation table number for the connection (Item 6) is the same as that used for the grid block, the scaled end-points for the grid block will be used.
  - If the connection uses a different table from the grid block, the end-points will be unscaled, as specified in the original saturation table data.

Non-defaulted values specified with COMPRP will override the end-points set for the grid block.

However, the COMPRP saturation scaling treatment differs from that of the End Point Scaling option. Even when the COMPRP end points are defaulted the results will not be the same, particularly if End Point Scaling scales the critical saturation differently from the connate saturation (COMPRP scales only on the connate water saturation at the lower end). In general, care should be taken when using COMPRP in conjunction with End Point Scaling, and the user must be aware that defaulting the end points will not necessarily reproduce the same results as in the absence of COMPRP.

- In three-phase problems, the gas and water scaling factors must be consistent with each other. If they are not, the scaled oil saturation may become unrealistic. For example,  $SS_w + SS_g$  could exceed 1.0, giving a negative scaled oil saturation. Or  $SS_w + SS_g$  may be less than 1.0 when  $S_o = 0.0$ , which could produce a non-zero oil mobility at the well when there is no oil in the grid block. A warning message will be printed if either situation arises.

## Representing the effects of partial penetration

Scaled end point saturations can be used to represent the effects of partial penetration in grid blocks where the oil, water and gas phases are assumed to be segregated into zones in vertical equilibrium.

Consider a grid block that originally contained only oil but now has water encroaching from the bottom. Above the water-oil contact the water saturation is  $S_w = S_{wco}$ , while below the contact it is  $S_w = 1-S_{owcr}$ . Let the well be unperforated over a fractional length  $l_t$  from the top of the grid block and over a fractional length  $l_b$  from the bottom (where the fractional lengths are the actual lengths divided by the vertical thickness of the block). Thus the well is perforated over a fraction  $1-l_t - l_b$  of the block thickness.

The scaled water saturation end points are derived as follows. SWMIN is the water saturation in the grid block when the water oil contact reaches the bottom of the perforations,

$$SWMIN = l_b(1-S_{owcr}) + (1-l_b)S_{wco} \quad \text{Eq. 3.43}$$

and SWMAX is the water saturation in the grid block when the contact reaches the top of the perforations,

$$SWMAX = (1-l_t)(1-S_{owcr}) + l_t S_{wco} \quad \text{Eq. 3.44}$$

Now consider the grid block when it has instead gas encroaching from the top. Above the gas oil contact the gas saturation is  $1-S_{ogcr} - S_{wco}$ . Below the contact it is reasonable to assume that solution gas has been released from the oil to form a critical gas saturation  $S_g = S_{gcr}$ . The scaled gas saturation end points are thus derived as follows. SGMIN is the gas saturation in the grid block when the gas oil contact reaches the top of the perforations,

$$SGMIN = l_t(1-S_{ogcr} - S_{wco}) + (1-l_t)S_{gcr} \quad \text{Eq. 3.45}$$

and SGMAX is the gas saturation in the grid block when the contact reaches the bottom of the perforations,

$$SGMAX = (1-l_b)(1-S_{ogcr} - S_{wco}) + l_b S_{gcr} \quad \text{Eq. 3.46}$$

In gas-water problems where water encroaches from the bottom, the scaled water saturation end points are

$$SWMIN = l_b(1-S_{gcr}) + (1-l_b)S_{wco} \quad \text{Eq. 3.47}$$

$$SWMAX = (1-l_t)(1-S_{gcr}) + l_t S_{wco}$$

## COMPRPL Scaled saturations for local grid well connections

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

COMPRPL is used to rescale the fluid saturations at the well connections, to take account of the position of the perforations and the distribution of the phases within large grid blocks. The local grid well connections must already be defined with the keyword [COMPDATL](#).

COMPRPL is followed by any number of records, described below, each record terminated by a slash (/). A record may be terminated early at any item; the remaining items will assume their default values. Defaults can also be specified by a null repeat count of the form  $n^*$ , where  $n$  is the number of consecutive items to be defaulted.

Note that, as with the [COMPVEL](#) keyword, the [COMPRPL](#) keyword cannot be used in non-VE runs with the Hysteresis option on if the imbibition and drainage table numbers are different in any connection.

The set of records must end with a blank record, containing only a slash (/).

Each record can contain some or all of the following items:

- Well name, well name template, well list or well list template
 

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).
- Name of local grid containing the connections specified in this record
 

If the local grid containing the well is not amalgamated (using keyword [AMALGAM](#)), this item may be defaulted or set to a blank string. The local grid name then defaults to the well's local grid named in keyword [WELSPECL](#).
- I - location of connecting grid block(s)
 

DEFAULT: 0 (allows any I-value)
- J - location of connecting grid block(s)
 

DEFAULT: 0 (allows any J-value)
- K - location of upper connecting block in this set of data
 

DEFAULT: 0 (corresponds to top connection of well)
- K - location of lower connecting block in this set of data
 

DEFAULT: 0 (corresponds to bottom connection of well)

The following rescaling quantities are applied to all the connections in the well which match the location indices specified in items 2 - 5. But if a location index is defaulted to zero, it plays no part in selecting which connections use the rescaling data. Thus if the I and J location indices are defaulted to zero, the rescaling data is applied to all connections in the well that are located between layers K1 and K2 specified in items 4 and 5. If all four location indices are defaulted, the rescaling data is applied to all the connections in the well.
- Saturation table number for connection relative permeabilities
 

If the number is zero or positive, it will override the saturation table number specified in item 7 of keyword [COMPDAT](#). If the number is zero, the relative permeabilities will be calculated using the same saturation table as the grid block containing the connection.

If the number is negative, the saturation table number will not be altered.

In runs using the hysteresis option (keyword `SATOPTS` in `RUNSPEC`), the saturation table number entered here will apply to both imbibition and drainage processes. Rescaling is not allowed if the imbibition and drainage table numbers for the connection are different.

DEFAULT: Negative

8. `SWMIN` Scaled value of the connate water saturation

The value is ignored in problems not containing water.

DEFAULT:  $S_{wco}$

9. `SWMAX` Scaled value of the maximum water saturation

The value is ignored in problems not containing water.

DEFAULT:  $1 - S_{owcr}$  in three-phase or oil-water problems, or  $1 - S_{gcr}$  in gas-water problems.

10. `SGMIN` Scaled value of the critical gas saturation

The value is ignored in problems not containing both gas and oil.

DEFAULT:  $S_{gcr}$

11. `SGMAX` Scaled value of the maximum gas saturation

The value is ignored in problems not containing both gas and oil.

DEFAULT:  $1 - S_{ogcr} - S_{wco}$

## Example

This example scales all connections in well `PROD1` located in the local grid `LGR1`, and scales layer-2 connections in the local grid `LGR2` for all wells with names beginning with `P`.

```

.....
COMPRPL
PROD1 LGR1 4*      3 .39 .63 .15 .29 /
'P*'  LGR2 2*  2 2 1* .39 .63 .15 .29 /
/
.....

```

See the `COMPRP` keyword for more details on the saturation scaling calculation.

## COMPSEGL Defines location of multisegment well completions in a local grid

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

ECLIPSE 100

This keyword defines the location of the completions in a multisegment well (see "Multisegment wells" in the *ECLIPSE Technical Description*), when the well is situated in a local grid, and instructs ECLIPSE to allocate each completion to a well segment. The well's segment structure must previously have been defined with the [WELSEGS](#) keyword. Note that there is no equivalent [WELSEGL](#) keyword, as the segment structure is defined independently of the grid.

The location of the well connection to each completed grid block is defined within the well by the branch number and the length down the tubing to the start and end of the connection. This information must be supplied for **all** the well's connections that have been specified with the [COMPDATL](#) keyword. ECLIPSE allocates each grid block connection to the segment whose nodal point lies nearest to the center of the connection (unless explicitly overridden by a user-specified segment). A segment (or to be more precise, its node) can accept flow from any number of grid-block connections. However, it is not possible to allocate a single grid-block connection to more than one segment.

The keyword must be used instead of [COMPSEGS](#) if the well is completed in one or more local grids that have been amalgamated. Either keyword may be used for wells completed in a single unamalgamated local grid.

The keyword can only be used on one well at a time, thus it must be specified more than once if there is more than one multisegment well.

The keyword is followed by a number of data records to define the location of all the grid block connections in the well. Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing just a slash.

### Record 1

The data for record 1 is identical to that of the [COMPSEGS](#) keyword.

### Each subsequent record

The data for the subsequent records is the same as [COMPSEGS](#) except that there is an additional item at the start of each record:

1. Name of local grid containing the connections or range specified in this record

This item may be defaulted or set to a blank string (provided that the local grid containing the well is not amalgamated in ECLIPSE 100). The local grid name then defaults to the well's local grid named in keyword [WELSPECL](#).

The connection locations in items 2, 3, 4 and 9 refer to their coordinates within this local grid.

The remaining items of these records (2 to 12) are the same as items 1 to 11 in [COMPSEGS](#).

### Example

A multilateral well with connections in two horizontal lateral branches in individual amalgamated local grids.

```

COMPSEGL
-- Name
  PROD /
-- Local I J K Brn Start End Dirn End Connection

```

--	Grid			No	Length	Length	Penet	Range	Depth
--	Top Branch								
	UPPER	2	3	3	2	30	1*	X	10 /
--	Bottom Branch								
	LOWER	2	3	3	3	230	1*	X	6 /
/									

## COMPSEGS Defines location of completions in a multisegment well

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword defines the location of the completions in a multisegment well (see "Multisegment wells" in the *ECLIPSE Technical Description*), and instructs ECLIPSE to allocate each completion to a well segment. The well's segment structure must previously have been defined with the [WELSEGS](#) keyword. The location of the well connection to each completed grid block is defined within the well by the branch number and the length down the tubing to the start and end of the connection. This information must be supplied for **all** the well's connections that have been specified with the [COMPDAT](#) (or [COMPDATL](#)) keyword. ECLIPSE allocates each grid block connection to the segment whose nodal point lies nearest to the center of the connection (unless explicitly overridden by a user-specified segment). A segment (or to be more precise, its node) can accept flow from any number of grid-block connections. However, it is not possible to allocate a single grid-block connection to more than one segment.

The keyword can only be used on one well at a time, thus it must be specified more than once if there is more than one multisegment well.

### ECLIPSE 100

If the well is completed in one or more local grids that have been amalgamated, the keyword [COMPSEGL](#) must be used instead of [COMPSEGS](#). Either keyword may be used for wells completed in single unamalgamated local grids

### ECLIPSE 300

If the well is completed in a local grid, the keyword [COMPSEGL](#) must be used instead of [COMPSEGS](#).

The keyword is followed by a number of data records to define the location of all the grid block connections in the well. Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing just a slash.

The data items in each record are:

### Record 1

The first record consists of a single item of data that identifies the well.

1. Name of the well

End the data record with a slash (/).

### Each subsequent record

The subsequent records set the start and end of each connection's perforations in terms of distance along the tubing from the well's zero tubing length reference point, and the branch number. The zero tubing length reference point is defined relative to the nodal point of the top segment by item 3 of the first record of keyword [WELSEGS](#). The connections must previously have been defined with keyword [COMPDAT](#) (or [COMPDATL](#) as required).

The connections may either be specified individually, or in one or more "ranges". A "range" is a contiguous row or column of grid blocks that are fully penetrated by the same branch of the well. The well is assumed to penetrate a "range" perpendicularly through the center of each grid block in the specified direction. The distance along the tubing to the start and end of each connection in the range is determined by summing the DX, DY or DZ thicknesses of the grid blocks in the range. **All** connections in the well must have their tubing distances set, either individually or within a range, working outwards along the main stem and each branch towards its "toe".

1. I - location of the individual connection, or the connection at the **start** of the range (nearest the tubing head)

2. J - location of the individual connection, or the connection at the **start** of the range (nearest the tubing head).
3. K - location of the individual connection, or the connection at the **start** of the range (nearest the tubing head)
4. Branch number on which this connection (or range of connections) is located
5. Distance down the tubing from the well's zero tubing length reference point to the **start** of the connection in **this grid block**.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: Zero, for the first of these records, or the distance to the end of the previous connection or range, for subsequent records

6. Distance down the tubing from the well's zero tubing length reference point to the **end** of the connection in **this grid block**.

This item, if set, must be greater than item 5.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: Value of item 5 + thickness of the grid block in the direction of penetration

7. Direction of penetration through the grid block or the range

X or I for horizontal penetration in the x-direction

Y or J for horizontal penetration in the y-direction

Z or K for vertical penetration

This item is used for calculating the distance to the end of the perforations in the connection (or the connections in the range), where it defines which component of the grid block size to add (DX, DY or DZ). The item must be set if item 6 is defaulted, or if a range is specified in item 8. Otherwise it may be defaulted as it is not required.

8. Grid block I, J, or K coordinate at the **end** of the range, depending on the direction of penetration set in item 7. (For example the I-coordinate of the grid block at the end of the range, if the branch penetrates in the I-direction.)

This may be greater than, or less than, the corresponding grid block coordinate in item 1, 2 or 3, depending on whether the branch penetrates out towards the positive or negative I, J or K direction.

If this item is set, the tubing lengths are calculated for all the well's connections that lie within the range. Should the range pass through an inactive grid block ECLIPSE prints a warning message and assume a zero thickness for that cell. If this is not appropriate, the range should be split and the thickness of the inactive grid block accounted for by explicitly defining the tubing lengths in items 5 and 6.

If this item is defaulted, this record sets the tubing lengths for the single connection identified by items 1, 2 and 3.

9. Depth of the well connections within the range, that is the depth of the center of the perforations within each grid block in the range.

If a default (or zero) value is entered, connection depths are calculated by linear interpolation from the segment data, according to the depths of the beginning and end of the segment and the position of the perforations within it.

If a negative value is entered, the connection depths remain at their original values, which are set equal to the center depths of the corresponding grid blocks when the connections are first defined with keyword `COMPDAT`.

ECLIPSE calculates the pressure difference between the connection and its corresponding segment from the fluid density within the segment, and adjusts the grid block pressure to the depth of the connection by adding a hydrostatic correction based on an average of the mobile fluid densities within the block (see "[Inflow performance](#)" in the *ECLIPSE Technical Description*).

ECLIPSE 100

See also [item 63](#) of the `OPTIONS` keyword.

UNITS: m (`METRIC`), ft (`FIELD`), cm (`LAB`), m (`PVT-M`)

DEFAULT: Zero, so that the depths are calculated from the segment data.

ECLIPSE 300 Thermal

10. Thermal contact length, that is, the length of the well in the completion cell.

This length is used with the specific thermal resistance, defined in `WSEGHEAT`, to calculate the conductive heat transfer between the well and the reservoir.

UNITS: m (`METRIC`), ft (`FIELD`), cm (`LAB`), m (`PVT-M`)

DEFAULT: The thickness of the grid block in the direction of penetration.

11. Segment number to allocate to all connections within the range.

If this record is negative or defaulted, then ECLIPSE allocates each grid block connection to the segment whose nodal point lies nearest to the center of the connection. If a segment number is provided then it is used instead - regardless of the physical tubing length positions of the segment and the connection.

DEFAULT: 0 (that is let ECLIPSE allocate the segment)

---

**Note:** If the segment number is specified using this item then the use of defaulting for the depth of the well connections ([item 9](#) of this keyword) should be avoided. This is particularly true if the distance down the tubing to the middle of the connection does not lie within the tubing range of the specified segment (as the ECLIPSE calculation may then result in connections depths outside the reservoir).

---

End the data record with a slash (/).

End the set of data records with a slash.

## Notes

Multilateral well data can be complicated to enter. It is advisable to check your data by examining the output generated in the Print file.

ECLIPSE 100

The output is generated by setting `RPTSCHEd` keyword switch 14 (mnemonic `WELSPECS`).

ECLIPSE 300

The output is generated by the `RPTPRINT` keyword switches 6 and 7. These activate the `WELL` and `COMPLETION` summaries. A new segment summary is given under the `WELL` report in addition to a multisegment well report, and a new completion summary is given when a `COMPLETION` report is specified.

## Example

A multilateral well with connections in three horizontal lateral branches.

```

COMPSEGS
-- Name
  PROD /
-- I J K Brn Start End Dirn End Connection
--      No Length Length Penet Range Depth
-- Top Branch
  2 5 2 2 30 1* X 6 /
-- Middle Branch
  2 5 5 3 170 1* X 6 /
-- Bottom Branch
  2 5 8 4 230 1* X 6 /
/

```

## COMPSOL Sets number of components in a SOLID, BLACKOIL run

```

## COMPVD

## Total composition with respect to depth

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises a table composition with respect to depth data for each equilibration region. Each table consists of  $N_c + 3$  columns of data, and is terminated by a slash (/).

Column 1	Depth values. The values should increase monotonically down the column. UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)
Columns 2 to $N_c + 1$	The corresponding values of $z_i$ , the total phase mole fractions. The $N_c$ mole fractions specified must add up to unity, and the program will check that this is the case.
Column $N_c + 2$	Either 0 (vapor) or 1 (liquid) indicating that the fluid at this depth is above or below the gas-oil contact depth, respectively.
Column $N_c + 3$	Observed saturation pressure, $P_{sat}$ , at this depth. UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M) The $P_{sat}$ values are reported by the program in the solution versus depth output, for comparison with calculated values. They may be set to 0 if not required.

For depth values outside the interval specified, constant value extrapolation is performed.

The default maximum number of lines of COMPVD data is 50; this may be reset using the third item of keyword [EQLDIMS](#).

For cases in which there is an initial gas-oil contact, compositions above the contact are taken as vapor compositions, and those below as liquid compositions. This is checked against the item value in column  $N_c + 2$  to confirm that gas compositions have been entered above the gas-oil contact, and oil compositions below.

See also "[Initial composition with respect to depth](#)" in the *ECLIPSE Technical Description*.

### Example

In this case a gas composition is specified at depths 4200, 4260 and 4350 feet, and a liquid composition at 4410 feet. This specifies the gas composition at the GOC of 4348 feet. Using compositional equilibration option 2 ([EQUIL](#) item 10), the program obtains the oil composition at the GOC from the gas dew point. Oil compositions below the GOC are interpolated from the table.

```

## COMPVE

## Well connection depth data

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

COMPVE is used to reset the top and bottom depths of well connections, to allow for partial penetration within a grid block when calculating the phase relative permeabilities at the connection. The skin factor can also be adjusted to allow for partial penetration.

In runs using the vertical equilibrium option (keyword **VE** in the RUNSPEC section), the relative permeabilities at a well connection depend upon the connection's top and bottom depths and the fluid contact depths. Unless modified with the COMPVE keyword, the top and bottom depths of each connection are set to the depths of the center of the top and bottom faces of the connecting grid block, giving full penetration of the grid block.

If the COMPVE keyword is entered when the vertical equilibrium option is **not** in use, the top and bottom depths are automatically converted into scaled saturation table endpoints, which are then treated as if they had been entered with the **COMPRP** keyword. The conversion is performed by assuming a VE-type segregation of phases within the grid block (see "[Representing the effects of partial penetration](#)" in the **COMPRP** keyword). Note that, as with the **COMPRP** keyword, the COMPVE keyword cannot be used in non-VE runs with the Hysteresis option on if the imbibition and drainage table numbers are different in any connection. There is also a restriction on using COMPVE in non-VE runs that are 'fast' restarts (see keyword **RESTART**). The required grid block geometry data are only stored on the SAVE file if the base run contained keyword COMPVE. So if you wish to use COMPVE during a subsequent 'fast' restart, you must include this keyword in your base run, followed by just a slash if you don't need to set any partial penetration data at that time. The restriction does not apply to flexible restarts, as the required data is generated from the GRID section.

When using the compressed vertical equilibrium option (item **COMPRESS** in RUNSPEC section keyword **VE**), each lumped column of cells may have several connections. If COMPVE is used for a vertical well in each of these connections, then the well have several distinct perforations in the lumped column of cells.

COMPVE is followed by any number of records, described below, each record terminated by a slash (/). A record may be terminated early at any item; the remaining items will assume their default values. The set of records must end with a blank record, containing only a slash (/).

Each record can contain some or all of the following items:

- Well name, well name template, well list or well list template  
A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword **WLIST**.
- I - location of connecting grid block(s)  
DEFAULT: 0 (Allows any I-value)
- J - location of connecting grid block(s)  
DEFAULT: 0 (Allows any J-value)
- K - location of upper connecting block in this set of data  
DEFAULT: 0 (Corresponds to top connection of well)
- K - location of lower connecting block in this set of data
- Saturation table number for connection relative permeabilities

The end-points of the specified saturation table is used to set the relative permeabilities in each saturation zone, to obtain the fluid mobilities at the well connection. If the table number is zero or positive, it overrides the saturation table number specified in item 7 of keyword `COMPDAT`. If the number is zero, the fluid mobilities at the connection are calculated using the same saturation table as the grid block containing the connection.

DEFAULT: Negative.

7. `CVEFRAC` Fraction of vertical equilibrium curves to be used in calculating relative permeabilities for the connection.

If `CVEFRAC` is 1.0, relative permeabilities are derived using a vertical equilibrium model, replacing the rock curve that applies to the connection. This assumes fully segregated flow into the connection. The end point values used in this Vertical Equilibrium model is taken from the table used for this connection, which may have been specified directly in item 6 above.

If `CVEFRAC` is 0.0, the rock curve alone is taken: this should be used if a well pseudo has been generated, or if fully dispersed flow into the well is to be assumed. Again, the table used may have been specified directly in item 6.

If `CVEFRAC` takes a value between 0.0 and 1.0, a combination of the two above extreme cases results: a fraction  $(1.0 - \text{CVEFRAC})$  of the rock curve and `CVEFRAC` of the vertical equilibrium curve will be taken.

If `CVEFRAC` < 0.0, the quantity is defaulted to the Vertical Equilibrium fraction for the grid block, specified in keyword `VEFRAC`. If the `VEFRAC` keyword was not specified, the default `VEFRAC` value of 1.0 is used.

This item is ignored in non-Vertical Equilibrium runs.

DEFAULT: Negative (The value is taken from `VEFRAC`)

8. `DTOP` The top depth of the top connection in the set matching the location indices in items 2 - 5.

The value should not be less than the depth of the top-most corner of the connecting grid block, or the depth of the top of the grid block at the well's position (set in item 12).

UNITS: m (`METRIC`), ft (`FIELD`), cm (`LAB`), m (`PVT-M`)

DEFAULT: Depth of the center of the top face of the connecting grid block.

9. `DBOT` The bottom depth of the bottom connection in the set matching the location indices in items 2 - 5.

The value should not exceed the depth of the bottom-most corner of the connecting grid block, or the depth of the bottom of the grid block at the well's position (set in item 13).

UNITS: m (`METRIC`), ft (`FIELD`), cm (`LAB`), m (`PVT-M`)

DEFAULT: Depth of the center of the bottom face of the connecting grid block.

10. Flag to recalculate the skin factor taking account of partial penetration

**YES** The partial penetration skin factor will be calculated from Odeh's formula (see Note below), overriding any value entered previously in item 11 of keyword `COMPDAT`. The connection transmissibility factor is then recalculated. The well bore diameter must be set in item 9 of keyword `COMPDAT`. The skin factor and transmissibility factor for the connection will also be recalculated each time there is a plug-back (see keyword `WPLUG`). Any skin due to other causes (for example damage or stimulation) should be entered in item 11 of this keyword.

Note that subsequent use of `COMPDAT` overrides the calculated skin with the value entered in `COMPDAT` item 11.

NO The skin factor and connection transmissibility factor will not be changed from their values set in `COMPDAT`.

DEFAULT: NO

11.  $S_d$  Skin factor due to damage (+ve) or stimulation (-ve).

This is used when recalculating the skin factor to take account of partial penetration, if item 10 above is set to `YES`. It is added to the partial penetration skin factor (see the note on calculation of the skin factor, below) to give the total mechanical skin. If the perforations penetrate the full thickness of the grid block, the partial penetration skin factor is zero and the total mechanical skin has the value entered here.

DEFAULT: 0.0

12. `GTOP` Depth of the top of the grid block at the position of the well connection. This is only relevant if the skin factor is to be recalculated for partial penetration, and the well is located in an off-center position in a sloping grid block.

The value should not be less than the depth of the topmost corner of the connecting grid block.

UNITS: m (`METRIC`), ft (`FIELD`), cm (`LAB`), m (`PVT-M`)

DEFAULT: Depth of the center of the top face of the connecting grid block.

13. `GBOT` Depth of the bottom of the grid block at the position of the well connection. This is only relevant if the skin factor is to be recalculated for partial penetration, and the well is located in an off-center position in a sloping grid block.

The value should not exceed the depth of the bottommost corner of the connecting grid block.

UNITS: m (`METRIC`), ft (`FIELD`), cm (`LAB`), m (`PVT-M`)

DEFAULT: Depth of the center of the bottom face of the connecting grid block.

**CAUTION:** If `DTOP` and `DBOT` are very close together, the fluid mobilities at the well connection are very sensitive to the contact depths or grid block saturations, which may cause convergence problems. This should be particularly noted when applying the keyword to horizontal wells.

## Example

The first line of data sets the saturation table number, vertical equilibrium fraction, top-of-perforation depth, and bottom-of perforation depth, for the connection(s) belonging to the well `PROD1`. The skin factor and connection transmissibility factor is recalculated to account for partial penetration. There is no skin due to damage.

The second line of data sets the top-of-perforation depth of the layer-3 connection of well `PROD2`. The skin factor and connection transmissibility factor remain unchanged at their values specified by the data in `COMPDAT`.

```
COMPVE
PROD1 4* 3 1.0 2010 2050 YES /
PROD2 2* 3 3 2* 2000 /
/
```

## Calculation of the skin factor

If the completed length of the well does not cover the whole thickness of the formation, the convergence of the flow lines towards the perforated interval results in an additional component of the skin factor. For a well subject to both damage and partial penetration, the total mechanical skin factor is

$$S = \frac{h_t}{h_p} S_d + S_p \quad \text{Eq. 3.48}$$

where

$h_t$  is the thickness of the formation

$h_p$  is the length of the perforated interval

$S_d$  is the skin factor due to damage

$S_p$  is the skin factor due to partial penetration.

$S_p$  is calculated from an equation given by Odeh (J. Pet. Tech., June 1980, p964):

$$S_p = 1.35 \left( \frac{h_t}{h_p} - 1 \right)^{0.825} \{ 1n(h_{tpr} + 7) - 1.9 \} - [0.49 + 0.1 \ln(h_{tpr}) \ln(r_{wc})] \quad \text{Eq. 3.49}$$

where

$h_{tpr} = h_t$  divided by the square root of the vertical to horizontal permeability ratio  $K_v/K_h$

$$r_{wc} = r_w e^{0.2126(z_m/(h_t+2.753))}$$

$z_m$  is the distance between the middle of the perforated interval and the top or bottom of the formation, whichever is nearer

$r_w$  is the wellbore radius.

All lengths are in feet.

The connection factor is then derived, using the calculated value of  $S$ , as described in "[The connection transmissibility factor](#)" in the *ECLIPSE Technical Description*. Since the effects of partial penetration are contained in  $S$ , the effective  $Kh$  value should be based on  $h_t$ , not  $h_p$ .

If the formation is divided vertically into two or more layers of grid blocks, the skin factor is calculated separately for each completed layer.

Thus

$$h_t = \text{GBOT-GTOP}$$

$$h_p = \text{DBOT-DTOP}$$

$$z_m = \text{MIN}\{0.5(\text{DTOP} + \text{DBOT}) - \text{GTOP}, \text{GBOT} - 0.5(\text{DTOP} + \text{DBOT})\}$$

Eq. 3.50

## COMPVEL Well connection depth data in local grids

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

COMPVEL is used to reset the top and bottom depths of local grid well connections, to allow for partial penetration within a grid block when calculating the phase relative permeabilities at the connection. The skin factor can also be adjusted to allow for partial penetration.

In runs using the vertical equilibrium option (keyword **VE** in the RUNSPEC section), the relative permeabilities at the well connection depend upon the connection's top and bottom depths and the fluid contact depths. Unless modified with the COMPVEL keyword, the top and bottom depths of each connection are set to the depths of the center of the top and bottom faces of the local grid block containing the connection, giving full penetration of the grid block.

If the COMPVEL keyword is entered when the vertical equilibrium option is **not** in use, the top and bottom depths are automatically converted into scaled saturation table endpoints, which are then treated as if they had been entered with the **COMPRPL** keyword. The conversion is performed by assuming a VE-type segregation of phases within the grid block (see "[Representing the effects of partial penetration](#)" in the **COMPRP** keyword). Note that, as with the **COMPRPL** keyword, the COMPVEL keyword cannot be used in non-VE runs with the Hysteresis option on if the imbibition and drainage table numbers are different in any connection. There is also a restriction on using COMPVEL in non-VE runs that are 'fast' restarts (see keyword **RESTART**). The required grid block geometry data is only stored on the **SAVE** file if the base run contained either keyword **COMPVE** or **COMPVEL**. So if you wish to use COMPVEL during a subsequent 'fast' restart, you must include either of these keywords in your base run, followed by just a slash if you don't need to set any partial penetration data at that time. The restriction does not apply to 'flexible' restarts, as the required data is generated from the **GRID** section.

COMPVEL is followed by any number of records, described below, each record terminated by a slash (/). A record may be terminated early at any item; the remaining items will assume their default values. The set of records must end with a blank record, containing only a slash (/).

Each record can contain some or all of the following items:

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword **WLIST**.

2. Name of local grid containing the connections specified in this record

If the local grid containing the well is not amalgamated (using keyword **AMALGAM**), this item may be defaulted or set to a blank string. The local grid name then defaults to the well's local grid named in keyword **WELSPECL**.

The connection locations in items 3 - 6 refer to their coordinates within this local grid.

3. I - location of connecting grid block(s).

DEFAULT: 0 (Allows any I-value)

4. J - location of connecting grid block(s)

DEFAULT: 0 (Allows any J-value)

5. K - location of upper connecting block in this set of data.

DEFAULT: 0 (Corresponds to top connection of well)

6. K - location of lower connecting block in this set of data.

DEFAULT: 0 (Corresponds to bottom connection of well)

The following data quantities are applied to all the connections in the well that match the location indices specified in items 3 - 6. But if a location index is defaulted to zero, it plays no part in selecting the connections to which the following data applies. Thus if the I and J location indices are defaulted to zero, the data is applied to all connections in the well that are located between layers K1 and K2 specified in items 5 and 6. If all four location indices are defaulted, the data is applied to all the connections in the well.

7. Saturation table number for connection relative permeabilities.

The end-points of the specified saturation table are used to set the relative permeabilities in each saturation zone, to obtain the fluid mobilities at the well connection. If the table number is zero or positive, it overrides the saturation table number specified in keyword `COMPDATL`. If the number is zero, the fluid mobilities at the connection are calculated using the same saturation table as the grid block containing the connection.

If the number is negative, the saturation table number specified in keyword `COMPDATL` is used.

DEFAULT: Negative

8. CVEFRAC Fraction of vertical equilibrium curves to be used in calculating relative permeabilities for the connection.

If CVEFRAC is 1.0, relative permeabilities are derived using a vertical equilibrium model, replacing the rock curve that applies to the connection. This assumes fully segregated flow into the connection. The end point values used in this Vertical Equilibrium model are taken from the table used for this connection, which may have been specified directly in item 7 above.

If CVEFRAC is 0.0, the rock curve alone will be taken: this should be used if a well pseudo has been generated, or if fully dispersed flow into the well is assumed. Again, the table used may have been specified directly in item 7.

If CVEFRAC takes a value between 0.0 and 1.0, a combination of the two above extreme cases results: a fraction  $(1.0 - \text{CVEFRAC})$  of the rock curve and CVEFRAC of the vertical equilibrium curve is taken.

If CVEFRAC < 0.0, the quantity is defaulted to the vertical equilibrium fraction for the grid block, specified in keyword `VEFRAC`. If the `VEFRAC` keyword was not specified, the default `VEFRAC` value of 1.0 is used.

This item is ignored in non-VE runs.

DEFAULT: Negative

(The value is taken from `VEFRAC`.)

9. DTOP The top depth of the top connection in the set matching the location indices in items 3 - 6.

The value should not be less than the depth of the top-most corner of the connecting grid block, or the depth of the top of the grid block at the well's position (set in item 13).

UNITS: m (`METRIC`), ft (`FIELD`), cm (`LAB`), m (`PVT-M`)

DEFAULT: Depth of the center of the top face of the connecting grid block.

10. DBOT The bottom depth of the bottom connection in the set matching the location indices in items 3 - 6.

The value should not exceed the depth of the bottom-most corner of the connecting grid block, or the depth of the bottom of the grid block at the well's position (set in item 14).

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: Depth of the center of the bottom face of the connecting grid block.

11. Flag to recalculate the skin factor taking account of partial penetration

**YES** The partial penetration skin factor will be calculated from Odeh's formula (see keyword [COMPVE](#)), overriding any value entered in keyword [COMPDATL](#). The connection transmissibility factor is then recalculated. The well bore diameter must be set in keyword [COMPDATL](#). The skin factor and transmissibility factor for the connection is also recalculated each time there is a plug-back (see keyword [WPLUG](#)). Any skin due to other causes (for example damage or stimulation) should be entered in item 12 of this keyword.

Note that subsequent use of [COMPDATL](#) overrides the calculated skin with the value entered in that keyword

**NO** The skin factor and connection transmissibility factor is not changed from their values set in [COMPDATL](#).

DEFAULT: NO

12.  $S_d$  Skin factor due to damage (+ve) or stimulation (-ve).

This is used when recalculating the skin factor to take account of partial penetration, if item 11 above is set to YES. It is added to the partial penetration skin factor to give the total mechanical skin. If the perforations penetrate the full thickness of the grid block, the partial penetration skin factor is zero and the total mechanical skin has the value entered here.

DEFAULT: 0.0

13.  $G_{TOP}$  Depth of the top of the grid block at the position of the well connection. This is only relevant if the skin factor is to be recalculated for partial penetration, and the well is located in an off-center position in a sloping grid block.

The value should not be less than the depth of the top-most corner of the connecting grid block.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: Depth of the center of the top face of the connecting grid block.

14.  $G_{BOT}$  Depth of the bottom of the grid block at the position of the well connection. This is only relevant if the skin factor is to be recalculated for partial penetration, and the well is located in an off-center position in a sloping grid block.

The value should not exceed the depth of the bottom-most corner of the connecting grid block.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: Depth of the center of the bottom face of the connecting grid block.

---

**CAUTION:** If  $D_{TOP}$  and  $D_{BOT}$  are very close together, the fluid mobilities at the well connection are very sensitive to the contact depths or grid block saturations, which may cause convergence problems. This should be particularly noted when applying the keyword to horizontal wells.

---

See also the keywords [COMPVE](#), [COMPRP](#) and [COMPRPL](#).

## Example

The first line of data sets the saturation table number, vertical equilibrium fraction, top-of-perforation depth and bottom-of perforation depth, for the connection(s) belonging to the well PROD1 in the local grid LGR1. The skin factor and connection transmissibility factor will be recalculated to account for partial penetration. There is no skin due to damage.

The second line of data sets the top-of-perforation depth of the layer-3 connection of well PROD2 in the local grid LGR2. The skin factor and connection transmissibility factor remain unchanged at their original values.

	SCHEDULE

The CONDFLTS keyword defines the geometry of the conductive faults. This facility is designed to help with the modeling of parts of the reservoir which can be regarded as being in vertical equilibrium (VE); for example, regions where the throughput is of one or more orders of magnitude faster than in other parts of the reservoir.

Whilst the order in which the grid blocks are entered is arbitrary, the code does internally nominate the first one to be the representative cell of the fault. If a well connects to the fault then this representative cell must also be a connection of the well. (It need not be open, of course.)

One conductive fault is specified in each CONDFLTS keyword.

The following restrictions apply:

- Only ECLIPSE 300 black oil models
- No AIM runs
- No GASWAT option
- No parallel runs
- No thermal runs.

The CONDFLTS keyword contains the following data, terminated by a slash (/):

1. Name of the conductive fault (up to 8 characters)
2. Type of solution method to be employed within the conductive fault

VE: the VE approximation will be applied within the fault

---

**Note:** The following solution method options are also available, but are only recommended for the use of developers.

---

OFF: calculates the geometry but performs no calculations

COARSEN: assumes the solution is identical in all cells of the fault (VE is not applied).

End the line by a slash (/)

The following lines define the grid cells in the conductive fault. There can be as many lines as needed to define the region.

1. I1 Lower I-coordinate of the box in the parent grid.
2. I2 Upper I-coordinate of the box in the parent grid.
3. J1 Lower J-coordinate of the box in the parent grid.
4. J2 Upper J-coordinate of the box in the parent grid.
5. K1 Lower K-coordinate of the box in the parent grid.
6. K2 Upper K-coordinate of the box in the parent grid.
7. ZGRID Name of the parent grid.

DEFAULT parent grid name: GLOBAL

Each line must be terminated by a slash (/).

---

**Note:** When using this keyword the conservation equations for **all** the cells are replaced with a conservation equation for **the** conductive fault. This is then solved for **one** pressure, water saturation and gas saturation. If using the VE option then the fluids will be redistributed among all the cells (water in the bottommost and gas in the topmost). However, there remains just the single pressure which can be a poor approximation in certain situations.

---

## Example

```
CONDFLTS
  CFAULT1 VE /
1 5 3 3 1 1 /
3 3 3 3 2 10 /
/
```

## CONDFRAC Specifies a conductive fracture

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The CONDFRAC keyword defines the geometry and properties of a single conductive fracture, to be modeled using the single medium conductive fracture formulation (see "Dual porosity" in the *ECLIPSE Technical Description* for further information.) The SCFDIMS keyword must be present to activate this feature. Multiple fractures may be defined using multiple instances of the CONDFRAC keyword.

The keyword should be followed by an initial record defining the fracture properties, and then a series of records describing the planar segments of the conductive fracture being modeled. There is no limit to the number of segments modeled, Note, however, that the total number of segments per cell modeled must not exceed the number declared in the SCFDIMS keyword.

### Record 1

The initial record should contain the following four entries, terminated by a slash (/):

1. Name of the conductive fracture (up to 8 characters).
2. The saturation table number to use for the fracture.
3. The fracture effective aperture.  
UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)
4. The fracture permeability.  
UNITS: mD (METRIC), mD (FIELD), mD (LAB), mD (PVT-M)

There are no defaults for these entries.

### Subsequent records

The planar segment definitions should contain the following entries (again terminated by a slash).

1. I1 Lower I-coordinate of the segment in the global grid
2. I2 Upper I-coordinate of the segment in the global grid
3. J1 Lower J-coordinate of the box in the global grid
4. J2 Upper J-coordinate of the box in the global grid
5. K1 Lower K-coordinate of the box in the global grid
6. K2 Upper K-coordinate of the box in the global grid
7. FACE Segment orientation: 'X'/'Y'/'Z', or 'I','J','K'.

Again, all information must be supplied - there are no defaults.

The whole of the keyword data should be terminated with a final slash (/).

### Example

```
CONDFRAC
  SCF1  2  1  1000 /
  6 6 4 5 1 4 'X' /
  6 7 5 5 1 4 'Y' /
  7 7 5 6 1 4 'X' /
  7 8 6 6 1 4 'Y' /
```

```
8 8 6 8 1 4 'X' /  
8 9 8 8 1 4 'Y' /  
9 9 8 9 1 4 'X' /  
/
```

## COORD

## Coordinate lines

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The presence of the COORD keyword implies corner point geometry and the automatic generation of fault transmissibilities.

A coordinate line defines the possible positions for grid block corner points, for each (i,j) cell and for each reservoir in the grid. Given the depth of a particular grid block corner, and the associated coordinate line, the X and Y coordinates of the corner point can be calculated.

A coordinate line is specified by two triplets of X, Y and Z coordinates, representing two distinct points on it. If the (X, Y) coordinates of the top and bottom points are identical, then the Z coordinates of the points are not used.

The amount of data for this keyword can be quite voluminous, so it is recommended that a pre-processor (for example PETREL) be used to construct it.

If multiple reservoirs are present, this keyword must be preceded with keyword [RESVNUM](#) specifying the reservoir to which COORD data applies.

This keyword may not be used with block-centered geometry keywords, namely DR, DRV, DTHETA, DTHETA\_V, DX, DXV, DY, DYV, DZ, INRAD, TOPS.

The keyword line is followed by (NDIVIX + 1)(NDIVIY + 1)NUMRES coordinate lines, each specified by two points, each consisting of 3 values, namely, the X, Y and Z coordinates. NUMRES represents the number of reservoirs (or sets of coordinate lines) in the grid, which can be set with keyword [NUMRES](#) in the RUNSPEC section. NDIVIX and NDIVIY are specified in RUNSPEC keyword [DIMENS](#).

The last coordinate line is followed by a slash (/).

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

**Note:** Theta values are always in **degrees** for radial runs.

## Example

Here NDIVIX=3, NDIVIY=2 and NDIVIZ=10, as specified in RUNSPEC keyword [DIMENS](#), and [NUMRES](#) =1:

```
COORD
0 0 1000 0 0 1000
1000 0 1000 1000 0 1000
2000 0 1000 2000 0 1000
3000 0 1000 3000 0 1000
0 2000 1000 0 2000 1000
1000 2000 1000 1000 2000 1000
2000 2000 1000 2000 2000 1000
3000 2000 1000 3000 2000 1000
0 4000 1000 0 4000 1000
1000 4000 1000 1000 4000 1000
2000 4000 1000 2000 4000 1000
3000 4000 1000 3000 4000 1000
/
```

## Combining multiple reservoirs

Normally the data for the whole grid is specified in one COORD keyword. However, COORD data for individual sections of the grid can be entered in conjunction with the [BOX](#) keyword and/or the [RESVNUM](#) keyword, which is useful if you are combining separate models into a larger grid.

If just the BOX keyword has been entered (without RESVNUM), the program expects the following COORD keyword to contain the coordinate lines for the X-Y region within the box, for all NUMRES reservoirs.  $(NDX + 1) * (NDY + 1) * NUMRES$  coordinate lines are expected, where NDX, NDY are the dimensions of the current box.

An easier way of combining multiple reservoirs is with the keyword RESVNUM, having set NUMRES in the RUNSPEC section equal to the number of reservoirs. The COORD data can be entered separately for each reservoir at a time, with the reservoir in question identified by the preceding RESVNUM keyword. Regions within each reservoir can be singled out with the BOX keyword. For a box of dimensions NDX, NDY, the number of coordinate lines expected is  $(NDX + 1) * (NDY + 1)$ .

ECLIPSE 100

If the separate reservoirs do not communicate with each other (in other words, they are coupled only via well group controls), they may be solved more efficiently as separate units if they are identified with the ISOLNUM keyword. Refer to "[Independent reservoir regions](#)" in the *ECLIPSE Technical Description*.

## COORDSYS **Coordinate system information for each reservoir**

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword supplies information about the coordinate system for each reservoir in the grid. For instance, it can assign layers of cells to multiple reservoirs.

This keyword is required only if the grid contains more than one reservoir (see keyword [NUMRES](#)). In ECLIPSE 100 the keyword may also be used if the grid completes the circle.

The keyword line is followed by NUMRES data records, each ending with a slash (/). Each record contains the following data items:

1. Lower bound for block index in K-direction (K1)

For grid blocks in this reservoir (integer)

2. Upper bound for block index in K-direction (K2)

For grid blocks in this reservoir (integer)

3. Completion of circle, for grid blocks in this reservoir

COMP Circle is completed in the Theta-(or Y-) direction

INCOMP Circle is not completed

For the circle to be completed, the coordinate lines to be identified must be coincident. In the case of cylindrical coordinates, this means that the Theta coordinates for nodes 1 and (NDIVY + 1) in the Theta-direction must differ by 360 degrees

DEFAULT: INCOMP

---

**Note:** For radial local grids, circle completion (COMP) is the default - see "[Local grid refinement and coarsening](#)" in the *ECLIPSE Technical Description*.

---

4. Connection to the reservoir below

Should be one of:

JOIN Transmissibilities are calculated to the reservoir below.

SEPARATE The reservoir is isolated from the reservoir below.

This option calculates a transmissibility between cells (i,j,k) and (i,j,k+1) when the layers are in different reservoirs. This allows the description of bending coordinate lines. Care needs to be taken that the reservoirs coincide in a sensible manner. Note that fault non-neighbor connections are not calculated between different reservoirs.

DEFAULT: SEPARATE

- ECLIPSE 100 only*
  5. Lower bound for reservoir number for lateral connection to cells in different reservoirs (integer) (R1)

DEFAULT: Current reservoir number

- ECLIPSE 100 only*
  6. Upper bound for reservoir number for lateral connection to cells in different reservoirs (integer) (R2)

DEFAULT: Current reservoir number

The first two items of data for this keyword must have values which are less than or equal to the number of global grid cells in the Z-direction (specified using item 3 in the `DIMENS` keyword in the `RUNSPEC` section).

ECLIPSE 100

Items 5 and 6 may be used to allow fault NNCs between cells in different reservoirs. R1 and R2 should lie between 1 and `NUMRES`, with  $R1 \leq R2$ . This allows a fault NNC to be calculated between cells (i,j,k1) in reservoir number l, and (i+1,j,km) in reservoir m, if the limits R1 and R2 specified for reservoir l satisfy  $R1 \leq m \leq R2$ . This may be useful in accounting for 'bending' coordinate lines near faults. If horizontal pinchouts are enabled by using `PINCHXY` in the `GRID` section, then fault NNCs may also be created between different reservoirs across inactive columns of cells which are pinched-out horizontally.

ECLIPSE 100

The values of R1 and R2 should be consistent between different reservoirs: if the data record for reservoir l allows lateral connection to reservoir m, then the values of R1 and R2 specified for reservoir m should also allow lateral connection to reservoir l. The program issues an error message if this is not so.

If `NUMRES` is 1, the bounds of the reservoir defaults to the whole grid.

## Example

ECLIPSE 100

Here `NDIVIX=5`, `NDIVIY=3`, `NDIVIZ=4`, as specified in `RUNSPEC` keyword `DIMENS`, and `NUMRES=2`.

```

----- K1 K2  completed      join below      lateral limits
COORDSYS
   1  2  COMP           /
   3  4  INCOMP        /

```

## COPY

## Copies data from one array to another

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
x	EDIT
x	PROPS
x	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is used to assign or replace the value of a property for a box of cells within the grid, using the value of another property.

The keyword may be followed by any number of records, each of which is terminated by a slash (/). The data is terminated by a null record (that is, a record with no data before the terminating slash(/)).

Each record consists of at least two items of data:

1. **From** array.

The name of the array to be used from which data is to be copied

2. **To** array.

The name of the array to be set. Only this array is altered.

The following data items may be used to redefine the input box for this and subsequent operations within the current keyword.

If these items are not defined (a slash is inserted after item 2), they default to the values which were used for the previous operation within the current keyword.

For the first operation in the keyword, the box defaults to the values set by the most recent [BOX](#) or [ENDBOX](#) keyword. If there is no preceding [BOX](#) or [ENDBOX](#) in the current section, the box is taken to include the entire reservoir.

3. First block to be modified on the X axis (IX1)
4. Last block to be modified on the X axis (IX2)
5. First block to be modified on the Y axis (JY1)
6. Last block to be modified on the Y axis (JY2)
7. First block to be modified on the Z axis (KZ1)
8. Last block to be modified on the Z axis (KZ2)

The data must satisfy:

$$1 \leq IX1 \leq IX2 \leq NDX$$

$$1 \leq JY1 \leq JY2 \leq NDY$$

$$1 \leq KZ1 \leq KZ2 \leq NDZ$$

where NDX, NDY, NDZ are the limits in the current BOX.

## ECLIPSE 100

In the REGIONS section, it is possible to copy from the flux region array defined using the [FLUXNUM](#) keyword in the GRID section. This enables, for example, the [FIPNUM](#) array to be copied from the [FLUXNUM](#) array. Note that if part of the field is defined as flux region zero and subsequently copied into an array in the REGIONS section, the destination array will be set to 1.

Almost any array defined across the grid may be used with COPY. Examples are shown below:

## ECLIPSE 100

This keyword may not be used with the [PBUB](#) or [PDEW](#) arrays as either **From** or **To**.

x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword may be followed by any number of records, each of which is terminated by a slash (/). The data is terminated by a null record (that is, a record with no data before the terminating slash).

Each record consists of the following items of data.

1. The name of the source array from which data is to be copied.

Items 2-7: Source box.

2. IX1S First block to be copied **from** on the X axis.
3. IX2S Last block to be copied **from** on the X axis.
4. JY1S First block to be copied **from** on the Y axis.
5. JY2S Last block to be copied **from** on the Y axis.
6. KZ1S First block to be copied **from** on the Z axis.
7. KZ2S Last block to be copied **from** on the Z axis.

Items 8-13 Destination box

8. IX1D First block to be copied **to** on the X axis.
9. IX2D Last block to be copied **to** on the X axis.
10. JY1D First block to be copied **to** on the Y axis.
11. JY2D Last block to be copied **to** on the Y axis.
12. KZ1D First block to be copied **to** on the Z axis.
13. KZ2D Last block to be copied **to** on the Z axis.

The data must satisfy:

$$1 \leq IX1S \leq IX2S \leq NDIVIX$$

$$1 \leq IX1D \leq IX2D \leq NDIVIX$$

$$1 \leq JY1S \leq JY2S \leq NDIVIY$$

$$1 \leq JY1D \leq JY2D \leq NDIVIY$$

$$1 \leq KZ1S \leq KZ2S \leq NDIVIZ$$

$$1 \leq KZ1D \leq KZ2D \leq NDIVIZ \text{ (where NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword DIMENS)}$$

The two boxes must be the same size in all three dimensions.

$$IX2S - IX1S = IX2D - IX1D$$

$$JY2S - JY1S = JY2D - JY1D$$

$$KZ2S - KZ1S = KZ2D - KZ1D$$

There must be no overlap between the two boxes.

**Note:** This keyword cannot be used if the [PARALLEL](#) keyword is present.

## Examples

x	SOLUTION
	SUMMARY
	SCHEDULE

The keyword is followed by any number of records, each containing the items of data described below, and each terminated by a slash (/).

The records can be terminated early using a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. **From** array

The name of the array to be used.

2. **To** array

The name of the array to be set.

3. The flux region number, **MULTNUM** region number, or **OPERNUM** region number (with choice of region determined using item 4)

The flux region number refers to the region defined using the **FLUXNUM** keyword in the **GRID** section. It is not necessary to use the Flux Boundary option.

The **MULTNUM** region number refers to the region defined using the **MULTNUM** keyword in the **GRID** section.

The **OPERNUM** region number refers to the region defined using the **OPERNUM** keyword in the **GRID** or **REGIONS** section.

4. Choice of region: **MULTNUM** (M), **FLUXNUM** (F) or **OPERNUM** (O).

DEFAULT: M

---

**Note:** The **FLUXNUM** keyword, **MULTNUM** keyword or **OPERNUM** keyword must be entered before the **COPYREG** keyword. If item 4 is defaulted, then the **MULTNUM** keyword is used.

---

ECLIPSE 100

This keyword may not be used with the **PBUB** or **PDEW** arrays as either **From** or **To**.

## COVTYPE

## Component oil viscosity type

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used with the [THERMAL](#) option to specify how the oil viscosity is computed, such as using the Lorentz-Bray-Clark viscosities. With the keyword present an equation of state (EoS) can be used.

The keyword should be followed by one value for each component. The value should be one of the following:

Type	Component
NO	Not used. The viscosity for this component is computed as if this keyword was not present.
LMIX	The LBC viscosity model is applied with these components' oil phase molar density.
LEMIX	The LBC viscosity model is applied on the LEMIX components densities where an EoS is used to compute the phase molar density.

Table 3.6: COVTYPE component values

If the keyword is present the default is LMIX.

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

**Note:** If only a subset of the mixture is modeled by an EoS and many of the light components are included, and the heavy components are not, the mixture could yield a molar volume similar to that of an GAS and consequently the viscosity will be similar to that of a gas.

**Note:** Special care should be taken when the LBC viscosity model is applied to heavy components or gas condensate components.

For more information see [Thermal option](#) in the *ECLIPSE Technical Description*.

## Example

In a thermal run with 4 hydrocarbon components:

```
COVTYPE
LMIX LMIX LMIX LMIX /
```

## CPR

## CPR Linear solver

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword activates the CPR linear solver. This alternative linear solver can often reduce simulation times for difficult problems, and is most likely to improve performance when the linear equations frequently fail to converge with the default linear solver. This situation can be identified from repeated linear convergence warnings output from the simulation. In these cases the CPR linear solver should be considered.

The CPR linear solver employs the constrained pressure residual (CPR) preconditioner, which provides a more robust method for solving the linear equations. For further details please refer to "[The Constrained Pressure Residual \(CPR\) Preconditioner](#)" in the *ECLIPSE Technical Description*

The maximum number of linear iterations allowed for the outer iterations can be controlled with the [TUNING](#) keyword. By default, the maximum number of linear iterations allowed, in a Newton iteration, is 25 for ECLIPSE 100 and 20 for ECLIPSE 300.

The keyword does not contain any data items, and must be terminated by a slash (/).

In ECLIPSE 100, there are some options that cannot be used with the CPR linear solver. These include [IMPES](#), the multiple independent reservoirs option, the Russian Doll option, the friction well option, triple porosity, nested local grid refinements, single phase simulations, item 1 of keyword [WSEGSOLV](#), [BTOBALFA](#), [BTOBALFV](#) and the rivers option.

In ECLIPSE 300, it is currently not possible to use the CPR linear solver for the thermal option, the multiple (including triple) porosity option, in a dual porosity (or dual permeability) run containing local grid refinements and the [IMPES](#) option.

In ECLIPSE 300, the CPR linear solver generally performs best when the simulation is fully implicit. For simulations that use the adaptive implicit ([AIM](#)) scheme, the performance may deteriorate if the fraction of fully implicit cells is small.

### Notes

- Each linear iteration of the CPR linear solver takes more time, when compared to the default linear solver. If the CPR preconditioner is unable to reduce the total number of linear iterations significantly, this may cause the overall simulation time to increase when the CPR linear solver is used. For this reason, the CPR linear solver is best suited to cases which experience linear convergence problems with the default linear solver.
- The CPR linear solver cannot be expected to improve performance if the simulation is experiencing convergence problems due to highly non-linear behavior, which requires short time steps to resolve. In these cases the input data and existing convergence criteria should be checked, to ensure that the behavior is intended.

### Example

```
CPR
/
```

## CREF

## Oil component compressibility

This keyword can only be used with the [THERMAL](#) option.

CREF specifies the liquid compressibility for each of the  $N_c$  hydrocarbon components.

The expression used to calculate oil component liquid densities is the following:

$$\rho_c = \frac{\rho_{ref,c}}{\left[1 - c_{P_c}(P - P_{ref,c})\right] \left[1 + c_{T1_c}(T - T_{ref,c})\right]} \quad \text{Eq. 3.51}$$

where

$\rho_{ref,c}$  is the reference density, specified with keyword [DREF](#)

$c_{P_c}$  is the oil component liquid compressibility, specified with this keyword

$P_{ref,c}$  is the reference pressure specified, with keyword [PREF](#)

$T_{ref,c}$  is the reference temperature, specified with keyword [TREF](#)

$c_{T1_c}$  is the thermal expansion coefficient, specified with keyword [THERMEX1](#).

There should be one value for each component:

UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB), 1/atm (PVT-M)

DEFAULT: 0.0

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of [TABDIMS](#). The use of multiple EoS regions is discussed in "Equations of state regions" in the *ECLIPSE Technical Description*.

## Example

For 3 components

```
CREF
--Compressibility
 5.0E-06 5.2E-6 5.4E-6 /
```

## CREFW

## Water component compressibility

x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

CREFW specifies the water compressibility for each of the  $N_w$  water components.

The water component densities, at pressure  $P$ , are calculated from:

$$\rho_w = \rho_{ref_w} \cdot (1 + X + X^2/2)$$

$$X = c_{P_w} \cdot (P - P_{ref_w})$$

where

$\rho_{ref_w}$  is the reference density, specified with keyword [DREFW](#)

$c_{P_w}$  is the water component compressibility, specified with this keyword

$P_{ref_w}$  is the reference pressure specified, with keyword [PREFW](#)

There should be one value for each component:

UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB), 1/atm (PVT-M)

DEFAULT: 4.0e-5 1/atm

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of [TABDIMS](#). The use of multiple EoS regions is discussed in "Equations of state regions" in the *ECLIPSE Technical Description*.

See "Water components" in the *ECLIPSE Technical Description* for further details of the water component option.

## Example

For 2 components

```
CREFW
--Compressibility
5.0E-06 5.2E-6
```

## CREFW

## Reference compressibility for water components for surface EoS

This optional keyword supplies reference compressibilities for water components for use in the surface calculations. The default, if this is not supplied, is for these to follow the reservoir values supplied with [CREFW](#).

If multiple equations of state are being used, a set of data should be entered for each surface EoS. The number of surface equation-of-state regions is entered as item 10 of [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

## CRITPERM Permeability criterion for Vertical Equilibrium cell compression

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The CRITPERM keyword may optionally be used in compressed vertical equilibrium runs (keyword [VE](#) in the RUNSPEC section). It specifies a critical permeability, above which cells can be collapsed, or merged with other cells in the same column, to form the larger compressed vertical equilibrium cells.

The keyword should be followed by a single real number that denotes the critical permeability for cell compression.

UNITS: mD (METRIC), mD (FIELD), mD (LAB), mD (PVT-M)

A cell is only collapsed into a larger compressed vertical equilibrium cell if the Z-direction permeability (entered using keyword [PERMZ](#)) exceeds this value.

If this keyword is not present, the critical permeability for cell compression defaults to 0.0, that is cells with Z-permeability > 0.0 can be collapsed.

A cell is merged with the next active cell below, provided that **none** of the following situations occur:

- An integer of 0 has been entered for that cell in keyword [COLLAPSE](#)
- $TRANZ = 0.0$
- $PERMZ \leq$  critical value entered in CRITPERM
- There is an inactive cell with  $DZ > 0.0$  between the two active cells
- Either cell has been refined using [RADFIN](#) or [CARFIN](#) (see "[Local grid refinement and coarsening](#)" in the *ECLIPSE Technical Description*).

See also keyword COLLAPSE and "[Compressed vertical equilibrium option](#)" in the *ECLIPSE Technical Description*.

### Example

```
CRITPERM
0.2 /

## CRNDENS **Rock density by coal regions**

	<b>ECLIPSE 100</b>
x	<b>ECLIPSE 300</b>
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword is used to specify a coal density used in connection with a coal region number.

For a coal bed methane run, the density of the coal can be set constant for each coal region. This is an alternative to the [ROCKDEN](#) keyword specifying the rock density on a cell by cell basis. If both [ROCKDEN](#) and [CRNDENS](#) are specified, [CRNDENS](#) will only apply to cells undefined by [ROCKDEN](#).

Each record consists of the following items:

1. The coal region number. This cannot be defaulted.
2. The corresponding rock/coal density.

UNITS: kg/m<sup>3</sup> ([METRIC](#)), lb/ft<sup>3</sup> ([FIELD](#)), gm/cc ([LAB](#)), kg/m<sup>3</sup> ([PVT-M](#))

Each record must be terminated by a slash(/), and the keyword is terminated by a second slash (/).

### Example

```
CRNDENS
 1 89.5 /
 2 99.0 /
/
```

## CSKIN

## Update well connection skin factors

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

CSKIN is used to update the skin factors for well connections. This subsequently changes the well connection transmissibility factors. The well connections must already be defined before this keyword can be used.

CSKIN is followed by any number of records, described below, each record terminated by a slash (/). A record may be terminated early at any item; the remaining items assume their default values. Default values can be specified before the slash by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records must end with a blank record, containing only a slash (/).

Each record can contain some or all of the following items:

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. I - location of connecting grid block(s)

DEFAULT: 0 (allows any I-value)

3. J - location of connecting grid block(s)

DEFAULT: 0 (allows any I-value)

4. K - location of upper connecting block in this set of data

DEFAULT: (corresponds to top connection of well)

5. K - location of lower connecting block in this set of data

DEFAULT: (corresponds to bottom connection of well)

6. Connection skin factor. User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

Large negative skin factors can cause problems if they increase the effective wellbore radius to approach the pressure equivalent radius of the grid block. Very high values of the connection transmissibility factor may result, which could cause convergence problems. In these circumstances, it may be preferable to change the grid block data near the well to model the physical cause of the negative skin (for example enhance the permeability out to a certain distance from the well). If the effective wellbore radius is increased beyond the pressure equivalent radius, the connection factor becomes negative and an error message is issued.

DEFAULT: 0.0

---

**Note:** Only one UDA may be defined for the skin factor per well at any one time. The skin factors may take different values for each connection but all must be calculated from the same UDQ formula. If two UDAs are defined for the skin factor for different connections on the same well then the skin factor for all UDA-controlled connections will be calculated using the most recently requested UDA.

---

## Example

```
CSKIN  
PROD1 4* CUSKN /  
'P*' 2* 2 2 -1.5 /  
/
```

	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This is an optional keyword which modifies the convergence criteria used to control the simulator in the SCHEDULE section. This keyword may be used more than once, for example to tighten up the criteria during a difficult part of the study.

The keyword may be followed by some or all of the following data items, terminated by a slash (/).

1. Maximum pressure change over an iteration.

If the largest pressure change (for any cell) for a non-linear iteration is less than this value the solution is accepted. The solution obtained is usually at least as accurate as this value.

This item is also used as the maximum pressure change over an iteration in the Multisegment Well Model. (*ECLIPSE 300 only*)

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

DEFAULT: 0.1 atm

2. Maximum number of non-linear iterations.

The timestep will be reduced if this number is exceeded before the non-linear equations are converged.

DEFAULT: 20 (Fully implicit)

15 (Fully implicit Thermal)

6 (IMPES)

12 (AIM or IMPSAT)

3. Required improvement in linear solver residual squared. **This is the required reduction in RMS<sup>2</sup>** and the RMS equations are given in [ECLIPSE 300](#) in the “*ECLIPSE Technical Description*”.

DEFAULT: 1.0E-10

4. Maximum number of linear iterations

DEFAULT: 40, or [NSTACK](#) if [NSTACK](#) is greater than 40

20, or [NSTACK](#) if [NSTACK](#) is greater than 20 if using the [JALS](#) solver or [CPR](#) solver

5. Maximum fugacity (phase equilibrium) error convergence criterion.

(This option is not valid with the Thermal option.)

DEFAULT: 0.001

6. Minimum number of linear iterations

DEFAULT: 1 (Non-Thermal) 2 (Thermal)

7. Maximum component specific volume change over an iteration.

If the largest change (for any cell and any component) for a non-linear iteration is less than this value the solution is accepted. This is effectively the contribution to the saturation change due to any component.

DEFAULT: 0.01 (Non-Thermal) 0.2 (Thermal)

*Thermal only*

8. Maximum temperature change over an iteration.

If the largest change for a non-linear iteration is less than this value the solution is accepted.

UNITS: K (METRIC), °R (FIELD), K (LAB), K (PVT-M)

DEFAULT: 10.0

9. Minimum number of non-linear iterations.

DEFAULT: 1

*Thermal*

DEFAULT: 2

10. Minimum rms linear solver residual for convergence of linear equations.

DEFAULT: 1.0E+20

11. The tolerance for the maximum-norm of the non-linear residual, regardless of the solution change criteria. The solution is flagged as converged if the maximum-norm of the non-linear residual is less than this value, regardless of the solution change criteria. Please also refer to item 41.

DEFAULT: 1.0E-4

12. The tolerance for the sum of the non-linear residual, regardless of the solution change criteria. The solution is flagged as converged if the sum of the non-linear residual is below this value, regardless of the solution change criteria. Please also refer to item 42.

DEFAULT: 1.0E-20

13. Maximum allowed change in molar densities per non-linear iteration

DEFAULT: 2 x target value given by item 10 of [TSCRIT](#)

*Thermal option only*

14. Maximum allowed change in temperature per non-linear iteration

UNITS: K (METRIC), °R (FIELD), K (LAB), K (PVT-M)

DEFAULT: target value given by item 17 of [TSCRIT](#)

15. Maximum allowed change in pressure per non-linear iteration.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

DEFAULT: Minimum of 100 atmospheres and 20% of the average pressure. Minimum of 100 atmospheres and the average pressure (Thermal)

16. Reserved for future use.

17. Reserved for future use.

18. Reserved for future use.

19. Reserved for future use.

20. Not used at present.

21. Not used at present.

22. Maximum  $L_2^2$  solver residual norm.

DEFAULT: 1.0E-11

23. Maximum number of iterations for converging the Multisegment Well Model.

DEFAULT: 40

24. Convergence tolerance for Multisegment Well Model molar densities.  
UNITS: kg-M/rm<sup>3</sup> (METRIC), lb-M/rb (FIELD), gm-M/rcc (LAB), kg-M/rm<sup>3</sup> (PVT-M)  
DEFAULT: 0.015 kg-M/rm<sup>3</sup>
25. Convergence tolerance for Multisegment Well Model molar flow rate (homogeneous flow segments).  
UNITS: kg-M/day (METRIC), lb-M/day (FIELD), gm-M/hr (LAB), kg-M/day (PVT-M)  
DEFAULT: 50 kg-M/day
26. Convergence tolerance for Multisegment Well Model energy density.  
UNITS: kJ/rm<sup>3</sup> (METRIC), Btu/rb (FIELD), J/rcc (LAB), kJ/rm<sup>3</sup> (PVT-M)  
DEFAULT: 50 kJ/rm<sup>3</sup>
27. Convergence tolerance for Multisegment Well Model velocity (drift flux segments).  
UNITS: m/s (METRIC), ft/s (FIELD), cm/s (LAB), m/s (PVT-M)  
DEFAULT: 10 m/s
28. Convergence tolerance for rock displacement in the geomechanics calculation  
UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)  
DEFAULT: 0.01 m
29. Convergence tolerance for porosity in the geomechanics calculation  
UNITS: dimensionless  
DEFAULT: 0.0001
30. Damping factor for partly coupled geomechanics  
DEFAULT: 1.0
31. Convergence tolerance for Multisegment Well Model maximum molar residual  
UNITS: kg-M/day (METRIC), lb-M/day (FIELD), gm-M/hr (LAB), kg-M/day (PVT-M)  
DEFAULT: 1000 kg-M/day
32. Convergence tolerance for Multisegment Well Model maximum energy residual  
UNITS: kJ/day (METRIC), Btu/day (FIELD), J/hr (LAB), kJ/day (PVT-M)  
DEFAULT: 1E20 kJ/day
33. The SAMG item CHKTOL.  
  
Defines the amount of checking performed on the sparse matrix input to the SAMG solver. Negative values imply no checking, zero gives standard checking and positive values give enhanced checking. See also [SAMG](#).  
  
DEFAULT: - 1.0.
34. The SAMG item IFIRST.  
  
Defines the initial approximation used in the SAMG linear solver (1 for a constant zero vector, 2 for a constant vector of one, and 3 for a random vector). See also [SAMG](#).

- DEFAULT: 1
35. Convergence tolerance for Geomechanics finite element plasticity  
DEFAULT: 0.001 times the norm of the initial solution
36. Maximum number of iterations for Geomechanics finite element plasticity  
DEFAULT: 15
37. Maximum pressure change in Multisegment Well Model above which the solution vector will be dampened  
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)  
DEFAULT: 250 atm
38. Maximum specific volume change in Multisegment Well Model above which the solution vector will be dampened.  
DEFAULT: 100
39. Maximum temperature change in Multisegment Well Model above which the solution vector will be dampened.  
UNITS: K (METRIC), °R (FIELD), K (LAB), K (PVT-M)  
DEFAULT: 200 K
40. Maximum fraction of Appleyard chop iterations per timestep.  
The Appleyard chop is used to stabilize the non-linear convergence. It modifies the Newton update in a cell, depending on phase appearance, phase disappearance and critical values of saturations. However, sometimes the Appleyard chop may actually prevent convergence. Therefore the Appleyard chop is switched off in a cell, during an iteration, if it has been performed more than  $f \times MAXITS$  times during a timestep, where  $MAXITS$  is defined by item 2 of this keyword and  $f$  is defined by this item. If  $f$  is set greater than 1, then the Appleyard chop will not be switched off, giving the pre-2011.1 behavior.  
DEFAULT: 0.5
41. Additional tolerance for the maximum-norm of the non-linear residual. The solution is only flagged as converged if it satisfies all other convergence criteria, including solution change, and the maximum-norm of the non-linear residual is less than this value.  
DEFAULT: 1.0E+20 (Not used)
42. Additional tolerance for the maximum sum of the non-linear residuals. The solution is only flagged as converged if it satisfies all other convergence criteria, including solution change, and the sum of the non-linear residual is less than this value.  
DEFAULT: 1.0E+20 (Not used)

## Example

```
CVCRIT

	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used with the [SOLID](#) option to identify solid phase components. It can also be used with the [THERMAL](#) option to specify whether a component exists only in the oil phase (a non-volatile component), or only in the gas phase (a non-condensable component).

The keyword should be followed by one value for each component. The value should be one of the following:

Type	Component	Option
LIVE	for components that are both volatile and condensable.	
SOLID	for components that are only in the solid phase	Solid
DEAD	for components that are only in the oil phase	Thermal
GAS	for components that are only in the gas phase	Thermal

Table 3.7: CVTYPE component values

These values may be enclosed in quotes. Only the first character is significant. If this keyword is not used all components are treated as live components. The phases corresponding to each volatility type are summarized below:

Type	Solid phase	Oil phase	Gas phase
LIVE		x	x
SOLID	x		
DEAD		x	
GAS			x

Table 3.8: Phases corresponding to each volatility type

Thermal only

This keyword will override the critical temperature entered using the [TCRIT](#) keyword; for DEAD components the critical temperature is set to a large value ( $10^4$ ); for GAS components the critical temperature is set to a small value ( $10^{-6}$ ).

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in [Equations of state regions](#) in the *ECLIPSE Technical Description*.

The solid option is described in [Solid phase](#) in the *ECLIPSE Technical Description*.

The thermal option is described in [Thermal option](#) in the *ECLIPSE Technical Description*.

## Example

	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used with the [SOLID](#) option and the [THERMAL](#) option to specify the component volatility type at surface conditions. If this keyword is not used, the surface volatility type will be the same as the reservoir volatility type, set using the [CVTYPE](#) keyword.

The keyword is used in the same way as the [CVTYPE](#) keyword. It should be followed by one value for each component. The value should be one of the following:

Type	Component	Option
LIVE	for components that are both volatile and condensable.	
SOLID	for components that are only in the solid phase	Solid
DEAD	for components that are only in the oil phase	Thermal
GAS	for components that are only in the gas phase	Thermal

Table 3.9: CVTYPES component values

These values may be enclosed in quotes. Only the first character is significant. The phases corresponding to each volatility type are summarized below:

Type	Solid phase	Oil phase	Gas phase
LIVE		x	x
SOLID	x		
DEAD		x	
GAS			x

Table 3.10: Phases corresponding to each volatility type

Thermal only

This keyword will override the critical temperature entered using the [TCRITS](#) keyword; for DEAD components the critical temperature will be set to a large value ( $10^4$ ); for GAS components the critical temperature is set to a small value ( $10^{-6}$ ).

If multiple equations of state are being used, a set of data should be entered for each surface EoS. The number of surface equation of state regions is entered as item 10 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in [Equations of state regions](#) in the *ECLIPSE Technical Description*.

The solid option is described in [Solid phase](#) in the *ECLIPSE Technical Description*.

The thermal option is described in [Thermal option](#) in the *ECLIPSE Technical Description*.

	SCHEDULE

This keyword requests the date to be written to the Summary file. The date is stored as three summary mnemonics DAY, MONTH, YEAR.

The date is not usually used for plotting summary data (use TIME or YEARS); however, it is useful when the summary data is tabulated either in GRAF or by using the RUNSUM keyword.

The DATE keyword has no associated data.

**Note:** The DAY, MONTH and YEAR are stored as real numbers on the summary files but are output as integers in the tabulated output from GRAF or RUNSUM. In addition, if the DATE keyword is used in conjunction with RUNSUM, then the date instead of the time is printed in the left most column of the run summary.

## Advances simulator to specified report date(s)

The keyword should be followed by a list of dates at which reports are required. Each date must be on a separate line terminated by a slash (/). The data is terminated by a null record (a slash on a line by itself).

A date consists of the following items of data:

1. The day of the month  
An integer between 1 and 31.
2. The name of the month abbreviated to three characters  
JAN, FEB, MAR, APR, MAY, JUN, JLY, AUG, SEP, OCT, NOV or DEC.  
JUL is an acceptable alternative to JLY.
3. The year  
A positive 4 digit integer.
4. The time  
A string of the format HH:MM:SS.SSSS.  
DEFAULT: 00:00:00

---

**Note:** The date at the start of the simulation (time 0) is entered using the keyword [START](#) in the RUNSPEC section.

---

### Example

```

DATES
1 FEB 1985 /
1 MAR 1985 06:00:00 /
1 MAY 1985 13:30:00 /
1 JAN 1986 /
1 JAN 1987 19:45:15.3333 /
/

```

## DATUM

## Datum depth for output of depth corrected pressures

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by a single positive real number, the datum depth for calculation of depth corrected pressures (or potentials), and a slash (/). DATUM is entirely optional. If it is not specified, and output of depth corrected pressures is requested, it defaults to the datum depth entered for equilibration region 1 using the [EQUIL](#) keyword, or to zero if there is no EQUIL keyword.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

---

**Note:** For ECLIPSE 100 only, it is possible to specify a negative depth value.

---

### Example

```
DATUM
4800 /
```

## DATUMR

## Datum depth for each FIP region

This keyword is optional and should be followed by the maximum number of fluid-in-place regions (NTFIP, see keyword [REGDIMS](#) or [TABDIMS](#)). Each number must be a positive real number, one for each FIP region in the model as defined by keyword [FIPNUM](#), followed by a slash (/). The datum depths are used to calculate the depth corrected pressures (potentials).

If the DATUMR keyword is used then the datum specified in any DATUM keyword will be ignored.

If different datum depths are used in different regions the field average potentials (for example FPPO) have little physical meaning as cells are averaged based on different datum depths. Typically the field values should be ignored and the region average potentials utilized (for example RPPO).

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

---

**Note:** For ECLIPSE 100 only, it is possible to specify a negative depth value.

---

### Example

```
DATUMR
4800 5000 5200 /
```

## DATUMRX Datum depth for each FIP region in each FIP set

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is optional and similar to [DATUMR](#). However, it allows the provision of datum depths for all fluid-in-place sets defined by the [FIP](#) keyword, in addition to the standard set defined with keyword [FIPNUM](#).

If the [DATUMRX](#) keyword is used then the datum specified in any [DATUM](#) keyword will be ignored.

Datum depths for all fluid-in-place sets must be specified unless the [DATUMR](#) keyword has been processed previously, in which case the datum values of any unspecified fluid-in-place set will be based on the [DATUMR](#) keyword.

---

**Note:** For ECLIPSE 100 only, an exception is the fluid-in-place set created by the keyword [FIPOWG](#) whose datum depths will be identical to the depths of the default fluid-in-place unless explicitly provided.

---

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. The fluid-in-place region family, to which the specified datum depths belong.

The family name should be up to 5 characters long.

A default (1\*) or blank ( ' ') entry refers to the standard set of fluid-in-place regions defined with the keyword [FIPNUM](#).

Additional families of fluid-in-place regions may optionally be defined, using the keyword [FIP](#). The family name is a string of up to 5 characters that makes up the second segment of the keyword name (characters 4 - 8). Each family can divide up the field in different ways. Thus, for example, the standard [FIPNUM](#) family may divide the field into layers, and an additional family can be defined to divide the field into areal sectors.

2. The datum depths for each region of the fluid-in-place family.

A maximum number of [NTFIP](#) values is allowed as defined by keywords [REGDIMS](#) or [TABDIMS](#). Each number must be a positive real number, one for each fluid-in-place region in the fluid-in-place.

UNITS: m ([METRIC](#)), ft ([FIELD](#)), cm ([LAB](#)), m ([PVT-M](#))

If a datum value is not specified for all fluid-in-place regions, the datum values for the remaining fluid-in-place regions will be based on the last specified region.

The datum depths are used to calculate the depth corrected pressures (potentials). The datum depths provided for the fluid-in-place sets specified by the [FIP](#) keyword are used when calculating the [SUMMARY](#) keywords [RPP0](#), [RPPW](#), [RPPG](#) and [RPPC](#) (ECLIPSE 100 only).

ECLIPSE 100 only

---

**Note:** It is possible to specify a negative depth value.

---

### Example

```

DATUMRX
'XXX ' 4800 5000 5200 /
1*     4850 5100 /
/

```

## DBGODD3P Controls debug output for ODD3P option

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to write out debug information for the `ODD3P` relative permeability and capillary pressure hysteresis option. The data are output to the Debug file.

The keyword should be followed by a status string, controlling whether the debug output is selected or deselected, plus 6 integers, which define the box of cells for which output will be generated, terminated with a slash (/)

1. STATUS This should be one of two values:

ON Switch debug output on

OFF Switch debug output off.

DEFAULT: OFF

2. IX1 First cell on X axis to be included in output
3. IX2 Last cell on X axis to be included in output
4. JY1 First cell on Y axis to be included in output
5. JY2 Last cell on Y axis to be included in output
6. KZ1 First cell on Z axis to be included in output
7. KZ2 Last cell on Z axis to be included in output

For items 2 to 7, the values must satisfy:

$$1 \leq IX1 \leq IX2 \leq NDIVIX$$

$$1 \leq JY1 \leq JY2 \leq NDIVIY$$

$$1 \leq KZ1 \leq KZ2 \leq NDIVIZ \text{ (where NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword DIMENS)}$$

**Note:** It is recommended that this facility should be used with caution to avoid excessive output to the Debug file. The format and content of this debug output is subject to change.

### Example

```
DBGODD3P
-- STATUS IX1 IX2 IY1 IY2 IZ1 IZ2
   ON    4  4   5  5   1  3 /
```

## DCQDEFN Definition of the DCQ - gas rate or energy

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword may be used to specify whether the DCQ targets set in keyword [GASYEAR](#), [GASPERIO](#), [GDCQ](#), [GASF'TARG](#) or [GASFDECR](#) refer to energy or gas production rate. It is relevant only when running the gas field operations model in conjunction with the gas calorific value control option. (See "[Gas field operations model](#)" and "[Gas calorific value control](#)" in the *ECLIPSE Technical Description* for further details.)

The keyword should be followed by a single data item, terminated by a slash (/):

- Quantity to which the DCQ refers.

**GAS** The DCQ refers to the gas rate, which is standard for the Gas Field Operations Model.

**ENERGY** The DCQ refers to the energy rate, and its target value should be entered in keyword [GASYEAR](#), [GASPERIO](#) or [GDCQ](#) in the appropriate units: kJ/day ([METRIC](#)), Btu/day ([FIELD](#)), J/hr ([LAB](#)), kJ/day ([PVT-M](#)). ECLIPSE give the contract groups a [GCONENG](#) target equal to the energy DCQ multiplied by the month's swing or profile factor. Any economic DCQ limits set in keyword [GDCQECON](#) should also refer to energy rate.

(The word may be abbreviated, as only the first character is significant.)

DEFAULT: [GAS](#).

End data record with a slash (/).

---

**CAUTION:** If the DCQDEFN keyword is used it **must** be entered before the keyword [SWINGFAC](#) or [GSWINGF](#).

---

### Example

```
DCQDEFN
ENERGY /
```

## The dead oil option is to be used

This keyword can only be used with the THERMAL option (see "[Thermal option](#)" in the *ECLIPSE Technical Description*). It does not allow a hydrocarbon component to occur in the gas phase. Oil and water K-values do not need to be specified if this option is chosen. DEADOIL is an alternative to [LIVEOIL](#) and [BLACKOIL](#).

This keyword has no associated data.

---

**Note:** This keyword cannot be used with more than one hydrocarbon component.

---

## DEBUG

## Controls on debug output

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
x	RUNSPEC
x	GRID
x	EDIT
x	PROPS
x	REGIONS
x	SOLUTION
x	SUMMARY
x	SCHEDULE

The DEBUG keyword is primarily intended for use as an aid to simulator development, and the function of its controls may change from version to version. Also there may be undocumented and limitations, without warnings, on its use. Debug output is not fully supported. The keyword is documented here for completeness.

Many of the controls will produce vast amounts of output and should be used with extreme caution.

The keyword should be followed by integers, each of which controls a particular form of debug output. A value less than or equal to zero switches the debug output off. To produce debug output from a particular option, the relevant debug switch should be set greater than zero. In some cases the volume of output depends on the value of the switch (in general larger values produce more output). The data field should be terminated by a slash (/). If fewer than the maximum number integers are read, the remainder are left unchanged. Once a particular debug item is activated, it remains activated in all subsequent uses of DEBUG keyword unless it is explicitly turned off.

**Note:** Repeat counts (for example 3\*0) can be used if required (but no spaces before or after the asterisk).

DEBUG item	Effect of DEBUG item
Item 1	Terminal output copied to debug file. Timing reports if > 1.
Item 2	Debug summary for all wells.
Item 3	Details of storage allocation. If set > 1 the local grid storage allocation is also output.
Item 4	Details of index arrays from RCINDX.
Item 5	Debug of environment variables.
Item 6	Debug from matrix set-up (see also switches 45-50). If controls 45-50 are set to 0, then the matrix set-up debug is produced for the cells with the largest normalized residuals. The number of cells for which output is produced increases as the value of switch 6 increases.
Item 7	Debug from linear solver.
Item 8	Debug from equilibrator.
Item 9	Debug from non-linear solver (chops of $S_w, S_g, S_o, P_o, R_s, R_v, BHP$ ). If >1 debug of PVT extrapolation, and state transitions.
Item 10	Debug from NNC generation.
Item 11	Debug from network option balancing calculation.
Item 12	Debug from Fetkovich or Carter-Tracy aquifer calculations.
Item 13	Debug from vertical equilibrium option.
Item 14	Debug from transmissibility calculations.
Item 15	Debug from threshold pressure calculation.

DEBUG item	Effect of DEBUG item
Item 16	<p>Debug from hysteresis option.</p> <p>If set &lt; 0, this removes the restriction on monotonically increasing relative permeability and rock compaction tables. If set &lt; -1, then, in addition, the restriction on monotonic capillary pressure functions is also removed. This is not recommended for general use because unphysical or non-monotone saturation functions will often cause severe convergence failures.</p>
Item 17	Debug from API tracking option.
Item 18	Debug from the ACTION keyword.
Item 19	If >0 grid displays of the non-linear residual function are produced in the debug file at each non-linear iteration.
Item 20	Debug from input parser and the I/O PUT and GET Routines.
Item 21	Debug from total compressibility check calculation.
Item 22	Debug from cascade solver.
Item 23	Debug from end-point scaling option.
Item 24	Debug from tracer tracking option.
Item 25	Debug from gravity imbibition and drainage calculation in dual porosity/dual permeability systems.
Item 26	This determines whether the checks specified by debug switches 6, 7, 27 and 38 apply to any local grids. When set to -1, all local grids are checked as well as the global grid; if set = 0, only the global grid is checked; if set = n>0, then only the n <sup>th</sup> local grid is checked.
Item 27	If >0 Jacobian is checked by numerical differentiation of the residual, and any errors reported to the debug file. The cells checked are limited by switches 45-50.
Item 28	Debug from polymer flood model.
Item 29	Debug from dynamic memory allocation module.
Item 30	Debug from Gi-condensate/volatile oil model.
Item 31	Debug from gas field operations model.
Item 32	Debug from Solvent Model.
Item 33	Subroutine indicator to detect the position of a program hang.
Item 34	Debug of internal tables generated from alternative keywords.
Item 35	Debug from the surfactant model.
Item 36	Debug from nine-point scheme.
Item 37	Debug from gas lift optimization calculation.
Item 38	<p>If &gt;0 a line search is performed along the newton direction.</p> <p>The following steps are used alpha = 10*0.1,-1,1. the search is only performed newton iteration &gt; debug(38).</p>

DEBUG item	Effect of DEBUG item
Item 39	<p>Debug for the parallel options, reservoir coupling and Open-ECLIPSE message passing routines.</p> <p>An output line for each message header is written to standard output for the master process. The equivalent slave data is written to a file called <code>kzpn.dbg</code>, where <code>N</code> is the process number.</p> <p>In addition consistency checking is performed between the header information and the subsequent message. Errors are written to the appropriate output streams if an inconsistency occurs.</p>
Item 40	Debug from local grid refinement.
Item 41	Debug from parallel LGR option.
Item 42	Debug from reservoir coupling facility.
Item 43	<p>Debug from the domain decomposition parallel option.</p> <p>When <code>set = 2</code>, if this is a distributed memory run the profile information for each slave task is output to the local debug file. The profile information is analogous to the standard profiling information output if the <code>CPU</code> mnemonic is used in the <code>RPTSCHED</code> keyword. The debug files have the form <code>root.n.dbg</code> where <code>n</code> is the slave number.</p>
Item 44	Debug information about the phase flows.
Item 45	Lower bound on X axis of matrix set-up debug output (switch 6).
Item 46	Upper bound on X axis of matrix set-up debug output (switch 6).
Item 47	Lower bound on Y axis of matrix set-up debug output (switch 6).
Item 48	Upper bound on Y axis of matrix set-up debug output (switch 6).
Item 49	Lower bound on Z axis of matrix set-up debug output (switch 6).
Item 50	Upper bound on Z axis of matrix set-up debug output (switch 6).
Item 51	Debug from the History Matching option.
Item 52	Writes the RFT file as a GRAF user file, provided the output files are formatted.
Item 53	Debug from the flow reversal code.
Item 54	Fraction of the Newton direction used if <code>DEBUG</code> switch 38 is set.
Item 55	Debug from viscous displacement.
Item 56	Replaces bands by NNCs in the solver.
Item 57	Reserved for experimental features.
Item 58	Reserved for experimental features.
Item 59	Debug from timestep selection.
Item 60	Nested LGRs.
Item 61	Debug from petro-elastic model. The cells for which output is to be written are specified by switches 45-50.
Item 76	Debug from rivers. If <code>set&gt;0</code> then a table of the river solution is output at every well iteration. If <code>set&gt;1</code> , solution obtained from river pre-solver is output.
Item 77	Debug from pseudo steady-state calculation.

DEBUG item	Effect of DEBUG item
Item 78	Statistics from SAMG solver setup and cycling.
Item 79	Outputs the norms of the residuals.
Item 80	Reserved for developer use.
Item 81	Reserved for experimental features.
Item 82	Debug from timestep selection.
Item 83	
Item 84	
Item 85	
Item 86	Reserved for developer use.
Item 87	Reserved for developer use.

Table 3.12: DEBUG keyword values

x	<b>ECLIPSE 300</b>
	<b>SPECIAL</b>
x	RUNSPEC
x	GRID
x	EDIT
x	PROPS
x	REGIONS
x	SOLUTION
x	SUMMARY
x	SCHEDULE

The DEBUG3 keyword is primarily intended for use in development work, and may change from version to version. Most controls are only partially documented if at all, in particular for limitations and warnings on their use. Debug output is not fully supported.

In parallel, a DEBUG3 keyword, possibly empty, must be present in the RUNSPEC section for the debug output files to be created properly for each task. The run may fail otherwise.

Many of the items produce enormous amounts of debug output, and should be used with extreme caution.

The keyword should be followed by integers, each of which controls a form of debug output. The default value is zero, and greater values activate the appropriate output. The data field should be terminated by a slash (/). If fewer than the maximum number integers are read, the remainder are left unchanged. Once a particular debug item is activated, it remains activated in all subsequent uses of DEBUG3 keyword unless it is explicitly turned off.

Item	Effect of DEBUG3 item
1	Debug from allocation/keyword reading. If 1, summary of storage allocation written to debug file. If >1, summary is also written to Print file, debug from allocation routines to Debug file.
2	Debug from file opening and closing.
3	Debug from table reading and checking.
4	Debug from equilibration. Can be set to 1 or 2.
5	Debug from timestepping.
6	Debug from residual calculation.
7	Matrix evaluation by differencing.
8	Debug from non-linear solver.
9	Debug from linear solver. Can be set to 1 or 2.
10	Clocks. Can be set to 1 or 2. 2 is for ECLIPSE 100-style output.
11	Debug from well calculations. Can be set to 1 or 2.
12	Debug from timestepping.
13	Debug of vector runs.
14	Debug from separators.
15	Debug of solution and properties. Can be set to 1 or 2.
16	Debug from flash calculations.
17	Null check of analytical and numerical flow Jacobians.

Item	Effect of DEBUG3 item
18	Set monitor flag to on (-1 sets back to off). If set to 2, will flag all subroutine entry and exit points and write message to the debug flag. If set to 3, will also write message to the screen or the log file.
19	If set to 1, check inter-array gaps at each memory release. If set to 2, also check inter-array gaps at each subroutine entry and exit point.
20	Force divide check on fatal error to get trace back.
21	ACTION debug.
22	Basic vector flash debug: If set to 1: Summary debug (includes iteration counts, cell states and max residual). If set to 2: also input/output debug for individual cells. If set to 3: also output of residuals, C/D matrices, Z-factors + derivatives.
23	Output of matrix.
24	Debug from NNC calculations. Can be set to 1 or 2.
25	Debug from Michelsen vector stability test. If set to 1: Individual cell information from SS/BFGS algorithms.
26	Not used.
27	Newton Search direction debug facility (use with IDEBUG (40)). Turned on after NEWTIT > IDEBUG (27), if IDEBUG (27)>0.
28	Debug of B matrix
29	Newton Search direction debug facility (see DEBUG (27)). Specifies the number of sub-steps (up to a max. of 100).
30	Lower x-index for debug output. DEFAULT: 1
31	Upper x-index for debug output. DEFAULT: $N_x$
32	Lower y-index for debug output. DEFAULT: 1
33	Upper y-index for debug output. DEFAULT: $N_y$
34	Lower z-index for debug output. DEFAULT: 1

Item	Effect of DEBUG3 item
35	Upper z-index for debug output. DEFAULT: $N_z$
36	Lower active index for debug output. DEFAULT: 1
37	Upper active index for debug output. DEFAULT: <i>inactive</i>
38	Fuel calculation debug enabled.
39	Debug of tracers.
40	Solution and property debug for the cells defined by items 30-35.
41	Residual, solution and property debug.
42	Debug from SUMMARY section.
43	State transition debug.
44	Check linear solution by back-substitution.
45	Difference test of domain results.
46	Aquifer debug.
47	Prevent pre-elimination of last equation/variable in implicit cases.
48	Select inner internal direction. Can be set to 1,2 or 3. (See also <a href="#">SOLVDIRS.</a> )
49	Select outer internal direction. Can be set to 1,2 or 3. (See also <a href="#">SOLVDIRS.</a> )
50	Debug of nested factorization pointers.
51	Debug of LGR.
52	<a href="#">PVTO</a> and <a href="#">PVTG</a> lookup debug.
53	Hysteresis debug.
54	Gas plant table handling debug.
55	VFP table handling debug.
56	Select solution variable for domain debug. DEFAULT: all
57	Null check by differencing of thermal flash: If set to 1: check flash Jacobian If set to 2: check property derivatives with respect to primaries, all states If set to 5-12: 2nd order difference of individual states OGW, OW, GW, W, OG, O, G, R, where 5=OGW, 6=OW and so on.
58	Miscible option debug.

Item	Effect of DEBUG3 item
59	Non-equilibrium restart debug.
60	Debug from K-value generation.
61	Obtain extra properties for debug (specify before RUNSPEC).
62	Suppress space saving in matrix storage.
63	Force corner point transmissibility calculations.
64	Debug from <code>OVERTR</code> , <code>OVERTTHT</code> , <code>OVERTX</code> , <code>OVERTY</code> , <code>OVERTZ</code> / <code>TRANR</code> , <code>TRANHTHT</code> , <code>TRANX</code> , <code>TRANZ</code> keywords. If set to 2, report modified transmissibilities.
65	Not used.
66	Difference check of separator flash.
67	Suppress oil/gas relative permeability interpolation.
68	Debug from thermal flash.
69	Zudkevitch-Joffe debug.
70	Debug from thermal flow.
71	Force initial is at ion of all new allocated arrays. If set to 1 then initializes to zero. If set to 2 then initializes to an undefined value.
72	Not used.
73	Suppress NNC generation.
74	Debug of multisegment well and well derivatives: <ol style="list-style-type: none"> <li>1. Check of Gamma inverse for each column J in LUD</li> <li>2. Check of solution of multisegment well matrix equation by multiplying out</li> <li>3. Check of full Jacobian by differencing</li> <li>4. Statistics of variable update (including well convergence information)</li> <li>5. Check of DMXP, derivatives of M-S well primary variables with respect to XP</li> <li>6. Check domain and MPRP inter-array gaps</li> <li>7. Check derivative of WRES with respect to BHP</li> <li>8. Check derivative of WRES with respect to XP (brief)</li> <li>9. Check derivative of WRES with respect to XP (verbose)</li> <li>10. Check derivative of Q with respect to XP (brief)</li> <li>11. Check derivative of Q with respect to XP (verbose).</li> </ol>
75	Debug from flux option.

Item	Effect of DEBUG3 item
76	$P_{sat}$ debug. 1: Trap $P_{sat}$ solution failures. 2: $P_{sat}$ solution debug.
77	Debug of heat loss to analytic rocks. Used in Thermal.
78	Debug of thermal cutback.
79	All completions cause AIM implicit cells, not just open ones.
80	Parallel code debug.
81	Force allocation of flow matrix.
82	Not used.
83	Force use of sudation NNC Jacobian generator.
84	Not used.
85	Velocity Dependent Relative Permeabilities. If set to 1: Capillary Number Modification output. If set to 2: Forchheimer Modification output. If set to 3: Both outputs.
86	Output Pseudo-Pressure Tables.
87	Debug from vector flash (phase-split calculation). If set to 1: Convergence of individual cells in GFE minimization. If set to 2: Additional detail.
88	Replace bands with NNCs. If set to 1: replace them for outer directions. If set to 2: replace them for all directions. If set to -1: suppress removal of inline NNCs.
89	Request debug from the KZP routine (generates kzp*.dbg).
90	Enable PSYNC to make more checks (note: this sets QMONTR=TRUE).
91	If > 0, skips Young re-ordering after an Appleyard chop.
92	Debug <a href="#">WARP</a> setup.
93	Debug solution/wells output at each Newton iteration (ECLIPSE 100 DEBUG (19)).
94	Rowsum debug $v = (B^{*-1})Av$ .
95	Reserved.
96	WARP LGR debug: if set to >0 then sets up solver pointers for LGRs, blocks NNCs by to-from LGRs and sets QQWARP to true. If set to >1, the NNCs are also blocked by <a href="#">AIM</a> state within each group.
97	<a href="#">GPMAINT</a> debug.

Item	Effect of DEBUG3 item

## DELAYACT Specifies a set of keywords to be processed after an ACTION is triggered

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The DELAYACT keyword marks the start of a set of SCHEDULE section keywords that are to be stored for later processing when a nominated **action** has been triggered and a specified amount of time has passed. The set of keywords must be terminated with the [ENDACTIO](#) keyword. The keywords between the DELAYACT and ENDACTIO keywords are processed at the end of the timestep when the condition defined in the DELAYACT keyword is satisfied. You can choose whether the action is to be performed only once, or repeatedly each timestep while the triggering condition is satisfied.

In ECLIPSE 100, almost any SCHEDULE section keyword may be placed between DELAYACT and ENDACTIO, with the exception of timestepping keywords (for example [TIME](#), [TSTEP](#), [DATES](#) and [GASYEAR](#)), the global keywords, and the [INCLUDE](#) keyword.

In ECLIPSE 300, practically any SCHEDULE section keyword may be placed between DELAYACT and ENDACTIO, with the exception of keywords described for [ACTIONACTIONG](#), [ACTIONR](#), [ACTIONW](#), [ACTIONS](#), [ACTIONX](#).

The amount of storage space reserved for these keywords is controlled by the RUNSPEC section keyword [ACTDIMS](#). The number of lines between a DELAYACT keyword and its corresponding ENDACTIO keyword (including the ENDACTIO keyword itself) is limited to MNLPAK in ACTDIMS item 2. The length of each line is limited to NCPLIN in ACTDIMS item 3.

Any number of action keyword sets may be declared, each with its own triggering condition; the maximum number being limited to MAXACT in ACTDIMS item 1. Each action keyword set must be bracketed by a pair of ACTION, ACTIONG, ACTIONR, ACTIONW, ACTIONS, ACTIONX and ENDACTIO keywords, and is distinguished by its action name defined in item 1. This name must be unique across all the action keyword family. If an ACTION, ACTIONG, ACTIONR, ACTIONW, ACTIONS, ACTIONX keyword is re-entered with the same action name as a previously declared action, the previously declared action is deleted and replaced with the new action.

The DELAYACT keyword is followed by the following items of data, terminated with a slash (/):

1. The action name.

A name of up to 8 characters, to distinguish this action from any others.

If an action with this name has already been declared in any of the action keyword family ACTION, ACTIONG, ACTIONR, ACTIONW, ACTIONS, ACTIONX and DELAYACT it is overwritten with the action data specified below.

2. Action name that triggers this action
3. The delay after which this action will be triggered, once the action in item 2 has been triggered. Must be greater than zero.

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

4. Number of times this action can be triggered.

The action is performed once at the end of each timestep while the action named in item 2 satisfies the triggering condition, until it has been performed the specified number of times. A number of 10,000 or greater is interpreted as 'infinity'.

DEFAULT: 1

5. Increment to the triggering condition.

After each time the action is performed, the specified increment is added to the triggering condition value (initialized in item 3). The increment may be negative, if desired.

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

DEFAULT: 0.0

End the data record with a slash (/).

---

**Note:** If the triggering action gets triggered repeatedly (in particular, before this action has been eliminated) the clock for triggering this action is not reset. That is, the countdown for the triggering of this action commences from the first time the action in item 2 is triggered.

---

**CAUTION:** It is possible to nest actions by including the definition of the ‘inner’ action within the keyword set of the ‘outer’ action (that is, before its **ENDACTIO** keyword). This offers great flexibility, but care should be exercised and the consequences of the nested actions should be thought through. For example: suppose that in the **ACTDIMS** keyword we have set **MAXACT=1** and have then defined an action **ACT1**. Suppose also that as part of this action we have defined another action, **ACT2**. ECLIPSE will only issue an error when **ACT1** is actually implemented, which may, of course, be well into the run. Alternatively we may call the inner action by the same name as the outer action, **ACT1**. This is perfectly allowable, but it must be remembered that each time an action of a given name is defined it overwrites the properties that the action may previously have had.

Suppose that we have an outer action that can be repeated a number of times. Within this action is an inner one that can also be repeated and that also increments its triggering condition each time. No matter how many times the inner action has been called, when the outer action is invoked again the inner action is redefined to its original specification.

---

**Note:** Full checking of the keywords entered with an action keyword cannot be performed until the action is actually implemented, since it is possible to use wild cards in many of the keywords. However, before a simulation run is attempted the data can be run in **NOSIM** mode. This mode does whatever checks it can on the keywords within any action keyword blocks that have been defined. All the most common types of errors of syntax and typing will be found, but errors resulting from wild cards feeding inappropriate well/group names to keywords are not found.

---

**Note:** As with the other **ACTION** type keywords, **DELAYACT** does not affect the report times or the overall length of a run. This is still fully determined by the **TIME**, **TSTEP** and **DATES** keywords following any **ACTION** type keywords. A run is not extended beyond the time it is to finish based on **TIME**, **TSTEP** and **DATES** information just because there is a delayed action waiting to be performed.

---

## Example

This example shows the **DELAYACT** keyword being used to help control a water reservoir. An **ACTIONW** keyword is used to close the producing well when the brine concentration becomes unacceptable. Water injection then takes place. At the same time a **DELAYACT** action is defined and this essentially allows the injection to go ahead for 210 days before the injection is turned off and production restarts. The cycle can then be repeated. Here we have chosen to shut all the wells the next time the brine concentration limit is violated, and a **DELAYACT** keyword has been used just to let the run continue for another 20 days so that graphics of the results will not appear to end quite so suddenly.

## DENAQA

## Specify coefficients of Ezrokhi's method for aqua density

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword enables the default Ezrokhi coefficients for the aqua density calculation to be overwritten. The data consists of a table composed of a series of 3 coefficients for each component which may dissolve in the aqua phase. In [GASSOL](#), these components are specified using the [SOLUAQA](#) table; within [CO2STORE](#), [GASWAT](#) and thermal with [KWTABTn](#), Ezrokhi's coefficients are specified for all components, although it should be noted that the coefficients for component H2O are automatically taken to be zero, irrespective of alternative user-supplied inputs. This keyword associates a contribution of each dissolved component into the aqua density calculation. See also "[GASSOL Solution in the Aqueous Phase](#)" in the *ECLIPSE Technical Description*.

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

This keyword is thus compatible with the [CO2STORE](#), [GASWAT](#), [GASSOL](#) and [KWTABTn](#) (THERMAL) options.

### Examples

#### Example 1

Input data for a four-component study:

```
DENAQA
2.01E-6 -6.34E-7 1.31E-9
1.01E-6 -5.34E-7 2.31E-9
2.01E-6 -4.34E-7 3.31E-9
2.03E-6 -4.54E-7 3.61E-9
/
```

#### Example 2

With two reservoir EoS regions and four-component study:

```
DENAQA
2.01E-6 -6.34E-7 1.31E-9
1.01E-6 -5.34E-7 2.31E-9
2.01E-6 -4.34E-7 3.31E-9
2.03E-6 -4.54E-7 3.61E-9
/
2.02E-6 -6.24E-7 1.21E-9
1.02E-6 -5.24E-7 2.21E-9
2.02E-6 -4.24E-7 3.21E-9
2.02E-6 -4.24E-7 3.21E-9
/
```

## DENSITY

## Fluid densities at surface conditions

The data comprises three fluid densities for each pressure table region. The number of pressure table regions is specified using keyword [TABDIMS](#) in the RUNSPEC section and defaults to 1. Each record consists of the following items of data, and is terminated by a slash (/).

- The density of oil at surface conditions.  
 UNITS: kg/m<sup>3</sup> (METRIC), lb/ft<sup>3</sup> (FIELD), gm/cc (LAB), kg/m<sup>3</sup> (PVT-M)  
 ECLIPSE 300 DEFAULT: 600 kg/m<sup>3</sup> = 37.457 lb/ft<sup>3</sup>
- The density of water at surface conditions.  
 UNITS: kg/m<sup>3</sup> (METRIC), lb/ft<sup>3</sup> (FIELD), gm/cc (LAB), kg/m<sup>3</sup> (PVT-M)  
 ECLIPSE 300 DEFAULT: 999.014 kg/m<sup>3</sup> = 62.366 lb/ft<sup>3</sup>
- The density of gas at surface conditions.  
 UNITS: kg/m<sup>3</sup> (METRIC), lb/ft<sup>3</sup> (FIELD), gm/cc (LAB), kg/m<sup>3</sup> (PVT-M)  
 ECLIPSE 300 DEFAULT: 1 kg/m<sup>3</sup> = 0.062428 lb/ft<sup>3</sup>

The keyword [GRAVITY](#) may be used as an alternative to DENSITY.

ECLIPSE 300

In compositional runs the oil and gas surface densities are obtained from the equation of state and the values entered under the density keyword are not used. A dummy value may be entered in this case. The water density is always required. Note that DENSITY always contains these items, even if not all three phases are present in the run.

ECLIPSE 100

**Note:** When using the API Tracking option (keyword [API](#) in the RUNSPEC section), the set of records must be entered in increasing order of oil surface density.

## Examples

### Example 1

For a black oil case, all three phase densities are specified:

```
DENSITY
45.0000 63.0200 .07020 /
```

### Example 2

For a compositional run, only the water density is required:

```
DENSITY
1* 62.0 1* /
```

ECLIPSE 300

## DEPTH

## Grid block center depths

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
x	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by one number for every grid block in the current input box, specifying the depth at the center of the grid block. The data must be terminated by a slash (/).

This keyword is entirely optional. Any depths that are not altered remain at the values calculated by ECLIPSE from the GRID data.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*6027). Note that spaces must not be inserted on either side of the asterisk.

---

**Note:** If the depth of a refined global cell is altered in the EDIT section, these changes are not applied to the local cells. Use [REFINE](#) to change the local cells as well.

---

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

## Example

```

----- IX1-IX2 JY1-JY2 KZ1-KZ2
BOX      11  14   3   8   6   6   /
DEPTH
24*6094 /

```

## DEPTHTAB Tables of river depth data

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is used to define the downstream depth boundary condition of a river as a function of the time.

The keyword is followed by NMDEPT tables with a maximum of MXDEPT entries in each. These numbers are set with the RIVRDIMS keyword. Each table is terminated with a slash (/).

Each table consists of 5 columns of data:

1. Day  
JAN, FEB, MAR, APR, MAY, JUN, JLY, AUG, SEP, OCT, NOV or DEC.  
JUL is an acceptable alternative to JLY.
2. Year  
Input the year as a four-digit integer number.
3. Time of observation in 24 hour clock format, hh:mm  
Do not use 24:00; use 00:00 of the following day
4. Depth at this time.  
UNITS: m (METRIC), ft (FIELD), cm (LAB)

The minimum number of rows of data per table is two. End the table with a slash (/). After the first tables subsequent tables may be defaulted to the previous table by just entering a slash.

The times, items 1-3 considered as a whole, must be monotonically increasing down the table.

### Example

```
DEPTHTAB
1 JAN 1995 00:00 1
8 FEB 1995 2:45 2
15 SEP 1995 12:00 3
/
```

## DETAILMF

## Initial mole fraction make-up of lumped components versus depth

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies the depth tables to be used for initializing the concentration of the tracers representing detailed components in a lumped simulation (keyword `LUMPDIMS` in the `RUNSPEC` section). The data consists of `NTTRVD` tables (item 4 of the `EQLDIMS` keyword), with one table for each tracer region defined under keyword `TNUM`.

**CAUTION:** The order of the entries in the tables is very important and should match exactly the order in which the lumpings and detailed components were entered in the `LUMPING` keyword.

The data consists of a depth followed by the mole fraction for each detailed component for each lumping. Each table must be terminated with a slash (/).

Column 1 Depth values.

The values should increase monotonically down the column.

UNITS: m (`METRIC`), ft (`FIELD`), cm (`LAB`), m (`PVT-M`)

Column 2 The mole fraction of the first lumped component to be associated with the first detailed component of this lumping.

Column 3 The mole fraction of the first lumped component to be associated with the second detailed component of the lumping.

...

...

Column n The mole fraction of the second lumped component to be associated with the first detailed component of this lumping.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than `NSTRVD` (see keyword `EQLDIMS`).

### Example

For the example in the `LUMPING` keyword.

```

DETAILMF
--Table 1
1.0 0.05 0.15
   0.25 0.25 0.3

10000.0 0.9 0.07 0.03 /

```

## DETAILVD

## Initial fraction make-up of lumped components versus depth

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies the depth tables to be used for initializing the concentration of the tracers representing detailed components in a lumped simulation (keyword [LUMPDIMS](#) in the [RUNSPEC](#) section). The data consists of [NTTRVD](#) tables (item 4 of the [EQLDIMS](#) keyword), with one table for each tracer region defined under keyword [TNUM](#).

---

**CAUTION:** The order of the entries in the tables is very important and should match exactly the order in which the lumpings and detailed components were entered in the [LUMPING](#) keyword.

---

The data consists of a depth followed by a fraction for each detailed component for each lumping. The fraction represents the proportion of the mole fraction of the carrier component to be associated with that tracer/detailed component. For each lumped phase the fractions must add up to 1.

Each table must be terminated with a slash (/)

Column 1 Depth values.

The values should increase monotonically down the column.

UNITS: m ([METRIC](#)), ft ([FIELD](#)), cm ([LAB](#)), m ([PVT-M](#))

Column 2 The fraction of the first lumped component to be associated with the first detailed component of this lumping.

Column 3 The fraction of the first lumped component to be associated with the second detailed component of the lumping.

.

.

Column n The fraction of the second lumped component to be associated with the first detailed component of this lumping.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than [NSTRVD](#) (see keyword [EQLDIMS](#)).

### Example

For the example in the [LUMPING](#) keyword.

## DGRDT

## Maximum rate of change of guide rate for wells under group control

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

When wells use the default guide rate option (using potentials rather than user assigned values or an equation defined by `GUIDERAT` keyword) there are cases, particularly with highly productive horizontal wells, when the guide rates can vary excessively from step to step. This keyword may be used to constrain the current timestep's guide rate to fall within bounds defined by the previous timestep's guide rate.

The keyword is followed by a line containing some or all of the following items of data, terminated with a slash (/).

The items are:

1. Limiting fractional rate of change of guide rate.

A lower fractional bound on the guide rate is formed by multiplying the value in this item by the current timestep and subtracting the result from 1.0.

An upper fractional bound on the guide rate is formed by multiplying the value in this item by the current timestep and adding the result to 1.0.

The limiting bounds on the current timestep's guide rate are formed by multiplying the above fractional bounds by the previous timestep's guide rate.

UNITS: 1/day (METRIC), 1/day (FIELD), 1/hr (LAB), 1/day (PVT-M)

DEFAULT: 100.0 (all unit sets)

2. The smallest permitted lower fractional bound as calculated above.

DEFAULT: 0.5

3. The largest permitted upper fractional bound as calculated above.

DEFAULT: 1.5

### Example

Allow guide rate changes of 1% per day:

```
DGRDT
0.01 /
```

## DGRID

## Dump section of grid

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword dumps a box of the current model to a .DGRD file. This file contains the geometric grid information, along with any input solution vectors for the defined box, in the GRID, EDIT, PROPS, REGIONS and SOLUTION sections of the current data set. The main purpose of this keyword is to use the .DGRD file to produce a smaller sector model from the current dataset. The keyword contains the following items:

1. First block on X axis of the box (IX1).  
DEFAULT: 1
2. Last block on X axis of the box (IX2).  
DEFAULT: NDIVIX
3. First block on Y axis of the box (JY1).  
DEFAULT: 1
4. Last block on Y axis of the box (JY2).  
DEFAULT: NDIVIY
5. First block on Z axis of the box (KZ1).  
DEFAULT: 1
6. Last block on Z axis of the box (KZ2).  
DEFAULT: NDIVIZ
7. LGR name. A blank is interpreted as the base grid.  
DEFAULT: ' '

The data must satisfy:

$$1 \leq IX1 \leq IX2 \leq NDIVIX$$

$$1 \leq JY1 \leq JY2 \leq NDIVIY$$

$$1 \leq KZ1 \leq KZ2 \leq NDIVIZ \text{ (where NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword DIMENS)}$$

The data must be terminated by a slash (/).

If the dataset is a restart run (using the flexible restart facility (that is the [RESTART](#) keyword in the SOLUTION section), then the keywords [SWAT](#), [SOIL](#), [PRESSURE](#), [XMF](#) and [YMF](#) will be output to the .DGRD file. This enables a non-equilibrium restart of the sector model.

If the current dataset is corner point, then the corner point keywords [COORD](#) and [ZCORN](#) are included in the GRID section of the .DGRD file. Similarly for block centered keywords. If a keyword in the current dataset is derived, for example, by using [EQUALS](#), [BOX](#) and [COPY](#) keywords, this derivation is NOT reproduced in the .DGRD file.

Note only the keywords that are solution vectors, over NX, NY, NZ are output to the .DGRD file. For example the [ACTNUM](#) data from the GRID section or the [FIPNUM](#) data from the REGIONS section.

---

**CAUTION:** This keyword does not work with either LGRs or the PARALLEL keyword.

---

## Example

```
GRID
-- output section 24-55, 128-140, 1-11 to the DGRD file
DGRID
24 55 128 140 1 11 /
```

## DIAGDISP

## Enables alternate form of tracer dispersion

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

There is no data associated with this keyword

**CAUTION:** Whilst, for simplicity, we use (x,y,z) below, these are not actually the coordinates used. The coordinate system used for dispersion follows the rock layers; that is we actually require data for, and do the calculations in, the i-direction, the j-direction and the k-direction. These may not be the same as (x,y,z) coordinates.

The form of dispersion used when this keyword is used replaces the dispersion matrix described in the [TRDIS](#) keyword with the one below:

$$\begin{pmatrix} A_1 & 0 & 0 \\ 0 & A_2 & 0 \\ 0 & 0 & A_3 \end{pmatrix}$$

where:

$$A_1 = D_1(|v_x|, c) + D_2(|v_y|, c) + D_3(|v_z|, c)$$

$$A_2 = D_4(|v_x|, c) + D_5(|v_y|, c) + D_6(|v_z|, c) \text{ and}$$

$$A_3 = D_7(|v_x|, c) + D_8(|v_y|, c) + D_9(|v_z|, c)$$

Note that for a brine tracer, if the [DSPDEINT](#) keyword has been used, the concentrations in the lookup tables are replaced with the cell's water density.

**Note:** The option does not work with two-phase or partitioned tracers.

See also keywords [DISPDIMS](#), [DISPERSE](#) and [DSPDEINT](#).

```

## DIFFAGAS

## Activity corrected gas diffusion coefficients

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies a gas phase activity-corrected diffusion coefficient for each component in a compositional run. These are used to define gas phase diffusive flows in terms of chemical potential differences.

The activity-corrected diffusion coefficient is defined in Reid, Prausnitz and Polling ([Ref. 90] in *ECLIPSE Technical Description*). These are also described in "Diffusion" in the *ECLIPSE Technical Description*. Activity-related coefficients may be related to the normal form of diffusion coefficient by:

$$D_i^a = D_i \left| \frac{\partial}{\partial \ln y_i} (\ln f_i) \right| \quad \text{Eq. 3.52}$$

where the normal diffusion coefficients are defined by the condition:

$$J_i = -cD_i \frac{\partial y_i}{\partial d} \quad \text{Eq. 3.53}$$

where

$c$  is the total molar concentration.

$J_i$  is the flux of component  $i$  per unit area.

$D_i$  is the diffusion coefficient of component  $i$ .

$\frac{\partial y_i}{\partial d}$  is molar concentration gradient of component  $i$ .

For gases, the normal and activity-corrected diffusion coefficients are similar, and become equal at low pressure.

The activity-corrected diffusion coefficients are used in ECLIPSE 300 to obtain inter block diffusive flows in terms of log fugacity (chemical potential) differences. The gas phase diffusive flow is:

$$F_{ig}^{\text{diff}} = TD D_{ig}^a (y_i S_g b_g^m)_u \Delta \left( \ln f_i - \frac{M_i Gh}{RT} \right) \quad \text{Eq. 3.54}$$

where  $TD$  is the diffusivity, the analogue of transmissibility for diffusive flow, and  $f_i$  are the component fugacities. For more details, see "Diffusion" in the *ECLIPSE Technical Description*. Diffusivities should be entered in the appropriate unit set. If the values available are in  $\text{cm}^2/\text{s}$ , they may be converted as follows:

LAB units:  $1 \text{ cm}^2/\text{s} = 3600 \text{ cm}^2/\text{hr}$

METRIC or PVT-M units:  $1 \text{ cm}^2/\text{s} = 8.64 \text{ m}^2/\text{day}$

FIELD units:  $1 \text{ cm}^2/\text{s} = 92.9979 \text{ ft}^2/\text{day}$

UNITS:  $\text{m}^2/\text{day}$  (METRIC),  $\text{ft}^2/\text{day}$  (FIELD),  $\text{cm}^2/\text{hr}$  (LAB),  $\text{m}^2/\text{day}$  (PVT-M)

## DIFFAOIL

	SCHEDULE

This keyword specifies an oil phase activity-corrected diffusion coefficient for each component in a compositional run. These are used to define oil phase diffusive flows in terms of chemical potential differences. Oil diffusion coefficients are typically an order of magnitude lower than gas diffusion coefficients.

The units and format of the DIFFAOIL keyword are entirely analogous to the [DIFFAGAS](#) keyword.

UNITS: m<sup>2</sup>/day (METRIC), ft<sup>2</sup>/day (FIELD), cm<sup>2</sup>/hr (LAB), m<sup>2</sup>/day (PVT-M)

## DIFFC

## Molecular diffusion data for each PVT region

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is used to specify the fluid diffusion data for runs using the molecular diffusion option (keyword **DIFFUSE** in the RUNSPEC section). The data comprises NTPVT (see keyword **TABDIMS**) records of molecular weights and diffusion coefficients, one for each PVT region.

Each record consists of 8 data items terminated by a slash (/):

- The oil molecular weight.  
UNITS: kg/kg-M (METRIC), lb/lb-M (FIELD), gm/gm-M (LAB)
- The gas molecular weight.  
UNITS: kg/kg-M (METRIC), lb/lb-M (FIELD), gm/gm-M (LAB)
- The gas-in-gas diffusion coefficient.  
UNITS: m<sup>2</sup>/day (METRIC), ft<sup>2</sup>/day (FIELD), cm<sup>2</sup>/hr (LAB)
- The oil-in-gas diffusion coefficient.  
UNITS: m<sup>2</sup>/day (METRIC), ft<sup>2</sup>/day (FIELD), cm<sup>2</sup>/hr (LAB)  
DEFAULT: Gas-in-gas coefficient's value
- The gas-in-oil diffusion coefficient.  
UNITS: m<sup>2</sup>/day (METRIC), ft<sup>2</sup>/day (FIELD), cm<sup>2</sup>/hr (LAB)  
DEFAULT: Gas-in-gas coefficient's value
- The oil-in-oil diffusion coefficient.  
UNITS: m<sup>2</sup>/day (METRIC), ft<sup>2</sup>/day (FIELD), cm<sup>2</sup>/hr (LAB)  
DEFAULT: Gas-in-oil coefficient's value
- The gas-in-oil diffusion coefficient for cross phase diffusion.  
UNITS: m<sup>2</sup>/day (METRIC), ft<sup>2</sup>/day (FIELD), cm<sup>2</sup>/hr (LAB)  
DEFAULT: 0.0
- The oil-in-oil diffusion coefficient for cross phase diffusion.  
UNITS: m<sup>2</sup>/day (METRIC), ft<sup>2</sup>/day (FIELD), cm<sup>2</sup>/hr (LAB)  
DEFAULT: 0.0

ECLIPSE calculates the diffusive flow from the following expression (in the gas-in-gas case):

$$F_{\text{diff}} = T_d D_{\text{gg}} S_g B_g (x_i - x_j) \quad \text{Eq. 3.55}$$

where:

$T_d$  = diffusivity

$D_{\text{gg}}$  = gas-in-gas diffusion coefficient

$S_g$  = gas saturation

$B_g$  = gas formation volume factor

$x_i, x_j$  = the gas mole fraction in the gas phase in cells  $i$  and  $j$ .

More details can be found in "[Diffusion](#)" in the *ECLIPSE Technical Description*.

The diffusion coefficients should be entered in the appropriate unit set. The diffusion coefficients are often quoted in  $\text{cm}^2/\text{sec}$ ; they may be converted as follows:

$$1 \text{ cm}^2/\text{s} = 8.64 \text{ m}^2/\text{day} \text{ (METRIC)}$$

$$1 \text{ cm}^2/\text{s} = 110.0976 \text{ ft}^2/\text{day} \text{ (FIELD)}$$

$$1 \text{ cm}^2/\text{s} = 3600 \text{ cm}^2/\text{hr} \text{ (LAB)}$$

ECLIPSE 100

---

**Note:** In 2014.1, the diffusion equation expressed in FIELD units has been modified. The pre 2014.1 behavior is restored by multiplying diffusion coefficients by 5.614583, which is the conversion factor between bbl and  $\text{ft}^3$ . METRIC and LAB unit systems remain unchanged.

---

## Examples

### Example 1

With NTPVT=2:

```

x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is used to specify the gas diffusion coefficient for each component in a coal bed methane run. A coal bed methane model can be divided into one or more regions. The number of regions is NTCREG and this number is input using REGDIMS item 6. Coal regions are input with the keyword COALNUM. There is one DIFFCBM record for each coal region up to NTCREG records. Each record contains the diffusion coefficients for the total number of components which is defined using keyword NCOMPS.

Record 1:  $d_1 \ d_2 \ d_3 \ \dots d_{ncomps}$

Diffusion coefficients for coal region number 1. The diffusion coefficients should be larger or equal to zero.

UNITS: m<sup>2</sup>/day (METRIC), ft<sup>2</sup>/day (FIELD), cm<sup>2</sup>/hr (LAB), m<sup>2</sup>/day (PVT-M)

DEFAULT: 0.0

Record 2:  $d_1 \ d_2 \ d_3 \ \dots d_{ncomps}$

Diffusion coefficients for coal region number 2.

Records 3 to NTCREG

The diffusion coefficients for coal regions 3 to NTCREG.

Each record is terminated by a slash (/). A final slash (/) terminates the keyword.

Diffusivities should be entered in the appropriate unit set, If the values available are in cm<sup>2</sup>/s, they may be converted as follows:

LAB units: 1 cm<sup>2</sup>/s = 3600 cm<sup>2</sup>/hr

METRIC or PVT-M units: 1 cm<sup>2</sup>/s = 8.64 m<sup>2</sup>/day

FIELD units: 1 cm<sup>2</sup>/s = 92.9979 ft<sup>2</sup>/day

For further information see "Coal bed methane model" in the *ECLIPSE Technical Description*.

## Example

```

## DIFFCGAS Gas diffusion coefficients

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies a gas phase diffusion coefficient for each component in a compositional run. These are used to define diffusive flows in terms of vapor mole fractions.

The normal diffusion coefficients input using by DIFFCGAS are defined by the condition (see Reid, Prausnitz and Polling [Ref. 90]):

$$J_i = -cD_i \frac{\partial y_i}{\partial d} \quad \text{Eq. 3.56}$$

where

$c$  is the total molar concentration.

$J_i$  is the flux of component  $i$  per unit area.

$D_i$  is the diffusion coefficient of component  $i$ .

$\frac{\partial y_i}{\partial d}$  is molar concentration gradient of component  $i$ .

These diffusion coefficients are used in ECLIPSE 300 to obtain gas interblock diffusive flows, which take the form:

$$F_{ig}^{\text{diff}} = TD D_{ig} (S_g b_g^m) \Delta y_i \quad \text{Eq. 3.57}$$

where

$TD$  is the diffusivity, the analogue of transmissibility for diffusive flow

$y_i$  are vapor mole fractions.

For more details, see "Diffusion" in the *ECLIPSE Technical Description*.

Diffusivity should be entered in the appropriate unit set. If the values available are in  $\text{cm}^2/\text{s}$ , they may be converted as follows:

LAB units:  $1 \text{ cm}^2/\text{s} = 3600 \text{ cm}^2/\text{hr}$

METRIC or PVT-M units:  $1 \text{ cm}^2/\text{s} = 8.64 \text{ m}^2/\text{day}$

FIELD units:  $1 \text{ cm}^2/\text{s} = 92.9979 \text{ ft}^2/\text{day}$

UNITS:  $\text{m}^2/\text{day}$  (METRIC),  $\text{ft}^2/\text{day}$  (FIELD),  $\text{cm}^2/\text{hr}$  (LAB),  $\text{m}^2/\text{day}$  (PVT-M)

DEFAULT: 0.0

This keyword specifies water-gas cross phase diffusion coefficient for each component in a compositional [CO2STORE](#) or [GASWAT](#) run. These are used to define cross phase molecular diffusion from a cell containing water to a cell containing gas. The opposite diffusive flow from a cell containing gas to a cell containing water should be specified by the keyword [DIFFCGW](#).

The potential is constructed by mixing the water composition and the gas composition. The potential is then determined by using the liquid and or vapor mole fraction of the mixed cell.

For more details, see "[Diffusion](#)" in the *ECLIPSE Technical Description*.

Diffusivity should be entered in the appropriate unit set. If the values available are in  $\text{cm}^2/\text{s}$ , they may be converted as follows:

LAB units:  $1 \text{ cm}^2/\text{s} = 3600 \text{ cm}^2/\text{hr}$

METRIC or PVT-M units:  $1 \text{ cm}^2/\text{s} = 8.64 \text{ m}^2/\text{day}$

FIELD units:  $1 \text{ cm}^2/\text{s} = 92.9979 \text{ ft}^2/\text{day}$

UNITS:  $\text{m}^2/\text{day}$  (METRIC),  $\text{ft}^2/\text{day}$  (FIELD),  $\text{cm}^2/\text{hr}$  (LAB),  $\text{m}^2/\text{day}$  (PVT-M)

DEFAULT: 0.0

## Example

```
DIFFCWG
--For      CO2      H2O      (field units)
           0.16     0.15     /
```

## Restricts molecular diffusion in dual porosity runs

This keyword is relevant only in dual porosity runs (keyword [DUALPORO](#) in RUNSPEC) that use the molecular diffusion option (keyword [DIFFUSE](#) in RUNSPEC).

If this keyword is present, the molecular diffusion calculation is only performed for the matrix-fracture flows.

This can be useful to minimize the computer cost in dual porosity cases where the diffusive flows have been shown to be negligible except in the matrix-fracture flow, where diffusion may be the dominant recovery mechanism.

The keyword has no associated data.

## DIFFMMF

**Matrix-fracture diffusivity multipliers**

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
X	SCHEDULE

This keyword is relevant only in dual porosity runs (keyword [DUALPORO](#) in the RUNSPEC section) which use either the molecular diffusion option (keyword [DIFFUSE](#) in the RUNSPEC section) or the coal bed methane option (keyword [COAL](#) in the RUNSPEC section).

The keyword should be followed by one non-negative real number for every grid block in the current input box. The values specified act as multipliers on the diffusivities calculated by ECLIPSE for the non-neighbor connections (NNCs) that represents the matrix-to-fracture flows in dual porosity runs. The DIFFMMF values from the upper half of the model (matrix cells) are used to modify the diffusivities; any values entered in the lower half (fracture cells) will be ignored. The data must be terminated by a slash (/).

Any DIFFMMF values that are not specified when the end of the GRID section is reached default to 1.0. If the keyword is specified in the SCHEDULE section then its effect will be cumulative on all values already specified or defaulted.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0). Note that spaces must not be inserted on either side of the asterisk.

**Example**

```
----- IX1-IX2 JY1-JY2 KZ1-KZ2
BOX
      1 10   1 10   1  2  /
DIFFMMF
200*0.80 /
```

## DIFFMR

## DIFFTGAS Thermal diffusion coefficients for gas

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies a gas phase thermal diffusion coefficient for each component in a compositional run. These are used to define gas phase diffusive flows in terms of temperature differences.

The gas phase diffusive flow is:

$$F_{ig}^{\text{diff}} = T_D D_{ig}^a \left( \frac{y_i S_g b_g^m}{RT} \right)_u \Delta \left( RT \ln f_i - M_i Gh + M_i D_{ig}^T \ln T \right) \quad \text{Eq. 3.58}$$

where

$T_D$  is the diffusivity, the analogue of transmissibility for diffusive flow,

$D_{ig}^a$  is the activity corrected gas diffusion coefficient, defined by the [DIFFAGAS](#) keyword,

$D_{ig}^T$  is the thermal gas diffusion coefficient, defined by this keyword, and

$T$  is the temperature.

For more details, see "[Diffusion](#)" in the *ECLIPSE Technical Description*.

There should be one value for each component.

UNITS: kJ/kg (METRIC), Btu/lb (FIELD), J/gm (LAB), kJ/kg (PVT-M)

DEFAULT: 0.0

### Example

For 5 components:

```
DIFFTGAS
1.0 1.0 1.0 1.0 1.0/
```

**Note:** The keyword can only be used when the keyword [DIFFAGAS](#) is used, and in non-isothermal runs when the reservoir temperature is set with keyword [TEMPVD](#) or [TEMPI](#).

## DIFFTHT

## Diffusivities in the theta direction

ECLIPSE 300

---

**Note:** For ECLIPSE 100 compatibility, the `EDIT` section keyword `DIFFTTHT` has been aliased to `DIFFTHT`. However, `DIFFTY` can still be used in the `EDIT` section.

---

Diffusivities are analogous to transmissibilities for diffusive flow, and are described in "[Diffusion](#)" in the *ECLIPSE Technical Description*.

### Example

```

----- IR1-IR2 JT1-JT2 KZ1-KZ2
BOX
      1   3   1   3   1   1   /
DIFFTHT
9*0.0 /

```

## DIFFTOIL

## Thermal diffusion coefficients for oil

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies an oil phase thermal diffusion coefficient for each component in a compositional run. These coefficients are used to define oil phase diffusive flows in terms of temperature differences. Oil diffusion coefficients are typically an order of magnitude lower than gas diffusion coefficients.

The units and format of the DIFFTOIL keyword are entirely analogous to the DIFFTGAS keyword. The keyword should only be used when the keyword DIFFFAOIL is used, and in non-isothermal runs when the reservoir temperature is set with keyword TEMPVD or TEMPI.

There should be one value for each component.

UNITS: kJ/kg (METRIC), Btu/lb (FIELD), J/gm (LAB), kJ/kg (PVT-M)

DEFAULT: 0.0

## DIFFUSE

## Enables molecular diffusion

This indicates that the molecular diffusion option is required (see "Diffusion" in the *ECLIPSE Technical Description*).

In ECLIPSE 100, the diffusivities are calculated from the grid data. These calculated values can be modified using the [DIFFMX](#) and related keywords in the GRID section, or they can be overwritten using the [DIFFX](#) and related keywords in the EDIT section. The diffusion coefficients are entered using [DIFFC](#) in the PROPS section.

IN ECLIPSE 300, the diffusivities are calculated from the grid data. These calculated values can be modified using the [DIFFMX](#) and related keywords in the GRID section, or they can be overwritten using the [DIFFX](#) and related keywords in the EDIT section. The diffusion coefficients are entered using [DIFFCGAS](#) or [DIFFCOIL](#) in the PROPS section.

The keyword has no associated data.

# DIFFX

## Diffusivities in the X-direction

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
x	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The DIFFX keyword is entirely optional. This keyword specifies the diffusivity values explicitly, replacing those calculated by the program. Any diffusivities that are not altered remain at the values calculated by the program from the GRID data.

The values specified overwrite the diffusivities calculated by the program for the +X face of each grid block when the molecular diffusion option is activated (using the DIFFUSE keyword in the RUNSPEC section) in a Cartesian grid.

Thus, a value specified for block (I, J, K) is the diffusivity between blocks (I, J, K) and (I+1, J, K).

The keyword should be followed by one non-negative real number for every grid block in the current input box. The data must be terminated by a slash (/).

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0). Note that spaces must not be inserted either side of the asterisk.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

---

**Note:** DIFFX does not affect non-neighbor connections generated by faults.

---

ECLIPSE 300

---

**Note:** For ECLIPSE 100 compatibility, the EDIT section keyword DIFFTX has been aliased to DIFFX. However, DIFFTX can still be used in the EDIT section.

---

Diffusivities are analogous to transmissibilities for diffusive flow, and are described in "Diffusion" in the *ECLIPSE Technical Description*.

### Example

```

----- IX1-IX2 JY1-JY2 KZ1-KZ2

## DIMENS

### Specifies the dimensions of the grid

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword defines the basic size of the simulation grid. It is followed by three integers, specifying the number of cells in the x, y and z directions respectively. (In the radial case, these values specify the number of cells in the r,  $\theta$  and z directions). In the documentation, the items in the DIMENS keyword are frequently referred to as  $N_x$ ,  $N_y$  and  $N_z$ , or NDIVIX, NDIVIY and NDIVIZ.

There is no default. It is an error not to supply the grid dimensions.

IN ECLIPSE 100, when using any discretized matrix option (keyword [NMATRIX](#)) including the discretized gravity drainage model activated by keywords [GRAVDRB](#) and [NMATOPTS](#) (option VERTICAL), the minimum value of the number of cells in the X direction is 2.

### Example

For a reservoir represented by a 10 x 3 x 4 grid the keyword would be:

```
DIMENS
10 3 4 /
```

## Dynamically sets IMPES solution procedure

The DIMPES keyword switches from the default implicit solution technique to the IMplicit Pressure Explicit Saturation solution procedure.

The data comprises the following data items terminated by a slash (/). If a slash is encountered before the end of the data, the remaining items are left at their default values.

### Data items

DSTARG Target maximum saturation change in any timestep

DEFAULT: 0.05

DSMAX Maximum tolerable saturation change in any timestep

DEFAULT: 0.1

DPMAX Maximum tolerable pressure change in any timestep

UNITS: bars (METRIC), psi (FIELD), atm (LAB)

DEFAULT: 200 psi

## Examples

### Example 1

To set the default values explicitly:

```
DIMPES
/
```

### Example 2

To set the maximum target saturation change in any grid block in any timestep to 2.5% and the maximum tolerable saturation change to 5%. ECLIPSE attempts to select timesteps such that the maximum saturation change in any grid block is 2.5% but it accepts a timestep if the maximum saturation change is less than 5%.

```
DIMPES
0.025 0.05 /
```

## Resets the solution procedure to fully implicit

This keyword requires no data and can be used to switch from the IMPES method back to the Fully Implicit method (see keywords [IMPES](#), [DIMPES](#) and [FULLIMP](#)). The [TUNING](#) parameters are reset to their default values.

This was formerly the [IMPLICIT](#) keyword in ECLIPSE 100.

---

**Note:** The DIMPLICT keyword cannot be used if the IMPES keyword has been specified in the RUNSPEC section. If the base case of a restart run was run with IMPES, however defined, the restart run cannot use the DIMPLICT keyword.

---

### Example

```
DIMPLICT
```

## DISGAS

## Run contains dissolved gas in live oil

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This indicates that the run contains dissolved gas in live oil.

The keyword may be used only if [OIL](#) and [GAS](#) are both present.

If oil has a constant and uniform dissolved gas concentration, and if the pressure never drops below the bubble point, then the model can be run more efficiently by omitting the [GAS](#) and [DISGAS](#) keywords from the [RUNSPEC](#) section, treating the oil as dead oil, and declaring a constant  $R_s$  value with keyword [RSCONST](#) or [RSCONSTT](#) in the [PROPS](#) section. The simulation is run as a dead oil problem with no gas, but the calculations take into account the constant dissolved gas concentration.

The keyword has no associated data.

When the [BLACKOIL](#) keyword is used in ECLIPSE 300 this option is automatically selected if the [PVTG](#) or [PVC](#) keywords are present.

## DISPBC

## Velocity boundary conditions for coupled rock and stress calculations

This keyword is being replaced by new keywords for setting displacement boundary conditions. Please refer to keyword [GMDISBC](#).

This keyword specifies displacement boundary conditions when a coupled rock stress and fluid flow calculation is specified with the keyword [GEOMECH](#) in the RUNSPEC section.

This keyword allows displacement boundary conditions to be specified on all boundaries. If a particular boundary is not specified in this keyword or by [TRACTBC](#) or [PSTRBC](#) keywords, then that boundary is defaulted to a rigid boundary.

This keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. A character string specifying the boundary to which the velocity boundary condition is applied.

This must be one of the following:

I+ Specify the boundary condition on the outer I+ edge

I- Specify the boundary condition on the outer I- edge

J+ Specify the boundary condition on the outer J+ edge

J- Specify the boundary condition on the outer J- edge

K+ Specify the boundary condition on the outer K+ edge

K- Specify the boundary condition on the outer K- edge

DEFAULT: There is no default for this item; it must be specified.

The K- boundary is the top boundary of the simulation, K+ is the bottom.

2. An integer specifying the type of boundary condition on this face

This must be one of the following:

1. A normal rock displacement velocity is specified on the boundary denoted in item 1.

2. A rock displacement velocity with X, Y, Z components. A single X, Y, Z velocity component is set in item 3 and the component name must be set in item 4. Separate lines are needed to set different components.

For boundary condition type 2, the X, Y, Z components conform to the X, Y, Z directions as specified in the [COORD](#) keyword for corner point geometry.

DEFAULT: 2

3. A normal rock displacement on this boundary, if the boundary condition type in item 2 is 1, or an X, Y, Z component of a rock displacement, if the boundary condition type in item 2 is 2.  
 UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)  
 DEFAULT: 0
4. A character string that gives the component of displacement or velocity if the boundary type in item 2 is 2. This must be one of 'X', 'Y' or 'Z'.  
 DEFAULT: None. It must be specified if item 2 is 2
5. First block to be modified in the I direction  
 DEFAULT: 1 if an I- face
6. Last block to be modified in the I direction  
 DEFAULT: NX if an I+ face
7. First block to be modified in the J direction  
 DEFAULT: 1 if a J- face
8. Last block to be modified in the J direction  
 DEFAULT: NY if a J+ face
9. First block to be modified in the K direction  
 DEFAULT: 1 if a K- face
10. Last block to be modified in the K direction  
 DEFAULT: NZ if a K+ face

## Example

```

-- set a normally rigid boundary in the x and y-directions
DISPBC
-- side type velocity
  'I+' 1 /
  'I-' 1 /
  'J+' 1 /
  'J-' 1 /
/

```

## DISPBCL

## Velocity boundary conditions for coupled rock and stress calculations in a Local Grid Refinement

This keyword is being replaced by new keywords for setting displacement boundary conditions. Please refer to keyword [GMDISBCL](#).

This keyword specifies displacement boundary conditions when a coupled rock stress and fluid flow calculation is specified with the keyword [GEOMECH](#) in the RUNSPEC section.

This keyword allows displacement boundary conditions to be specified on all boundaries of a local grid refinement. If a particular boundary is not specified by this keyword or by [TRACTBC](#) or [PSTRBC](#) keywords, then that boundary is defaulted to a rigid boundary.

This keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\* where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. A character string specifying the boundary to which the velocity boundary condition is applied

This must be one of the following:

I+ Specify the boundary condition on the outer I+ edge

I- Specify the boundary condition on the outer I- edge

J+ Specify the boundary condition on the outer J+ edge

J- Specify the boundary condition on the outer J- edge

K+ Specify the boundary condition on the outer K+ edge

K- Specify the boundary condition on the outer K- edge

DEFAULT: There is no default for this item; it must be specified.

The K- boundary is the top boundary of the simulation, K+ is the bottom.

2. An integer specifying the type of boundary condition on this face

This must be one of the following:

1. A normal rock displacement velocity is specified on the boundary denoted in item 1.

2. A rock displacement velocity with X, Y, Z components. A single X, Y, Z velocity component is set in item 3 and the component name must be set in item 4. Separate lines are needed to set different components.

For boundary condition type 2, the X, Y, Z components conform to the X, Y, Z directions as specified in the [COORD](#) keyword for corner point geometry.

DEFAULT: 2

3. Name of the Local Grid Refinement
4. A normal rock displacement on this boundary, if the boundary condition type in item 2 is 1, or an X, Y, Z component of a rock displacement, if the boundary condition type in item 2 is 2.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: 0

5. A character string that gives the component of displacement or velocity if the boundary type in item 2 is 2. This must be one of 'X', 'Y' or 'Z'.

DEFAULT: None. It must be specified if item 2 is 2

6. First block to be modified in the I direction in an LGR specified in item 3

DEFAULT: 1 if an I- face

7. Last block to be modified in the I direction in an LGR specified in item 3

DEFAULT: NX if an I+ face

8. First block to be modified in the J direction in an LGR specified in item 3

DEFAULT: 1 if a J- face

9. Last block to be modified in the J direction in an LGR specified in item 3

DEFAULT: NY if a J+ face

10. First block to be modified in the K direction in an LGR specified in item 3

DEFAULT: 1 if a K- face

11. Last block to be modified in the K direction in an LGR specified in item 3

DEFAULT: NZ if a K+ face

## Example

```

-- set a normally rigid boundary in the x and y-
directions for the local grid refinement LGR1
DISPBCL
-- side type velocity
  'I+' 1 'LGR1' /
  'I-' 1 'LGR1' /
  'J+' 1 'LGR1' /
  'J-' 1 'LGR1' /
/

```

## DISPDIMS **Dispersion dimension data**

	<b>ECLIPSE 300</b>
	<b>SPECIAL</b>
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data consists of the following items, describing the dimensions of the dispersion tables to be used in the run (see [TRDIS](#)). The data must be terminated by a slash (/).

The items are:

1. The number of dispersion tables  
DEFAULT: 1
2. The maximum number velocity nodes in any dispersion table (there must be a minimum of 2)  
DEFAULT: 2
3. The maximum number of concentration nodes per velocity node in any dispersion table.  
DEFAULT: 1

See also [TRDIS](#), [DISPERSE](#) and [DSPDEINT](#).

### Example

```
DISPDIMS
 9 4 4 /
```

## DISPERSE Dispersion tables

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises MXDIST (see item 1 in keyword `DISPDIMS` in the `RUNSPEC` section) tables of dispersion coefficients (see `TRDIS`). A single table consists of at least 2 and up to MXVVP (item 2 in keyword `DISPDIMS`) records, each terminated by a slash (/). A table is terminated by a null record (that is a record with no data before the terminating slash). Most records contain the following items of data, terminating with a slash.

1. Velocity (absolute value)  
The values must be monotonically increasing.  
UNITS: m/day (`METRIC`), ft/day (`FIELD`), cm/hr (`LAB`)
2. Tracer concentration
3. Dispersion coefficient.  
UNITS: m<sup>2</sup>/day (`METRIC`), ft<sup>2</sup>/day (`FIELD`), cm<sup>2</sup>/hr (`LAB`)

The first velocity in the table must be zero.

However, some records (optionally all) contain additional data that defines the dispersion coefficient, at a given velocity, as a function of tracer concentration. For each velocity the first tracer concentration value must always be zero. The additional data takes the form of 2 columns which continue from items 2 and 3 above. There can only be a maximum of MXCVPV (item 3 in keyword `DISPDIMS`) concentration nodes per velocity node. The concentration values must be monotonically increasing.

---

**Note:** For a brine tracer, item 2 can be replaced with water density if the `DSPDEINT` keyword is used.

---

**Note:** There is no need for the dispersion coefficient to be monotonically increasing or decreasing, and it is perfectly allowable to use constant values (two velocity nodes will still be needed). A particularly common table will have 2 velocity nodes, both with a zero dispersion coefficient to effectively turn off certain terms (see `TRDIS`). Non-zero constants can be used to enable heterogeneous diffusion. If dispersion is only being used to enable a non-homogeneous diffusion then the calculations can be significantly speeded up by using the `TRNHD` keyword.

---

## DNGL

## Partial densities for NGLs

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

In a compositional run using gas plants which produce NGLs, that is natural gas liquids (specified using [GPTABLEN](#)), this keyword specifies the partial densities of the NGLs. These are converted to partial molar volumes internally, and the molar volume of a NGL mixture is obtained as a mole fraction weighted sum. Note that for a volatile component, an apparent partial density should be entered.

See also "[Gas Plants and NGLs](#)" in the *ECLIPSE Technical Description*.

The keyword should be followed by  $N_c$  values.

UNITS: kg/m<sup>3</sup> (METRIC), lb/ft<sup>3</sup> (FIELD), gm/cc (LAB), kg/m<sup>3</sup> (PVT-M)

## Example

```

DNGL
50.192      48.507      61.991      26.532      34.211      36.333

## DOMAIN

## Set non-default domain size for phase property evaluation

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword may be used to override the default treatment of domains used for phase property evaluation.

The active cells within a reservoir are split into domains of cells, which are treated together in the phase equilibrium and property evaluation parts of the code.

Reducing the number of cells in a domain slightly reduces the memory used, as the workspace required is reduced, at the expense of vector length.

It is inadvisable to use very small domain sizes (below 50) as the loop and subroutine calling overheads become significant.

The actual domain size used will, in any event, never be greater than the number of cells in the problem.

If the Local Grid Refinement option is active then this keyword can be used in conjunction with the [CARFIN](#) keyword to alter the partitioning of a [CARFIN](#) that is being processed in parallel. In this case the LGR must have been flagged to run in parallel and the [DOMAIN](#) keyword must appear between the [CARFIN](#) and the corresponding [ENDFIN](#). The [DOMAIN](#) keyword should NOT be used if the refinement is part of an amalgamation.

### Example

```
DOMAIN
100 /
```

## DOMAINS

**Modifies the size of parallel domains**

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is optional, and allows the user to modify the number of planes allocated to each domain.

The keyword should be followed by one positive real number for each domain in the model. The number of domains is specified using keyword [PARALLEL](#) in the [RUNSPEC](#) section. The data must be terminated by a slash. The total number of planes must sum to the number of cells in the outer solver direction. The solver direction sequence determined by ECLIPSE can be output using the [DOMAINS](#) mnemonic in the [RPTGRID](#) keyword. However, it is advisable to set the outer solver direction manually using the [SOLVDIRS](#) keyword when using this keyword.

**Example**

Outer direction X, NX=40 and NDMAIN=8

```
SOLVDIRS
'-X' /
DOMAINS
7 6 4 3 3 4 6 7 /
```

## DPCDT

## Maximum rate of change of capillary pressure

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data consists of a single item:

1. The maximum rate of change of capillary pressure in explicit cells.

UNITS: bars/day (METRIC), psi/day (FIELD), atm/hr (LAB), atm/day (PVT-M)

DEFAULT: 0.0099972 psi/day in IMPES and AIM runs, no limit in fully implicit runs.

Rather than freezing the capillary pressure we limit the rate at which it can change from step to step. This stabilizes the run without seriously affecting the modeling of imbibition driven recovery. In the implicit cells in AIM cases this limit can cause convergence problems, in these cells the limit is replaced by a limit of the rate of change with respect to saturation.

By default [IMPES](#) and [AIM](#) modes have a maximum rate of change of capillary pressure  $dP_c / dt = 0.0099972$  psi/day. This limit can be reset using the [DPCDT](#) keyword. The option of freezing the capillary pressures is retained through the [FREEZEPC](#) keyword. This has the same effect as setting [DPCDT](#) to 0 in [IMPES](#) mode.

The [DPCDT](#) limit may be disabled by using the [NODPCDT](#) keyword.

---

**Note:** By default, if you are using the [CFLLIMIT](#) keyword, then no limit is applied to the capillary pressure change.

---

### Example

## Use matrix cell grid data for fracture cells

This keyword may be used to simplify the input of data for dual porosity runs. It enables grid data to be entered for the matrix cells only (the first  $NDIVIZ / 2$  layers), the missing values for the remaining fracture layers being obtained from the corresponding matrix cell.

This operation will be performed for the [DX](#), [DY](#), [DZ](#), [PERMX](#), [PERMY](#), [PERMZ](#), [PORO](#), [TOPS](#), [MIDS](#), [NTG](#), [DZNET](#), [ZCORN](#), [PERMXY](#), [PERMYZ](#) and [PERMZ](#) keywords. The copying of the matrix cell value into the fracture cell value will only occur if the fracture cell value has not been defined by the user.

In the case of the [ZCORN](#) keyword, only half the normal set of corner point depths need be supplied (and generated by [PETREL](#)). This is useful when preparing faulted dual porosity runs. As in the case of the other keywords, the [BOX](#) keyword may be used to specify values for the cells required.

When using an unstructured grid supplied by FloGrid, the [DEPTHS](#) entered in the [EDIT](#) section are also copied from matrix to fracture.

When using the Temperature Option, the thermal conductivity [THCONR](#) is also copied from the matrix to the fracture.

When using the Thermal Option, the thermal conductivity [THCONR](#), and the rock heat capacity data [HEATCR](#) and [HEATCRT](#) are copied from the matrix to the fracture.

When using the Thermal Option, the rock thermal conductivity [THCROCK](#), and the phase thermal conductivities [THCOIL](#), [THCGAS](#), [THCWATER](#) or [THCSOLID](#) are also copied from the matrix to the fracture.

This keyword contains no items.

## DPKRMOD

## Modifies the matrix oil relative permeability in dual porosity cases

x	ECLIPSE 100

	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is optional in dual porosity runs, and gives you control of the matrix relative permeability. The keyword provides a simple way of modifying the oil relative permeability to help match a single porosity model of a single matrix block, and optionally allows the fracture to matrix flow to reflect the maximum relative permeability in the matrix.

The keyword should be followed by NTSFUN (see keyword [TABDIMS](#) in the RUNSPEC section) records, each consisting of three items of data terminated by a slash (/):

1. The modification parameter ( $m_w$ ) for oil-in-water relative permeability.

The value should be between -1.0 and 1.0.

DEFAULT: 0.0

2. The modification parameter ( $m_g$ ) for oil-in-gas relative permeability.

The value should be between -1.0 and 1.0

DEFAULT: 0.0

3. Scale the relative permeabilities for fracture-to-matrix flow, to reflect the maximum relative permeability at the residual saturation of the displaced phase?

YES Modify the fracture relative permeabilities for fracture-matrix flow.

NO No modification to the fracture relative permeabilities.

DEFAULT: NO

The relative permeability curves are modified by applying a quadratic multiplier function, such that the end-points ( $S_{OCR}$ ,  $1-S_{WCO}$ ) are preserved and the relative permeability at a saturation half way between the end-points is invariant.

The modification parameter is not a physical quantity and should be regarded only as a tuning parameter to match a dual porosity block with a finely gridded single porosity model.

If the modification parameter = 0.0, then no modification occurs.

If the modification parameter > 0.0, then the  $K_r$  at low oil saturation is boosted and the  $K_r$  at high oil saturation is reduced relative to the original curve.

If the modification parameter < 0.0, then the  $K_r$  at low oil saturation is reduced and the  $K_r$  at high oil saturation is increased relative to the original curve.

The scaling for oil-in-water relative permeability is as follows for the case where  $m_w$  is greater than 0.0:

$$K_r = \bar{K}_r + M(K_r(s) - \bar{K}_r) \quad \text{Eq. 3.59}$$

where

$\bar{K}_r$  is the relative permeability at  $\bar{s} = (S_{OWCR} + 1.0 - S_{WCO}) / 2$

$K_r(s)$  is the input table relative permeability

SOWCR is the critical oil to water saturation

SWCO is the connate water saturation

$M$  is the modification function, which is given by  $M = 4.0m_w K_r(s)^2 - 4.0m_w K_r(s) + 1$

If  $m_w$  is less than 0.0, then the same scaling is applied but with the X and Y axes ( $s$ ,  $K_r(s)$ ) reversed:

For a given saturation  $s$ , a new saturation  $s'$  is calculated such that:

$$\bar{s} + M(s' - \bar{s}) = s \quad \text{Eq. 3.60}$$

where

$\bar{s}$  is  $(\text{SOWCR} + 1.0 - \text{SWCO}) / 2$

$M$  is the modification function, which is given by  $M = 4.0m_w K_r(s')^2 - 4.0m_w K_r(s') + 1$

$K_r$  is then taken as  $K_r(s')$ .

The third data item initiates scaling of the fracture relative permeability curves when calculating the fracture to matrix flow only. The fracture relative permeability is scaled such that the maximum relative permeability is that of the matrix at the residual saturation of the displaced phase. For example in the water case:

$$K_{rf}(S_w) = K_{rf}^{table}(S_w) \cdot K_{rmmax} / K_{rfmax} \quad \text{Eq. 3.61}$$

where

$K_{rf}^{table}(S_w)$  is the relative permeability looked up using the input table

$K_{rmmax}$  is the matrix relative permeability at  $S_w = 1.0 - S_{owcr}$

$K_{rfmax}$  is the maximum fracture relative permeability

$S_{owcr}$  is the critical oil saturation to water.

See "Dual porosity" in the *ECLIPSE Technical Description*.

## DPNUM

## Identifies extent of dual porosity region

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The DPNUM keyword may be used for a dual porosity, single permeability run to specify regions within the reservoir to be treated as single porosity only.

The keyword should be followed by the integer 0 or 1 for each grid block in the first NDIVIZ /2 layers, to indicate whether the grid block should be modeled as single porosity (0) or dual porosity (1). Any grid blocks that do not have a DPNUM value entered default to dual porosity (1).

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0). Note that spaces must not be inserted on either side of the asterisk.

---

**Note:** Grid data for single porosity cells is only required in the first NDIVIZ /2 layers. That is the grid block properties are only required for the matrix cells; the fracture cells are made inactive and ignored. Within single porosity regions, flow is between matrix blocks. Wells may only connect with the matrix blocks in single porosity regions.

---

The keyword is ignored unless dual porosity, single permeability is enabled in the RUNSPEC section using keyword [DUALPORO](#). Single porosity regions specified by the keyword DPNUM are not allowed in a dual permeability run, so the keyword [DUALPERM](#) must not be specified in this case.

ECLIPSE 300

This keyword is not permitted if multi porosity is specified, either as a general multi porosity run using [NMATRIX](#) with value greater than 1, or as a triple porosity run using [TRPLPORO](#).

ECLIPSE 100

For ECLIPSE 100, there are technical problems if all the DPNUM values in the grid are set to zero, so this is prohibited; it is not possible to use DPNUM in this way to switch between single and dual porosity.

ECLIPSE 100

For LGRs in ECLIPSE 100, all the DPNUM values in the local grid must be the same, so that the LGR is either single or dual porosity. The values are specified for the region of the global grid occupied by the LGR, not in the [CARFIN](#) or [RADFIN](#) block.

ECLIPSE 300

For ECLIPSE 300, DPNUM cannot be used when alternative transmissibility multipliers are used, that is, when the first item of the [GRIDOPTS](#) keyword is set to 'YES'.

### Example

To specify an 8 x 4 x 4 run as dual porosity in half of the reservoir, specify [DUALPORO](#) in RUNSPEC, and add the following in the GRID section:

```

DPNUM
4*0 4*1 4*0 4*1
4*0 4*1 4*0 4*1
4*0 4*1 4*0 4*1
4*0 4*1 4*0 4*1 /

```

## Reference densities

In a run with  $N_c$  components this keyword specifies the fluid densities at the reference pressures and temperatures. The keyword can be used either in a run which uses the Zudkevitch Joffe equation, or in a Thermal run (keyword [THERMAL](#) in the RUNSPEC section).

In a live-oil thermal run, the oil component liquid densities are given by:

$$\rho_c = \frac{\rho_{ref_c}}{\left[1 - c_{P_c}(P - P_{ref_c})\right] \left[1 + c_{T1_c}(T - T_{ref_c})\right]} \quad \text{Eq. 3.62}$$

where

$\rho_{ref,c}$  is the reference density, specified with this keyword

$c_{P_c}$  is the oil component liquid compressibility, specified with keyword [CREF](#)

$P_{ref_c}$  is the reference pressure, specified with keyword [PREF](#)

$T_{ref_c}$  is the reference temperature, specified with keyword [TREF](#)

$c_{T1_c}$  is the thermal expansion coefficient, specified with keyword [THERMEX1](#).

There should be one value for each component:

UNITS: kg/m<sup>3</sup> (METRIC), lb/ft<sup>3</sup> (FIELD), gm/cc (LAB), kg/m<sup>3</sup> (PVT-M)

DEFAULT: 80% of the density of water.

DREF is an alternative to [GREF](#).

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

## Example

DREF

## Reference densities for water components

DREFW specifies the water density at a reference pressure for each of the  $N_w$  water components.

The water component densities, at pressure  $P$ , are calculated from:

$$\rho_w = \rho_{ref_w} \cdot (1 + X + X^2/2)$$

$$X = c_{P_w} \cdot (P - P_{ref_w})$$

where

$\rho_{ref_w}$  is the reference density, specified with this keyword

$c_{P_w}$  is the water component compressibility, specified with keyword [CREFW](#)

$P_{ref_w}$  is the reference pressure, specified with keyword [PREFW](#)

There should be one value for each component:

UNITS: kg/m<sup>3</sup> (METRIC), lb/ft<sup>3</sup> (FIELD), gm/cc (LAB), kg/m<sup>3</sup> (PVT-M)

DEFAULT: 999.014 kg/m<sup>3</sup>

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

See "[Water components](#)" in the *ECLIPSE Technical Description* for further details of the water component option.

## DRILPRI

## Defines the default priority formula for the prioritized drilling queue

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used to set the coefficients that define the default priority formula for the prioritized drilling queue. It must be used if any wells are placed in this queue with the [WDRILPRI](#) keyword without a fixed priority set in [WDRILPRI](#) item 2.

Wells are opened from the drilling queue whenever they are needed to maintain a group rate target under group control by guide rate ([GCONPROD](#), [GCONINJE](#), [GCONSALE](#)). They may also be opened from the drilling queue in ECLIPSE 100 should they be needed to maintain a group's production potential ([GDRILPOT](#)). The drilling queue may either be a sequential drilling queue constructed with keyword [QDRILL](#), or a prioritized drilling queue constructed with keywords [WDRILPRI](#) and [DRILPRI](#). In a sequential drilling queue wells are opened in the sequence in which they were placed in the queue. In a prioritized drilling queue wells are opened in decreasing order of their drilling priority. In ECLIPSE 100 the order of opening may, however, be affected by the availability of drilling rigs (see keywords [WDRILTIM](#) and [GRUPRIG](#)). If multiple wells have the same highest drilling priority, the well which is first defined by [WELSPECS](#) or [WELSPECL](#) will be drilled first. Only one type of drilling queue may exist at any given time in the run; the two types of queue cannot operate together.

Drilling priorities for wells in the prioritized drilling queue are calculated at regular intervals (see item 1) as a function of their potential production rates (see "[Well potentials](#)" in the *ECLIPSE Technical Description*). For production wells, the drilling priorities are calculated from the formula

$$\text{Priority} = \frac{A + BQ_o + CQ_w + DQ_g}{E + FQ_o + GQ_w + HQ_g} \quad \text{Eq. 3.63}$$

where

$Q_o$ ,  $Q_w$  and  $Q_g$  are the well's potential oil, water and gas production rates, and

A-H are 8 coefficients set by the user with this keyword.

The equation allows the drilling priority to be set equal to, for example, the potential oil rate, or the reciprocal of the potential gas rate, or the reciprocal of the water cut. For injection wells, the drilling priorities are set equal to their potential injection rates. Individual wells may have their calculated priorities replaced by fixed values input in item 2 of keyword [WDRILPRI](#), if required.

For injector wells this formula is not used and the drilling priority is calculated directly from the potential injection rate of the well unless an alternative drilling priority has been set using the [WDRILPRI](#) keyword.

The drilling priority of a well is based on the instantaneous production potential of that well unless items 10 and 11 are used. These items cause ECLIPSE to save the model state and run wells in the prioritized drilling queue for a period of time before calculating their priority. After these calculations the model is reset. This gives a better idea of the running state of the well. This "look-ahead" calculation of drilling priority is computationally expensive, so to avoid wasteful calculation priority it is only calculated when it is needed if item 1 is set to zero and item 10 is greater than zero.

The most recent calculation of well drilling priority may be output using [WDRPR](#) in the [SUMMARY](#) section. This will report zero for wells which are not in the prioritized drilling queue, either because they have not been added or because they have been drilled.

The [DRILPRI](#) keyword is followed by a line containing some or all of the following items of data:

- 1 The minimum time interval between drilling priority calculations.

Wells in the prioritized drilling queue have their drilling priorities calculated from the formula above at the beginning of each timestep that starts after the specified interval has elapsed since the previous calculation (except for wells given fixed drilling priorities in item 2 of keyword `WDRILPRI`).

A zero value causes the priorities to be recalculated every timestep if item 10 is defaulted. If item 10 is set, a zero value causes the drilling priority to be calculated when a drilling event is triggered.

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

DEFAULT: Zero

- 2-9 The coefficients  $A - H$  in the drilling priority formula.

None of the coefficients can have negative values. At least one of the first four coefficients ( $A - D$ ) must be non-zero, and similarly at least one of the last four coefficients ( $E - H$ ) must be non-zero.

DEFAULT: Zero

- 10 Lookahead period.

If this field is defaulted then drilling priorities are calculated using the potential rates of each well at the time of calculation. If this field is set to a positive value then ECLIPSE will save the model state, open one or more wells and run forward for this period before calculating the potentials to make the drilling priority calculation. The model is restored to the condition at the start of the drilling priority calculation once all well drilling priorities have been calculated.

If field 11 below is set to 'SINGLE' then the model state is run forward once for each well placed in the drilling queue by `WDRILPRI`, with one well opened and one drilling priority calculated per run forward. If field 11 is set to 'ALL' then all applicable wells are opened and have their drilling priority calculated at once. 'SINGLE' will give better results while 'ALL' will run more quickly as it involves fewer save, run, restore cycles.

The purpose of the look ahead calculation is to allow the engineer to determine the best available well if the initial flowing conditions are not likely to persist. This may be because water coning is likely to give a high water cut a short period after a well is opened, or it may be because an initial period of water production is expected from a coal bed methane development. If the look ahead period is set to a large value and the recalculation interval is set to a small interval then there will be significant performance implications.

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

DEFAULT: Zero

- 11 Look ahead calculation type.

Available options for this field are 'SINGLE' and 'ALL'. See field 10 for an explanation of this field.

DEFAULT: SINGLE

## Examples

## Maximum rate of increase of solution GOR

This keyword controls the rate at which the solution gas-oil ratio is allowed to rise. The keyword should be followed by some or all of the following items data terminated by a slash (/):

1. DRSDT Represents the maximum rate at which the solution gas-oil ratio in any grid block ( $R_s$ ) is allowed to increase.

UNITS:  $\text{sm}^3/\text{sm}^3/\text{day}$  (METRIC), Mscf/stb/day (FIELD), scc/scc/hr (LAB)

2. Option flag

ALL Apply the DRSDT limit to all cells

FREE Apply the DRSDT limit only to cells containing free gas

DEFAULT: 'ALL'

This keyword controls the way in which free gas and undersaturated oil coexist within a grid block. For example, if DRSDT is set to 0,  $R_s$  cannot rise and free gas does not dissolve in undersaturated oil (no re-resolution). At the other extreme, if DRSDT is very large,  $R_s$  rises very quickly until either the oil is saturated or no free gas remains (total re-resolution).

If the keyword is not used, the resolution rate is unrestricted (equivalent to a resolution rate limit of infinity).

---

**Note:** This keyword has no effect on reductions in  $R_s$  (for example during pressure decline). Moreover increases in  $R_s$  are constrained by the availability of free gas and the oil saturation limit ( $R_{ssat}$ ).

---

If this keyword is used in a system containing both dissolved gas and vaporized oil, the application of the DRSDT limit will be disabled by the subsequent use of the VAPPARS keyword. Similarly, the constraints imposed by the VAPPARS keyword will be disabled by the subsequent specification of the DRSDT keyword.

If  $\text{DRSDT} = 0$  and the model contains undersaturated oil with a variation of  $R_s$  values, then non-physical behavior can occur when high  $R_s$  oil moves in to a cell containing a lower  $R_s$ . The DRSDT limit prevents the  $R_s$  increasing, and free gas develops, even though the oil is undersaturated. This behavior can be prevented by setting the option flag in item 2 to 'FREE'. The DRSDT limit then only applies to the two-phase regions. (Note that in this case gas flowing from a two-phase cell into an undersaturated cell will dissolve in the destination cell, as the  $R_s$  is allowed to rise.)

### Example

```
DRSDT
0.0003 / (in Mscf/stb/day)
```

## DRV

## Radial-direction grid block sizes (vector)

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies the size of the cells in the radial direction.

The keyword should be followed by up to `NDIVIX` positive real numbers, where `NDIVIX` is the grid radial dimension entered using the `DIMENS` keyword in the `RUNSPEC` section.

The  $I^{\text{th}}$  number specifies the size in the radial direction of all the grid blocks with the R axis index equal to  $I$ . In other words, blocks ( $I$ ,  $1$ - $NDIVIY$ ,  $1$ - $NDIVIZ$ ).

DRV causes the `DR` value for every grid block in the reservoir to be set. Repeat counts may be used for repeated values (for example `11*208.4`). Note that spaces must not be inserted on either side of the asterisk.

UNITS: m (`METRIC`), ft (`FIELD`), cm (`LAB`), m (`PVT-M`)

The data must be terminated by a slash (/).

## Notes

- The inner radius of the innermost column ( $I = 1$ ) of grid blocks must be set. To do this, refer to the `INRAD` keyword, for ECLIPSE 100, and the `RADFIN` keyword, for ECLIPSE 300. These blocks has an outer radius equal to the sum of the inner radius and their DRV value.
- If the outer radius is not entered (either using the `OUTRAD` keyword in ECLIPSE 100, or the `RADFIN` keyword in ECLIPSE 300), a complete set (`NDIVIX`) of DRV values must be entered. The outer radius of these blocks is equal to the sum of the inner radius and the accumulated DRV values.
- If keyword `OUTRAD` is entered, it is not necessary to specify all (or any) DRV values. For ECLIPSE 100, any DRV values not specified are completed using a geometric series (see keyword `OUTRAD`), and for ECLIPSE 300, any DRV values not specified are completed using a logarithmic series.
- This keyword **cannot** be used to specify the grid data for a Local Grid Refinement (between the `RADFIN` and `ENDFIN` pair).

ECLIPSE 300

## Example

With `NDIVIX=11` as specified in `RUNSPEC` keyword `DIMENS`:

```
DRV
1 2 4 8 16 32 64 128 256 512 1024 /
INRAD
1 /
```

## Maximum rate of increase of vapor OGR

The keyword should be followed by a single real number which represents the maximum rate at which the vapor oil-gas ratio in any grid block ( $R_v$ ) is allowed to increase. The data field should be terminated by a slash (/).

This keyword controls the way in which free oil and undersaturated gas coexist within a grid block. For example, if DRVDT is set to 0,  $R_v$  cannot rise and free oil does not vaporize in undersaturated gas (no re-vaporization). At the other extreme, if DRVDT is very large,  $R_v$  rises very quickly until either the gas is saturated or no free oil remains (total re-vaporization).

If the keyword is not used, the re-vaporization rate is unrestricted (equivalent to a re-vaporization rate limit of infinity).

---

**Note:** This keyword has no effect on reductions in  $R_v$ .

Moreover increases in  $R_v$  are constrained by the availability of free oil and the gas saturation limit ( $R_{vsat}$ ).

---

If this keyword is used in a system containing both dissolved gas and vaporized oil, the application of the DRVDT limit will be disabled by the subsequent use of the [VAPPARS](#) keyword. Similarly, the constraints imposed by the VAPPARS keyword will be disabled by the subsequent specification of the DRVDT keyword.

UNITS:  $\text{sm}^3/\text{sm}^3/\text{day}$  (METRIC),  $\text{stb}/\text{Mscf}/\text{day}$  (FIELD),  $\text{scc}/\text{scc}/\text{hr}$  (LAB)

### Example

	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

When using the tracer dispersion option for a [BRINE](#) tracer, item 2 of the [DISPERSE](#) keyword can be changed from tracer concentration to water density by using this keyword.

See also keywords [DISPDIMS](#), [TRDIS](#) and [DISPERSE](#).

The DSPDEINT keyword has no associated data.

**Example**

```
DSPDEINT
```

## DSTNUM

## Tertiary hysteresis saturation function region numbers

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by one integer for every grid block in the current input box specifying the tertiary hysteresis saturation function region to which it belongs. This keyword is used together with [PSTNUM](#) and [ISTNUM](#) if the [ODD3P](#) relative permeability and capillary pressure hysteresis model has been selected in the [PROPS](#) section. The region number should not be less than 1 or greater than [NTSFUN](#) (see keyword [TABDIMS](#)). The data must be terminated by a slash (/).

The tertiary hysteresis saturation function region number specifies which set of saturation functions (input using [SOF3](#), [SGF3](#), and [SWF3](#) in the [PROPS](#) section) should be used to calculate the tertiary hysteresis relative permeabilities and capillary pressures in each grid block.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

For grid blocks for which the tertiary hysteresis saturation function region numbers are not specified, the values will be assigned from those defined for the corresponding secondary hysteresis saturation function region numbers using the [ISTNUM](#) keyword. The [ODD3P](#) model is implicitly hysteretic. However, hysteresis may be deselected on a per grid block basis by setting the secondary and tertiary hysteresis saturation region numbers equal to the primary saturation region numbers.

See also the saturation function keywords [SOF3](#), [SGF3](#) and [SWF3](#) in the [PROPS](#) section and the primary and secondary hysteresis saturation region numbers [PSTNUM](#) and [ISTNUM](#) in the [REGIONS](#) section.

### Example

With [NTSFUN](#)=2, [NDIVIX](#)=8, [NDIVIY](#)=6 and [NDIVIZ](#)=5, as specified in [RUNSPEC](#) keyword [DIMENS](#), and no input [BOX](#) set:

```
DSTNUM
144*1 96*2 /
```

## DTHETA

## Theta-direction grid block sizes

 6*60 61 62 63 65 67 70
12*40
12*53
12*67
12*80 /

```

## DTHETAV

**Angular sizes of grid blocks (vector)**

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies the size of the cells in the theta direction.

The keyword should be followed by `DIVIIY` positive real numbers, where `NDIVIIY` is the grid theta dimension entered using the `DIMENS` keyword in the `RUNSPEC` section.

The  $J^{\text{th}}$  number specifies the angular size in the theta direction of all the grid blocks with the theta axis index equal to  $J$ . In other words, blocks (1- `NDIVIX`,  $J$ , 1- `NDIVIZ`).

`DTHETAV` causes the `DTHETA` value for every grid block in the reservoir to be set. Repeat counts may be used for repeated values (for example 6\*60). Note that spaces must not be inserted on either side of the asterisk.

UNITS: degrees (`METRIC`), degrees (`FIELD`), degrees (`LAB`), degrees (`PVT-M`)

The data must be terminated by a slash (/).

---

**Note:** In ECLIPSE 300, this keyword **must not** be used to specify the grid data for a Local Grid Refinement (between the `RADFIN` and `ENDFIN` pair).

---

**Example**

With `NDIVIIY=8`, specified in `RUNSPEC` keyword `DIMENS`:

```
DTHETAV
 20 20 30 40 4*50 / entire reservoir subtends 310 degrees
```

## DUALPERM **Run is to use dual permeability**

	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This requests that the dual porosity option is used in the run.

If either DUALPORO or dual permeability ([DUALPERM](#)) are used, the number of layers entered in item 3 of the [DIMENS](#) keyword must be even. ECLIPSE interprets the first half of the grid layers as matrix cells, and the remainder as fracture cells. The non-neighbor connections representing matrix-fracture flow transmissibilities are automatically constructed.

See "[Dual porosity](#)" in the *ECLIPSE Technical Description* for further information.

The keyword has no associated data.

## DUMPCUPL Tells master run to write a reservoir coupling file

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The DUMPCUPL keyword may be used in a Reservoir Coupling master run if you wish it to write the flows and applied constraints of the master groups to the output Reservoir Coupling file (see "[Reservoir coupling files](#)" in the *ECLIPSE Technical Description*).

The file may then be used for two purposes:

- In the master run, it can take the place of one or more of the slave reservoirs. Their slave runs are not activated, and instead the associated master groups take their production and injection rates from this file.
- A slave run may be performed on its own, instead of being activated by the master run. It will read from this file the constraints that the master run originally applied to its slave groups over the course of the simulation, and apply them again in the same sequence.

Runs using the Reservoir Coupling file must have the keyword [USECUPL](#) entered.

The DUMPCUPL keyword is followed by a record containing a single character, terminated with a slash (/). The character dictates the type of file to be written. The choices are:

U Write an unformatted file

F Write a formatted file.

Formatted files occupy much more disk space than unformatted files, but should be chosen if the Reservoir Coupling file is going to be used on a system that does not have binary compatibility with the one on which it was created. Note that the formatted/unformatted status of the Reservoir Coupling file can be chosen independently of keyword [FMTOU](#) in the RUNSPEC section.

The Reservoir Coupling file created has the same root name as the Master Run's data file. The filename's extension is .CPL for an unformatted file, and .FCP for a formatted file.

Note that the DUMPCUPL instruction is **not** carried over on the Restart file. If you wish to restart the Master Run and continue writing a Reservoir Coupling file (which is a new file having the restart run's root name), you must include the DUMPCUPL keyword in the restart run's SCHEDULE section. A suitable place for the keyword is at the beginning of the SCHEDULE section, or next to the [SLAVES](#) keyword.

### Example

```
DUMPCUPL
U /
```

## DUMPFLUX **Makes a full-field run write a flux file**

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The DUMPFLUX keyword is used in the full-field run to tell ECLIPSE to write a Flux file containing the flows across the flux region boundaries.

If the base run is either a Blackoil or a Compositional model, and the reduced run is a Thermal model, then the keyword [FLUXOPTS](#) must be used to tell ECLIPSE to output the necessary information for the reduced case. For a full field thermal to reduced thermal case, the FLUXOPTS keyword is not required.

The extent of the flux regions are defined by the [FLUXNUM](#) keyword.

The keyword has no associated data.

See "[Flux boundary conditions](#)" in the *ECLIPSE Technical Description* for further information about this option.

---

**Note:** A thermal reduced run can only be carried out from an ECLIPSE 300 base run.

## DYNAMICR Define regions based on when a set of conditions are satisfied

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword may be used to define regions based on when a set of conditions are satisfied, with conditions defined using Boolean logic and collections of objects. These regions may be static or allowed to change dynamically. These new regions can be used with ECLIPSE keywords, for instance [ACTIONX](#) and [UDQ](#).

This will allow property and reporting regions to be defined and altered throughout the run by user definition.

The keyword is followed by a series of records each terminated by a slash (/) with the keyword terminated by a blank record containing only a slash (/):

The data items in each record are:

### Record 1

1. The region name.

A name of up to 8 characters, to distinguish this region name from any others. The first 3 characters must be "FIP". The family name is a string of up to 5 characters that makes up the second part of the keyword name (characters 4-8). These names must be distinct from ordinary FIP region families defined in the `REGIONS` section.

2. Region number.

This will be the region number affected by the conditions specified in subsequent records. The value specified here should be an integer between 0 and `MNUMDR`, given in item 1 of `DYNRDIMS` keyword.

DEFAULT: 0

### Each subsequent record

The conditions defined will be applied to the region number and name defined in record 1 above.

Please refer to "[Each subsequent record](#)" for details of the format of a condition and lists of mnemonics.

When `DYNAMICR` is specified in the `SOLUTION` section, many of the mnemonic values are not meaningful - for instance, no wells have yet been defined. Conditions containing undefined values will be ignored and a warning given.

### Specific requirements for DYNAMICR conditions

The left hand side of the condition must be either a block keyword or one of the `DYNAMICR` special keywords. Grid indexes are not specified for the block keywords as each grid block will be considered individually in turn.

To create a `DYNAMICR` condition which is also dependent on a condition which is not evaluated block-by-block, the non-block-by-block condition should be specified in an `ACTIONX` keyword so that the `DYNAMICR` keyword is only evaluated if the other condition is fulfilled. See examples.

### DYNAMICR special mnemonics

Note that these mnemonics cannot be used with `ACTIONX`, and that the double quotes are required as part of the mnemonic.

**DIST\_TO\_GRIDBLOCK** This can be used on either the left or right hand side of a condition - or both. It is followed by the x, y, z indexes of the reference grid block. The distance to the center of this grid block is then evaluated for each grid block.

One or more of the indexes can be defaulted. If this is done, the default value used for each evaluation will be the same as that index for the grid block to which the distance is being calculated. This allows the calculation of the distance to a row or layer of cells rather than a single cell.

---

**Note:** Indexes cannot be defaulted when running in parallel.

---

**DIST\_TO\_WELLNAME** This can be used on either the left or right hand side of a condition - or both. It is followed by the name of the well and the number of the connection to be used. The distance to the center of the grid block in which the connection is situated is then evaluated for each grid block. Note that the connection number refers to a single grid block only. This mnemonic cannot be used in the SOLUTION section since the wells have not yet been defined. See [Example 5](#).

ECLIPSE 300

Template characters or well lists can be used in place of a well name. However, only the first well which matches the requirements will be considered. If, for instance, the minimum distance to one of two wells is required, two separate conditions on the two wells must be specified and combined using OR.

### DYNAMICR special conditions

Note that these conditions cannot be used with **ACTIONX**, and that the double quotes are required as part of the condition.

When “region families” are referred to generically, they can be either dynamic region families, or ordinary FIP region families defined in the **REGIONS** section.

**ALL** this can be used in two ways:

- As an entire condition by itself. This allows a default region value to be set for a particular dynamic region family without having to evaluate a quantity for every grid block.
- Or by following it with pairs of region family name + region number. This allows a dynamic region to be set up which combines all the cells in several regions. Up to three pairs can be specified per condition; if more than this are required then multiple **ALL** conditions can be combined using the standard methods for combining conditions.

**IN** this condition has no associated value on the left hand side. The right hand side has a region family name and region number. Each grid block’s region number is set to the specified value if it is in the given region. Used alone, it simply duplicates an existing region. Its utility comes when it is combined with other conditions.

**NOT\_IN** this condition has no associated value on the left hand side. The right hand side has a region family name and region number. Each grid block’s region number is set to the specified value if it is not in the given region. It can be used simply to set up a region consisting of all those grid blocks not in an existing region, or in combination with other conditions.

---

**Note:** While it is possible to use NOT\_IN to set a default region value for all cells which don't meet an already calculated complex condition, it requires much less computation to use ALL to set a default value for all cells first.

---

## Local grids

Dynamic regions cannot be specified for local grid blocks. However, if required, local grid mnemonics can be used on the right hand side of a condition in exactly the same way as for ACTIONX.

The methods of use for this keyword are:

Statically	DYNAMICR is used to define a region family in the SOLUTION section, or once only in the SCHEDULE section. Once defined, the region values for the cells never change. This is very similar to an ordinary FIP region family defined in the REGIONS section, except that conditions can be used to determine the region values. See <a href="#">Example 1</a> .
Dynamically - automatic	The DYNAMICR keyword is specified inside an ACTIONX keyword using the ALWAYS condition. Region values will be recomputed every timestep. See <a href="#">Example 2</a> .
Dynamically - conditional	The DYNAMICR keyword is specified inside an ACTIONX keyword using any condition. Normal ACTIONX functionality is used to determine when the region values will be recomputed. See ACTIONX examples for sample conditions.
Dynamically - manual	The DYNAMICR keyword is specified at multiple points within the SCHEDULE section for the same dynamic region family. Region values will be recomputed each time the keyword is encountered. There is no reason why the conditions on the region values should be the same in all definitions. See <a href="#">Example 3</a> .

These methods can be freely combined as required for a single dynamic region family.

## Notes

- The order of the items in the quantities is similar to the way summary mnemonics are defined, that is the mnemonic is the first item and it is then followed by a well or group name for example.
- No checks are in place on the type of quantities that are compared in a condition. So for example, a condition on this distance between two grid blocks being less than a connection's water cut would be allowed.
- Unlike ACTIONX, details of whether conditions are met are not written to file - since they are calculated for every block.
- Full checking of the keywords entered with a DYNAMICR keyword cannot be performed until the action is actually implemented, since it is possible to use wild cards in many of the keywords. However, before a simulation run is attempted the data can be run in NOSIM mode. This then does whatever checks it can on the keywords within any keyword blocks that have been defined. All the most common types of 'grammatical' and typographical errors will be found, but errors resulting from wild cards feeding inappropriate well/group names to keywords are not found.
- When using DYNAMICR inside an ACTIONX keyword, it is important to note that no keywords inside an ACTIONX keyword are processed until the following timestep is run. This means that, for instance, it is not possible to specify a dynamic region in an ACTIONR keyword immediately following the ACTIONX keyword in which it is defined.

- The DYNREG argument has been added to the **RPTRST** keyword in both the SOLUTION and SCHEDULE sections. This outputs the cell indices corresponding to the dynamic regions specified using the DYNAMICR keyword.
- When running in **NOSIM** mode, the block-by-block calculations of region numbers are not performed for speed reasons, so values output to the restart file with the DYNREG argument are not meaningful.

## Examples

Only simple right hand conditions have been used here to demonstrate the use of the new DYNAMICR facilities. For examples of more complex conditions, please see the **ACTIONX** examples.

### Example 1

This sets up a dynamic region family FIPYYY for which region 1 is initially identical to region 1 of the region family FIPXXX. Region 2 contains all those cells which are in either FIPXXX regions 2 or 3. Region 3 consists of all those grid blocks with block oil in place less than or equal to 500,000. Note that any cells which fulfil none of the conditions will be in region 1 by default. This dynamic region will not be updated.

```
DYNAMICR
  FIPYYY  1  /
    "IN"  FIPXXX 1  /
  /
  FIPYYY  2  /
    "ALL" FIPXXX 2 FIPXXX 3 /
  /
  FIPYYY  3  /
    BOIP <= 500000 /
/ENDDYN
```

### Example 2

The dynamic region family FIPYYY is set up exactly as in the previous example. However, due to being wrapped in an **ACTIONX** keyword with the ALWAYS condition, the region numbers for each cell will be recalculated every timestep.

```
ACTIONX
  ACT2 10000 /
  "ALWAYS" /
  /
DYNAMICR
  FIPYYY  1  /
    "IN"  FIPXXX 1  /
  /
  FIPYYY  2  /
    "ALL" FIPXXX 2 FIPXXX 3 /
  /
  FIPYYY  3  /
    BOIP <= 500000 /
  /
ENDDYN
ENDACTIO
```

### Example 3

This sets up the same dynamic region family FIPYYY as example 1. Then, after a time interval of 10, all grid blocks with BOIP less than 400000 are added to region 3.

Note that no other grid blocks will have their region values changed at all - any grid block which was previously part of region 3 will remain part of it, even if its BOIP value is now greater than 400,000. To remove cells which no longer fit the condition, the second DYNAMICR keyword would have to also recompute regions 1 and 2.

```

DYNAMICR
  FIPYYY 1 /
  "IN" FIPXXX 1 /
/
  FIPYYY 2 /
  "ALL" FIPXXX 2 FIPXXX 3 /
/
  FIPYYY 3 /
  BOIP <= 500000 /
/
ENDDYN

TSTEP
10 /

DYNAMICR
  FIPYYY 3 /
  BOIP <= 400000 /
/
ENDDYN

```

#### Example 4

These two uses of the DYNAMICR keyword produce exactly the same region values, but the first one is to be greatly preferred as only half as many distance calculations are required.

Dynamic region family FIPYYY is set up so that all grid blocks are in region 2 except for those which are closer to grid block 3,3,2 than to grid block 5,5,1.

```

DYNAMICR
  FIPYYY 2/
  "ALL" /
/
  FIPYYY 1/
  "DIST_TO_GRIDBLOCK" 3 3 2 <= "DIST_TO_GRIDBLOCK" 5 5 1/
/
ENDDYN

DYNAMICR
  FIPYYY 1/
  "DIST_TO_GRIDBLOCK" 3 3 2 <= "DIST_TO_GRIDBLOCK" 5 5 1/
/
  FIPYYY 2/
  "DIST_TO_GRIDBLOCK" 3 3 2 > "DIST_TO_GRIDBLOCK" 5 5 1/
/
ENDDYN

```

#### Example 5

This demonstrates the use of the DIST\_TO\_WELLNAME mnemonic.

Dynamic region family FIPYYY is set up so that all grid blocks are in region 2 except for those which are within 10 of the second connection of well INJ.

This will give exactly the same results as using the DIST\_TO\_GRIDBLOCK mnemonic with the x,y,z indexes of connection 2.

```

DYNAMICR
  FIPYYY 2/
  "ALL" /
/

```

```
FIPYYY 1/  
    "DIST_TO_WELLNAME" INJ 2 <= 10 /  
/  
ENDDYN
```

## DYNRDIMS

## Specify dimensions required for the dynamic region feature

x	ECLIPSE 300
	<b>SPECIAL</b>
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword determines the size of storage set aside for dynamic regions specified with the [DYNAMICR](#) keyword, and must be present if dynamic regions are to be specified.

The data consists of some or all of the following items.

The data must be terminated by a slash (/).

1. The maximum number of dynamic regions (MNUMDR).

If item 1 of [REGDIMS](#) or item 5 of [TABDIMS](#) are also set, the greatest value of the three settings is used.

---

**Note:** Since the fluid-in-place balance sheet reports region-to-region flows, the storage required is proportional to the square of MNUMDR. Very large values of MNUMDR should therefore be avoided, as excessive storage may be required and in addition the restart files will be very large.

---

DEFAULT: 0

2. The maximum number of dynamic region families (MXDYNF).

DEFAULT: 0

3. The maximum number of dynamic region records which can be defined under the [DYNAMICR](#) keyword (MXDYNR).

DEFAULT: 0

### Example

```
DYNRDIMS
5 2 10 /
```

## DYV

## Y-direction grid block sizes (vector)

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies the size of the cells in the Y-direction.

The keyword should be followed by `NDIVY` positive real numbers, where `NDIVY` is the grid Y dimension entered using the `DIMENS` keyword in the `RUNSPEC` section.

The  $J^{\text{th}}$  number specifies the size in the Y-direction of all the grid blocks with the Y axis index equal to  $J$ . In other words, blocks (1- `NDIVX`,  $J$ , 1- `NDIVZ`). See the `DIMENS` keyword for the specification of `NDIVX` and `NDIVZ`.

`DYV` causes the `DY` value for every grid block in the reservoir to be set. Repeat counts may be used for repeated values (for example 11\*208.4). Note that spaces must not be inserted on either side of the asterisk.

UNITS: m (`METRIC`), ft (`FIELD`), cm (`LAB`), m (`PVT-M`)

The data must be terminated by a slash (/).

---

**Note:** This keyword **must not** be used to specify the grid data for a Local Grid Refinement (between the `CARFIN` and `ENDFIN` pair).

---

### Example

With `NDIVY = 11`, specified in `RUNSPEC` keyword `DIMENS`:

```
DYV
1000 500 7*200 500 1000 /
```

ECLIPSE 300

# DZ

## Z-direction grid block sizes

x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies the size of the cells in the Z-direction.

The keyword should be followed by one positive real number for every grid block in the current input box specifying its size in the Z-direction.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*208.4). Note that spaces must not be inserted on either side of the asterisk.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

The data must be terminated by a slash(/).

### Notes

#### ECLIPSE 100

Every DZ value in the top plane (K = 1) must be specified in one way or another by the end of the GRID section. Values in lower planes (K > 1) that are not specified default to the value in the plane above.

#### ECLIPSE 300

If  $DZ \leq 10^{-6}$  for any cell, the cell will be either be made inactive or in thermal cases it may become rock-filled.

### Examples

#### Example 1

```

----- IX1-IX2 JY1-JY2 KZ1-KZ2
BOX

	SCHEDULE

If the dual porosity gravity imbibition option is being used (keywords [DUALPORO](#) and [GRAVDR](#) or [GRAVDRM](#), or the [VERTICAL](#) option of [NMATOPTS](#), in the [RUNSPEC](#) section), this keyword should be used to specify the vertical dimension of a typical block of matrix material (see also  $l_z$  in keyword [SIGMA](#)).

The strength of the gravity imbibition effect is directly proportional to DZMTRX. The effect is usually very small. However, in the absence of capillary pressure, there is no other mechanism to equalize the fluid levels in matrix and corresponding fracture cells. For further details, see "[Dual porosity](#)" in the *ECLIPSE Technical Description*.

This keyword specifies the DZMTRX factor for the entire grid. However the DZMTRX factor can be specified on a cell by cell basis using the [DZMTRXV](#) keyword.

UNITS: m ([METRIC](#)), ft ([FIELD](#)), cm ([LAB](#)), m ([PVT-M](#))

DEFAULT: 0.0 (Throughout the grid.)

---

**Note:** This is typically much smaller than the vertical dimension of a simulation matrix cell, [DZ](#).

---

### Example

In the following example, the vertical dimension of a block of matrix material is 2ft.

```
DZMTRX
2.0 /
```

## DZMTRXV

## The vertical dimension of a block of matrix material

x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

If the dual porosity gravity imbibition option is being used (keywords [DUALPORO](#) and [GRAVDR](#), [GRAVDRM](#), or the VERTICAL option of [NMATOPTS](#), in the RUNSPEC section), either this keyword or keyword [DZMTRX](#) should be used to specify the vertical dimension of a typical block of matrix material. This keyword allows the DZMTRX values to be specified on a cell by cell basis.

The strength of the gravity imbibition effect is directly proportional to DZMTRX. The effect is usually very small. However, in the absence of capillary pressure, there is no other mechanism to equalize the fluid levels in matrix and corresponding fracture cells. For further details, see "[Dual porosity](#)" in the *ECLIPSE Technical Description*.

The keyword should be followed by one positive real number for every grid block in the current box within the top  $NDIVIZ / 2$  layers of the grid. Any values input in the bottom half of the grid (the lower  $NDIVIZ / 2$  layers) are ignored. When the DZMTRX values are output (mnemonic DZMTRXV in the [RPTGRID](#) keyword) the first  $NDIVIZ / 2$  layers are copied into the lower half of the grid.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: 0.0 (throughout the grid.)

---

**Note:** This is typically much smaller than the vertical dimension of a simulation matrix cell, [DZ](#).

---

### Example

In the following example, the vertical dimension of a block of matrix material is 2ft.

```

----- IX1-IX2 JY1-JY2 KZ1-KZ2
BOX
      1   4   1   2   1   1   /
DZMTRXV
  8*2.0 /

```

## DZNET

## Specifies the cell net DZ values

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies the net thickness value for each grid block.

These values are used in the calculation of grid block pore volumes and transmissibilities in the X and Y (or R and theta) directions.

If DZNET is used, the net to gross ratio is calculated as follows:

$$NTG_i = \frac{DZNET_i}{DZ_i} \quad \text{Eq. 3.64}$$

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

Any DZNET values which are not specified when the end of the GRID section is reached default to the gross grid block thickness (entered using DZ).

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0). Note that spaces must not be inserted on either side of the asterisk.

The keyword should be followed by one non-negative real number for every grid block in the current input box.

The data must be terminated with a slash (/).

---

**CAUTION:** The use of both DZNET and NTG keywords in the same run is not allowed.

---

### Example

```

-- IX1-IX2 JY1-JY2 KZ1-KZ2
BOX
 6  11  4  9  2  3  /
DZNET
6*8 6*8 6*9.6 6*10.2 6*14 6*14.2
6*8 6*8 6*9.6 6*10.2 6*14 6*14.2 /

```

x	SUMMARY
x	SCHEDULE

The keyword turns on the echoing of the input file to the Print file at the start of the run. This echoing may be disabled using **NOECHO**, for example when large machine generated input files are entered.

The default status for echoing is **on**, which may be set to **off** using **NOECHO**. **ECHO** is normally only required, therefore, to turn echoing back on after a **NOECHO** keyword.

**ECHO** and **NOECHO** may be specified in any section, and any number of times in an input file.

## ECLMC

**Activates multi-component option**

	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword activates the multi-component option in ECLIPSE 100. The keyword is required in runs using the multi-component brine model.

Note that the multi-component brine model is distinct from the standard brine option (latter specified using keyword [BRINE](#) without keyword [ECLMC](#)). Thus, functionality that is specific to the standard brine model, such as [PLYVISC](#), is not compatible with ECLMC.

The keyword has no associated data.

See "[Brine tracking](#)" in the *ECLIPSE Technical Description*.

## EDITNNC

## Multiply a non-neighbor connection

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
x	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

Non-neighbor connections may be generated by geological faults in the grid. This keyword can be used to modify these fault generated non-neighbor connections.

Each line following the EDITNNC keyword specifies a non-neighbor connection to be modified and is terminated with a slash (/). After the last non-neighbor modification, a single (/) terminates the list.

The items in each line are:

1. I-index of first cell joined to the non-neighbor connection (IX)
2. J-index of first cell joined to the non-neighbor connection (IY)
3. K-index of first cell joined to the non-neighbor connection (IZ)
4. I-index of second cell joined to the non-neighbor connection (JX)
5. J-index of second cell joined to the non-neighbor connection (JY)
6. K-index of second cell joined to the non-neighbor connection (JZ)

The cell coordinates must be defined and cannot be defaulted.

7. Transmissibility multiplier for the non-neighbor connection (TRANM).

The transmissibility is set to  $TR * TRANM$ , where TR is the non-neighbor connection transmissibility calculated by the program or entered directly using the [NNC](#) keyword.

The multiplier TRANM should not be negative but can be zero.

DEFAULT: 1.0

8. Saturation table number to be associated with flow from the first to the second cell (IST1)

DEFAULT: 0

9. Saturation table number to be associated with flow from the second to the first cell (IST2)

DEFAULT: 0

10. Pressure table number to be associated with flow from the first to the second cell (PT1)

DEFAULT: 0

11. Pressure table number to be associated with flow from the second to the first cell (IPT2)

DEFAULT: 0

*ECLIPSE 100 only*

12. The face associated with flow from the first to the second cell (ZF1)

Choose either: X+, X-, Y+, Y-, Z+, Z-

This information is used with the [VE](#) option only

*ECLIPSE 100 only*

13. The face associated with flow from the second to the first cell (ZF2).

Choose either: X+, X-, Y+, Y-, Z+, Z-

This information is used with the [VE](#) option only

*ECLIPSE 100 only*

14. Diffusivity multiplier for the non-neighbor connection (DIFFM)

The diffusivity is set to  $DF * DIFFM$ , where  $DF$  is the non-neighbor connection diffusivity calculated by the program or entered directly using the `NNC` keyword.

The multiplier `DIFFM` should not be negative but can be zero.

DEFAULT: 0

ECLIPSE 100

The last seven items are optional: if they are input then they supersede the original table numbers and VE flow faces. However if a slash (/) is placed after the `TRANM` item, then the original table numbers and VE flow faces will remain and diffusivities will not be altered.

---

**Note:** When the Local Grid Refinement option is employed, the `EDITNNC` keyword cannot be used within local grids. If an `NNC` is edited in the global grid, then the corresponding `NNCs` in any local grids are **not** edited. In this case, it is advisable to employ multipliers, for example `MULTX`, instead (where applicable) or else consider using inter-region transmissibility multipliers defined by keyword `MULTREGT` to replace the `EDITNNC` records.

---

If a non-neighbor connection to be edited cannot be found, then a warning message is issued and the `EDITNNC` line ignored.

## Example

```

EDITNNC
IX IY IZ JX JY JZ TRANM IST1 IST2 IPT1 IPT2 /
.
.
/

```

## EDITNNCR **Replace a non-neighbor connection**

x	ECLIPSE 100
x	ECLIPSE 300

## EHYSTR

## Hysteresis parameters and model selection

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword should be used if the hysteresis option has been requested (item HYSTER in keyword [SATOPTS](#) in the RUNSPEC section). It is followed by a line containing some or all of the following items, terminated with a slash (/)

If the [ODD3P](#) relative permeability and capillary pressure hysteresis model has been specified this keyword should not be used.

- Curvature parameter for capillary pressure hysteresis.  
It must be greater than zero, and should normally lie in the range 0.05 to 0.1.  
DEFAULT: 0.1
- Integer flag to select model for relative permeability hysteresis (capillary pressure hysteresis always uses the Killough model):

Water wet hysteresis models:

- Carlson's hysteresis model used for the non-wetting phase(s), drainage ([SATNUM](#)) curve used for the wetting phase.
- Carlson's hysteresis model used for the non-wetting phase(s), imbibition ([IMBNUM](#)) curve used for the wetting phase.
- Killough's hysteresis model used for the non-wetting phase(s), drainage ([SATNUM](#)) curve used for the wetting phase.
- Killough's hysteresis model used for the non-wetting phase(s), imbibition ([IMBNUM](#)) curve used for the wetting phase.
- Killough's hysteresis model used for both wetting and non-wetting phases.

Oil wet to water hysteresis models:

- Carlson's non-wetting model for gas and water phases (if present), drainage ([SATNUM](#)) curve used for the oil phase.
- Killough's non-wetting model for the gas and water phases (if present), drainage ([SATNUM](#)) curve used for the oil phase.
- Killough's hysteresis model used for non-wetting gas and water phases (if present) and the wetting oil phase.

Water wet hysteresis models:

- |                    |  |
|--------------------|--|
| <i>ECLIPSE 300</i> | 8 Jargon's hysteresis model used for the non-wetting phase(s), drainage ( <a href="#">SATNUM</a> ) curve used for the wetting phase.   |
| <i>ECLIPSE 300</i> | 9 Jargon's hysteresis model used for the non-wetting phase(s), imbibition ( <a href="#">IMBNUM</a> ) curve used for the wetting phase. |
| <i>ECLIPSE 100</i> | -1 Equilibration only option:  |

Option to equilibrate the model using the drainage curve (SATNUM) but to run the simulation using the imbibition curve (IMBNUM).

Hysteresis is not accounted for during the simulation; the drainage capillary pressure curves are used for equilibration but the simulation advances using the imbibition relative permeability and capillary pressure curves.

---

**Note:** This option is not recommended. If different capillary pressure curves are used then the model will not be in initial equilibrium.

---

ECLIPSE 300

DEFAULT: 2

ECLIPSE 100

DEFAULT: 0

3. Curvature parameter for Killough's wetting phase relative permeability hysteresis. It must be a positive number.

This item is ignored if item 2 is set to anything other than 4 or 7.

DEFAULT: 1.0

4. Modification parameter for the trapped non-wetting phase saturation in the Killough model.

If this parameter is zero (the standard Killough Model) or set to a small value, the trapped saturation is close to the maximum attained saturation when the maximum itself is small. This can lead to convergence problems.

DEFAULT: 0.1

5. Flag limiting hysteresis to either relative permeability or capillary pressure only.

**BOTH** Apply the hysteresis model to both the relative permeability and the capillary pressure curves, using the model selected in item 2 for the relative permeability and the Killough model for the capillary pressures.

**PC** Apply the hysteresis model to the capillary pressure only, using the Killough capillary pressure hysteresis model.

**KR** Apply the hysteresis model to the relative permeability only, using the model selected in item 2.

DEFAULT: BOTH

When the hysteresis model is not applied, the relative permeability or the capillary pressure is taken from the drainage curve (keyword [SATNUM](#)).

ECLIPSE 100

6. Flag controlling the shape of the capillary pressure scanning curves when secondary reversals occur. This flag **only** applies to capillary pressure hysteresis (with the Killough model).

**RETR** When an imbibition process on a scanning imbibition curve is reversed into a drainage process, the secondary drainage process will **re-traverse** the same scanning curve.

**NEW** When an imbibition process on a scanning imbibition curve is reversed into a drainage process, the secondary drainage will follow a **new** scanning drainage curve described by the Killough model. If further reversals are encountered, then a new scanning curve is constructed each time.

DEFAULT: RETR

7. Flag controlling whether the initial fluid mobility correction (flag MOBILE in keyword EQLOPTS) or the transition zone calculation (keyword TZONE) applies just to the drainage curve or to both the drainage and imbibition curves.

DRAIN The end-points of the drainage curves only are modified to achieve the initial fluid mobility correction in each grid block.

BOTH The end-points of both the drainage and imbibition curves are modified to achieve the initial fluid mobility correction in each grid block.

DEFAULT: DRAIN

ECLIPSE 100

For the initial fluid mobility correction to be applied to the imbibition curves, the EQLOPTS option MOBILE must also be specified.

8. Flag selecting the wetting phase, between oil and gas, in three-phase cases. In two-phase gas-oil systems, oil is always wetting to gas. The oil-gas relative permeability is then calculated with the method selected in item 2.

OIL Oil is treated as wetting to gas in three-phase cases. The oil-gas relative permeability can then be calculated using the drainage (SATNUM) curve (option 0 and 2 and 8), or the imbibition (IMBNUM) curve (option 1 and 3 and 9), or using the Killough's method (option 4).

GAS Oil is treated as non-wetting to gas in three-phase cases. The oil-gas relative permeability can then be calculated using the Carlson's method (option 0 and 1), or the Killough's method (option 2 and 3 and 4), or using the Jargon's method (option 8 and 9).

In a three-phase system, oil is always default wetting phase.

---

**Note:** The choice between oil and gas as the wetting phase only applies to the modeling of the oil relative permeability to gas. The gas relative permeability is modeled as a non-wetting phase irrespective of the value ascribed here.

---

9. Flag selecting the BAKER1 or BAKER2 relative permeability models with hysteresis for the oil-phase case. The two phase relative permeability is then calculated with the method selected in the item 2.

DEFAULT: NO

10. Flag selecting the BAKER1 or BAKER2 relative permeability models with hysteresis for the gas-phase case. The two phase relative permeability is then calculated with the method selected in the item 2.

DEFAULT: NO

11. Flag selecting the BAKER1 or BAKER2 relative permeability models with hysteresis for the water-phase case. The two phase relative permeability is then calculated with the method selected in the item 2.

DEFAULT: NO

12. A threshold saturation of Killough's hysteresis model for both wetting and non-wetting phases. This threshold allows better control of the numerical sensitivity of the system, preventing it from being too unstable.

DEFAULT: 0.0

13. Integer flag which can be used to specify that a modification is to be made to the wetting phase relative permeability scanning curve to mitigate the departure of the scanning curve from the region enclosed by the drainage and imbibition curves. This can sometimes occur if the initial gradients of the relative permeability curves are small. This modification is only applicable to the Killough wetting phase relative permeability hysteresis model, that is, if item 2 of this keyword set to 4 or 7, otherwise it will be ignored. See "[Relative Permeability Hysteresis in the Wetting Phase](#)" in the *ECLIPSE Technical Description* for more information.

DEFAULT: 0

## Notes

### Water wet system

- Item 8 set to GAS: water is wetting to oil and wetting to gas; oil is non-wetting to water and non-wetting to gas; gas is non-wetting to water and wetting to oil. This means that in terms of wettability the phases can be ordered as  $W > G > O$  (where  $>$  means "is wetting").
- Item 8 set to OIL: water is wetting to oil and wetting to gas; oil is non-wetting to water and wetting to gas; gas is non-wetting to water and non-wetting to oil. Similarly we have  $W > O > G$ .

### Oil wet system

- Item 8 set to GAS water is non-wetting to oil and non-wetting to gas; oil is wetting to water and non-wetting to gas; gas is wetting to water and wetting to oil. The wettability order is then  $G > O > W$ .
- Item 8 set to OIL water is non-wetting to oil and wetting to gas; oil is wetting to water and wetting to gas; gas is non-wetting to water and non-wetting to oil. The wettability order is  $O > W > G$ .

**Note:** Pre-2002A: Oil was **always** treated as non-wetting to gas, whatever the wettability of the system modeled.

2002A onwards: Oil can be treated **also** as wetting to gas with item 8, whatever the wettability of the system modeled.

The picture below depicts the segregation order of the phases with respect to their wettability as described above.

	water wet		oil wet	
item 8	G	O	G	O
	O	G	W	G
	G	O	O	W
	W	W	G	O

Figure 3.4. Segregation order of phases

The hysteresis models are described in more detail in the "[Hysteresis](#)" and "[Hysteresis in WAG floods](#)" sections in the *ECLIPSE Technical Description*. Killough's model for capillary pressure and relative permeability hysteresis is described in his paper (1976) [[Ref. 64](#)]. See also keyword [HYSTCHCK](#).

## ECLIPSE 100

The default values will be used if EHYSTR is not entered in a run that uses the Hysteresis option. Note that for ECLIPSE 100, the default value of item 2 is 0.

## ECLIPSE 300

For the 2014.1 version, if hysteresis is specified via the HYSTER option of the SATOPTS keyword in the RUNSPEC section, the default values will be used if EHYSTR is not entered. Prior to the 2014.1 version, if the HYSTER option of SATOPTS was specified but EHYSTR omitted, no hysteresis was selected. Pre-2014.1 behavior can be restored by setting [item 320](#) of the [OPTIONS3](#) keyword to 1. Note that for ECLIPSE 300, the default value of item 2 is 2.

## Example

Killough's hysteresis model applied to both capillary pressure and relative permeability, for the non-wetting phase on a water-wet system:

```
EHYSTR  
0.07 2 1.0 0.1 BOTH RETR /
```

Killough's hysteresis model used for relative permeability only. Hysteresis is implemented in both wetting and non-wetting phases for an oil-wet system, with the correction for the wetting-phase relative-permeability scanning curve:

```
EHYSTR  
0.07 7 1.0 0.1 KR RETR 6* 1 /
```

## EHYSTRR Hysteresis parameters by region

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is entirely optional and allows the hysteresis curvature parameters to be entered on a saturation region basis. The keyword should be followed by `NTSFUN` records (see item 1 of keyword `TABDIMS` in the `RUNSPEC` section), each terminated by a slash (/).

Each record consists of the following items of data:

1. Curvature parameter for capillary pressure hysteresis.  
It must be greater than zero, and should normally lie in the range 0.05 to 0.1.  
DEFAULT: 0.1.
2. Curvature parameter for Killough's wetting phase relative permeability hysteresis.  
It must be a positive number. This item will be ignored if item 2 of the `EHYSTR` keyword is set to anything other than 4.  
DEFAULT: 1.0.
3. Modification parameter for the trapped non-wetting phase saturation in the Killough Model.  
If this parameter is zero (the standard Killough model) or set to a small value, the trapped saturation will be close to the maximum attained saturation when the maximum itself is small. This can lead to convergence problems.  
DEFAULT: 0.1.

The three data items for each region are the same as data items 1, 3 and 4 of the `EHYSTR` keyword. If the `EHYSTRR` keyword is present this overrides the data supplied in the `EHYSTR` keyword even if the `EHYSTRR` data is defaulted.

The `EHYSTRR` data for a cell is taken from the record corresponding to the drainage region number (`SATNUM`). The data associated with the imbibition region numbers (`IMBNUM`) will be ignored.

### Example

```

--
-- NTSFUN=4
--
EHYSTRR
0.05 1.0 0.1 /
0.07 1.0 0.1 /
0.1 1.0 0.1 /
0.1 1.0 0.1 /

```

## END

## Logical end of input file

This keyword terminates the input of data.

The END keyword need not be the actual end of the input file. However, if no END keyword is provided, one is generated at the end of the input data file.

END contains no items.

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>

	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The ENDACTIO keyword may only be used after an [ACTION](#), [ACTIONG](#), [ACTIONR](#) or [ACTIONW](#) keyword has been entered. It indicates the end of the set of SCHEDULE section keywords associated with the preceding ACTIONG, ACTIONR or ACTIONW keyword.

The set of keywords between the ACTIONG, ACTIONR, ACTIONW and ENDACTIO keywords are processed when the condition defined in the ACTIONG, ACTIONR, or ACTIONW keyword has been satisfied.

The ENDACTIO keyword has no associated data.

## ENDBOX

## Reset current input box to encompass the entire grid

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
x	EDIT
x	PROPS
x	REGIONS
x	SOLUTION
	SUMMARY
x	SCHEDULE

The ENDBOX keyword has no associated data.

It causes the input box to be reset so that it encompasses the entire grid.

Note that at the end of each input section, the program effectively supplies an ENDBOX and resets the input box.

See also keywords [BOX](#), [ADD](#), [COPY](#), [EQUALS](#), [MULTIPLY](#), [MINVALUE](#) and [MAXVALUE](#).

### Example

Thus, for an 11 by 19 by 4 grid, it has the same effect as:

```
BOX
1 11 1 19 1 4 /
```

## ENDDYN

### Indicates end of DYNAMICR keyword sequence

The ENDDYN keyword may only be used after a [DYNAMICR](#) keyword has been entered. It indicates the end of the set of conditions associated with the preceding DYNAMICR keyword.

The ENDDYN keyword has no associated data.

x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
x	EDIT
x	PROPS
x	REGIONS
x	SOLUTION
	SUMMARY
x	SCHEDULE

In the GRID section, the ENDFIN keyword tells the program to finish reading GRID data for the local grid named in the previous CARFIN, RADFIN, RADFIN4 or REFINE keyword. Any subsequent GRID section keywords are taken to apply to the global grid, until another local grid is specified by CARFIN, RADFIN, RADFIN4 or REFINE.

It is not necessary to insert ENDFIN between successive RADFIN, RADFIN4, CARFIN or REFINE keywords. The primary purpose of ENDFIN is to revert the program to reading data for the global grid system.

In the EDIT, PROPS, REGIONS, SOLUTION and SCHEDULE sections, the ENDFIN keyword tells the program that subsequent data no longer applies to the local grid named in the previous REFINE keyword.

The ENDFIN keyword has no associated data.

---

**Note:** The RADFIN4 keyword is not available in ECLIPSE 300.

---

Local grid refinement is described in "[Local grid refinement and coarsening](#)" in the *ECLIPSE Technical Description*.

## Example

In the GRID section:

```

CARFIN
-- NAME      I1-I2 J1-J2 K1-K2 NX NY NZ NWMAX--
   LGR1      2  2  3  3  3  4  5  5  8      5  /
PORO
200*0.2 /
EQUALS
  PERMX 500 /
  PERMY 500 /
  PERMZ 50 /
/
ENDFIN

```

## ENDINC

### Logical end of include file

The ENDINC keyword terminates the input of data from an [INCLUDE](#) file, returning control to the reading of the main file.

This keyword should not normally be entered, as an ENDINC is generated automatically at the end of the included file. It may, however, be used to end the reading of an included file before the actual end of file.

## End point scaling versus depth region numbers

The keyword should be followed by one integer for every grid block in the current input box, specifying the end point scaling versus depth table region to which it belongs. The region number should not be less than 1 or greater than NTENDP (item 3 in keyword [ENDSCALE](#)). The data must be terminated by a slash (/).

The region number specifies which end point scaling versus depth table (input using [ENPTVD](#) and/or [ENKRVD](#)) should be used to calculate the saturation table end points for each grid block. The end point scaling option should be activated by specifying keyword [ENDSCALE](#) in RUNSPEC.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

See "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for more information.

### Examples

#### Example 1

With NTENDP=4; NDIVIX=8, NDIVIY=6, NDIVIZ=5 specified in RUNSPEC keyword [DIMENS](#); and no input BOX set:

```
ENDNUM
8*1 16*2 8*3 16*4
8*1 16*2 8*3 16*4
8*1 16*2 8*3 16*4
8*1 16*2 8*3 16*4
8*1 16*2 8*3 16*4 /
```

#### Example 2

- A 12 x 4 x 5 grid
- Layers 1, 2, 3 assigned to end point scaling region number 1
- Layers 4, 5 assigned to end point scaling region number 2

```
ENDNUM
144*1 96*2 /
```

## ENDSCALE Use saturation table end-point scaling

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This indicates that the saturation table end-point scaling option is to be used. It is often convenient to scale the end-points of the relative permeability curves for each cell. This option is enabled by the **ENDSCALE** keyword. Table end-points can then be entered cell by cell (keywords such as **SWL**, **SWCR**, **SWU**, **KRW** and **PCW**) or with respect to depth (**ENPTVD**, **ENKRVD** and **ENPCVD**).

The keyword should be followed by some or all of the following data items, indicating whether the end-point scaling should be directional and irreversible, and setting the dimensions of the end-point scaling tables.

The data should be terminated by a slash (/).

### 1. Directional end-point scaling switch

**DIRECT** Indicates that the saturation table end-point scaling option is directional (that is, different saturation table end-points may be applied to saturation tables for flow in the X, Y or Z directions). End-point saturations are entered either under the appropriate directions (X,Y,Z) associated with the keywords **SWL**, **SWCR**, **SWU**, **SGL**, **SGCR**, **SGU**, **SOWCR**, **SOGCR** in the **PROPS** section, or using the keywords **ENPTVDX**, **ENPTVDY**, **ENPTVDZ** in the **PROPS** section and **ENDNUM** in the **REGIONS** section. If the end-point relative permeabilities are also scaled, the directional forms of keywords **KRW**, **KRG**, **KRO** or **ENKRVD** must be entered.

**NODIR** The saturation table end-point scaling is not directional. The same saturation table is used for flow in the X, Y or Z directions.

DEFAULT: **NODIR**

### 2. Irreversible end-point scaling switch

**IRREVERS** Indicates that the saturation table end-point scaling is irreversible (that is different saturation end points are to be used depending on whether flow is from I to I+1 or from I to I-1). Irreversible end-point saturations are entered either under the appropriate directions (+X, -X, +Y, -Y, +Z, -Z) associated with the keywords **SWL**, **SWCR**, **SWU**, **SGL**, **SGCR**, **SGU**, **SOWCR**, **SOGCR** in the **PROPS** section, or using the keywords **ENPTVDX**, **ENPTVDX-**, **ENPTVDY**, **ENPTVDY-**, **ENPTVDZ**, **ENPTVDZ-** in the **PROPS** section and **ENDNUM** in the **REGIONS** section. If the end-point relative permeabilities are also scaled, the positive and negative directional forms of keywords **KRW**, **KRG**, **KRO** or **ENKRVD** must be entered.

**REVERS** The end-point scaling is reversible. The same table is used whether the flow is from I to I+1 or from I to I-1.

The **IRREVERS** option can only be specified if **DIRECT** is also specified.

DEFAULT: **REVERS**

### 3. The number of saturation end-point versus depth tables (see keywords **ENPTVD**, **ENKRVD** in the **PROPS** section).

This quantity may also be defined by item 8 of **TABDIMS**; if it is set in both places, ECLIPSE will use the maximum of the two values.

DEFAULT: 1

4. The maximum number of nodes in any saturation end-point versus depth table (see keywords ENPTVD, ENKRVD in the PROPS section).

DEFAULT: 20

ECLIPSE 300

5. Options for combining the temperature-independent end-point scaling arrays (keywords such as SWL, SWCR, SWU, KRW and PCW) with the temperature-dependent end-point tables (ENPTVT, ENKRVT and ENPCVT).

0 Combination not permitted. ENDSALE and ENPTVT, ENKRVT and ENPCVT are mutually exclusive.

1 Temperature-independent grid-block end-points are superseded by temperature-dependent table end-points where non-defaulted table columns are specified.

2 Temperature-independent grid-block end-points are combined with temperature-dependent table end-points, where non-defaulted table columns are specified, using a scaling factor such that the resulting value at the lowest temperature in the table will correspond to the original grid block value.

DEFAULT: 0

The default option corresponds to the only option available prior to the 2011.1 version of ECLIPSE 300 for which the two end-point scaling mechanisms are mutually exclusive.

---

**Note:** The modeling of temperature-dependent end-points is only available for the THERMAL option. For non-thermal models item 5 will be ignored.

---

See "Saturation table scaling" in the *ECLIPSE Technical Description* for more information.

ECLIPSE 100

End-point scaling cannot be used in conjunction with the vertical equilibrium model (keyword VE).

ECLIPSE 300

The directional and reversible end-point scaling options are not available with the ODD3P relative permeability and capillary pressure hysteresis model.

ECLIPSE 300

Note this keyword had no items in pre-99A versions of ECLIPSE 300; existing datasets with this format will continue to run with no apparent difference.

---

**Note:** When directional forms of the keywords are used, the isotropic form is still required for use in equilibration and well block flows.

---

## Example

End-point scaling is directional and irreversible.

```
ENDSCALE
DIRECT  IRREVERS  /
```

## ENDSKIP

### End skipping of keywords

This keyword terminates the skipping of keywords initiated by the [SKIP](#), [SKIP100](#) or [SKIP300](#) keywords. An instance of the ENDSKIP keyword must be provided for each of the SKIP, SKIP100 and SKIP300 keywords.

## Relative permeabilities at saturation end point versus composition

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data consists of tables of relative permeabilities versus composition, one for each saturation table region, as specified in [TABDIMS](#) item 1. Each table consists of 8 columns of data (described below), and must be terminated by a slash (/).

### Column

1. Molar concentration of the component identified with the [EPSCOMP](#) keyword (moles per reservoir volume). Values should increase monotonically down the column. Component molar concentrations can be output in the SUMMARY section using the BMLSC and BMWAT keywords, and in the SOLUTION and SCHEDULE section using the MLSC and MWAT mnemonics in the [RPTRST](#), [RPTSOL](#) and [RPTSCHEd](#) keywords.

UNITS: kg-M/rm<sup>3</sup> (METRIC), lb-M/rb (FIELD), gm-M/rcc (LAB), kg-M/rm<sup>3</sup> (PVT-M)

2. Maximum water relative permeability.
3. Maximum gas relative permeability.
4. Maximum oil relative permeability.
5. Water relative permeability at critical oil saturation
6. Gas relative permeability at critical oil saturation
7. Oil relative permeability at an oil saturation = 1 - minimum water saturation - critical gas saturation.
8. Oil relative permeability at an oil saturation = 1 - critical water saturation - minimum gas saturation.

There must be the same number of entries in each column of a given table. The number of rows should not exceed the maximum number of entries in a quantity versus composition table, [EQLDIMS](#) item 3.

If all the permeability values in a column are defaulted then the values will be taken from the corresponding saturation function table. However, if a permeability value is defaulted whilst for other molar densities in the column values have been specified, the defaulted points will be filled via linear interpolation within the table and constant extrapolation at the ends.

---

**Note:** The ENKRVC keyword is only allowed in compositional simulations.

---

**Note:** By default, only one of the following end-point scaling methods can be used within a simulation: conventional end-point scaling initiated with the [ENDSCALE](#) keyword, temperature dependent end-point scaling or composition dependent end-point scaling. This behavior can be controlled using argument 5 of the [ENDSCALE](#) keyword.

---

### Example

With NTSFUN=1, reducing the oil relative permeability in the presence of the nominated component.

```

ENKRVC
0.0 5* 1.0 1.0
1.0 5* 0.5 0.5 /

```

## ENKRVD

## Relative permeability end point versus depth tables

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The different forms of this keyword allow the user to specify the depth variation of the maximum relative permeability for the three phases. These keywords complement the [ENPTVD](#) keyword, which specifies how the end point saturation values vary with depth.

Seven keywords are provided to allow the relative permeability end points within each grid cell to be scaled independently. These keywords are:

ENKRVD Relative permeability end points for the non-directional saturation function tables

ENKRVDX Relative permeability end points for the +X face of each grid cell

ENKRVDX- Relative permeability end points for the -X face of each grid cell

ENKRVDY Relative permeability end points for the +Y face of each grid cell

ENKRVDY- Relative permeability end points for the -Y face of each grid cell

ENKRVDZ Relative permeability end points for the +Z face of each grid cell

ENKRVDZ- Relative permeability end points for the -Z face of each grid cell

In radial grids the same directional keywords should be used to represent the relative permeability end points for flows in the +R, -R, +T, -T, +Z, -Z directions respectively.

The keyword [ENDSCALE](#) in the RUNSPEC section should also be specified.

The data comprises NTENDP (item 3 of keyword [ENDSCALE](#)) tables of relative permeability end points vs. depth, one for each end point scaling region. Each table consists of eight columns of data, and must be terminated by a slash (/):

Column;

1. Depth values. The values should increase monotonically down the column.  
UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)
2. The corresponding values of the maximum water relative permeability.
3. The corresponding values of the maximum gas relative permeability.
4. The corresponding values of the maximum oil relative permeability.
5. Water relative permeability at the critical oil (or gas) saturation.
6. Gas relative permeability at the critical oil (or water) saturation.
7. Oil relative permeability at the critical gas saturation.
8. Oil relative permeability at the critical water saturation.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSENDP (item 4 of keyword [ENDSCALE](#)). If an end point is defaulted for all depth values, in a problem where a value could correctly be defined, then the end point for each cell in the same scaling region will be the value in the appropriate saturation function table. However if an end point is defaulted at a certain depth but has been defined at other depths, the end point vs. depth table will be 'filled

in' by linear interpolation within the table and constant extrapolation at the ends of the table. End point values entered for absent phases are ignored.

**Note:** Versions of ECLIPSE 100 prior to 93A only require 4 columns of data. Hence the old datasets will require 4 extra default values on each row to run on version 93A or later. See the second example below.

If both directional and irreversible end-point scaling is requested using switches 'DIRECT' and 'IRREVERS' in [ENDSCALE](#), then the relative permeability end points for flow across the +X and -X faces of a grid cell are set using the keywords ENKRVDX, ENKRVDX-. Similarly ENKRVDY, ENKRVDY- are used for the +Y, -Y faces and the keywords ENKRVDZ, ENKRVDZ- for the +Z, -Z faces. Scaling of the well connection relative permeability tables is performed using the ENKRVD keyword.

When the end-point scaling is directional and reversible ('DIRECT' but not 'IRREVERS' is specified in [ENDSCALE](#)), the keyword ENKRVDX defines the relative permeability end points for the +X and -X faces of each grid cell. Keywords ENKRVDY, ENKRVDZ are used for both the +Y, -Y faces and the +Z, -Z faces of each grid cell respectively. Scaling of well connection relative permeability tables is performed using the ENKRVD keyword.

If [ENDSCALE](#) is specified without either switch 'DIRECT' or 'IRREVERS', then none of the directional forms of the ENKRVD keyword are allowed. The ENKRVD keyword then defines the new relative permeability end points for flow out of each grid cell face, and the well connection relative permeabilities.

If the hysteresis model (switch 'HYSTER' in keyword [SATOPTS](#)) is active then ENKRVD data applies to the drainage curve and the [IMKRVD](#) keyword is available to specify the imbibition end points as a function of depth. The IMKRVD keyword is used in exactly the same way as ENKRVD.

See also keyword [ENDNUM](#) in the REGIONS section, and the keyword [ENPTVD](#) in the PROPS section.

## ENKRVT

## Relative permeabilities at saturation end point versus temperature

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can only be used with the [THERMAL](#) option.

The data consists of tables of relative permeabilities versus temperature, one for each saturation table region, as specified in [TABDIMS](#) item 1. Each table consists of 8 columns of data (described below), and must be terminated by a slash (/).

Column:

- Temperature values.  
Should increase monotonically down the column.  
UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)
- Maximum water relative permeability.
- Maximum gas relative permeability.
- Maximum oil relative permeability.
- Water relative permeability at critical oil saturation
- gas relative permeability at critical oil saturation
- Oil relative permeability at an oil saturation = 1 - minimum water saturation - critical gas saturation.
- Oil relative permeability at an oil saturation = 1 - critical water saturation - minimum gas saturation.

There must be the same number of entries in each column of a given table. This number should not be greater than the maximum number of entries in a quantity versus temperature table ([EQLDIMS](#) item 3). Each relative permeability entry should be non-negative. Default values may be entered in columns 2 to 8 as required.

When temperature-dependent end-point scaling is used independently of grid-block end-point scaling, if an end point is defaulted for all temperature values, in a model where a value could correctly be defined, the end point for each cell in the same scaling region will be the value in the appropriate saturation function table. However, when used in combination with [ENDSCALE](#) item 5 set to 1 or 2, the end point will default to the temperature-independent grid-block scaling value for the maximum water, gas and oil relative permeabilities (columns 2, 3 and 4). However, for the water and gas relative permeabilities at critical oil saturation (columns 5 and 6) and the oil relative permeabilities at residual oil saturation (columns 7 and 8), the defaults will be supplied by scaling according to the current values of the maximum relative permeabilities.

If one or more end points in a given table column are not defaulted such that the end point has been defined for at least one temperature, the end-point versus temperature table will be filled in by linear interpolation within the table and constant extrapolation at the ends of the table. End-point values entered for absent phases are ignored.

### Example

```
ENKRVT

## Capillary pressures at saturation end point versus composition

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data consists of tables of capillary pressures versus composition, one for each saturation table region, as specified in [TABDIMS](#) item 1. Each table consists of 3 columns of data (described below), and must be terminated by a slash (/).

Column:

1. Molar concentration of the component identified with the [EPSCOMP](#) keyword (moles per reservoir volume). Values should increase monotonically down the column.

Component molar concentrations can be output in the SUMMARY section using the BMLSC and BMWAT keywords, and in the SOLUTION and SCHEDULE section using the MLSC and MWAT mnemonics in the [RPTRST](#), [RPTSOL](#) and [RPTSCHED](#) keywords.

UNITS: kg-M/rm<sup>3</sup> (METRIC), lb-M/rb (FIELD), gm-M/rcc (LAB), kg-M/rm<sup>3</sup> (PVT-M)

2. Maximum oil-gas capillary pressure

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

3. Maximum water-oil capillary pressure

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

There must be the same number of entries in each column of a given table. The number of rows should not exceed the maximum number of entries in a quantity versus composition table, [EQLDIMS](#) item 3.

If all the capillary pressure values in a column are defaulted then the values will be taken from the corresponding saturation function table. However, if a capillary pressure value is defaulted whilst for other molar densities in the column values have been specified, the defaulted points will be filled via linear interpolation within the table and constant extrapolation at the ends.

---

**Note:** The ENPCVC keyword is only allowed in compositional simulations.

---

**Note:** By default, only one of the following end-point scaling methods can be used within a simulation: conventional end-point scaling initiated with the [ENDSCALE](#) keyword, temperature dependent end-point scaling or composition dependent end-point scaling. This behavior can be controlled using item 5 of the [ENDSCALE](#) keyword.

---

### Example

With NTSFUN=1, modifying the water capillary pressure in the presence of the nominated component.

```
ENPCVC
0.0 1* 45
1.0 1* 500/
```

## ENPCVD

## Maximum capillary pressure versus depth tables

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies the depth variation of the maximum capillary pressure for different end-point scaling regions within the reservoir. The keyword can only be used when the end-point scaling option is active (keyword [ENDSCALE](#) in the RUNSPEC section).

The data comprises NTENDP (item 3 of keyword [ENDSCALE](#)) tables of maximum capillary pressure end points versus depth, one for each end point scaling region. Each table consists of 3 columns of data, and must be terminated by a slash (/).

Column:

1. Depth values.

The values should increase monotonically down the column.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

2. The corresponding values of the maximum gas-oil capillary pressure.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

3. The corresponding values of the maximum water-oil capillary pressure.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSENDP (item 4 of keyword [ENDSCALE](#)). If a maximum capillary pressure is defaulted for all depth values, in a problem where a value could correctly be defined, then the end point for each cell in the same scaling region will be the value in the appropriate saturation function table. However, if a maximum capillary pressure is defaulted and the end-point has been defined at other depths, the end-point versus depth table will be filled in by linear interpolation within the table and constant extrapolation at the ends of the table. End-point values entered for absent phases are ignored.

ECLIPSE 100

If the hysteresis model (switch 'HYSTER' in keyword [SATOPTS](#)) is active, the ENPCVD data applies to the drainage curve and the [IMPCVD](#) keyword is available to specify the imbibition end points as a function of depth. The [IMPCVD](#) keyword is used in exactly the same way as ENPCVD.

See also keyword [ENDNUM](#) in the REGIONS section, and the keywords [ENPTVD](#), [ENSPCVD](#), [ENKRVD](#) and [IMPCVD](#) in the PROPS section.

### Example

```

## ENPCVT

## Capillary pressures at saturation end point versus temperature

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can only be used with the [THERMAL](#) option.

The data consists of tables of capillary pressures vs. temperature, one for each saturation table region, as specified in [TABDIMS](#) item 1. Each table consists of 3 columns of data (described below), and must be terminated by a slash (/).

Column:

1. Temperature values.

Should increase monotonically down column.

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

2. Maximum oil-gas capillary pressure

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

3. Maximum water-oil capillary pressure

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

There must be the same number of entries in each column of a given table. This number should not be greater than the maximum number of entries in a quantity versus temperature table ([EQLDIMS](#) item 3). Each capillary pressure entry should be non-negative. Default values may be entered in columns 2 and 3 as required.

When temperature-dependent end-point scaling is used independently of grid-block end-point scaling, if an end point is defaulted for all temperature values, in a model where a value could correctly be defined, the end point for each cell in the same scaling region will be the value in the appropriate saturation function table. However, when used in combination with [ENDSCALE](#) item 5 set to 1 or 2, the end point will default to the temperature-independent grid-block scaling value.

If one or more end points in a given table column are not defaulted such that the end point has been defined for at least one temperature, the end point versus temperature table will be filled in by linear interpolation within the table and constant extrapolation at the ends of the table. End-point values entered for absent phases are ignored.

### Example

x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

ENPTVC specifies the composition variation of the saturation table end-points for the saturation table regions within the reservoir. The flow of each phase across each grid block face is calculated using transformed capillary pressure and relative permeability curves obtained by linearly scaling the tabulated curves between the end-points specified using the ENPTVC keyword. ENPTVC also permits scaling of the relative permeability tables used in computing the flow of phases between grid cells and well connections and the scaling of capillary pressure functions in the equilibration algorithm.

The data comprises a number of tables of saturation end-points versus composition, one for each saturation table region, as specified in TABDIMS item 1. Each table consists of 9 columns of data (described below), and must be terminated by a slash (/).

Column:

1. Molar concentration of the component identified with the EPSCOMP keyword (moles per reservoir volume). Values should increase monotonically down the column.

Component molar concentrations can be output in the SUMMARY section using the BMLSC and BMWAT keywords, and in the SOLUTION and SCHEDULE section using the MLSC and MWAT mnemonics in the RPTRST, RPTSOL and RPTSCHED keywords.

UNITS: kg-M/rm<sup>3</sup> (METRIC), lb-M/rb (FIELD), gm-M/rcc (LAB), kg-M/rm<sup>3</sup> (PVT-M)

2. Connate water saturation.
3. Critical water saturation.
4. Maximum water saturation.
5. Connate gas saturation.
6. Critical gas saturation.
7. Maximum gas saturation.
8. Critical oil-in-water saturation
9. Critical oil-in-gas saturation.

There must be the same number of entries in each column of a given table. The number of rows should not exceed the maximum number of entries in a quantity versus composition table, EQLDIMS item 3.

Each saturation entry should be in the range 0.0 to 1.0 inclusive. If all the saturation values in a column are defaulted then the values will be taken from the corresponding saturation function table. However, if a saturation value is defaulted whilst for other molar densities in the column values have been specified, the defaulted points will be filled via linear interpolation within the table and constant extrapolation at the ends.

---

**Note:** The ENPTVC keyword is only allowed in compositional simulations.

---

**Note:** By default, only one of the following end-point scaling methods can be used within a simulation: conventional end-point scaling initiated with the ENDSCALE keyword, temperature dependent end-point scaling or composition dependent end-point scaling. This behavior can be controlled using item 5 of the ENDSCALE keyword.

---

## ENPTVD

## Saturation end-point versus depth tables

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The different forms of this keyword specify the depth variation of the saturation table end-points for different end-point scaling regions within the reservoir. The flow of each phase across each grid block face is calculated using transformed capillary pressure and relative permeability curves obtained by linearly scaling the tabulated curves between the end-points specified using the ENPTVD keyword. The ENPTVD keyword also permits scaling of the relative permeability tables used in computing the flow of phases between grid cells and well connections and the scaling of capillary pressure functions in the equilibration algorithm.

Seven keywords are provided to allow the saturation end-points within each grid cell to be scaled independently. These keywords are:

ENPTVD Saturation end-points for the non-directional saturation function tables

ENPTVDX Saturation end-points for the +X face of each grid cell

ENPTVDX- Saturation end-points for the -X face of each grid cell

ENPTVDY Saturation end-points for the +Y face of each grid cell

ENPTVDY- Saturation end-points for the -Y face of each grid cell

ENPTVDZ Saturation end-points for the +Z face of each grid cell

ENPTVDZ- Saturation end-points for the -Z face of each grid cell

In radial grids the same directional keywords should be used to represent the saturation end-points for flows in the +R, -R, +T, -T, +Z, -Z directions respectively.

The keyword [ENDSCALE](#) should be specified in the RUNSPEC section.

The data comprises NTENDP (item 3 of keyword [ENDSCALE](#)) tables of saturation end-points vs. depth, one for each end-point scaling region. Each table consists of 9 columns of data, and must be terminated by a slash (/).

1. Depth values. The values should increase monotonically down the column.  
UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)
2. The corresponding values of the connate water saturation.
3. The corresponding values of the critical water saturation.
4. The corresponding values of the maximum water saturation.
5. The corresponding values of the connate gas saturation.
6. The corresponding values of the critical gas saturation.
7. The corresponding values of the maximum gas saturation.
8. The corresponding values of the critical oil-in-water saturation.
9. The corresponding values of the critical oil-in-gas saturation.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSENDP (item 4 of keyword [ENDSCALE](#)). Each saturation entry should be in the range 0.0 to 1.0 inclusive. If a saturation end-point is defaulted for all depth values, in a problem where a

value could correctly be defined, then the end-point for each cell in the same scaling region will be the value in the appropriate saturation function table. However if a saturation end point is defaulted and the end-point has been defined at other depths, the end-point versus depth table will be filled in by linear interpolation within the table and constant extrapolation at the ends of the table. End point values entered for absent phases are ignored.

If both directional and irreversible end-point scaling is requested using switches 'DIRECT' and 'IRREVERS' in [ENDSCALE](#), then saturation end-points for flow across the +X and -X faces of a grid cell are set using the keywords ENPTVDX, ENPTVDX-. Similarly ENPTVDY, ENPTVDY- are used for the +Y, -Y faces and the keywords ENPTVDZ, ENPTVDZ- for the +Z, -Z faces. Scaling of the well connection relative permeability tables and capillary pressure functions for equilibration are performed using the ENPTVD keyword.

When the end-point scaling is directional and reversible ('DIRECT' but not 'IRREVERS' is specified in [ENDSCALE](#)), the keyword ENPTVDX defines the saturation end-points for the +X and -X faces of each grid cell. Keywords ENPTVDY, ENPTVDZ are used for both the +Y, -Y faces and the +Z, -Z faces of each grid cell respectively. Scaling of well connection relative permeability tables and capillary pressure tables for equilibration are performed using the ENPTVD keyword.

If [ENDSCALE](#) is specified without either switch 'DIRECT' or 'IRREVERS', then none of the directional forms of the ENPTVD keyword are allowed. The ENPTVD keyword then defines the new saturation end-points for flow out of each grid cell face, for well connection relative permeabilities and for capillary pressure evaluations in the equilibration algorithm.

ECLIPSE 100

If the Hysteresis Model (switch 'HYSTER' in keyword [SATOPTS](#)) is active then ENPTVD data applies to the drainage curve and the [IMPTVD](#) keyword is available to specify the imbibition end-points as a function of depth. The IMPTVD keyword is used in exactly the same way as ENPTVD.

See also keyword [ENDNUM](#) in the REGIONS section, and the keywords [ENKRVD](#) and [IMPTVD](#) in the PROPS section.

## ENPTVT

## Saturation end-point versus temperature

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can only be used with the [THERMAL](#) option.

ENPTVT specifies the temperature variation of the saturation table end-points for the saturation table regions within the reservoir. The flow of each phase across each grid block face is calculated using transformed capillary pressure and relative permeability curves obtained by linearly scaling the tabulated curves between the end-points specified using the ENPTVT keyword. ENPTVT also permits scaling of the relative permeability tables used in computing the flow of phases between grid cells and well connections and the scaling of capillary pressure functions in the equilibration algorithm.

The data comprises a number of tables of saturation end-points versus temperature, one for each saturation region, as specified in [TABDIMS](#) item 1. Each table consists of 9 columns of data (described below), and must be terminated by a slash (/).

1. Temperature: should increase monotonically down column.  
UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)
2. Connate water saturation.
3. Critical water saturation.
4. Maximum water saturation.
5. Connate gas saturation.
6. Critical gas saturation.
7. Maximum gas saturation.
8. Critical oil-in-water saturation.
9. Critical oil-in-gas saturation.

There must be the same number of entries in each column of a given table. This number should not be greater than the maximum number of entries in a quantity versus temperature table ([EQLDIMS](#) item 3). Default values may be entered in columns 2 to 9 as required.

Each saturation entry should be in the range 0.0 to 1.0 inclusive when used to specify the temperature-dependent value directly. However, when used with [ENDSCALE](#) item 5 set to 2, the values can exceed 1.0.

When temperature-dependent end-point scaling is used independently of grid-block end-point scaling, if an end-point is defaulted for all temperature values, in a model where a value could correctly be defined, the end-point for each cell in the same scaling region will be the value in the appropriate saturation function table. However, when used in combination with [ENDSCALE](#) item 5 set to 1 or 2, the end-point will default to the temperature-independent grid-block scaling value.

If one or more end-points in a given table column are not defaulted such that the end-point has been defined for at least one temperature, the end-point versus temperature table will be filled in by linear interpolation within the table and constant extrapolation at the ends of the table. End-point values entered for absent phases are ignored.

## Example

```

If an equation of state is being used in the compositional mode, this keyword enables one of four possibilities to be chosen. The keyword is followed by an item, the first letter of which is significant.

The possible options are:

PR Peng-Robinson

RK Redlich-Kwong

SRK Soave-Redlich-Kwong

ZJ Zudkevitch-Joffe-Redlich-Kwong

Details of the equations of state are discussed in ["Equations of state"](#) in the *ECLIPSE Technical Description*.

A slight modification to the Peng-Robinson equation is available, by using the [PRCORR](#) keyword.

If multiple equations of state are being used, an equation of state should be chosen for each reservoir EoS region. The use of multiple EoS regions is discussed in ["Equations of state regions"](#) in the *ECLIPSE Technical Description*.

DEFAULT: Peng-Robinson

## Examples

### Example 1

## Controls debug for end-point scaling option

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to write out the scaled relative permeability curves for multiple sets of grid blocks when the end-point scaling option is active (keyword [ENDSCALE](#) in the RUNSPEC section). The curves are output as tables to the Debug file, and may optionally be output in the form of a GRAF user file which can be read directly into the GRAF program.

The keyword can also be used to switch on checking of curves in hysteresis models.

The keyword consists of the following records of data, each record terminated with a slash (/).

The data items in each record are:

### Record 1

The first record defines control parameters for the debug:

1. Table output type
  - 0 Output in tabular form
  - 1 Output as GRAF user data

DEFAULT: 0
2. Checks whether the drainage and imbibition curves cross in hysteresis cases. The scaled table output can be suppressed to allow large grids to be checked without creating large output files.
  - 0 No check performed. Scaled tables are output for all cells.
  - 1 Check performed. The scaled table output is switched off.
  - 2 Check performed. The scaled table output is switched off, except for cells where hysteresis problems are found.
  - 3 Check performed. Scaled tables are output for all cells.

DEFAULT: 0

The hysteresis check can only be performed with Hysteresis enabled. See keyword [SATOPTS](#) option [HYSTER](#). It checks the relative permeability and/or capillary pressure depending on which type of hysteresis has been selected. See item 5 of keyword [EHYSTR](#).

End the data record with a slash (/).

### Each subsequent record

The subsequent records, up to a maximum of 50, define the grid block data, each containing the following items of data. Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing just a slash.

Each record should consist of 6 integers and optionally a local grid name, terminated with a slash (/). The first 6 integers define the box of cells for which the debug output will be generated.

1. IX1 First cell on X axis to be included in output
2. IX2 Last cell on X axis to be included in output

3. JY1 First cell on Y axis to be included in output
4. JY2 Last cell on Y axis to be included in output
5. KZ1 First cell on Z axis to be included in output
6. KZ2 Last cell on Z axis to be included in output

The values must satisfy:

$$1 \leq IX1 \leq IX2 \leq \text{NDIVIX}$$

$$1 \leq JY1 \leq JY2 \leq \text{NDIVIY}$$

$$1 \leq KZ1 \leq KZ2 \leq \text{NDIVIZ} \text{ (where NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword DIMENS)}$$

7. Grid name

' ' Output cells in global and all local grids

GLOBAL Output cells in global grid only

'lgr name' Output cells in the named local grid.

DEFAULT: ' '

This item will be ignored if local grid refinement is not used (see "[Local grid refinement and coarsening](#)" in the *ECLIPSE Technical Description*). The output can be quite extensive, and hence only small numbers of cells should be output from large models.

---

**Note:** Use of either of EPSTDBGS or EPSTDEBUG keywords for a particular run is recommended, and not both. In the event of both the keywords being used, ECLIPSE will only honor the last keyword entered.

---

ECLIPSE 100

For parallel runs where separate debug files are written for the individual processors, the output information for one or more grid blocks may be reported in more than one debug file if the grid blocks are used as halo cells.

ECLIPSE 300

The EPSTDBGS keyword is not available with the ODD3P relative permeability and capillary pressure hysteresis model.

ECLIPSE 300

The EPSTDBGS keyword can also be used in the SCHEDULE section for thermal models when temperature-dependent scaled end-points are being modeled via a combination of grid-block end-points (ENDSCALE keyword item 5 set to 1 or 2) and temperature dependent table end-points (ENPTVT, ENKRVT and ENPCVT). Under these circumstances, the debug output will be reported at each timestep for which the EPSTDBGS keyword is specified.

ECLIPSE 300

In parallel, a DEBUG3 keyword, possibly empty, must be present in the RUNSPEC section for the debug output files to be created properly for each task. The run may fail otherwise. Separate debug files are used for reporting end-point scaling information for grid blocks associated with individual processors.

---

**Note:** If WAG hysteresis has been specified via the WAGHYSTR keyword and if the WAG hysteresis alternative water relative permeability saturation regions WH2NUM or WH3NUM have been specified, the alternative water relative permeabilities will be reported in the scaled tables for saturation regions for which

WAG hysteresis has been applied to the water phase. This is described under "[Hysteresis in WAG floods](#)" in the *ECLIPSE Technical Description*.

/

```

## Example output

The format of the output produced by this keyword has been revised for the 2013.1 version and an example of this revised output is shown below for the water-oil saturation functions. A similar set of outputs is also produced for the gas-oil saturation functions. The output consists of a header listing the set of end-points followed by a table of relative permeabilities and capillary pressure versus saturation.

The header lists the unscaled end-points, which are determined from the input saturation table functions, together with the scaled end-points which are specified via the end-point scaling arrays (or defaulted from their corresponding table end-points if not specified). The exceptions to this are the end-points SW(KRWR), SOWL, SOW(KRORW) and SOWU which are included for completeness and which are calculated as described below:

- SW(KRWR) corresponds to the scaled water saturation at which the water relative permeability at the critical oil in water saturation occurs.
  - For two-point scaling (SCALECRS keyword not specified or specified with item 1 set to No), this corresponds to the saturation  $S_w = 1 - S_{owcr} - S_{gco}$  scaled according to the linear transformation  $(S_{wcr}, S_{wmax}) \Rightarrow (SWCR, SWU)$
  - For three-point scaling (SCALECRS keyword specified with item 1 set to Yes), this corresponds to the scaled saturation  $SW = 1 - SOWCR - SGL$ .
- SOWL corresponds to the lower limit of the scaled oil-water saturation extent and is calculated according to  $SOWL = 1 - SWU - SGL$ .
- SOW(KRORW) corresponds to the scaled oil saturation at which the oil relative permeability to water at the critical water saturation occurs.
  - For two-point scaling (SCALECRS keyword not specified or specified with item 1 set to No), this corresponds to the saturation  $S_{ow} = 1 - S_{wcr} - S_{gco}$  scaled according to the linear transformation  $(S_{owcr}, S_{omax}) \Rightarrow (SOWCR, SOWU)$
  - For three-point scaling (SCALECRS keyword specified with item 1 set to Yes), this corresponds to the scaled saturation  $SOW = 1 - SWCR - SGL$ .
- SOWU corresponds to the upper limit of the scaled oil-water saturation extent and is calculated according to  $SOWU = 1 - SWL$  or  $SOWU = 1 - SWL - SGL$  in ECLIPSE 100, depending upon whether [item 205](#) of the OPTIONS keyword is set to 0 or 1 respectively, and according to  $SOWU = 1 - SWL - SGL$  in ECLIPSE 300.

For illustration purposes, these four inferred end-points are shown underlined in the example on the next page which uses two-point scaling. For the gas-oil end-point scaling output, the scaled end-points SG(KRGR), SOGL, SOG(KRORG) and SOGU are calculated in an analogous manner.

The table of relative permeabilities and capillary pressure versus saturation extends from zero to unity saturation with saturation nodes specified at 5% intervals plus the lower and upper limits of the scaled saturation extents together with the critical saturations defined in the header information.

ECLIPSE 100

The pre-2013.1 version of the EPSDBGS output can be selected by setting [item 202](#) of the OPTIONS keyword to 1.

ECLIPSE 300

The pre-2013.1 version of the EPSDBGS output can be selected by setting [item 297](#) of the OPTIONS3 keyword to 1.

**Note:** In ECLIPSE 100, the maximum unscaled water and gas saturations are taken from the maximum saturation entries in the respective tables. However, in ECLIPSE 300, these are calculated from the connate saturations (lowest saturation table entries) of the other phases according to  $S_{wmax} = 1 - S_{owco} - S_{gco}$  and  $S_{gmax} = 1 - S_{ogco} - S_{wco}$ . This can cause differences between the simulators for the unscaled end-points in cases where the maximum saturation table entries do not concur with the values inferred from the connate saturations.

## EPSDEBUG Controls debug for end-point scaling option

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to write out the scaled relative permeability curves for individual grid blocks when the end-point scaling option is active (keyword [ENDSCALE](#) in the RUNSPEC section). The curves are output as tables to the Debug file, and may optionally be output in the form of a GRAF user file which can be read directly into the GRAF program.

The keyword can also be used to switch on the checking of curves in hysteresis models.

See also keyword [EPSDBGS](#) which allows scaled relative permeability curves to be written for multiple sets of grid block data.

The keyword should be followed by 7 integers and optionally a local grid name, terminated with a slash (/). The first 6 integers define the box of cells for which the debug output will be generated. This box should be restricted to a single matrix or fracture porosity. The debug data is output for all matrix and fracture porosities by default. The 7<sup>th</sup> integer controls the form of the debug output.

1. IX1 First cell on X axis to be included in output
2. IX2 Last cell on X axis to be included in output
3. JY1 First cell on Y axis to be included in output
4. JY2 Last cell on Y axis to be included in output
5. KZ1 First cell on Z axis to be included in output
6. KZ2 Last cell on Z axis to be included in output

The values must satisfy:

$$1 \leq IX1 \leq IX2 \leq NDIVIX$$

$$1 \leq JY1 \leq JY2 \leq NDIVIY$$

$$1 \leq KZ1 \leq KZ2 \leq NDIVIZ \text{ (where NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword [DIMENS](#))}$$

7. Table output type
  - 0 Output in tabular form
  - 1 Output as GRAF user data

DEFAULT: 0

8. Grid name
  - ' ' Output cells in global and all local grids
  - GLOBAL Output cells in global grid only
  - 'lgr name' Output cells in the named local grid.

DEFAULT: ' '

This item will be ignored if local grid refinement is not used (see "[Local grid refinement and coarsening](#)" in the *ECLIPSE Technical Description*). The output can be quite extensive, and hence only small numbers of cells should be output from large models.

9. Checks whether the drainage and imbibition curves cross in hysteresis cases. The scaled table output can be suppressed to allow large grids to be checked without creating large output files.
  - 0 No check performed. Scaled tables are output for all cells
  - 1 Check performed. The scaled table output is switched off.
  - 2 Check performed. The scaled table output is switched off, except for cells where hysteresis problems are found.
  - 3 Check performed. Scaled tables are output for all cells

DEFAULT: 0

The hysteresis check can only be performed with Hysteresis enabled. See keyword [SATOPTS](#) option [HYSTER](#). It checks whether the drainage and imbibition relative permeability and/or capillary pressure curves cross, depending on which type of hysteresis has been selected. See item 5 of keyword [EHYSTR](#).

---

**Note:** It is recommended to use either the [EPSDEBUG](#) or [EPSDBGS](#) keyword for a particular run, but not both. If both the keywords are used, ECLIPSE will only honor the last keyword entered.

---

ECLIPSE 100

For parallel runs where separate debug files are written for the individual processors, the output information for one or more grid blocks may be reported in more than one debug file if the grid blocks are used as halo cells.

ECLIPSE 300

The [EPSDBGS](#) keyword is not available with the [ODD3P](#) relative permeability and capillary pressure hysteresis model.

ECLIPSE 300

The [EPSDEBUG](#) keyword can also be used in the [SCHEDULE](#) section for Thermal models when temperature-dependent scaled end-points are being modeled using a combination of grid-block end-points ([ENDSCALE](#) keyword item 5 set to 1 or 2) and temperature-dependent table end-points ([ENPTVT](#), [ENKRVT](#) and [ENPCVT](#)). Under these circumstances, the debug output will be reported at each timestep for which the [EPSDEBUG](#) keyword is specified.

ECLIPSE 300

In parallel, a [DEBUG3](#) keyword, possibly empty, must be present in the [RUNSPEC](#) section for the debug output files to be created properly for each task. The run may fail otherwise. Separate debug files are used for reporting end-point scaling information for grid blocks associated with individual processors.

---

**Note:** If WAG hysteresis has been specified via the [WAGHYSTR](#) keyword and if the WAG hysteresis alternative water relative permeability saturation regions [WH2NUM](#) or [WH3NUM](#) have been specified, the alternative water relative permeabilities will be reported in the scaled tables for saturation regions for which WAG hysteresis has been applied to the water phase. This is described under "[Hysteresis in WAG floods](#)" in the *ECLIPSE Technical Description*.

---

## Example

```

EPSDEBUG
-- IX1 IX2   IY1 IY2   IZ1 IZ2   TAB  LGR  HYST
   4   4     5   5     1   3     0   1*   0/

```

## Example output

The format of the output produced by this keyword has been revised for the 2013.1 version and an example of this revised output is shown below for the water-oil saturation functions. A similar set of outputs is also produced for the gas-oil saturation functions. The output consists of a header listing the set of end-points followed by a table of relative permeabilities and capillary pressure versus saturation.

The header lists the unscaled end-points which are determined from the input saturation table functions, together with the scaled end-points which are specified via the end-point scaling arrays (or defaulted from their corresponding table end-points if not specified). The exceptions are the end-points SW(KRWR), SOWL, SOW(KRORW) and SOWU which are included for completeness and which are calculated as described below:

1. SW(KRWR) corresponds to the scaled water saturation at which the water relative permeability at the critical oil in water saturation occurs.
  - For two-point scaling (SCALECRS keyword not specified or specified with item 1 set to No), this corresponds to the saturation  $S_w = 1 - S_{owcr} - S_{gco}$  scaled according to the linear transformation  $(S_{wcr}, S_{wmax}) \Rightarrow (SWCR, SWU)$
  - For three-point scaling (SCALECRS keyword specified with item 1 set to Yes), this corresponds to the scaled saturation  $SW = 1 - SOWCR - SGL$ .
2. SOWL corresponds to the lower limit of the scaled oil-water saturation extent and is calculated according to  $SOWL = 1 - SWU - SGL$ .
3. SOW(KRORW) corresponds to the scaled oil saturation at which the oil relative permeability to water at the critical water saturation occurs.
  - For two-point scaling (SCALECRS keyword not specified or specified with item 1 set to No), this corresponds to the saturation  $S_{ow} = 1 - S_{wcr} - S_{gco}$  scaled according to the linear transformation  $(S_{owcr}, S_{omax}) \Rightarrow (SOWCR, SOWU)$
  - For three-point scaling (SCALECRS keyword specified with item 1 set to Yes), this corresponds to the scaled saturation  $SOW = 1 - SWCR - SGL$ .
4. SOWU corresponds to the upper limit of the scaled oil-water saturation extent and is calculated according to  $SOWU = 1 - SWL$  or  $SOWU = 1 - SWL - SGL$  in ECLIPSE 100, depending upon whether [item 205](#) of the OPTIONS keyword is set to 0 or 1 respectively, and according to  $SOWU = 1 - SWL - SGL$  in ECLIPSE 300.

For illustration purposes, these four end-points are shown underlined in the example over the page which uses two-point scaling. For the gas-oil end-point scaling output, the scaled end-points SG(KRGR), SOGL, SOG(KRORG) and SOGU are calculated in an analogous manner.

The table of relative permeabilities and capillary pressure versus saturation extends from zero to unity saturation with saturation nodes specified at 5% intervals plus the lower and upper limits of the scaled saturation extents together with the critical saturations defined in the header information.

ECLIPSE 100

The pre-2013.1 version of the EPSDEBUG output can be selected by setting [item 202](#) of the OPTIONS keyword to 1.

ECLIPSE 300

The pre-2013.1 version of the EPSDEBUG output can be selected by setting [item 297](#) of the OPTIONS3 keyword to 1.

**Note:** In ECLIPSE 100, the maximum unscaled water and gas saturations are taken from the maximum saturation entries in the respective tables. However, in ECLIPSE 300, these are calculated from the connate saturations (lowest saturation table entries) of the other phases according to  $S_{wmax} = 1 - S_{owco} - S_{gco}$  and  $S_{gmax} = 1 - S_{ogco} - S_{wco}$ . This can cause differences between the simulators for the unscaled end-points in cases where the maximum saturation table entries do not concur with the values inferred from the connate saturations.

	SUMMARY
	SCHEDULE

The data comprises NTSFUN (see item 1 of keyword [TABDIMS](#) in the RUNSPEC section) tables of end-point scaling control data, each terminated by a slash (/). Only one row per table should be entered. This keyword is only used with the [ODD3P](#) relative permeability and capillary pressure hysteresis option and is optional.

Each table consists of a single row containing 26 columns of data:

- Oil saturation end-point Land process scaling control.
  - Deselect oil saturation Land process end-point scaling.
  - Select oil saturation Land process end-point scaling.

DEFAULT: 0

For miscible runs, a value of 1 is recommended.

- Gas saturation end-point Land process scaling control.
  - Deselect gas saturation Land process end-point scaling.
  - Select gas saturation Land process end-point scaling.

DEFAULT: 0

For miscible runs, a value of 1 is recommended.

- Water saturation end-point Land process scaling control.
  - Deselect water saturation Land process end-point scaling.
  - Select water saturation Land process end-point scaling.

DEFAULT: 0

For miscible runs, a value of 1 is recommended.

- Capillary pressure scaling control.
  - Deselect capillary pressure scaling.
 

If a value of 0 is specified, no capillary pressure scaling is performed.

- Select capillary pressure scaling using reference surface tensions.

If a value of 1 is specified, the capillary pressure scaling is based upon the ratios of the calculated values of oil-gas, oil-water and gas-water surface tensions to the corresponding reference surface tension values defined in columns 6, 7 and 8.

- Select capillary pressure scaling using reference surface tensions plus exponents.

If a value of 2 is specified, the capillary pressure scaling is based upon the ratios of the calculated values of oil-gas, oil-water and gas-water surface tensions to corresponding reference surface

tension values defined in columns 6, 7 and 8, raised to the corresponding exponents defined in columns 9, 10 and 11.

DEFAULT: 0

5. End-point saturation and relative permeability scaling control.

0 Deselect end-point saturation relative permeability scaling.

If a value of 0 is specified, no end-point scaling is performed.

1 Select end-point saturation and relative permeability scaling using threshold surface tensions.

If a value of 1 is specified, the end-point saturation and relative permeability scaling is based upon the calculated values of oil-gas, oil-water and gas-water surface tensions and the corresponding threshold surface tension values defined in columns 15, 16 and 17 below.

2 Select end-point saturation and relative permeability scaling using threshold surface tensions plus exponents

If a value of 2 is specified, the end-point saturation and relative permeability scaling is based upon the calculated values of oil-gas, oil-water and gas-water surface tensions, the corresponding reference surface tension values defined in columns 15, 16 and 17 below raised to the corresponding exponents defined in columns 24, 25 and 26.

3 Select end-point saturation and relative permeability scaling using threshold capillary numbers.

If a value of 3 is specified, the end-point saturation and relative permeability scaling is based upon the calculated values of oil-gas, oil-water and gas-water surface tensions, the calculated capillary numbers and the threshold capillary numbers specified in columns 15 to 20.

4 Select end-point saturation and relative permeability scaling using threshold capillary numbers plus exponents.

If a value of 4 is specified, the end-point saturation and relative permeability scaling is based upon the calculated values of oil-gas, oil-water and gas-water surface tensions, the calculated capillary numbers and the threshold capillary numbers specified in columns 15 to 20 raised to the exponents defined in columns 24, 25 and 26.

DEFAULT: 0

Relative permeability scaling is only applied for a given phase pair when the calculated surface tension is less than the threshold surface tension (options 1 and 2) or the calculated capillary number is greater than the threshold capillary number (options 3 and 4); that is, the relative permeability scaling factors are constrained to lie between 0.0 and 1.0. A small (or zero) threshold surface tension value or a large capillary number threshold value for a given phase pair, therefore, will have the effect of disabling scaling for that phase pair.

6. Gas-oil surface reference surface tension.

DEFAULT: 1.0

UNITS: dynes/cm (METRIC), dynes/cm (FIELD), dynes/cm (LAB), dynes/cm (PVT-M)

This value is only used if the capillary pressure scaling control parameter (column 4) is defined to be 1 or 2.

7. Oil-water reference surface tension.

DEFAULT: 1.0

UNITS: dynes/cm (METRIC), dynes/cm (FIELD), dynes/cm (LAB), dynes/cm (PVT-M)

This value is only used if the capillary pressure scaling control parameter (column 4) is defined to be 1 or 2.

8. Gas-water reference surface tension.

DEFAULT: 1.0

UNITS: dynes/cm (METRIC), dynes/cm (FIELD), dynes/cm (LAB), dynes/cm (PVT-M)

This value is only used if the capillary pressure scaling control parameter (column 4) is defined to be 1 or 2.

9. Gas-oil capillary pressure surface tension scaling factor exponent.

DEFAULT: 1.0

This value is only used if the capillary pressure scaling control parameter (column 4) is defined to be 2.

10. Oil-water capillary pressure surface tension scaling factor exponent.

DEFAULT: 1.0

This value is only used if the capillary pressure scaling control parameter (column 4) is defined to be 2.

11. Gas-water capillary pressure surface tension scaling factor exponent.

DEFAULT: 1.0

This value is only used if the capillary pressure scaling control parameter (column 4) is defined to be 2.

12. First constant  $A_1$  in water-hydrocarbon interfacial tension correlation equation.

DEFAULT: 1.0

The hydrocarbon-water interfacial tension is calculated according to the equation:

$$\sigma_{hw} = A_1 + (\Delta\rho (A_2 + \Delta\rho A_3))$$

with  $\Delta\rho$  given by:

$\Delta\rho = \rho_w - \rho_h$  where  $\rho_w$  and  $\rho_h$  are the densities of water and hydrocarbon phases (oil or gas) respectively in gm/cc.

This value is only used if the capillary pressure scaling control parameter (column 4) is defined to be greater than 0 or the end-point saturation and relative permeability scaling control parameter (column 5) is defined to be greater than 0.

13. Second constant  $A_2$  in water-hydrocarbon interfacial tension correlation equation.

DEFAULT: 0.0

The hydrocarbon-water interfacial tension is calculated according to the equation:

$$\sigma_{hw} = A_1 + (\Delta\rho (A_2 + \Delta\rho A_3))$$

with  $\Delta\rho$  given by:

$\Delta\rho = \rho_w - \rho_h$  where  $\rho_w$  and  $\rho_h$  are the densities of water and hydrocarbon phases (oil or gas) respectively in gm/cc.

This value is only used if the capillary pressure scaling control parameter (column 4) is defined to be greater than 0 or the end-point saturation and relative permeability scaling control parameter (column 5) is defined to be greater than 0.

14. Third constant  $A_3$  in water-hydrocarbon interfacial tension correlation equation.

DEFAULT: 0.0

The hydrocarbon-water interfacial tension is calculated according to the equation:

$$\sigma_{hw} = A_1 + (\Delta\rho (A_2 + \Delta\rho A_3))$$

with  $\Delta\rho$  given by:

$\Delta\rho = \rho_w - \rho_h$  where  $\rho_w$  and  $\rho_h$  are the densities of water and hydrocarbon phases (oil or gas) respectively in gm/cc.

This value is only used if the capillary pressure scaling control parameter (column 4) is defined to be greater than 0 or the end-point saturation and relative permeability scaling control parameter (column 5) is defined to be greater than 0.

15. Threshold interfacial tension or capillary number value for activating scaling on the oil phase property in an oil-gas system.

DEFAULT: 0.0

UNITS (for interfacial tension): dynes/cm (METRIC), dynes/cm (FIELD), dynes/cm (LAB), dynes/cm (PVT-M)

This value is only used if the end-point saturation and relative permeability scaling control parameter (column 5) is defined to be greater than 0.

16. Threshold interfacial tension or capillary number value for activating scaling on the oil phase property in an oil-water system.

DEFAULT: 0.0

UNITS (for interfacial tension): dynes/cm (METRIC), dynes/cm (FIELD), dynes/cm (LAB), dynes/cm (PVT-M)

This value is only used if the end-point saturation and relative permeability scaling control parameter (column 5) is defined to be greater than 0.

17. Threshold interfacial tension or capillary number value for activating scaling on the gas phase property in a gas-water system.

DEFAULT: 0.0

UNITS (for interfacial tension): dynes/cm (METRIC), dynes/cm (FIELD), dynes/cm (LAB), dynes/cm (PVT-M)

This value is only used if the end-point saturation and relative permeability scaling control parameter (column 5) is defined to be greater than 0.

18. Threshold capillary number value for activating scaling on the gas phase property in a gas-oil system.

DEFAULT: 0.0

This value is only used if the end-point saturation and relative permeability scaling control parameter (column 5) is defined to 3 or 4.

19. Threshold capillary number value for activating scaling on water phase property in a water-oil system.

DEFAULT: 0.0

This value is only used if the end-point saturation and relative permeability scaling control parameter (column 5) is defined to be 3 or 4.

20. Threshold capillary number value for activating scaling on the water phase property in a water-gas system.

DEFAULT: 0.0

This value is only used if the end-point saturation and relative permeability scaling control parameter (column 5) is defined to be 3 or 4.

21. Primary to hysteresis grid-block end-point rate of change.

UNITS: 1/day (METRIC), 1/day (FIELD), 1/hr (LAB), 1/day (PVT-M)

DEFAULT: 0.01

22. Minimum change in saturation required to signal change in saturation direction.

DEFAULT: 0.000001 (IMPES), 0.001 (AIM, FULLIMP and IMPSAT)

23. First contact miscible control

0 Do not check for phase label switching

1 Check for phase label switching

If a value of 1 is specified a check for phase label switching is performed when a first contact miscible condition occurs. In this case, in order to ensure consistency, the gas-water residual saturations will be taken from the oil-water values.

DEFAULT: 0

24. Gas-oil end-point saturation and relative permeability surface tension and capillary number scaling factor exponent.

DEFAULT: 1.0

This value is only used if the end-point saturation and relative permeability scaling control parameter (column 5) is defined to be 2 or 4. For capillary number scaling this exponent is applied to both the gas-oil and oil-gas scaling factors.

25. Oil-water end-point saturation and relative permeability surface tension and capillary number scaling factor exponent.

DEFAULT: 1.0

This value is only used if the end-point saturation and relative permeability scaling control parameter (column 5) is defined to be 2 or 4. For capillary number scaling this exponent is applied to both the oil-water and water-oil scaling factors.

26. Gas-water end-point saturation and relative permeability surface tension and capillary number scaling factor exponent.

DEFAULT: 1.0

This value is only used if the end-point saturation and relative permeability scaling control parameter (column 5) is defined to be 2 or 4. For capillary number scaling this exponent is applied to both the gas-water and water-gas scaling factors.

Default values (represented by 1\*) may be inserted as required in columns 1 to 26. Each row may span more than one line of input data if required. When the table is read in, these defaults are replaced by the default values specified above.

The second and subsequent tables may be defaulted entirely. Defaulted tables are replaced with a copy of the previous table.

Only the tables associated with the primary saturation region numbers defined using the `PSTNUM` keyword are used. Tables associated with the secondary and tertiary hysteresis saturation region numbers defined using the `ISTNUM` and `DSTNUM` keywords respectively are ignored and may be defaulted.

See "[Saturation functions](#)" in the *ECLIPSE Technical Description* for a description of the method used to compute the oil relative permeability in blocks where all three phases are present.

The reference and exponent surface tensions and the hydrocarbon-water interfacial tension correlation coefficients defined in columns 6 to 17 above are used only when values of 1 or 2 have been specified in columns 4 or 5. These values are used both in the scaling of the values of relative permeability and capillary pressure obtained from table look-up and also in the scaling of the primary and hysteresis grid-block end-point saturations. For these options no distinction is made between oil-gas/gas-oil, oil-water/water-oil and gas-water/water-gas in applying the end-point scaling; that is, the same scaling is applied to each member of these pairs of end-points. If capillary number end-point scaling is selected, however, the six end-points are determined individually and the values in column 15 to 17 and 18 to 20 should be used to define the six threshold capillary number values.

See also the keywords `PCODD3P`, `PCODD3PG` and `PCODD3PW`.

## Example

With `NTSFUN=3` and assuming that the primary saturation region is associated with table 1:

```

## EQLDIMS

## Dimensions of equilibration tables

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data consists of some or all of the following items which specify the dimensions of the equilibration tables. The data must be terminated by a slash (/).

1. NTEQUL, the number of equilibration regions entered using EQLNUM in the REGIONS section. Different equilibration regions may be used to initialize different parts of the reservoir that are not in mutual hydrostatic equilibrium. (See keywords [EQLNUM](#) in the REGIONS section and [EQUIL](#) in the SOLUTION section.)

DEFAULT: 1

2. The number of depth nodes in any table of pressure versus depth constructed internally by the equilibration algorithm.

(ECLIPSE 100) DEFAULT: 100

(ECLIPSE 300) DEFAULT: 50

3. NDRXVD, the maximum number of depth nodes in any [RSVD](#), [RVVD](#), [RSWVD](#), [RTEMPVD](#), [PBVD](#) or [PDVD](#) table entered in the SOLUTION section to define the initial  $R_s$ ,  $R_v$ ,  $T_r$ ,  $P_b$  or  $P_d$  versus depth.

For ECLIPSE 300 this parameter also applies to:

- The number of entries in the [ZMFVD](#) keyword.
- The maximum number of rows for the end-point versus temperature keywords [ENKRVT](#), [ENPCVT](#), [ENPTVT](#).
- The maximum number of rows for the end-point versus composition keywords [ENKRVC](#), [ENPCVC](#), [ENPTVC](#).

DEFAULT: 20

DEFAULT: 50

4. NTTRVD, the number of tables of initial tracer concentration versus depth (keyword [TVDP](#) in the SOLUTION section).

DEFAULT: 1

5. NSTRVD, the maximum number of depth nodes in any table of initial tracer concentration versus depth (keyword [TVDP](#) in the SOLUTION section).

DEFAULT: 20

DEFAULT: 50

See "[Initializing the study](#)" in the *ECLIPSE Technical Description* for more information.

### Example

Two equilibration regions ([EQLNUM](#)) with the default number of nodes in the internal pressure versus depth tables and 30 nodes in an [RSVD](#) table.

```
EQLDIMS
2 1* 30 /

## EQLDKVCR Equilibrium deviation reaction k-values

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword is used to specify k-values for modeling reactions that deviate from an equilibrium state. See keyword [EQLDREAC](#) which specifies the equilibrium deviation terms. The number of k-values,  $N_k$ , is specified by the third item in the [REACTION](#) keyword. K-values are specified in a similar manner to the [KVCR](#) keyword where up to five constants can be used to define each equilibrium value:

$$K(P, T) = (A + B / P + C \cdot P) \cdot e^{-D/(T-E)}$$

where

$T$  is the temperature (K (METRIC), °R (FIELD), K (LAB), K (PVT-M))

$P$  is the pressure (barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)).

The temperature and pressure values used to calculate these equilibrium values can be limited using the [REACLIMS](#) keyword.

DEFAULT: 0.0

This keyword is followed by up to five rows, each containing  $N_k$  columns of data described below. The set of records is ended by a blank record, containing only a slash.

1. A,  $N_k$  values

UNITS: dimensionless

2. B,  $N_k$  values

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

3. C,  $N_k$  values

UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB), 1/atm (PVT-M)

4. D,  $N_k$  values

UNITS: K (METRIC), °R (FIELD), K (LAB), K (PVT-M)

5. E,  $N_k$  values

UNITS: K (METRIC), °R (FIELD), K (LAB), K (PVT-M)

See "[Chemical reactions](#)" in the *ECLIPSE Technical Description*.

If multiple equations of state are being used, only one set of data is entered for this keyword, unlike keyword [KVCR](#), where one set of data is used for each equation of state.

### Example

With item 3 of [REACTION](#) set to 2:

```

EQLDKVCR
-- K1  K2
1.23E6  212
833.4E6  155.4E3
0  0
16000  4000

## EQLDREAC Equilibrium deviation terms for reactions

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

Equilibrium deviation terms can be used to model deviation from an equilibrium state. A reaction rate is multiplied by a term:

$$|d|^n, \quad d > 0$$

$$\text{or}$$

$$-|d|^n, \quad d < 0$$

where  $n$  is the order of the equilibrium deviation term and  $d$  is given by one of the following models:

$$d = \theta \cdot b_o \cdot S_o \cdot (x_i - y_j / K_k), \quad m = 1 \quad \text{Eq. 3.65}$$

$$d = \theta \cdot b_g \cdot S_g \cdot (K_k \cdot x_i - y_j), \quad m = 2 \quad \text{Eq. 3.66}$$

$$d = \theta \cdot b_w \cdot S_w \cdot (a_i - 1 / K_k), \quad m = 3 \quad \text{Eq. 3.67}$$

$$d = \theta \cdot (F_k(a_i) - C_a), \quad m = 4 \quad \text{Eq. 3.68}$$

Here:

$\theta$  is the porosity,

$b_o, b_g$  and  $b_w$  are the molar densities of the oil, gas and water phases,

$S_o, S_g$  and  $S_w$  are the oil, gas and water phase saturations,

$x_i, y_j, a_i$  and  $a_j$  are oil, gas and water component mole fractions,

$C_a$  is the adsorbed solid concentration

$K_k$  and  $F_k$  are equilibrium values.

The keyword is followed by a number of records, each specifying an equilibrium deviation term. The number of records is specified by the second item in the [REACTION](#) keyword. Each record contains a number of items of data and is terminated by a slash.

1. The reaction number.
2. The model number  $m$  for the deviation term, between 1 and 4, see equations 3.65 - 3.68. Models 3 and 4 can only be used with the Multiple Water Component Model, which is activated with the [COMPW](#) keyword. Model 4 can only be used with [SOLID](#).
3. The component number  $i$ .
4. The component number  $j$ .
5. The equilibrium value number  $k$ , which specifies either
  - a k-value  $K_k$  defined by keyword [EQLDKVCR](#) ( $m \leq 3$ ) or
  - an equilibrium function  $F_k$  defined by keyword [EQLDTAB](#) ( $m = 4$ )
6. The direction in which the reaction can proceed:
 

FORWARD    Reaction rate set to zero if less than zero

BACKWARD Reaction rate set to zero if more than zero

BOTH Reaction can proceed in both directions depending on the sign of the rate.

DEFAULT: BOTH

7. The order  $n > 0$ .

DEFAULT: 1.0

The reaction can be limited to proceed in only one direction via the 6th item. However, since the derivative of the rate will generally not be smooth around zero this can cause stability issues.

The reaction stoichiometry ([STOREAC](#) and [STOPROD](#)) should be set so that component  $i$  reacts to form component  $j$  for positive reaction rates.

For  $m \leq 2$ , the component numbers  $i$  and  $j$  must be between 0 and the number of hydrocarbon components,  $0 \leq i, j \leq N_c$ . If a value of 0 is given then the mole fraction ( $x_i$  or  $y_j$ ) is replaced by a 1 in equation 3.65 and equation 3.66.

For  $m = 3$  or  $m = 4$  the component number  $i$  must represent a water component,  $N_c < i \leq N_c + N_w$ . The component number  $j$  is not used for these models and should be set to 0.

See "[Chemical reactions](#)" in the *ECLIPSE Technical Description*.

## Notes

- The first two models  $m \leq 2$  are provided for thermal simulations where they can be used with non-volatile or non-condensable components. The second two models  $m \geq 3$  can be used with water components. The keyword can be used outside these limitations, but it may compete with the flash and cause convergence problems when used with components that are not inert.
- To ensure that the reaction rate of zero-order reactants tends to zero as the reactant disappears, the reaction rate is multiplied by a factor  $m / (m + s)$  where  $m$  is the molar density of the reactant and  $s$  is given by item 4 of keyword [REACOPS](#).
- If [item 305](#) of keyword [OPTIONS3](#) is set to 1, the simulator reverts to the pre-2013.1 treatment of zero-order reactants when calculating the equilibrium deviation terms.

## Example

In this example the equilibrium deviation reaction rates for reactions 1 and 2 are:

$$d = \theta \cdot b_o \cdot S_o \cdot (x_1^{-y_2} / K_1)$$

and

$$d = \theta \cdot b_o \cdot S_o \cdot (x_3^{-1} / K_2).$$

This second term can be used to model a trapped gas phase where  $y_j = 1$  since the trapped gas phase is separate from the free gas phase. In this example, item 2 of [REACTION](#) is set to 2:

```
EQLDREAC
-- R M I J K DIR
  1 1 1 2 1 BOTH /
  2 1 3 0 2 BOTH /
```

## EQLDTAB

## Equilibrium values for water-solid deviation reactions

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword is used to specify tables of equilibrium values for modeling reactions that deviate from an equilibrium state. The equilibrium states are defined by the amount of adsorbed solid as a function of a water component mole fraction. The number of tables,  $N_T$ , is specified by the item 5 in the [REACTION](#) keyword. Each table consists of two columns of data and is terminated by a slash (/).

1. A water component mole fraction.

The values should be between 0 and 1 and increase monotonically down the column.

2. The corresponding adsorbed solid concentration, defined as mass of solid per mass of rock.

UNITS: kg/kg (METRIC), lb/lb (FIELD), gm/gm (LAB), kg/kg (PVT-M)

The maximum number of rows in each table is NPPVT (item 4 of keyword [TABDIMS](#)).

The [EQLDREAC](#) keyword is required to specify the equilibrium deviation terms and the [ROCKDEN](#) keyword is required to specify the rock density.

See "[Chemical reactions](#)", "[Water components](#)" and "[Solid phase](#)" in the *ECLIPSE Technical Description*.

### Example

```

## EQLNUM

## Equilibration region numbers

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by one integer for every grid block in the current input box specifying the equilibration region to which it belongs. The region number should not be less than 1 or greater than NTEQUL (item 1 in keyword [EQLDIMS](#)). All blocks with the same equilibration region number must also have the same PVT region number (see keyword [PVTNUM](#)). The data must be terminated by a slash (/).

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

See also the keywords [EQUIL](#), [RSVD](#), [RVVD](#) and [PBVD](#) in the SOLUTION section.

## Example

With NTEQUL=6:

```

8*1 8*2 8*3 8*4 8*5 8*6 /

```

## EQLOPTS Options for equilibration

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by up to four items, which set options for the initial equilibration algorithm. The data should be terminated by a slash (/). The possible values of the options are:

**MOBILE** Activates the initial mobile fluid critical saturation end point correction. A fine scale Equilibration option should be used (see keyword [EQUIL](#)). The option should not be used in VE runs (keyword [VE](#)). See "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for more information.

This option applies to *ECLIPSE 100 only*. **QUIESC** Enables pressure modifications to achieve initial quiescence (that is to produce a true steady state solution). A block-center equilibration (item 9 in keyword [EQUIL](#) set to 0) is always quiescent, but the more accurate options are not absolutely quiescent. If this switch is set, modifications are applied to the phase pressures to make the initial solution quiescent. These modifications continue to be applied for the duration of the run. This option should not be used if the Vertical Equilibrium option is switched on (keyword [VE](#)).

**THPRES** Enables the threshold pressure option.

This prevents flow from occurring between different equilibration regions until the potential difference exceeds a threshold value, threshold values must be specified with keyword [THPRES](#) in the [SOLUTION](#) section. This option switch is also required if named faults have threshold pressures (see keyword [THPRESFT](#)).

**IRREVER** The threshold pressures for flow in each direction between equilibration regions will be different. Threshold pressures must be specified separately for each direction. This is relevant only if the option [THPRES](#) is specified.

DEFAULT: None of the above

### Example

Enable the irreversible threshold option.

```
EQLOPTS
THPRES  IRREVERS /
```

## EQLZCORN **Reset part of the corner point depth array**

	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword may be followed by any number of records, each of which is terminated by a slash (/). The data is terminated by a null record (that is a record with no data before the terminating slash). Each record consists of at least one item of data.

1. The new value of the corner point (**ZCORN**) array.

UNITS: m (**METRIC**), ft (**FIELD**), cm (**LAB**), m (**PVT-M**)

Each record may also contain the following items of data.

Items 2-7 are used to redefine the input box for the modification to the corner depths. The input box usually only includes a single layer (**KZ1=KZ2**); a warning is issued if this is not the case.

All the corner point depths for either the top or bottom (see item 12 below) of the layer will be set to the value specified in item 1.

The modification is either continuous with the surrounding cells or discontinuous, depending on the settings of data items 8 to 11.

If items 2-7 are not defined (a slash is inserted after item 1), they default to the values that were used for the previous operation within the current keyword. For the first operation in the keyword, the box defaults to the values set by the most recent **BOX** or **ENDBOX** keyword. If there is no preceding **BOX** or **ENDBOX** in the current section, the box is taken to include the entire reservoir.

2. **IX1** First block to be modified on the X axis.
3. **IX2** Last block to be modified on the X axis.
4. **JY1** First block to be modified on the Y axis.
5. **JY2** Last block to be modified on the Y axis.
6. **KZ1** First block to be modified on the Z axis.
7. **KZ2** Last block to be modified on the Z axis.

The data must satisfy

$$0 \leq \text{IX1} \leq \text{IX2} \leq \text{NDIVIX}$$

$$0 \leq \text{JY1} \leq \text{JY2} \leq \text{NDIVIY}$$

$$0 \leq \text{KZ1} \leq \text{KZ2} \leq \text{NDIVIZ} \text{ (where NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword } \text{DIMENS})$$

However, if only certain individual corner depths within a block require to be set, any of **IX1**, **IX2**, or **JY1**, **JY2** may be zero (consider the possibilities in "Example 2").

Items 8-11 are used to specify whether the modification should be continuous with the surrounding cells.

8. **IX1A** = **IX1** -1 or **IX1** (default = **IX1** -1 if **IX1** >1)
9. **IX2A** = **IX2** +1 or **IX2** (default = **IX2** +1 if **IX2** < **NDIVIX**)
10. **JY1A** = **JY1** -1 or **JY1** (default = **JY1** -1 if **JY** >1)
11. **JY2A** = **JY2** +1 or **JY2** (default = **JY2** +1 if **JY2** < **NDIVIY**)

The data must satisfy

$$0 \leq IX1A \leq NDIVIX, 0 \leq IX2A \leq NDIVIX$$

$$0 \leq JY1A \leq NDIVIY, 0 \leq JY2A \leq NDIVIY$$

If, for example,  $IX2A = IX2$ , then blocks with  $I = IX2 + 1$  are not modified and a discontinuity (or fault) is added to the surface. However, if  $IX2A = IX2 + 1$ , then the corner points in blocks at  $I = IX2 + 1$  adjacent to the blocks at  $I = IX2$  have the constant added, so preserving a continuous surface.

If the surface is discontinuous between  $I = IX2$  and  $I = IX2 + 1$  prior to the action of the EQLZCORN keyword, then no action is taken with the blocks at  $I = IX2 + 1$ .

By default items 8-11 are set to give a continuous surface.

#### 12. Action required:

**TOP** Modify both top and bottom corner points of all cells, except for the bottom layer, in which the top cells only are modified

**BOTTOM** Modify both top and bottom corner points of all cells, except for the top layer, in which the bottom corners only are modified.

(The word may be abbreviated; only the first character is significant.)

DEFAULT: TOP

## Modifying selected corner point depths within a grid block

It is possible to modify selected corner depths within a grid block by specifying a zero in either the IX1, IX2 or JY1, JY2 box limits (or both). In this case only the corner depth on the appropriate side of the cell will be modified.

If data items 8-11 are defaulted or set to a box outside the box defined in data items 2-7, then the adjacent cell depths are modified to give a continuous surface. Note that if the surface was discontinuous prior to the EQLZCORN keyword, the adjacent cells are not modified.

See "Example 2".

See also the [BOX](#), [ENDBOX](#), and [ADDZCORN](#) keywords.

## Examples

### Example 1

With NDIVIZ=5 specified in RUNSPEC keyword [DIMENS](#):

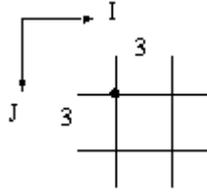

```

.....
EQLZCORN
4100.0  3  4  3  4  1  1           / Set the top of a region to
                                         4100 ft without
                                         introducing faults.
4500.0 10 13 15 15 5 5 4* BOTTOM /Set the bottom surface/
.....

```

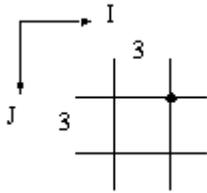

### Example 2

Set the top-left corner of cell (3,3,1) to 10890.0 ft

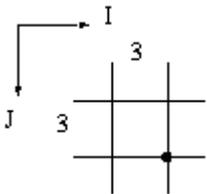

```
EQLZCORN
10890.0      3 0 3 0 1 1 /
```

Set the top-right corner of cell (3,3,1). Modifying the top corner depth leaving the adjacent cells unmodified.

```
10890.0      0 3 3 0 1 1 3 3 3 3 /
```

Set the lower-right corner of cell (3, 3, 5). Modifying the bottom corner depth leaving the adjacent cells unmodified.

```
10890.0      0 3 0 3 5 5 3 3 3 3 BOTTOM /
```

## EQUALREG Sets an array to a constant value in a region

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
x	EDIT
x	PROPS
x	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

The keyword is followed by any number of records, each containing the items of data described below, and each terminated by a slash (/). It can be used to set an array to a constant value in a flux, [MULTNUM](#) or [OPERNUM](#) region

The records can be terminated early using the slash (/) character, the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

Each record consists of the following items of data:

1. The name of the array to be modified
2. The constant to be assigned to the array, specified by item 1

The constant should be positive, and, for the [REGIONS](#) section, should be integer.

DEFAULT: 0.0

3. The flux region number, [MULTNUM](#) region number, or [OPERNUM](#) region number (with choice of region determined using item 4)

The flux region number refers to the region defined using the [FLUXNUM](#) keyword in the [GRID](#) section. It is not necessary to use the Flux Boundary option.

The [MULTNUM](#) region number refers to the region defined using the [MULTNUM](#) keyword in the [GRID](#) section.

The [OPERNUM](#) region number refers to the region defined using the [OPERNUM](#) keyword in the [GRID](#) or [REGIONS](#) section.

4. Choice of region: [MULTNUM](#) (M), [FLUXNUM](#) (F) or [OPERNUM](#) (O).

DEFAULT: M

The set of records is ended by a blank record, containing only a slash (/).

---

**Note:** The [FLUXNUM](#) keyword, [MULTNUM](#) keyword or [OPERNUM](#) keyword must be input before the [EQUALREG](#) keyword. If item 4 is defaulted, then the [MULTNUM](#) keyword is used.

---

*ECLIPSE 100*

This keyword may not be used to modify the [PBUB](#) or [PDEW](#) arrays.

*ECLIPSE 300*

This keyword may be used in [SCHEDULE](#) section. However, this is a specialist facility.

---

**Note:** In the [SCHEDULE](#) section, regions (predefined by the [FIPxxxx](#) keyword in the [REGIONS](#) section) can be used in item 4.

---

**Notes**

- The above list is not exhaustive, but includes the most common examples.
- Keywords in brackets are for radial geometry runs.
- In the REGIONS section only integer values should be used.
- Each record must refer to the same region. It is not possible to choose a different region for each data record.
- The EQUALREG keyword is not available for use with local grid systems.

ECLIPSE 100 only

See also keywords [ADDREG](#), [FLUXNUM](#), [MULTNUM](#), [OPERNUM](#), [MULTIREG](#), and [COPYREG](#).

**Additional notes**

ECLIPSE 300 only

Additional notes for the use of this keyword in the SCHEDULE section. Again, this is a specialist facility. In the SCHEDULE section, the effect of this keyword will be as follows:

Keyword	Description
<a href="#">DIFFMMF</a>	Modifies the matrix-fracture diffusivity in dual-porosity runs. If output is required for flexible restart in the model, these multiplier values will be output as DIFFMMFS.
<a href="#">MULSGGD</a> <a href="#">MULSGGDV</a>	Modifies the matrix-fracture coupling transmissibility for oil-gas gravity drainage in dual-porosity runs. If output is required for flexible restart in the model, these multiplier values will be output as MULSGGDS.
<a href="#">MULTSIG</a> <a href="#">MULTSIGV</a>	Modifies the matrix-fracture coupling transmissibility in dual-porosity runs. If output is required for flexible restart in the model, these multiplier values will be output as MULTSIGS.
<a href="#">MULTX</a> <a href="#">MULTY</a> <a href="#">MULTZ</a>	Modifies transmissibility in the X/Y/Z-direction. If output is required for flexible restart in the model, the multiplier values will be output as MULTX/ MULTY/MULTZ.

Keyword	Description
PERMX PERMY PERMZ	Modifies permeability in the X/Y/Z-direction. Also approximates the corresponding transmissibility multiplier MULTX/MULTY/MULTZ determined from the ratio of the new permeability value to the old one. If output is required for flexible restart in the model, the permeability values will be output as MODPERMX / MODPERMY / MODPERMZ.
PORO	Modifies porosity. Modifies the corresponding pore volume by a multiplier MULTPV determined from the ratio of the new porosity value to the old one. If output is required for flexible restart in the model, the porosity values will be output as MODPORO, and the pore volume multipliers will be output as MULTPVS.
SIGMA SIGMAV	Modifies the matrix-fracture coupling transmissibility in dual-porosity runs. If output is required for flexible restart in the model, these multiplier values will be output as SIGMA.
WORK ( 1 / 2 )	These are work arrays to be stored for subsequent use. If output is required for flexible restart in the model, these values will be output as WORK ( 1 / 2 ) .

## Set array to a constant in current box

This keyword is used to assign or replace the value of a property for a box of cells within the grid.

The keyword may be followed by any number of records, each of which is terminated by a slash (/). The data is terminated by a null record (that is, a record with no data before the terminating slash(/)).

Each record consists of at least two items of data:

1. The name of the array to be modified
2. The constant to be assigned to the array specified by item 1

The constant should be positive, and must be an integer if the array contains integer region numbers (for example, [FIPNUM](#)). The constant may be real if the array contains real data (for example, [TOPS](#) or [TRANX](#)). This item should not be defaulted.

The following items of data may be used to redefine the input box for this and subsequent operations within the current keyword.

If these items are not defined (a slash is inserted after item 2), they default to the values which were used for the previous operation within the current keyword.

For the first operation in the keyword, the box defaults to the values set by the most recent [BOX](#) or [ENDBOX](#) keyword. If there is no preceding [BOX](#) or [ENDBOX](#) in the current section, the box is taken to include the entire reservoir.

3. First block to be modified on the X axis (IX1)
4. Last block to be modified on the X axis (IX2)
5. First block to be modified on the Y axis (JY1)
6. Last block to be modified on the Y axis (JY2)
7. First block to be modified on the Z axis (KZ1)
8. Last block to be modified on the Z axis (KZ2)

The data must satisfy:

$$1 \leq IX1 \leq IX2 \leq NDX$$

$$1 \leq JY1 \leq JY2 \leq NDY$$

$$1 \leq KZ1 \leq KZ2 \leq NDZ,$$

where NDX, NDY, NDZ are the limits in the current BOX.

See also keywords [BOX](#), [ENDBOX](#), [ADD](#), [MULTIPLY](#) and [COPY](#).

## Notes

- The above list is not exhaustive, but includes the most common examples.
- Keywords in brackets are for radial geometry runs
- In the REGIONS section only integer values should be used
- The [ADD](#), [COPY](#), [EQUALS](#) and [MULTIPLY](#) keywords are processed as they are read, so that repeated operations are possible
- For arrays marked with an asterisk, EQUALS may only be used to replace existing values, not assign the array from scratch.
- **Item 2 should not be defaulted.** However, this facility is retained for back-compatibility. If this item is defaulted, this will be treated differently by ECLIPSE 100 and ECLIPSE 300. For ECLIPSE 100, the defaulted value is assumed to be undefined, whereas for ECLIPSE 300, the defaulted value is assumed to be zero. The subsequent processing will depend, therefore, both upon the specific keyword to which the operation is being applied and which simulator is being used.

## Examples

### Example 1

In the GRID section:

```

----- ARRAY      CONSTANT  ----- BOX -----
EQUALS
      DX      1000      1 11 1 19 1 1 /
      DY      1000      / defaults to last specified box
      DZ       10      / defaults to last specified box
      PORO     0.19     / defaults to last specified box
      PERMX   230      / defaults to last specified box
      TOPS    6845     / defaults to last specified box
      TOPS    6872     1 11 1 19 2 2 /
      TOPS    6901     1 11 1 19 3 3 /
      TOPS    6933     1 11 1 19 4 4 /
/
    
```

### Example 2

In the EDIT section:

```

----- ARRAY      CONSTANT  ----- BOX -----
EQUALS
      TRANY   1000     1 11 1 19 1 1 /
      PORV    1000     / defaults to last specified box
/
    
```

## EQUIL

## Equilibration data specification

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

The keyword sets the contacts and pressures for conventional hydrostatic equilibrium. It should be followed by NTEQUL records of data, each record terminated with a slash (/). NTEQUL refers to the number of equilibration regions, as entered in the RUNSPEC section (keyword [EQLDIMS](#)).

For non-Thermal simulations, this keyword should not be used for non-equilibrium initialization runs, and precludes the use of [PBUB](#), [PDEW](#), [SWAT](#), [SGAS](#), [SOIL](#), [XMF](#) and [YMF](#) for example. For more information, refer to "[Initializing the study](#)" in the *ECLIPSE Technical Description*.

---

**Note:** An additional initialization method has been added for Thermal simulations. This mixed hydrostatic equilibration option should be triggered using only items 1 and 2 of the EQUIL keyword, together with saturation arrays ([SOIL](#), for instance) and the [NEI](#) keyword. For more information, refer to "[Initializing the study](#)" in the *ECLIPSE Technical Description*. This initialization method should not be mixed with the standard equilibration method, otherwise an error message will be issued.

---

Each record refers to a separate equilibration region (1 to NTEQUL), and contains the following items of data:

1. Datum depth

In problems containing dissolved gas or vaporized oil, if  $R_S$  or  $R_V$  versus depth tables are not provided (see items 7 and 8), the datum depth must lie at the gas-oil contact.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: 0.0

*ECLIPSE 100 only*

Default not defined

*ECLIPSE 300 only*

2. Pressure at the datum depth.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

---

**Note:** If the datum depth lies above the gas-oil contact, the pressure refers to the gas phase. If the datum depth lies below the water-oil contact, the pressure refers to the water phase. Otherwise, the pressure refers to the oil phase.

---

3. Contact depth

Depth of the water-oil contact (for three-phase or oil-water problems) or

Depth of the gas-water contact (for gas-water problems).

This value is ignored in single-phase and oil-gas problems.

The contact can lie below the bottom of the reservoir if there is no mobile water initially present.

The values of the water saturation above and below the transition region are set at the end-point saturations in the water capillary pressure table.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: 0.0

Thermal only

---

**Note:** If the water-oil contact lies above the reservoir and if, based on the composition provided at the datum depth, oil is heavier than water, then the pressure in item 2 refers to the oil phase and the reservoir will be initialized with heavy oil. A non-zero value for `OPTIONS3` item 217 can be used to restore pre-2010.1 behavior for thermal heavy oil equilibration.

---

4. Capillary pressure at the contact

Oil-water capillary pressure at the water-oil contact (for three-phase or oil-water problems) or

Gas-water capillary pressure at the gas-water contact (for gas-water problems).

This value is ignored in single-phase and oil-gas problems.

Capillary pressures rather than saturations are used in order that more than one saturation table may be used in an equilibration region.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

DEFAULT: 0.0

ECLIPSE 100 only

5. Depth of the gas-oil contact.

This value is ignored in single-phase, oil-water and gas-water problems.

---

**Note:** The contact should lie above the top of the reservoir if there is no initial free gas. The contact should lie below the bottom of the reservoir if there is only free gas (with vaporized oil) initially present. The values of the gas saturation above and below the transition region are set at the end-point saturations in the gas capillary pressure table.

In three-phase gas condensate problems in which there is no initial free oil (that is all the oil is initially contained in the gas phase), the gas-oil contact should be at the same depth as the water-oil contact. It then acts as a gas-water contact, and the initial solution is calculated in a manner analogous to a gas-water problem.

---

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: 0.0

6. Gas-oil capillary pressure at the gas-oil contact

This value is ignored in single-phase, oil-water and gas-water problems.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

DEFAULT: 0.0

Black Oil cases only

7. Integer selecting the type of initialization for live black oil

A positive integer causes the dissolved gas concentration in undersaturated oil to be calculated from either an  $R_s$  versus depth table or a  $P_b$  versus depth table, subject to an upper limit equal to the saturated  $R_s$  value at the local pressure. The  $R_s$  versus Depth table is entered using keyword `RSVD`. The  $P_b$  versus Depth table is entered using keyword `PBVD`. If multiple tables are defined, the table applicable to a grid cell is that specified by the `EQLNUM` keyword, which defines equilibration regions.

A zero or negative value causes the dissolved gas concentration in undersaturated oil to be set equal to the saturated  $R_s$  value at the gas-oil contact. In this case, an  $R_s$  versus depth or a  $P_b$  versus depth table need not be provided, but the datum depth (item 1) must coincide with the gas-oil contact, that is the bubble point is set to the local pressure at the reference depth).

This value is ignored if dissolved gas is not present in black oil runs.

This value is ignored in compositional runs.

DEFAULT: 0

- Black Oil cases only* 8. Integer selecting the type of initialization for black oil runs with wet gas

A positive integer causes the vaporized oil concentration in undersaturated gas to be calculated from either an  $R_v$  versus depth table or a  $P_d$  versus Depth table, subject to an upper limit equal to the saturated  $R_v$  value at the local pressure. The  $R_v$  versus depth table is entered using keyword [RVVD](#). The  $P_d$  versus depth table is entered using keyword [PDVD](#). If multiple tables are defined, the table applicable to a grid cell is that specified by the [EQLNUM](#) keyword, which defines equilibration regions.

A zero or negative value causes the vaporized oil concentration in undersaturated gas to be set equal to the saturated  $R_v$  value at the gas-oil contact, subject to an upper limit equal to the saturated  $R_v$  value at the local pressure. In this case, an  $R_v$  versus Depth or a  $P_d$  versus depth table need not be provided, but the datum depth (Item 1) must coincide with the gas-oil contact (that is the dew point is set to the local pressure at the reference depth).

This value is ignored if vaporized oil is not present in black oil runs.

This value is ignored in compositional runs.

DEFAULT: 0

9. Integer (N) defining the accuracy of the initial fluids in place calculation.

$N=0$  Causes the simulator to set the fluid saturations in each grid block according to the conditions at the center of the block. This produces a steady-state solution, but the fluids in place will not be accurate if a contact passes near the center of a large grid block.

$N < 0$  Causes the simulator to take an average of the conditions at  $2|N| + 1$  equally-spaced sub-blocks within each grid block. The blocks are treated as being horizontal. The larger N is, the more accurate will be the initial fluids in place calculation. But the resulting initial conditions will not be absolutely steady-state, in that there will be a small readjustment if the simulator is run for a period with no wells.

$N > 0$  Is equivalent to the  $N < 0$  option, but the grid blocks are treated as being tilted. If the [NEWTRAN](#) method has been used, the tilt on the top and bottom faces of each grid block is determined from the block's corner point depths. Otherwise the top and bottom faces are orientated towards their neighbors within the equilibration region. The simulator takes an average of the conditions at N levels within each half (upper and lower) of the block, weighted according to the block's horizontal cross-section at each level.

This option cannot be used in radial geometry.

N is limited to 20.

ECLIPSE 100

---

**Note:** When N is non-zero, if the [QUIESCENCE](#) option is selected (using keyword [EQLOPTS](#)), modifications will be applied to the phase pressures to make the initial solution a true steady-state. These pressure modifications will be applied for the duration of the run. The absolute size of N is limited to 20.

The [QUIESCENCE](#) option should not be selected when  $N=0$  as the initial conditions will always be quiescent in this case.

---

ECLIPSE 300

---

**Note:** For back compatibility with pre-2000A versions of ECLIPSE 300, the OLDEQUIL will cause ECLIPSE 300 to use horizontal block integration in equally spaced N layers.

---

ECLIPSE 100

**Note:** If the vertical equilibrium option is being used, however, (keyword VE), an exact VE equilibration method will be used if N = 0. The fluid saturations are determined directly from the depth of the contact levels within each block. This is the preferred option for VE runs. Refer to the VEFIN keyword and see also "Vertical equilibrium" in the *ECLIPSE Technical Description* for details of the behavior in mixed VE/non-VE LGR runs.

---

DEFAULT: In ECLIPSE 100, the value is defaulted to -5 (giving a 10-point average of conditions within each block), unless the vertical equilibrium option is being used, in which case it is defaulted to 0. In ECLIPSE 300, the value is defaulted to 0.

ECLIPSE 300

10. Integer selecting the type of initialization in the compositional case.

For a gas-water run, the data is entered as for an oil-water system - that is the contact depth and capillary pressure as items 3 and 4.

See "Initializing the study" in the *ECLIPSE Technical Description* for more details of the initialization of compositional studies.

Possible values are:

- 1 Continuous hydrocarbon phase initial state (that is no gas-oil contact in the reservoir). This includes super critical fluids which make a smooth transition from a gas to an oil.
- 2 Gas-oil contact, with vapor composition specified at contact. Pressure at datum depth will be set to retrograde dew point pressure
- 3 Gas-oil contact, with liquid composition specified at contact. Pressure at datum depth is set to bubble point pressure

DEFAULT: 1.

---

**Note:** If item 10 is set to 1 and a gas-oil contact is specified within the reservoir, then to ensure proper phase-labeling there must be compositional variation across the contact. The compositional variation can be specified using COMPVD or ZMFVD. This requirement is implemented in 2009.1. For the pre-2009.1 calculation, item 172 of OPTIONS3 should be set to a non-zero value.

---

ECLIPSE 300

11. If this is set to 1 the field pressure is not set to the saturation pressure at the contact if options 2 or 3 are selected in item 10.
- 

**Note:** If item 10 is set to 2 or 3 in the compositional case, it is assumed that the datum depth corresponds to the Gas-oil contact. Given the vapor composition at the contact (if item 10 = 2) or the oil compositional at the contact (if item 10 = 3), then the dew point or bubble point pressure will be calculated. This saturation pressure,  $P_{sat}$ , should be equal to the datum pressure,  $P_{datum}$ , specified in item 2 of this keyword. If item 11 is not set, then the test  $|P_{datum} - P_{sat}| < \epsilon$  where  $\epsilon$  is 1 atmosphere is performed. If the condition is not true, the datum pressure is reset to the calculated saturation pressure. Setting item 11 = 1 ensures the user specified datum pressure is retained regardless of the result of the

above test; note this is not an equilibrium system. See "Initializing the study" in the *ECLIPSE Technical Description* for more details.

## Notes

The end points of the water and gas saturation tables (see [SWFN](#) and [SGFN](#)) determine the phase saturations outside the transition zones. It is therefore important that these should be consistent with each other. The highest gas saturation value ( $S_{g,max}$ ) in the gas table should not exceed one minus the lowest water saturation value ( $S_{w,min}$ ) in the water saturation table, otherwise a negative oil saturation would result in the gas cap. If there is to be no oil in the gas cap above the gas-oil transition zone, then set

$$S_{g,max} = 1 - S_{w,min} \quad \text{Eq. 3.69}$$

A residual oil saturation ( $S_{o,res}$ ) in the gas cap can be produced by setting

$$S_{g,max} = 1 - S_{w,min} - S_{o,res} \quad \text{Eq. 3.70}$$

In problems containing a gas-water contact, the water saturation tables are assumed to contain the water-gas capillary pressure values versus water saturation. The gas capillary pressure values should be set to zero.

The equilibration calculation assumes that gas is lighter than oil and oil is lighter than water at reservoir conditions. An error condition may result if this is not so.

*ECLIPSE 100 only*

It is also possible to specify negative depth values.

*ECLIPSE 300 only*

By default, oil and gas phase pressures are derived from the pressure solution variable  $P$  using the formula

$$P_{oil} = P - P_{cog} \times \left( \frac{S_g}{S_o + S_g} \right)$$

and

$$P_{gas} = P + P_{cog} \times \left( \frac{S_o}{S_o + S_g} \right)$$

where

$P_{cog}$  is the gas-oil capillary pressure,

$S_o$  and  $S_g$  are the oil and gas saturations respectively.

This Pc-splitting technique is performed to enable better convergence and property smoothness above the critical point. It may be disabled using keyword [FORMOPTS](#), option [NOPCSEPT](#). When reporting initialization data using the [RPTST](#), [RPTSOL](#) or [OUTSOL](#) keywords, the mnemonic [PRESSURE](#) is the solution variable  $P$  which is derived from the phase pressures calculated during the [EQUIL](#) hydrostatic equilibration and reported with the [SOLVD](#) option in [RPTSOL](#), [POIL](#) is the oil phase pressure  $P_{oil}$  and [PGAS](#) is the gas phase pressure  $P_{gas}$ , as discussed in the above two equations.

---

**Note:** The Pc-splitting technique applies only to the ECLIPSE 300 compositional mode.

---

## Example

With NTEQUL=2:

```
EQUIL  
7100 4000 8000 0.0 6500 0.0 1 0 -3 /  
7000 4000 7800 0.0 7000 0.0 /
```

## ESPNODE

## Salt concentration nodes for polymer viscosity multiplier

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTPVT (see RUNSPEC keyword [TABDIMS](#)) tables of effective salinity values, each terminated by a slash (/), describing the nodal values to be used in the calculation of polymer viscosity multipliers.

Each table consists of up to NPPVT (see RUNSPEC keyword [TABDIMS](#)) values of the effective salinity calculated as specified by the [SALTEFF](#) keyword. Within each table the values should be strictly increasing.

The number of entries in each table must correspond to the number of viscosity multiplier entries used in the [PLYVISC](#) keyword.

See "[Polymer flood model](#)" in the *ECLIPSE Technical Description* for further information.

### Example

With NTPVT=2 and NPPVT≥3:

```
ESPNODE
  0
  50
 100/
  0
  15
  35/
```

### Units

Depending on the coefficients provided in the [SALTEFF](#) keyword, effective salinity can have the following units (see "[Effective salinity calculations](#)" in the *ECLIPSE Technical Description*):

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB), or

UNITS: sm<sup>3</sup>/kg (METRIC), stb/lb (FIELD), scc/gm (LAB), or

UNITS: dimensionless.

## ESSNODE **Salt concentration nodes for water/oil surface tension**

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTPVT (see RUNSPEC keyword [TABDIMS](#)) tables of salt concentration (or effective salinity) values, each terminated by a slash (/), describing the nodal values for salt concentration (or effective salinity) to be used in the calculation of the oil-water surface tension.

Each table consists of up to NPPVT (see RUNSPEC keyword [TABDIMS](#)) values of the salt concentration. Within each table the values should be strictly increasing.

The number of entries in each table must correspond to the number of surface tension entries used in the [SURFSTES](#) keyword.

In ECLIPSE 100, the values of salt concentration should be non-negative. If keyword [ECLMC](#) is selected, the [BRINE](#) keyword activates the Multi-Component Brine Model which can be used with [SURFSTES](#) and [ESSNODE](#).

In ECLIPSE 300, the effective salinity of the water phase is computed as a function of the water component concentrations. The exact expression for this computation can be specified by keyword [SALTEFF](#).

### Example

With NTPVT=2 and NPPVT≥3:

```
ESSNODE
0
50
100 /
0
15
35 /
```

### Units

*ECLIPSE 100 only*

Depending on whether salinity-dependent surfactant model is activated together with brine or multi-component brine options, [ESSNODE](#) will contain values of salt concentration or effective salinity respectively. Accordingly, the units will be

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB), or

UNITS: dimensionless.

*ECLIPSE 300 only*

Depending on the coefficients provided in the [SALTEFF](#) keyword, effective salinity can have the following units (see "[Effective salinity calculations](#)" in the *ECLIPSE Technical Description*):

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB), or

UNITS: dimensionless.

## EXCAVATE Remove grid blocks during a run

x	ECLIPSE 100
	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword should be followed by one integer for every grid block in the current input box. The data must be terminated by a slash (/).

The values indicate whether the corresponding grid block is to be excavated. A value of 0 indicates the block is to remain and a value of 1 indicates the block should be removed.

Excavated grid blocks are technically still present in the simulation but have transmissibilities of zero in all directions resulting in no communication with the rest of the reservoir. An aquifer may be attached to the edge of an excavated region to model boundary conditions. Note that [AQUCON](#) item 11 must be set to YES in order to do this.

Any well or aquifer connections in excavated blocks will be automatically shut. Blocks containing river connections cannot be excavated.

EXCAVATE can be placed between a [REFINE](#) / [ENDFIN](#) pair, enabling the excavation of cells in a local grid refinement. If a global cell containing a local grid refinement is excavated, the corresponding local grid cells will be excavated as well.

Fluid-in-place calculations and pressure averages (such as field pressure) do not include contributions from excavated blocks unless [OPTIONS](#) item 146 is set to a non-zero value.

The excavation status of a grid block can be visualized as a 3D property using the identifier EXCAVNUM.

EXCAVATE is not permitted in dual porosity runs.

### Example

```

BOX
2 4 5 10 1 1 /

EXCAVATE
0 1 0 12*1 0 1 0 /

ENDBOX

```

## EXCEL

## Requests run summary output to be in Excel format

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
x	SUMMARY
	SCHEDULE

This keyword requests that the run summary output, generated by using the [RUNSUM](#) keyword, should be written in a format that can be easily imported into Excel.

In ECLIPSE 100, if this keyword is used the run summaries are output to a separate file rather than appended to the end of the Print file. (There is no need to use the keyword [SEPARATE](#) with EXCEL.) The separate run summary file name is the root with the extension RSM.

In ECLIPSE 300, the run summary file name is the root with the extension RSM. This separate file is automatically generated.

Columns of data are tab-delimited. The file can be imported into Excel by using the File | Open option from within the spreadsheet. No further commands are required; the import wizard can be finished immediately without any further steps.

The EXCEL keyword has no associated data.

### Example

```
EXCEL
```

## EXTFIN

# Specifies an external local grid refinement

x	<b>ECLIPSE 100</b>
x	<b>ECLIPSE 300</b>
x	<b>SPECIAL</b>
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword must be used to specify local grid refinements when using an unstructured grid from an external source, typically FloGrid. It is not intended for general use. The keywords [EXTHOST](#) and [TRANGL](#) must also be specified, and [EXTREPGL](#) may also be specified if required.

The keyword is followed by the following items, terminated with a slash (/).

1. Name of the local grid refinement (up to 8 characters).
2. NX I-dimension of the refinement.
3. NY J-dimension of the refinement.
4. NZ K-dimension of the refinement.
5. NREPG Number of replaced global cells in the refinement.
6. NHALO Number of global halo cells for the refinement (this is the number of cells in the global grid that connect to cells in the local grid using non-neighbor connections across the local grid boundary).
7. NFLOG Maximum number of global flows into or within the refinement.
8. NUMINT Maximum number of internal local flows in the refinement crossing boundaries between global cells.
9. NUMCON Maximum number of global-local connections.
10. NWMAX Maximum number of wells in the refinement.

Any other GRID section keywords (for example [PORO](#) and [EQUALS](#)) following this are taken to apply to this local refined grid, until [ENDFIN](#) or another [REFINE](#), [EXTFIN](#), [CARFIN](#), [RADFIN](#) or [RADFIN4](#) keyword is encountered.

Any data entered for items 6-10 is ignored.

### Example

```

EXTFIN
-- NAME      NX  NY  NZ  NHOST  NHALO  NFLOG  NUMINT  NUMCON  NWMAX
   EAST      12  10   6   15     9     10     65     34     2 /
    
```

x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is obligatory for local grids defined using keyword [EXTFIN](#) for an unstructured host grid, being typically supplied by FloGrid. It specifies the global host cells in natural cell ordering. See also keywords [EXTFIN](#), [EXTREPGL](#) and [TRANGL](#).

The keyword should be followed by an integer for every cell in the current box. A value equal to or less than zero signifies that the local cell is just a fill-in in the  $NX \times NY \times NZ$  mapping used for the unstructured local grid.

Host cell data must be input for every cell in the external local grid. Grid blocks are ordered with the I-direction cycling fastest, followed by the J and then the K indices. Repeat counts may be used for repeated values.

## Example

```
EXTHOST
-- NX*NY*NZ=8
  2 4 5 2 4 5 2 5 /
```

## EXTRAPMS Requests warning messages for table extrapolation

The keyword should be followed by a line containing a single integer, terminated with a slash (/). The integer requests that warning messages should be printed at the end of a timestep in which the PVT or VFP tables have been extrapolated.

- 0 No warnings given
- 1 Warnings given for PVT table extrapolation
- 2 Warnings given for VFP table extrapolation
- 3 Warnings given for PVT and VFP table extrapolation
- 4 As for 3, but report additional diagnostics to the Print file

$R_s$  and  $R_v$  extrapolation warnings will be given for values 1 and 3.

If this keyword is omitted, no extrapolation warnings will be given.

### Example

```
EXTRAPMS
3 /
```

## EXTREPGL Specify replaced global cells for an external local grid refinement

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword may be used for local grids defined using keyword [EXTFIN](#) for an unstructured local grid in a structured host grid, being typically supplied by FloGrid. It specifies the global cells which are to be replaced by cells in the unstructured LGR in natural cell ordering. See also keywords [EXTFIN](#), [EXTHOST](#) and [TRANGL](#).

The keyword should be followed by NREPG integers, where NREPG is the number of replaced global cells specified in item 5 of the [EXTFIN](#) keyword.

Grid blocks in the parent structured grid are ordered with the I-direction cycling fastest, followed by the J and then the K indices. Repeat counts may be used for repeated values.

If this keyword is not specified for an [EXTFIN](#) refinement, the replaced global cells are assumed to be identified wholly by the host cells specified using [EXTHOST](#).

### Example

```
EXTREPGL
-- NHOST=5
  2 5 9 4 15 /
```

## **F**

This section contains an alphabetic listing of keywords starting with the letter F.

## FACTLI

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

## Modify Li critical temperature correlation

The keyword modifies the Li critical temperature correlation. This is normally set up automatically, but the FACTLI keyword allows this to be modified.

A value is required for each equilibration region.

DEFAULT: 1.0

The Li correlation for the critical temperature of a fluid mixture is:

$$T_{\text{crit}}^{\text{mix}} = \frac{\sum_j T_{cj} \cdot V_{cj} \cdot z_j}{\sum_j V_{cj} z_j} \quad \text{Eq. 3.71}$$

For single phase cells for which no bubble or dew point fluid can be found, this critical temperature is compared with the reservoir temperature to establish if the fluid is an oil or a gas. This is usually only required well away from the two phase region.

The item in FACTLI adds a multiplying factor to  $T_{\text{crit}}^{\text{mix}}$ . This may be used to tune the point at which a cell is nominally deemed to be oil or gas. For example, for a rich condensate, a value less than 1 might be entered to prevent states being taken as oil.

Typical FACTLI values lie between 0.7 and 1.3.

---

**Note:** If compositional equilibration option 1 is selected in item 10 of keyword [EQUIL](#) (single phase system) and the GOC is set within the reservoir, then the FACTLI value will be set so that states above the GOC are labelled as gas and those below as oil. This will only occur when compositional variation with depth exists and is entered using [ZMFVD](#) or [COMPVD](#).

---

## Examples

### Example 1

If the reservoir is known to be a gas, but single phase oil cells are being predicted, the Li estimate of the critical point is modified by 0.8 to lower it so that one phase cells are more inclined to be reported as gas:

```
FACTLI
0.8 /
```

### Example 2

Example with two equilibration regions:

```
FACTLI
0.98 0.87 /
```

## FASTTRAC

**Enable shortcuts in tracer calculations**

	<b>ECLIPSE 100</b>
x	<b>ECLIPSE 300</b>
	<b>SPECIAL</b>
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This indicates that no checks are performed on the tracer solution to ensure convergence. There is no recalculation of the residual of the tracer equations and there is only the one update (one Newton iteration).

Enabling this option can save substantial amounts of time when large numbers of tracers are present, for example when using the [TRACK](#) or delumping options.

---

**CAUTION:** However, it does mean there is no control to ensure that the residuals do meet the (stringent) convergence tests of the tracer tracking code. This could possibly lead to differences between results with and without this keyword.

---

The keyword has no associated data.

## FAULTDIM Dimensions for fault data

	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

## Specifies faults for later editing

This keyword is used to define a set of faults, which can subsequently have their transmissibilities (and diffusivities) modified using the keyword [MULTFLT](#).

The **FAULTS** keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/):

1. Fault name (up to 8 characters)

The fault is made up of all the segments with the same name. The segments may be placed in any order.

2. Lower I-coordinate of cells along the fault (IX1)

3. Upper I-coordinate of cells along the fault (IX2)

IX1 must equal IX2 if the face (item 8) is X or I

4. Lower J-coordinate of cells along the fault (IY1)

5. Upper J-coordinate of cells along the fault (IY2)

IY1 must equal IY2 if the face (item 8) is Y or J

6. Lower K-coordinate of cells along the fault (IZ1)

7. Upper K-coordinate of cells along the fault (IZ2)

IZ1 must equal IZ if the face (item 8) is Z or K

8. Face of the fault

This should be one of X, Y, Z or I, J, K.

If negative direction transmissibility multipliers, [MULTX-](#), [MULTY-](#), or [MULTZ-](#) are enabled (using keyword [GRIDOPTS](#) in the RUNSPEC section), then the face may also be one of X-, Y-, Z- or I-, J-, K-.

The set of records must end with a blank record, containing only a slash (/).

### Notes

- The **FAULTS** keyword may be used more than once within the **GRID** section.

*ECLIPSE 100*

Recall that the [FAULTDIM](#) keyword in the RUNSPEC section is used to specify the maximum number of fault segments that can be entered using the **FAULTS** keyword. Therefore, for this simulator, the **FAULTS** keyword may be used more than once within the **GRID** section, provided that the total number of records does not exceed the value specified in [FAULTDIM](#).

- The faults defined in this keyword do not have to correspond to the actual displacement faults in the corner-point geometry (keywords [COORD](#) and [ZCORN](#)). The faults defined here are only used as a convenient way of varying the transmissibility along the fault trajectory with the [MULTFLT](#) keyword. The generation of the non-neighbor connections is still governed by the corner-point geometry, and does not depend on the fault definitions in the **FAULTS** keyword (except that keyword [MULTFLT](#) modifies any non-neighbor connection transmissibilities across named fault segments).
- The fault data can be printed out by including the mnemonic **FAULTS** in the [RPTGRID](#) keyword.

## Example

```

FAULTS
--
'zigzag'  1  1  1  2  1  4  X /
'zigzag'  2  2  2  2  1  4  Y /
'zigzag'  2  2  3  4  1  4  X /
'zigzag'  3  3  4  4  1  4  Y /
'zigzag'  3  3  5  6  1  4  X /
'zigzag'  4  4  6  6  1  4  Y /
'zigzag'  4  4  7  8  1  4  X /
'zigzag'  5  5  8  8  1  4  Y /
'zigzag'  5  5  9 10  1  4  X /
'zigzag'  6  6 10 10  1  4  Y /
'block'   19 19 20 30  1  4  X /
'block'   30 30 20 30  1  4  X /

	SCHEDULE

This keyword provides information that is used to modify the partially mixed water viscosity in the Polymer Flood. Therefore this keyword has to be used in conjunction with the polymer flood option (refer to the [POLYMER](#) keyword).

The reference viscosity is the water viscosity in the Polymer Flood Model. This keyword must be used in conjunction with the [NNEWTF](#) keyword in the RUNSPEC section. For more details please refer to the "[Non-Newtonian fluid flows](#)" option in the *ECLIPSE Technical Description*.

The data comprises NTHRBL tables of NLNHBL lines of input. Each table must terminate by a slash (/). Each line contains the items detailed below:

1. Polymer concentration in the solution

The values should increase monotonically down the column.

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB)

2. Tortuosity of the porous media,  $\delta$ .

UNITS: dimensionless

DEFAULT:  $\text{SQRT}(2) = \sqrt{2} = 1.414$

3. Fluid flow behavior index, or power law exponent,  $n$ .

UNITS: dimensionless

DEFAULT: 1.0

4. Yield stress of the polymer solution,  $\tau_0$ .

UNITS: barsa (METRIC), psia (FIELD), atma (LAB)

DEFAULT: 0.0

### Example

With NTHRBL=1 and NLNHBL=2:

```
FHERCHBL
-- Cp.  δ      n      τ0
  0.0   1.414  1.0    0.0
 10.0   1.414  0.6    0.5 /

The keyword has no associated data.

## FIELDSEP Introduces a field separator

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword introduces a field separator, used to define separator oil and gas in place. Several lines of FIELDSEP data may be used to build up a multistage separator. The maximum number of stages can be defined by the WELLDIMS keyword. Stages must be specified in increasing order.

If a FIELDSEP keyword is entered, it specifies the default separator conditions for the wells.

The default limit on the number of stages per separator is 5. This may be increased using the 5<sup>th</sup> item in the WELLDIMS keyword. The default limit on the number of separators (including the FIELDSEP separator) is 4. This may be increased using the 8<sup>th</sup> item in the WELLDIMS keyword.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated by a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. The stage index.
2. The field separator stage temperature.

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

DEFAULT: 15.56 °C (METRIC, LAB and PVT-M), 60 °F (FIELD)

3. The field separator stage pressure.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: 1.01325 barsa (METRIC), 14.6959 psia (FIELD), 1 atma (LAB and PVT-M)

4. This defines the destination of the liquid output from the field separator.

For all but the last stage in a field separator, this will be to a later stage, usually the next stage.

Setting this item to 0 implies the next stage for all except the last stage, and the stock tank for the last stage.

If -1 is specified for a stage before the last, this volume is added to the stock tank oil. Care must be taken, as this may result in the accumulation of oil volumes at different pressures or temperatures.

DEFAULT: 0

5. This defines the destination stage of the vapor output from the field separator.

This is usually accumulated with the stock tank or field separator vapor, the volume rate being taken by conversion to a volume at standard conditions. This is done when the destination stage is set to 0.

In the unusual case in which the vapor output from the field separator is fed to a subsequent stage, a non-default value of the destination stage may be entered. Note that, in this case, if intermediate stage separator gas is used as a source of reinjection gas, ECLIPSE 300 will calculate and report export oil rates. This export rate will be less than the produced oil rate which is the 'formation' oil rate prior to any reinjection work. The difference then between the formation oil and export oil is the oil vapor that is contained in the reinjected gas that would otherwise have been separated in the subsequent separator stage. See also the discussion under "Export tables" in the *ECLIPSE Technical Description*

DEFAULT: 0

6. The K-value table number.

This is required if a K-value table rather than an equation of state is being used for the field separator. A value of 0, indicates no K-value table, and implying an equation of state calculation.

DEFAULT: 0

7. The gas plant table number.

This is required if a gas plant table rather than an equation of state is being used for a stage of the field separator. A value of 0, indicates no gas plant table, and implying an equation of state calculation.

DEFAULT: 0

8. The surface equation of state number.

This should only be specified if multiple equations of state are used. When this option is employed, it may still be defaulted, in which case fluid in place calculation for a cell uses the equation of state for that cell.

If an equation of state index is specified, this forces the use of a given surface equation of state. The value must lie between 1 and the maximum number of equations of state for surface conditions, [TABDIMS](#) item 10.

If `FIELDSEP` defines well separator conditions, a default equation of state index again implies using the value for the cells in which the well is completed.

This is discussed further in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

9. Temperature for natural gas liquid (NGL) density evaluation.

UNITS: °C (`METRIC`), °F (`FIELD`), °C (`LAB`), °C (`PVT-M`)

10. Pressure for NGL density evaluation.

UNITS: barsa (`METRIC`), psia (`FIELD`), atma (`LAB`), atma (`PVT-M`)

If both items 9 and 10 are specified, an equation of state NGL density calculation is performed, rather than using Amagat's law.

## Related keywords

For well production, surface volumes are calculated using a well separator, defined by the [WSEPCOND](#) keyword. If a well separator is not defined, the group separator defined by the [SEPCOND](#) keyword is used. If the group separator is not defined, the field separator defined by this keyword `FIELDSEP` is used. If the field separator is not defined, a single flash to standard conditions given by [STCOND](#) is used.

For fluid-in-place calculations, surface volumes are calculated using region separators, defined by the [FIPSEP](#) keyword. If the region separator is not defined, the field separator defined by this keyword `FIELDSEP` is used. If the field separator is not defined, a single flash to standard conditions given by [STCOND](#) is used.

## Examples

### Example 1

Defines a two stage field separator. The first stage has a pressure of 815 psi and a temperature of 80°F. The second stage is connected to the liquid output of the first, and represents stock tank conditions.

```
FIELDSEP
1 80 815 /
2 60 14.7 /
/
```

### Example 2

For a much more complex case, the following field separator configuration, in which the first stage uses an equation of state flash, the vapor output feeding a gas plant stage to extract NGLs, and the liquid output feeding a stock tank flash stage.

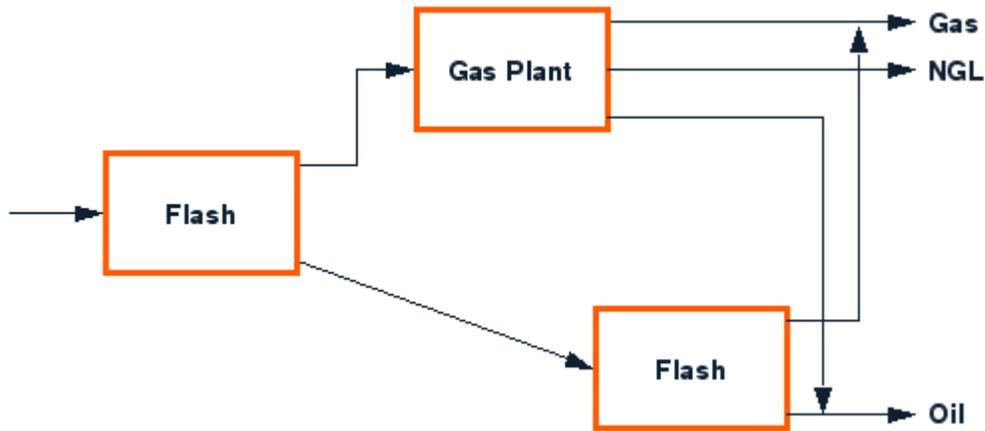

Figure 3.5. A complex field separator configuration

```
FIELDSEP
1 60 15 3 2 1* 1* / --Flash first stage, liquid to 3, vapor to 2
2 15 1.03 -1 1* 1* 1 / --Gas plant second stage for NGL recovery
3 15 1.03 1* 1* 1* 1* / --Stock tank for oil recovery
/
```

## FILEUNIT

## Confirm units of a data set

The keyword should be followed by an item, which specifies the units being used. The data should be terminated by a slash (/).

The possible values of the option are:

**METRIC** The data is specified using the same unit system as for the **METRIC** keyword.

**FIELD** The data is specified using the same unit system as for the **FIELD** keyword.

**LAB** The data is specified using the same unit system as for the **LAB** keyword.

**PVT-M** This option is for ECLIPSE 300 only. The data is specified using the same unit system as for the **PVT-M** keyword.

There is no default value.

---

**Note:** This keyword does **not** provide conversion between different unit systems. It is intended to facilitate checking where, for instance, a data set may contain several sections in separate files which were created by different programs possibly using different units. All occurrences of **FILEUNIT** in a data set have to match.

---

### Example

Specify that the data is in **FIELD** units.

```
FILEUNIT
FIELD /
```

## FILLEPS

## Requests that saturation end points for all grid blocks are written to the INIT file

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword affects the output of grid block end point data in the INIT file. Normally, the values of SWL, SWCR, SOWCR and similar keywords are written to the INIT file only when end point scaling is on (keyword [ENDSCALE](#) in the RUNSPEC section) or if (ECLIPSE 100) the initial mobile fluid correction is on (switch 'MOBILE' set in the RUNSPEC keyword [EQLOPTS](#)). The grid block endpoints are also by default only output for those cells for which the user has explicitly defined the rescaled end points with the appropriate keywords in the PROPS section (including keywords [SWL](#), [SWCR](#), [SOWCR](#)). Grid blocks for which rescaling data has not been explicitly defined are indicated as undefined, meaning that the original saturation tables (for example, the families of keywords including SWOF/SGOF, or SWFN/SGFN/SOF3) are to be employed for these blocks without rescaling.

The keyword FILLEPS instructs ECLIPSE to output the actual end points for each block, whether taken from the saturation tables or rescaled values, whether or not the end point scaling option is used. FILLEPS has no effect if the [INIT](#) keyword is not present in the GRID section.

The keyword has no associated data.

### Example

```
FILLEPS
```

## FIP Additional sets of fluid-in-place region numbers

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is used to specify an array of region numbers for extra sets of fluid-in-place regions, in addition to the standard set defined with keyword [FIPNUM](#).

The keyword name should consist of two segments:

1. Characters 1-3 must be the character string FIP
2. Characters 4-8 must be the name of the set of fluid-in-place regions. Note that 5 characters may be used, but only the first 3 characters are significant; hence the first 3 characters should be unique.

The keyword should be followed by one integer for every grid block in the current input box, specifying the fluid-in-place region number to which it belongs in this set. The region numbers should not be less than 1 or greater than NTFIP (see keyword [REGDIMS](#)). The data must be terminated by a slash (/).

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

The total number of FIP type keywords in a run (including FIPNUM) must not exceed NMFIPR (set by keyword [REGDIMS](#)).

The FIP type keywords can also be used in conjunction with the [COPY](#), [ADD](#) and [EQUALS](#) keywords.

Any grid blocks not assigned a region number in each set of FIP regions when the end of the REGIONS section is reached are assigned to FIP region 1.

A set of balance sheets is produced for each set of fluid-in-place regions supplied using the FIP keyword, when the FIP mnemonic is set >2 in [RPTSCHED](#). The first set of regions in the report is the set constructed with the FIPNUM keyword. The subsequent balance sheets report the additional fluid-in-place regions constructed with the FIP keyword. These have a title mnemonic of the form BALnnnnn, where nnnnn is the name of the set of fluid-in-place regions specified with the keyword FIPnnnnn.

[SUMMARY](#) section quantities can be written to the summary files by using one of the summary keywords for region output (keywords beginning with R) compounded with the first 3 characters of the name of the set of fluid-in-place regions. Summary keywords having less than 5 characters should be extended to 5 characters with underscores before adding the 3-character region set name; for example,

```

ROIPLFST  for the oil-in-place in the liquid phase for region 2 of 2
/         the set of regions named FST.
ROIP_SND  for the total oil-in-place in all the regions in the
/         set named SND.

```

ECLIPSE 100 only

See also keyword [FIPOWG](#), which automatically constructs a set of FIP regions to represent the gas, oil and water zones at equilibration.

### Example

With NMFIPR ≥ 3 and NTFIP=4 specified in keyword [REGDIMS](#); NDIVIX=8, NDIVIY=6 and NDIVIZ=3 specified in RUNSPEC keyword [DIMENS](#); and no input BOX set:

```

-- FIPNUM by layer, for standard fluid-in-place region
FIPNUM
48*1
48*2
48*3 /
-- FIP by area, X strips (region name XAREA)
FIPXAREA

## FIPNUM

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

## Fluid-in-place region numbers

The keyword should be followed by one integer for every grid block in the current input box, specifying the fluid-in-place region to which it belongs.

A balance sheet showing fluid in place and cumulative flows to and from wells and other regions is produced for each fluid-in-place region at every report time, if the FIP mnemonic in the [RPTSCHED](#) keyword is set >1.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

Any grid blocks not assigned a value of FIPNUM when the end of the REGIONS section is reached will be assigned to region 1.

The region numbers should not be less than 1 or greater than NTFIP (see keyword [REGDIMS](#) or [TABDIMS](#)). The data must be terminated by a slash (/).

This keyword defines the standard set of fluid-in-place regions. Additional sets of fluid-in-place regions can be defined, if required, with the [FIP](#) keyword. Each set of fluid-in-place regions produces its own set of balance sheets, independently of the other sets of fluid-in-place regions. The number of sets of fluid-in-place regions must not exceed NMFIPR (keyword [REGDIMS](#)).

---

**Note:** The pore volume reported in the balance sheet will include the pore volume of any aquifers associated with the region. Aquifer cells with no explicit region number are assigned to region 1.

---

ECLIPSE 100 only

See also the keyword [FIPOWG](#).

### Example

With NDIVIX=8, NDIVIY=6 and NDIVIZ=5 specified in RUNSPEC keyword [DIMENS](#), and no input BOX set:

```
FIPNUM
40*2 8*1
40*3 8*1
40*4 8*1
40*5 8*1
40*6 8*1 /
```

## FIPOWG

## Sets up a family of FIP regions representing the original GAS, OIL and WATER zones

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword requests that a family of fluid-in-place regions should be set up automatically to represent the original gas, oil and water zones at equilibration.

The keyword has no associated data.

The total number of FIP type keywords in a run (including [FIPNUM](#)) must not exceed NMFIPR, and NTFIP should be set to at least a value of 3 because there will be three regions in this family. (Both NMFIPR and NTFI are set by keyword [REGDIMS](#).)

Three regions are set up according to the depth of the cells.

Region:

1. Gas zone, containing all cells with depths above the GOC specified in item 5 of the [EQUIL](#) keyword.
2. Oil zone, containing the cells with depths between the GOC and WOC.
3. Water zone, containing all cells with depths below the WOC specified in item 3 of the [EQUIL](#) keyword.

This family of regions is treated in a similar way to any other FIP region family constructed manually with the [FIP](#) keyword. A set of balance sheets is produced for the FIPOWG fluid-in-place regions, when the FIP mnemonic is set >2 in [RPTSCHED](#). These have a title mnemonic BALOWG.

[SUMMARY](#) section quantities can be written to the Summary files by using one of the Summary keywords for region output (keywords beginning with R) compounded with the 3 characters OWG. [SUMMARY](#) keywords having less than 5 characters should be extended to 5 characters with underscores before adding the 3-character region set name; for example,

```

ROIPOWG   for the oil-in-place in the liquid phase for the original oil zone.
2 /
ROIPOWG   for the total oil-in-place in all three regions
/

```

See also the [FIPNUM](#) and [FIP](#) keywords.

### Example

```

FIPOWG

```

## FIPSEP

## Introduces a fluid-in-place region separator

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword introduces a separator that will be used to define separator oil- and gas-in-place volumes for a specific fluid-in-place region. Several lines of FIPSEP data may be used to build up a multi-stage separator. The maximum number of stages can be defined by the WELLDIMS keyword. Stages must be specified in increasing order.

The default limit on the number of stages per separator is 5. This may be increased using the item 5 in the WELLDIMS keyword. The default limit on the number of separators (including the FIELDSEP separator) is 4. This may be increased using the 8<sup>th</sup> item in the WELLDIMS keyword.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated by a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. The number of the fluid-in-place region in which this separator is used for oil-and gas-in-place volume calculation. The region numbers should not be less than 1 or greater than NTFIP (see keyword REGDIMS).

2. The stage index.

3. The separator stage temperature.

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

DEFAULT: 15.56 °C (METRIC, LAB and PVT-M), 60 °F (FIELD)

4. The separator stage pressure.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: 1.01325 barsa (METRIC), 14.6959 psia (FIELD), 1 atma (LAB and PVT-M)

5. This defines the destination of the liquid output from the separator.

For all but the last stage in a separator, this is to a later stage, usually the next stage.

Setting this item to 0 implies the next stage for all except the last stage, and the stock tank for the last stage.

If -1 is specified for a stage before the last, this volume is added to the stock tank oil. Care must be taken, as this may result in the accumulation of oil volumes at different pressures or temperatures.

DEFAULT: 0

6. This defines the destination stage of the vapor output from the separator.

This is usually accumulated with the stock tank or separator vapor, the volume rate being taken by conversion to a volume at standard conditions. This is done when the destination stage is set to 0.

In the unusual case in which the vapor output from the separator is fed to a subsequent stage, a non-default value of the destination stage may be entered.

DEFAULT: 0

7. The K-value table number.

This is required if a K-value table rather than an equation of state is being used for the separator. A value of 0 indicates no K-value table, and implies an equation of state calculation.

DEFAULT: 0

8. The gas plant table number.

This is required if a gas plant table rather than an equation of state is being used for a stage of the separator. A value of 0 indicates no gas plant table, and implies an equation of state calculation.

DEFAULT: 0

9. The surface equation of state number.

This should only be specified if multiple equations of state are used. When this option is employed, it may still be defaulted, in which case the fluid in place calculation for a cell uses the equation of state for that cell.

If an equation of state index is specified, this forces the use of a given surface equation of state. The value must lie between 1 and the maximum number of equations of state for surface conditions, [TABDIMS](#) item 10.

This is discussed further in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

10. Temperature for natural gas liquid (NGL) density evaluation.

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

11. Pressure for NGL density evaluation.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

If both items 10 and 11 are specified, an equation of state NGL density calculation is performed, rather than using Amagat's law.

## Related keywords

For fluid-in-place calculations, surface volumes are calculated using region separators, defined by this keyword `FIPSEP`. If the region separator is not defined, the field separator `FIELDSEP` is used. If the field separator is not defined, a single flash to standard conditions given by `STCOND` is used.

## Notes

- This keyword allows different fluid-in-place regions to use different separators for calculating the in-place volumes of oil and gas, as reported in the print file. If this keyword is omitted, all regions use the `FIELDSEP` separator for this calculation.
- The in-place total volumes for the whole field are calculated using the `FIELDSEP` separator, and so these oil and gas totals do not in general equal the sum of the oil and gas volumes from fluid-in-place regions with differing separators.
- The presence of this keyword does not alter the default separator assignment for wells; this is still taken as the `FIELDSEP` separator, regardless of which fluid-in-place region the well is in.

## Example

Defines a two-stage separator for the fluid-in-place region number 1, a one-stage separator for region number 2, and a three-stage separator for region number 3.

```
FIPSEP
1 1 80 815 /
1 2 60 14.7 /
2 1 60 14.7 /
3 1 90 730 /
3 2 80 345 /
3 3 60 14.7 /
/
```

## FLUXNUM **Identifies extent of each flux region**

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The FLUXNUM keyword has two uses. Firstly, it provides a convenient way of defining a region in the GRID section for subsequent modification of its data using the [EQUALREG](#), [ADDREG](#), [COPYREG](#), [MULTIREG](#), [MULTREGP](#) and [MULTREGT](#) keywords. Secondly, the keyword is used with the flux boundary option to define regions that can be run as separate models with boundary fluxes defined in a previous full field run.

The keyword should be followed by one integer for each grid cell in the full field model, specifying the flux region number to which it belongs. The region numbers should not exceed the value of NTFREG entered using keyword [REGDIMS](#) in the RUNSPEC section (item 4). The data must be terminated by a slash (/).

The FLUXNUM array can be copied into the REGIONS section arrays (for example [FIPNUM](#) and [SATNUM](#)) using the [COPY](#) keyword. It is recommended that NTFREG should be set greater than 1 if this facility is to be used. If a zero FLUXNUM region is copied in to a REGIONS array then the destination array will be set to 1.

*ECLIPSE 100*

Any cells not explicitly assigned a FLUXNUM value will be defaulted to a value of 1.

*ECLIPSE 300*

Any cells not explicitly assigned a FLUXNUM value will be defaulted to a value of -1.

Set FLUXNUM to zero explicitly for any cells not required in flux regions.

The FLUXNUM keyword should be used before the [EQUALREG](#), [ADDREG](#), [COPYREG](#), [MULTIREG](#) and [MULTREGT](#) keywords are used to modify grid properties within a flux region.

*ECLIPSE 100 only*

The FLUXNUM keyword cannot be used inside a [CARFIN/RADFIN ... ENDFIN](#) bracket.

*ECLIPSE 100*

For use with the dual porosity option, only the matrix cells or the fracture cells need to be input. The cell values in the other porosity will be copied automatically. If the user wants to specify matrix cells and fracture cells separately, then [item 117](#) in [OPTIONS](#) should be set greater than 1. This will also affect use of the [MULTNUM](#), [PINCHNUM](#) or [OPERNUM](#) keywords.

*ECLIPSE 300*

For use with dual porosity option, both matrix and fracture cells should be provided. FLUXNUM use with [MULTREGT](#) or [MULTREGP](#), will automatically copy all matrix cells to the corresponding fracture cells, so dummy fracture values could be input. For other FLUXNUM uses, there is no copying of data from the matrix to fracture cells.

### Flux option cases

See "[Flux Boundary Conditions](#)" in the *ECLIPSE Technical Description* for more information on this option.

The FLUXNUM keyword must be used in both the full-field ([DUMPFLUX](#)) run and the reduced ([USEFLUX](#)) run to identify the cells belonging to each flux region. The [DUMPFLUX](#) or [USEFLUX](#) keyword must have been entered previously.

For runs in which the full field has just a single flux region (NTFREG=1), the cells inside the flux region should have a region number of 1, and 0 for the cells outside. For runs involving multiple flux regions (NTFREG>1), the region numbers should lie between 1 and NTFREG, and the [FLUXREG](#) keyword is used in the reduced run to indicate which flux regions are active.

*ECLIPSE 100 only*

(A negative region number will automatically be converted to positive.)

The contents of the FLUXNUM keyword in a reduced run must be identical with the original full-field run.

## Examples

### Example 1

To establish a single 2\*2\*2 flux region in a 4\*4\*3 field:

```
FLUXNUM
1 1 0 0
1 1 0 0
0 0 0 0
0 0 0 0
1 1 0 0
1 1 0 0
1 1 0 0
0 0 0 0
0 0 0 0
16*0 /
```

### Example 2

To define 9 separate flux regions in a 4\*4\*3 field:

```
FLUXNUM
1 1 2 2
1 1 2 2
3 3 3 3
4 4 4 4
5 5 5 5
6 7 8 8
6 7 8 8
6 7 8 8
16*9 /
```

## FLUXOPTS Options for flux boundary runs

	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword should be used in the full-field run to tell ECLIPSE whether the reduced run will be a thermal run or not.

The FLUXOPTS keyword should be followed by one of the following values:

YES The simulator will output the necessary information to run a thermal reduced run

NO The simulator will not output the necessary information to run a thermal reduced run

DEFAULT: NO

The data should be terminated by a slash (/).

---

**Note:** There is no need to use this keyword if the base run is thermal or there is no intention of running a thermal sector model from the base run.

---

### Example

The reduced run will be a thermal run

```
FLUXOPTS
YES /
```

## FLUXREG

**Identifies which flux regions are active**

x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The FLUXREG keyword should be used in a reduced ([USEFLUX](#)) run where there is more than one flux region in the [FLUXNUM](#) keyword. It tells the simulator which flux regions are active in the reduced run. The keyword should be entered after the USEFLUX keyword.

The keyword should be followed by up to NTFREG (see item 4 in the RUNSPEC section keyword [REGDIMS](#)) integers, terminated with a slash (/). The integers form a list of the flux regions that are active. The remaining flux regions that are not on the list are made inactive, and their flows into the active regions are read from the Flux file.

The keyword is not required in full-field ([DUMPFLUX](#)) runs, or in runs where there is only one flux region in the full field (NTFREG = 1).

See also "[Flux boundary conditions](#)" in the *ECLIPSE Technical Description*.

**Example**

To perform a reduced run on a sector of the field defined by flux regions 2, 3 and 5:

```
FLUXREG
 2 3 5 /
```

## FLUXTYPE Specify type of flux boundary condition

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The FLUXTYPE keyword specifies the type of boundary conditions to be used for the reduced run.

The boundary conditions supplied from the full field run are used in the reduced run. ECLIPSE allows two types of boundary condition:

- Flow boundary conditions supply the boundary fluxes for each phase from the full field run.
- Pressure boundary conditions use the pressures, saturations,  $R_s$  and  $R_v$  values from the full field run as boundary conditions for the reduced run in 'halo' cells surrounding the reduced region activated by [USEFLUX](#) and [FLUXREG](#).

The same type of boundary condition must be used in both the full field run ([DUMPFLUX](#)) and the reduced run ([USEFLUX](#)).

The keyword is followed by a single item to select the chosen boundary condition, terminated by a slash (/).

### 1. Type of boundary condition

'FLUX' Use flows of oil, water and gas from the full field run as boundary conditions on the reduced run

'PRESSURE' Use pressures and saturations from the full field run in 'halo' cells adjoining the reduced flux region as boundary conditions on the reduced run.

DEFAULT: 'FLUX'

If this keyword is not present in the data file, FLUX boundary conditions are used.

## Example

To establish pressure boundary conditions:

```
FLUXTYPE
'PRESSURE' /
```

## FMTHMD

**Indicates that HMD file is to be formatted**

	SCHEDULE

Declares that the HMD output file, used by the ECLIPSE Gradient option, containing the derivatives is to be formatted.

The default is unformatted.

See "[Gradient option](#)" in the *ECLIPSE Technical Description* for further information.

The keyword has no associated data

This option is for ECLIPSE 100 only. If an RFT gradients file `.GRFT` is produced, this is also formatted.

## FMTIN

### Indicates that input files are formatted

This indicates that input files which may be either formatted or unformatted, such as restart files, are to be formatted. The default, if this keyword is not specified, is to use unformatted files, as this reduces file size and processing time.

FMTIN contains no items.

	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTSFUN (see keyword [TABDIMS](#)) tables of foam adsorption functions, each terminated by a slash (/), describing the adsorption of foam by the rock formation. See "Foam model" in the *ECLIPSE Technical Description* for further information.

Each table consists of 2 columns of data:

1. The local foam concentration in the solution surrounding the rock. The values should increase monotonically down the column.

If item 1 of [FOAMOPTS](#) is set to 'GAS':

UNITS: kg/sm<sup>3</sup> (METRIC), lb/Mscf (FIELD), gm/scc (LAB)

If item 1 of [FOAMOPTS](#) is set to 'WATER':

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB)

2. The corresponding saturated concentration of foam adsorbed by the rock formation. These values should be level, or increase down the column.

UNITS: kg/kg (METRIC), lb/lb (FIELD), gm/gm (LAB)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (see keyword [TABDIMS](#)).

---

**CAUTION:** The first row in the adsorption tables should consist of a pair of zeroes.

---

See also [FOAMROCK](#), [SURFADS](#), [PLYADS](#), [PLYADSS](#) and [ADSORP](#).

### Example

With NTSFUN=2 and SSFUN≥6)

```

FOAMADS
.0000 .00000
.0001 .00001
.0003 .00005
.0005 .00007
.0008 .00008
.0010 .00008 /
.0000 .00000
.0010 .00010 /

	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The FOAMDCYO keyword inputs data describing the decay of foam as a function of oil saturation. See "Foam model" in the *ECLIPSE Technical Description* for further information.

The data comprises NTSFUN (see keyword [TABDIMS](#)) tables of foam decay data, each terminated by a slash (/). Each table consists of 2 columns of data:

1. The local oil saturation.  
The values should increase monotonically down the column.
2. The corresponding decay half-life.  
UNITS: day (METRIC), day (FIELD), hr (LAB)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (see keyword [TABDIMS](#)).

Note that if the [FOAMDCYW](#) keyword is also present, the decay half-life is taken to be the minimum of the two values for each cell.

See also keywords [FOAMDCYW](#) and [FOAMADS](#).

### Example

With NTSFUN=2 and NSSFUN ≥ 3:

```
FOAMDCYO
--
-- Constant half-life
--
0.0 12.0
1.0 12.0 /
--
-- Reduced half-life if oil is present.
--
0.0 15.0
0.1 5.0
1.0 5.0 /
```

## FOAMFCN

## Gas mobility reduction dependence upon capillary number

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTSFUN (see keyword [TABDIMS](#)) tables defining the parameters which control the gas mobility reduction due to foam as a function of capillary number. Each table consists of one row of data containing two items which should be terminated with a slash (/):

1. The reference capillary number.
2. An exponent controlling the steepness in the change of mobility according to the ratio of reference to calculated capillary numbers.

DEFAULT: 1.0

The first item in the first table must be specified. The second item may be defaulted. If the second or subsequent tables are completely defaulted, the associated parameters will be copied from the previous table.

This keyword is only relevant if the foam model is used with the functional gas mobility reduction model.

## ECLIPSE 100

In ECLIPSE 100 this requires the [FOAM](#) option to be specified in the RUNSPEC section and FUNC to be set for item 2 of the [FOAMOPTS](#) keyword.

## ECLIPSE 300

In ECLIPSE 300 the foam model is activated by using an additional water component [COMPW](#) to represent the foam surfactant [CWTYPE](#). ECLIPSE 300 only supports the functional form of the gas mobility model, so this need not be specified.

In both simulators, the [FOAMFSC](#) keyword must be specified with the functional gas mobility reduction model. See "Foam model" in the *ECLIPSE Technical Description* for further information.

For the functional model of gas mobility reduction, the mobility reduction factor  $M_{rf}$  is expressed in the form:

$$M_{rf} = \frac{1}{1 + (M_r \cdot F_s \cdot F_w \cdot F_o \cdot F_c)}$$

where

$M_r$  is the reference mobility reduction factor ([FOAMFRM](#) keyword).

$F_s$  is the mobility reduction factor dependence upon surfactant concentration ([FOAMFSC](#) keyword).

$F_w$  is the mobility reduction factor dependence upon water saturation ([FOAMFSW](#) keyword).

$F_o$  is the mobility reduction factor dependence upon oil saturation ([FOAMFSO](#) keyword).

$F_c$  is the mobility reduction factor dependence upon capillary number (this keyword).

The mobility reduction factor functional dependence upon capillary number  $F_c$  is expressed in the form:

$$F_c = \left( \frac{N_c^r}{N_c} \right)^e \tag{Eq. 3.72}$$

where

$N_c$  is the capillary number.

$N_c^r$  is the reference capillary number.

$e_c$  is an exponent which controls the steepness of the transition about the point where  $N_c = N_c^r$ .

The capillary number is a dimensionless parameter which provides a measure of the ratio of viscous forces to capillary forces. The calculation of the capillary number is described in "[Capillary number](#)" in the *ECLIPSE Technical Description*. The viscous forces are proportional to the velocity, which is calculated from the flows into and out of the cell, while the capillary forces are proportional to the gas-water surface tension defined by the [FOAMFST](#) keyword.

Several simplifications are made when calculating the velocity term:

ECLIPSE 100

- In ECLIPSE 100 non-neighbor flows are not included

ECLIPSE 300

- In ECLIPSE 300 non-neighbor flows are included, except
  - user-defined non-neighbor flows ([NNC](#) keyword)
  - non-neighbor flows stored in flux boundary files
  - non-neighbor flows arising from grid coarsening
- Well flows are not included.

The gas-water interfacial tension is tabulated as function of the foam concentration using the [FOAMFST](#) keyword. The contribution of the capillary number mobility reduction component to the overall gas mobility reduction is determined by the ratio of reference to calculated grid block capillary number and the value of the exponent which controls the steepness of the change about the transition point  $N_c = N_c^r$ . This keyword is optional; however, if this keyword is specified the [FOAMFST](#) keyword must also be specified. If this keyword is not specified the component of the overall mobility reduction factor which models the functional dependence upon capillary number will default to 1.0. See also the [FOAMFRM](#), [FOAMFSC](#) and [FOAMFSW](#) keywords.

The capillary number functional mobility reduction term is only applied in grid blocks which contain foam with a concentration which is greater than or equal to the minimum concentration specified by item 3 of the [FOAMFSC](#) keyword.

## Example

With [NTSFUN](#)=5

```
FOAMFCN
1.0E-07 /
2.0E-07 1.5 /
/
1.0E-07 3.0/
/
```

## FOAMFRM

## Gas mobility reduction dependence upon reference mobility reduction

x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTSFUN (see keyword [TABDIMS](#)) tables defining the parameters which control the gas mobility reduction as a function of the reference mobility reduction factor. Each table consists of one row of data containing one item which should be terminated with a slash(/):

1. The reference mobility reduction factor. This value must be greater than zero and should typically lie in the region of 1 to 100

The single item in the first table must be specified. If the single item is omitted from the second or subsequent tables, the reference mobility reduction factor will be copied from the previous table.

This keyword is only relevant if the foam model is used with the functional gas mobility reduction model.

In ECLIPSE 100 this requires the [FOAM](#) option to be specified in the RUNSPEC section and FUNC to be set for item 2 of the [FOAMOPTS](#) keyword.

In ECLIPSE 300 the foam model is activated by using an additional water component [COMPW](#) to represent the foam surfactant [CWTYPE](#). ECLIPSE 300 only supports the functional form of the gas mobility model, so this need not be specified.

In both simulators, the [FOAMFSC](#) keyword must be specified with the functional gas mobility reduction model. See "[Foam model](#)" in the *ECLIPSE Technical Description* for further information.

For the functional model of gas mobility reduction, the mobility reduction factor  $M_{rf}$  is expressed in the form:

$$M_{rf} = \frac{1}{1 + (M_r \cdot F_s \cdot F_w \cdot F_o \cdot F_c)}$$

where

$M_r$  is the reference mobility reduction factor (this keyword).

$F_s$  is the mobility reduction factor dependence upon surfactant concentration ([FOAMFSC](#) keyword).

$F_w$  is the mobility reduction factor dependence upon water saturation ([FOAMFSW](#) keyword).

$F_o$  is the mobility reduction factor dependence upon oil saturation ([FOAMFSO](#) keyword).

$F_c$  is the mobility reduction factor dependence upon capillary number ([FOAMFCN](#) keyword).

This keyword is optional. If this keyword is not specified the reference mobility reduction factor will default to 1.0. See also the [FOAMFCN](#), [FOAMFSC](#), [FOAMFSO](#) and [FOAMFSW](#) keywords. The reference mobility reduction factor is only applied in grid blocks which contain foam with a concentration which is greater than or equal to the minimum concentration specified by item 3 of the [FOAMFSC](#) keyword.

## FOAMFSC

## Gas mobility reduction dependence upon foam surfactant concentration

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTSFUN (see keyword [TABDIMS](#)) tables defining the parameters which control the gas mobility reduction as a function of foam surfactant concentration. Each table consists of one row of data and should be terminated with a slash(/):

- The reference foam surfactant concentration above which a strong foam can form.  
UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB)
- An exponent controlling the steepness in the change of mobility reduction due to surfactant concentration.  
DEFAULT: 1.0
- The minimum surfactant concentration for which gas mobility reduction due to the presence of foam will be calculated.  
UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB)  
DEFAULT: 10<sup>-20</sup>
- The minimum water saturation below which foam has no effect.  
DEFAULT: 10<sup>-6</sup>

ECLIPSE 300

The first item in the first table must be specified. The second and third items may be defaulted.

The fourth term is only used in ECLIPSE 300. It is intended to prevent small numerical errors from causing convergence problems: when the water saturation is very low, a small amount of foam surfactant will lead to a large surfactant concentration, which could have a spuriously large effect on the gas mobility.

If the second or subsequent tables are completely defaulted, the associated parameters will be copied from the previous table.

This keyword is only relevant if the foam model is used with the functional gas mobility reduction model.

ECLIPSE 100

In ECLIPSE 100 this requires the [FOAM](#) option to be specified in the RUNSPEC section and FUNC to be set for item 2 of the [FOAMOPTS](#) keyword.

ECLIPSE 300

In ECLIPSE 300 the foam model is activated by using an additional water component [COMPW](#) to represent the foam surfactant. The [CWTYPE](#) keyword is used to identify which water component(s) acts as the foam surfactant (SURFF). ECLIPSE 300 only supports the functional form of the gas mobility model, so this need not be specified.

See "[Foam model](#)" in the *ECLIPSE Technical Description* for further information.

For the functional model of gas mobility reduction, the mobility reduction factor  $M_{rf}$  is expressed in the form:

$$M_{rf} = \frac{1}{1 + (M_r \cdot F_s \cdot F_w \cdot F_o \cdot F_c)}$$

where

$M_r$  is the reference mobility reduction factor ([FOAMFRM](#) keyword).

$F_s$  is the mobility reduction factor dependence upon surfactant concentration (this keyword).

$F_w$  is the mobility reduction factor dependence upon water saturation ([FOAMFSW](#) keyword).

$F_o$  is the mobility reduction factor dependence upon oil saturation ([FOAMFSO](#) keyword).

$F_c$  is the mobility reduction factor dependence upon capillary number ([FOAMFCN](#) keyword).

The mobility reduction factor dependence upon surfactant concentration  $F_s$  is expressed in the form:

$$F_s = \left( \frac{C_s}{C_s^r} \right)^{e_s}$$

where

$C_s$  is the surfactant concentration.

$C_s^r$  is the reference surfactant concentration such that  $C_s < C_s^r$  denotes a weak foam and  $C_s > C_s^r$  denotes a strong foam.

$e_s$  is an exponent which controls the steepness of the transition about the point where  $C_s = C_s^r$ .

The contribution of this component to the overall gas mobility reduction is determined by the reference surfactant concentration, above which the presence of surfactant becomes significant in the creation of foam, and the value of the exponent which controls how quickly this factor changes about the transition point  $C_s = C_s^r$ . In addition, gas mobility reduction due to the presence of foam will only be calculated for grid blocks in which the foam concentration is greater than or equal to the specified minimum value.

It is important to note that if  $e_s < 1$ , the slope of  $F_s$  will be infinite at  $C_s = 0$ . In this case, small surfactant concentrations may have a significant effect on the mobility, particularly if the reference concentration  $C_s^r$  is also small. Therefore it may be necessary to use item 3 of this keyword to set a minimum surfactant concentration to prevent “noise” in the form of small numerical errors from affecting the simulation.

This keyword is mandatory if the functional model of gas mobility reduction due to foam has been specified. See also the [FOAMFCN](#), [FOAMFRM](#), [FOAMFSO](#) and [FOAMFSW](#) keywords.

## Example

With `NTSFUN =5` specified in keyword [TABDIMS](#):

```
FOAMFSC
0.001 /
0.002 1.01 /
/
0.001 0.9 /
0.002 1.02 /
```

## FOAMFSO

## Gas mobility reduction dependence upon oil saturation

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTSFUN (see keyword [TABDIMS](#)) tables defining the parameters which control the gas mobility reduction due to foam as a function of oil saturation. Each table consists of one row of data containing two items which should be terminated with a slash(/):

1. The maximum oil saturation above which foam ceases to be effective.
2. An exponent controlling the steepness in the change of mobility reduction due to oil saturation.

DEFAULT: 1.0

The first item in the first table must be specified. The second item may be defaulted. If the second or subsequent tables are completely defaulted, the associated parameters will be copied from the previous table.

This keyword is only relevant if the foam model is used with the functional gas mobility reduction model.

## ECLIPSE 100

In ECLIPSE 100 this requires the [FOAM](#) option to be specified in the RUNSPEC section and FUNC to be set for item 2 of the [FOAMOPTS](#) keyword.

## ECLIPSE 300

In ECLIPSE 300 the foam model is activated by using an additional water component [COMPW](#) to represent the foam surfactant [CWTYPE](#). ECLIPSE 300 only supports the functional form of the gas mobility model, so this need not be specified.

In both simulators, the [FOAMFSC](#) keyword must be specified with the functional gas mobility reduction model. See "[Foam model](#)" in the *ECLIPSE Technical Description* for further information.

For the functional model of gas mobility reduction, the mobility reduction factor  $M_{rf}$  is expressed in the form:

$$M_{rf} = \frac{1}{1 + (M_r \cdot F_s \cdot F_w \cdot F_o \cdot F_c)}$$

where

$M_r$  is the reference mobility reduction factor ([FOAMFRM](#) keyword).

$F_s$  is the mobility reduction factor dependence upon surfactant concentration ([FOAMFSC](#) keyword).

$F_w$  is the mobility reduction factor dependence upon water saturation ([FOAMFSW](#) keyword)

$F_o$  is the mobility reduction factor dependence upon oil saturation (this keyword).

$F_c$  is the mobility reduction factor dependence upon capillary number ([FOAMFCN](#) keyword)

The mobility reduction factor functional dependence upon oil saturation  $F_o$  is expressed in the form:

$$F_o = \left( \frac{S_o^m - S_o}{S_o^m} \right)^{e_o}$$

where

$S_o$  is the oil saturation.

$S_o^m$  is the maximum oil saturation above which the foam ceases to be effective.

$e_o$  is an exponent which controls the steepness of the transition about the point where  $S_o = S_o^m$ .

The contribution of this component to the overall gas mobility reduction is determined by the maximum oil saturation, above which the foam ceases to be effective, and the value of the exponent which controls the steepness of the change about the transition point  $S_o = S_o^m$ . This keyword is optional. If this keyword is not specified the component of the overall mobility reduction factor which models the functional dependence upon oil saturation will default to 1.0. See also the FOAMFCN, FOAMFSC, FOAMFRM and FOAMFSW keywords.

The oil saturation functional mobility reduction term is only applied in grid blocks which contain foam with a concentration which is greater than or equal to the minimum concentration specified by item 3 of the FOAMFSC keyword.

## Example

With NTSFUN =5

```
FOAMFSO
-- F_o = ((S_o^m - S_o) / S_o^m)**e_o
-- S_o^m  e_o
  0.4    1.    /
  0.4    1.01  /
/
  0.3    0.9   /
  0.3    1.02  /
```

## FOAMFST

## Gas-water surface tension versus foam surfactant concentration

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword supplies tables of gas-water surface tension as a function of foam surfactant concentration in the water.

The data comprises NTSFUN (see keyword [TABDIMS](#)) tables of gas-water surface tension versus foam surfactant concentration. Each table consists of two columns of data, terminated with a slash (/).

1. The foam surfactant concentration.

Values should increase monotonically down the column.

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB), kg/sm<sup>3</sup> (PVT-M)

2. The corresponding gas-water surface tension.

UNITS: N/m (METRIC), lbf/in (FIELD), dynes/cm (LAB), N/m (PVT-M)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFU (see keyword [TABDIMS](#)).

This keyword is only relevant if the foam model is used with the functional gas mobility reduction model.

### ECLIPSE 100

In ECLIPSE 100, this requires the [FOAM](#) option to be specified in the RUNSPEC section and FUNC to be set for item 2 of the [FOAMOPTS](#) keyword.

### ECLIPSE 300

In ECLIPSE 300, the foam model is activated by using an additional water component [COMPW](#) to represent the foam surfactant [CWTYPE](#). ECLIPSE 300 only supports the functional form of the gas mobility model, so this need not be specified.

See the "Foam model" in the *ECLIPSE Technical Description* for further information.

## Examples

### Example 1

With NTSFUN=1 and NSSFUN ≥ 5 and Metric units:

```
FOAMFST
--
-- Conc      ST
-- kg/sm3    N/m
--
--   0.0      0.01
--   10.0     0.005
--   15.0     0.002
--   20.0     0.001
--   25.0     0.0001 /
```

### Example 2

With NTSFUN=1 and NSSFUN ≥ 5 and Field units:

```
FOAMFST
--
-- Conc      ST
-- lb/stb    lbf/in
--
--   0.0      0.000057
```

```
3.5      0.000028
5.25     0.000011
7.0      0.0000057
8.75     0.0000006 /
```

### Example 3

With NTSFUN=1 and NSSFUN  $\geq$  5 and Lab units:

```
FOAMFST
--
-- Conc   ST
-- gm/scc dyne/cm
----
0.00     10.0
0.01     5.0

where the different sets of values are intended to be illustrative of the different orders of magnitudes associated with the different input unit systems.

## FOAMFSW

## Gas mobility reduction dependence upon water saturation

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTSFUN (see keyword [TABDIMS](#)) tables defining the parameters which control the gas mobility reduction due to foam as a function of water saturation. Each table consists of one row of data containing two items which should be terminated with a slash (/):

1. The limiting water saturation below which the foam ceases to be effective.
2. A weighting factor which controls the sharpness in the change of mobility.

DEFAULT: 1.0

The first item in the first table must be specified. The second item may be defaulted. If the second or subsequent tables are completely defaulted, the associated parameters will be copied from the previous table.

This keyword is only relevant if the foam model is used with the functional gas mobility reduction model.

## ECLIPSE 100

In ECLIPSE 100 this requires the [FOAM](#) option to be specified in the RUNSPEC section and FUNC to be set for item 2 of the [FOAMOPTS](#) keyword.

## ECLIPSE 300

In ECLIPSE 300 the foam model is activated by using an additional water component [COMPW](#) to represent the foam surfactant [CWTYPE](#). ECLIPSE 300 only supports the functional form of the gas mobility model, so this need not be specified.

In both simulators, the [FOAMFSC](#) keyword must be specified with the functional gas mobility reduction model. See "[Foam model](#)" in the *ECLIPSE Technical Description* for further information.

For the functional model of gas mobility reduction, the mobility reduction factor  $M_{rf}$  is expressed in the form:

$$M_{rf} = \frac{1}{1 + (M_r \cdot F_s \cdot F_w \cdot F_o \cdot F_c)}$$

where

$M_r$  is the reference mobility reduction factor ([FOAMFRM](#) keyword).

$F_s$  is the mobility reduction factor dependence upon surfactant concentration ([FOAMFSC](#) keyword).

$F_w$  is the mobility reduction factor dependence upon water saturation (this keyword).

$F_o$  is the mobility reduction factor dependence upon oil saturation ([FOAMFSO](#) keyword).

$F_c$  is the mobility reduction factor dependence upon capillary number ([FOAMFCN](#) keyword).

The mobility reduction factor functional dependence upon water saturation  $F_w$  is expressed in the form:

$$F_w = 0.5 + \frac{\text{atan}(f_w(S_w - S_w^l))}{\pi}$$

where

$S_w$  is the water saturation.

$S_w^l$  is the limiting water saturation below which the foam ceases to be effective.

$f_w$  is a weighting factor which controls the sharpness in the change in mobility.

The contribution of this component to the overall gas mobility reduction is determined by the limiting water saturation, below which the foam ceases to be effective, and the value of the weighting factor which controls the sharpness of the change about the transition point  $S_w = S_w^l$ . This keyword is optional. If this keyword is not specified the component of the overall mobility reduction factor which models the functional dependence upon water saturation will default to 1.0. See also the [FOAMFCN](#), [FOAMFSC](#), [FOAMFRM](#) and [FOAMFSO](#) keywords.

The water saturation functional mobility reduction term is only applied in grid blocks which contain foam with a concentration which is greater than or equal to the minimum concentration specified by item 3 of the [FOAMFSC](#) keyword.

## Example

With `NTSFUN=5`

```
FOAMFSW
-- S_w^1   f_w
   0.3     1E3 /
   0.31    1E3 /
/
   0.32    2e4 /
   0.32    2e4 /
```

## FOAMMOB Gas mobility reduction data

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword supplies tables of the gas phase mobility reduction factor as a function of foam concentration. The keyword is obligatory in runs using the foam model as described in "Foam model" in the *ECLIPSE Technical Description*.

The data comprises NTPVT (see keyword [TABDIMS](#)) tables of mobility reduction factors. Each table consists of two columns of data, terminated with a slash (/).

1. The foam concentration.

The values should increase monotonically down the column.

If item 1 of [FOAMOPTS](#) is set to 'GAS':

UNITS: kg/sm<sup>3</sup> (METRIC), lb/Mscf (FIELD), gm/scc (LAB)

If item 1 of [FOAMOPTS](#) is set to 'WATER':

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB)

2. The corresponding gas mobility reduction factor

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NPPVT (see keyword [TABDIMS](#)).

### Example

With NTPVT=1 and NPPVT ≥ 5:

```

FOAMMOB
--
-- Concentration      Mobility factor
--
      0.00              1.0
      0.01              0.2
      0.015             0.1
      0.02              0.09
      0.025             0.09 /

```

## FOAMMOBP Pressure dependence of foam mobility reduction

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT

	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is optional in runs using the foam model, and supplies tables of data to describe the pressure dependence of the foam mobility reduction factor. See "Foam model" in the *ECLIPSE Technical Description* for further information.

The data comprises NTPVT (see keyword [TABDIMS](#)) tables of mobility data. Each table consists of two columns of data, terminated with a slash (/).

- The oil phase pressure.  
The values should increase monotonically down the column.  
UNITS: barsa (METRIC), psia (FIELD), atma (LAB)
- The corresponding pressure modifier on the foam mobility reduction factor,  $M_p(P)$ . The values are usually between zero and 1.

0.0 leaves the mobility reduction factor unaffected

1.0 returns the gas mobility to the pure gas mobility.

$$MP = (1 - M(C_{\text{foam}})) \cdot M_p(P) + M(C_{\text{foam}})$$

where

$MP$  is the mobility reduction factor with the pressure effect

$M(C_{\text{foam}})$  is the original reduction factor as a function of foam concentration ([FOAMMOB](#) keyword)

$M_p(P)$  is the pressure dependency function

$P$  is the oil pressure.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NPPVT (see keyword [TABDIMS](#)).

### Example

With NTPVT=1 and NPPVT≥3:

```
FOAMMOBP
--
-- Pressure      Pressure modifier
--
   3000           0.0
   5000           0.0
  10000           0.8 /
```

# FOAMMOBS Shear dependence of foam mobility reduction

	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is optional in runs using the foam model, and supplies tables of data to describe the shear dependence of the foam mobility reduction factor. See "Foam model" in the *ECLIPSE Technical Description* for further information.

The data comprises NTPVT (see keyword [TABDIMS](#)) tables of mobility data. Each table consists of two columns of data, terminated with a slash (/).

1. The gas phase flow velocity.

The values should increase monotonically down the column.

The first entry should be 0.0.

UNITS: m/day (METRIC), ft/day (FIELD), cm/hr (LAB)

2. The corresponding shear modifier on the foam mobility reduction factor,  $M_s v$ .

The values are usually between zero and 1.

0.0 leaves the mobility reduction factor unaffected

1.0 returns the gas mobility to the pure gas mobility.

$$MF = (1-MP)M_s(v) + MP$$

where

MF is the final mobility reduction factor

MP is the mobility reduction factor including the pressure effect (from the [FOAMMOB](#) and [FOAMMOBP](#) keywords)

$M_s(v)$  is the shear dependency function

$v$  is the gas velocity.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NPPVT (see keyword [TABDIMS](#)).

## Example

With NTPVT=1 and NPPVT ≥4:

```

FOAMMOBS
--
-- Velocity          Shear modifier
--
    0.0              0.0
    0.02             0.0
    0.04             1.0
    0.06             1.0 /
    
```

## FOAMOPTS Foam Model options

	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword consists of two items which define the form of the foam model:

1. Transport phase for foam surfactant.

**GAS** Specifies that the foam is transported in the gas phase.

**WATER** Specifies that the foam is transported in the water phase.

DEFAULT: GAS

2. Gas mobility reduction factor model.

**TAB** Specifies that the gas mobility reduction factor is to be modeled using the tabulated functions of gas mobility reduction versus concentration (**FOAMMOB** keyword) and optionally versus shear (**FOAMMOBS** keyword) and pressure (**FOAMMOBP** keyword). This tabular form of modeling the gas mobility reduction factor is available with either **GAS** or **WATER** specified as the transport phase for foam.

**FUNC** Specifies that the gas mobility reduction factor is to be modeled using the functional form in which the mobility reduction factor is defined to be a combination of the mobility reduction factors due to a reference mobility factor (**FOAMFRM** keyword) and a function of surfactant concentration (**FOAMFSC** keyword), water saturation (**FOAMFSW** keyword), oil saturation (**FOAMFSO** keyword) and capillary number (**FOAMFCN** and **FOAMFST** keywords). This functional form of modeling the gas mobility reduction factor is only available if the transport phase for foam is specified to be **WATER**.

DEFAULT: TAB

This keyword is only relevant if the **FOAM** option has been specified in the **RUNSPEC** section.

See "[Foam model](#)" in the *ECLIPSE Technical Description* for further information.

### Example

```
FOAMOPTS
WATER FUNC /
```

## FOAMROCK Specifies the foam-rock properties

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTSFUN (see keyword [TABDIMS](#)) tables specifying the rock properties which are required for the foam model. Each table requires the following items of data, terminated by a slash (/).

1. The adsorption index to be used for this rock type.

Possible values for the adsorption index are 1 or 2.

If a value of 1 is selected, then the foam adsorption isotherm is retraced whenever the local foam concentration in the solution decreases.

If a value of 2 is selected, then no foam desorption may occur.

DEFAULT: 1

2. The mass density of this rock type at reservoir conditions.

This quantity is used in the calculation of the foam loss due to adsorption.

UNITS: kg/rm<sup>3</sup> (METRIC), lb/rb (FIELD), gm/rcc (LAB)

Note that if the Polymer or Surfactant Models are being used, then the mass density may be ignored. The mass density will be taken from the first keyword present in the following hierarchy: [PLYROCK](#), [SURFROCK](#), [FOAMROCK](#).

See also keyword [FOAMADS](#) and "[Foam model](#)" in the *ECLIPSE Technical Description* for further information.

---

**Note:** When non-zero initial foam concentrations are specified via the [SFOAM](#) or [TVDP](#) keywords, the concentration specified in that keyword will be honored and extra adsorped foam is added to the rock so that it is in equilibrium with the input fluid concentration.

---

### Example

With NTSFUN=3:

```
FOAMROCK
2 2381 /
2 2342 /
1 2520 /
```

## FORMFEED Sets the formfeed character in the print file

x	SOLUTION
x	SUMMARY
x	SCHEDULE

This keyword allows the user to specify how ECLIPSE should insert formfeeds in the Print and Run Summary files. The keyword is optional, the default being standard FORTRAN carriage control. The most appropriate place for the keyword is at the top of the dataset.

The keyword should be followed by a single integer, terminated by a slash (/), to select one of the following options:

1. Standard FORTRAN carriage control
2. Formfeed character, ASCII(12)
3. No formfeed

DEFAULT: 1 (standard FORTRAN carriage control)

### Example

Set the formfeed to a formfeed character for a laserjet printer.

```
FORMFEED
 2 /
```

## FORMOPTS Formulation options

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword allows the user control of some formulations options typically associated with compositional effects in ECLIPSE 300. These options should only make very small differences to the simulator output but in some cases may significantly affect the performance of the simulation. In future versions of the program the default options may change, with this keyword available for back compatibility.

The keyword should be followed by a list of options required. The default is for all these options to be switched off.

The data should be terminated by a slash (/).

---

**Note:** From the 2002A release onwards HCSCAL has been turned on by default. Back compatibility can be enforced by using the NOHCSCAL keyword.

---

**HCSCAL** If the HCSCAL option is active an extra scaling of the hydrocarbon relative permeabilities is performed. In a compositional model, oil can change to gas without passing through a two-phase state. The hydrocarbon relative permeabilities are interpolated to give a smooth transition between the two states (see "[Near critical oil and gas relative permeabilities](#)" in the *ECLIPSE Technical Description*). However, if the gas relative permeability at connate water differs from the oil relative permeability (note that  $K_{rog}$  has to equal  $K_{row}$  at connate water) then a discontinuity can occur in the hydrocarbon relative permeability as a system becomes two phase. This discontinuity can be avoided by making  $K_{rg}$  equal  $K_{ro}$  at connate water, which is not an unreasonable assumption. Alternatively, the HCSCAL option scales  $K_{rg}$  near the critical point in an analogous manner to the hydrocarbon relative permeability, again avoiding a discontinuity.

**NOHCSCAL** Turns off the HCSCAL option

The HCSCAL option will be turned off automatically if the **ODD3P** relative permeability and capillary pressure hysteresis model is selected or if the Surfactant Model is active (see "[Surfactant model](#)" in the *ECLIPSE Technical Description*). This is equivalent to specifying NOHCSCAL.

**SINGLEP** The SINGLEP option modifies the densities used in the hydrostatic term for flow between two cells when the fluid is a single phase hydrocarbon. By default the code labels a single phase hydrocarbon as oil or gas, depending on the fluid critical temperature as estimated by the Li correlation. The density for each phase is then taken as the saturation weighted density of the two cells between which a flow is being calculated. In the case of a single phase hydrocarbon this leads to discontinuities as a cell changes state, whereas physically we know the fluid is a continuous single phase. The SINGLEP option treats a single phase hydrocarbon as just that, with the density taken to be the (saturation weighted) hydrocarbon density without worrying if the hydrocarbon is an oil or a gas. Note that two phase behavior is unaltered.

The SINGLEP option cannot be used in thermal runs.

**NOPCSPT** The NOPCSPT (No Pc Split) option modifies how the gas-oil capillary pressure is treated. By default ECLIPSE 300 (only in the compositional mode) splits the gas-oil capillary pressure between the oil and gas phases based on the saturation:

$$P_{oil} = P - P_{cog} \times \left( \frac{S_g}{S_o + S_g} \right)$$

$$P_{gas} = P + P_{cog} \times \left( \frac{S_o}{S_o + S_g} \right)$$

Essentially, the solution variable pressure,  $P$ , is the hydrocarbon pressure rather than the phase pressure for either gas or oil. This prevents many of the discontinuities associated with the single phase transition of oil to gas; given a phase relabeling the phase pressure will remain the same. However because of the upwinding of mobilities in the flow, discontinuities can still occur in the flows

If the `NOPCSEPT` option is used then the capillary pressure is assumed to be associated with the gas phase:

$$P_{oil} = P$$

$$P_{gas} = P + P_{cog}$$

This option is not recommended in compositional cases where the fluid is likely to reach a state near to the critical point.

Note that this is the assumption in ECLIPSE 100.

The `NOPCSEPT` option will be turned on automatically if the `ODD3P` relative permeability and capillary pressure hysteresis model is selected.

## Example

Use the single phase density options, but leave the default capillary pressure treatment.

```
FORMOPTS
SINGLEP /
```

## FREEZEPC **Freeze all capillary pressures in a run**

	<b>ECLIPSE 100</b>
x	<b>ECLIPSE 300</b>
	<b>SPECIAL</b>
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword selects the FREEZEPC solution option. This is useful in [IMPES](#) or [AIM](#) runs which involve large capillary pressure. These effectively turns saturation variation into pressure variation, and can cause instability. This type of instability is not related to well or cell throughputs, and can cause an instability to build up from a quiescent initial solution.

FREEZEPC is not used by default in any mode, and the rate at which capillary pressures may change is limited in IMPES and AIM modes (by the [DPCDT](#) keyword); this is usually sufficient to prevent stability problems.

FREEZEPC contains no items.

## FRICITION

### Enables the wellbore friction option

x	ECLIPSE 100
	ECLIPSE 300

## Specify miscibility variation with surface tension

This provides the variation of the relative permeability miscibility factor  $F_K$  with surface tension.  $F_K$  is the weight factor for the **immiscible** contribution (see equation 3.73), and should increase with increasing surface tension.

If FVST is not entered the miscibility factor will be obtained using the Coats expression:

$$F_K = \left( \frac{\sigma}{\sigma_0} \right)^N \quad \text{Eq. 3.73}$$

where  $N$  is the exponent set using [MISCEXP](#) and defaulted to 0.25.

In either case  $F_K$  is used to define the oil and gas relative permeability curves:

$$K_r = F K_r^{\text{imm}} + (1-F) K_r^{\text{mis}} \quad \text{Eq. 3.74}$$

The two contributions are scaled so that they both have the same critical saturation, given by  $FS_{\text{cr}}^{\text{imm}}$ .

FVST avoids the use of both  $P$  and  $\sigma_0$  in relative permeability calculations.  $\sigma_0$  is still used in modifying capillary pressures:

$$P_{\text{cog}}^{\text{corr}} = \left( \frac{\sigma}{\sigma_0} \right) P_{\text{cog}} \quad \text{Eq. 3.75}$$

The number of tables should be equal to the number of pressure tables in the run - one is required for each pressure table ([PVTNUM](#)) region.

Items in each table:

1. The surface tension.  
UNITS: dynes/cm (METRIC), dynes/cm (FIELD), dynes/cm (LAB), dynes/cm (PVT-M)
2. The miscibility factor  $F_K$ .  
UNITS: dimensionless

A table is terminated with a slash (/).

### Example

```

FVST
0 0.0
5 0.25
10 0.5
20 1.0
40 1.0 /

```

## FWELLS

### Fractured well completion option

If this keyword is entered in the RUNSPEC section, it is possible to request fracture completions (FX and FY) in the [WELLCOMP](#) keyword (item 12) or the [COMPDAT](#) keyword (item 13).

The keyword FWELLS contains no items.

This keyword specifies that the permeability tensor is assumed to be input as a diagonal tensor on the basis defined by the cell tangent vectors. It is supplied only for FrontSim compatibility.

This is equivalent to using item 2 in the [TBASIS](#) keyword as long as the off-diagonal coefficients, for example [PERMXY](#), are zero.

See "[Tensor permeability](#)" in the *ECLIPSE Technical Description* for further information.

**Example**

```
GADJUST
```

## GADVANCE Assign advance import gas to a group

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword assigns a supply of advance import gas to a group supplying gas for reinjection (see keywords [GINJGAS](#), [WINJGAS](#), [GRUPINJE](#) and [WELLINJE](#)). When gas from this group is reinjected, the advance gas will be used for reinjection prior to the gas produced by this group from the reservoir. If the reinjection requirements can be met by the advance gas stream alone, then no produced gas is reinjected and all of it remains available for fuel and/or sales usage. If the advance and available produced gas streams together are not sufficient to satisfy the reinjection requirements, make-up gas, if specified for the injection group or well, is used to make up the shortfall.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated by a slash (/). The set of records must be ended by a blank record, containing only a slash.

- Group name or group name root,  
or FIELD (for import to the Field group)  
  
A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.
- The name of the well stream (defined using the [WELLSTRE](#) keyword) which defines the composition of the advance gas.
- The maximum rate at which advance gas can be supplied.

UNITS: sm<sup>3</sup>/day (METRIC), Mscf/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

By setting [OPTIONS3item 30](#), an alternative 'mixing tank' treatment may be invoked, where the advance gas is mixed with the produced gas and gas from this 'mixing tank' is reinjected. The fraction of advance gas in this mixture is equal to the ratio of the specified advance gas rate (item 3) to the sum of the specified advance gas rate and the available gas production rate. With this option, the advance gas is not used in preference to the produced gas.

If advance gas is used, the injection calculation may have to be iterated to match the injection gas composition with the injection rate (see keyword [GCONTOL](#)).

---

**Note:** Advance gas is assigned to the source group supplying the gas, while make-up gas is assigned to the group or well having the injection target.

Also, advance gas cannot be used for fuel and sales; it can only be used for injection.

---

### Example

Advance gas is assigned to group GA1 at a maximum rate of 10000 Mscf/day.

```
GADVANCE
GA1 STR1 10000 /
/
```

## GAS

	SCHEDULE

## Run contains GAS

This keyword indicates that a run contains gas. This may be specified whenever a gas phase exists or could exist.

In ECLIPSE 300, this keyword is automatically supplied for any compositional mode run.

The keyword GAS contain no items.

## GASADCO Initial coal gas adsorbed concentration

	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies the initial coal gas concentration for each grid cell. The keyword should be followed by  $N_x \cdot N_y \cdot N_z \cdot N_c$  values. The data field should be terminated by a slash (/).

UNITS:  $\text{sm}^3/\text{m}^3$  (METRIC),  $\text{Mscf}/\text{ft}^3$  (FIELD),  $\text{scc}/\text{cc}$  (LAB)

Grid blocks are ordered with the X axis index cycling fastest (from 1 to NDIVIX), followed by the Y axis index (from 1 to NDIVIY), and then the Z axis index (from 1 to NDIVIZ) for each component. NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword [DIMENS](#). Repeat counts may be used for repeated values (for example 115\*0.22). Note that spaces must not be inserted on either side of the asterisk (\*).

The keyword is not compatible with the instant adsorption model ([CBMOPTS](#)).

Only values for coal cells are used. The keyword resets the coal concentration but YMF values still need to be specified. The YMF values are however only used if [GASADEC](#) or [GASSATC](#) are used.

Note that the keyword cannot be used together with [GASCONC](#).

### Example

With NDIVIX=5, NDIVIY=4, NDIVIZ=10 and NCOMPS=2

```
GASADCO
--matrix fracture
100*86.0 100*0.0 --component 1
100*43.0 100*0.0 --component 2/
```

	SCHEDULE

This keyword specifies the initial equilibrium coal gas concentration for each grid cell. The keyword should be followed by  $N_x \cdot N_y \cdot N_z \cdot N_c$  values. The data field should be terminated by a slash (/).

UNITS:  $\text{sm}^3/\text{m}^3$  (METRIC),  $\text{Mscf}/\text{ft}^3$  (FIELD),  $\text{scc}/\text{cc}$  (LAB)

Grid blocks are ordered with the X axis index cycling fastest (from 1 to NDIVIX), followed by the Y axis index (from 1 to NDIVIY), and then the Z axis index (from 1 to NDIVIZ) for each component. NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword [DIMENS](#). Repeat counts may be used for repeated values (for example 115\*0.22). Note that spaces must not be inserted on either side of the asterisk (\*).

This information is used to scale the Langmuir isotherm, as specified by the [LANGMEXT](#) or the [LANGMUIR](#) keyword, at the initial pressure and composition in the reservoir. This means that a non-zero initial composition needs to be specified for each component in order to perform the scaling. If the component is not present initially, the keyword [GASADCO](#) can be used to set the initial coal gas concentration.

Only values for coal cells are used. Note that the composition (YMF) and pressure value of the coal cell is used and not the connected pore volume (fracture) composition and pressure.

Note that the keyword cannot be used together with [LANGMULT](#), [LANGMULC](#) or [GASSATC](#).

### Example

With NDIVIX=4, NDIVIY=5, NDIVIZ=10 and NCOMPS=2

```
GASADEC
--matrix fracture
100*86.0 100*0.0 --component 1
100*43.0 100*0.0 --component 2/
```

## GASBEGIN Starts set of keywords for annual scheduling file

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

GASBEGIN denotes the start of the set of keywords to be placed in the annual scheduling file, for use with the gas field operations model (see "[Gas field operations model](#)" in the *ECLIPSE Technical Description*). This keyword has no associated data.

All keywords entered between the keywords GASBEGIN and [GASEND](#) are placed on the Annual Scheduling File. If the GASBEGIN - GASEND pair are subsequently entered again, the contents of the Annual Scheduling file is replaced with the new set of intervening keywords. The Annual Scheduling file can be emptied by following immediately with GASEND.

### The annual scheduling file

The annual scheduling file is designed for use with the Gas Field Operations Model, to enable the engineer to change well controls and request printed reports during the year, at times other than the start or end of a contract period.

The keywords [GASYEAR](#) and [GASPERIO](#) advance the simulation through one or more complete contract years or contract periods. Well operations can be performed in the usual manner at the end of a contract period, and a printed report is generated at the end of each contract period depending on the [RPTSCHED](#) switches. But in order to perform well operations or request printed reports during a contract period, an annual scheduling file must be set up.

To set up an annual scheduling file, enter the keywords defining the required operations before the [GASYEAR](#) or [GASPERIO](#) keyword on the input data file, bracketed with the keywords GASBEGIN and GASEND. When ECLIPSE reads the keyword GASBEGIN during the simulation, it copies the subsequent keywords up to GASEND to a separate file that it sets up automatically. It does not read the keyword data and perform the appropriate actions until it reads the [GASYEAR](#) or [GASPERIO](#) keyword. The keywords in the annual scheduling file is then read and processed each year while the simulation is being advanced with the [GASYEAR](#) or [GASPERIO](#) keyword. The contents of the file are ignored if the simulation is being advanced with a [DATES](#), [TIME](#) or [TSTEP](#) keyword.

---

**Note:** Please ensure that the keyword data (but not the keyword itself) is indented by at least one space from the left hand margin.

---

When the [GASYEAR](#) or [GASPERIO](#) keyword instructs ECLIPSE to advance the simulation through a contract year or period, ECLIPSE reads the keyword data on the annual scheduling file and performs the required actions at the appropriate times. The actions can be requested at the beginning of each month named with the keyword [GASMONTH](#). If the contract period is solved in two or more passes (to work out the DCQ), the Annual Scheduling file is rewound and read from the beginning of the period again at the start of each pass.

Once an Annual Scheduling file has been set up, ECLIPSE reads its keywords and perform the required actions during **every** subsequent contract period specified with a [GASYEAR](#) or [GASPERIO](#) keyword. Thus if the same actions are to be performed every year, the Annual Scheduling file need only be set up once. But if the actions must be changed during the simulation, a new annual scheduling file must be set up. The new file is set up in the same way as before; bracketing the required keywords with GASBEGIN and [GASEND](#). The contents of the original file are erased, and replaced with the new set of keywords. If no more actions are required, the Annual Scheduling file can be emptied by following GASBEGIN immediately with GASEND.

In a restart run, the annual scheduling file must be set up again using GASBEGIN and GASEND; it is **not** automatically carried over in the Restart file. If you forget to do this, ECLIPSE issues an error message, as

it detects that the base run had an Annual Scheduling file but there was no such file in the restart run. If you no longer need an Annual Scheduling file in the restart run, you must still set up an empty one.

## Allowed keywords for the annual scheduling file

Only a subset of the ECLIPSE keywords is allowed on the Annual Scheduling file. These are:

Restriction	Keyword	Description
	BRANPROP	to change branch properties when using the extended network model
E100	DEBUG	to change debug switches.
E300	DEBUG3	to change debug switches.
Compulsory	GASEND	to mark the end of the annual scheduling file.
	GASMONTH	to indicate the time of the next set of operations.
	GCONPRI	to change group limits under prioritization group control.
	GCONPROD	to change group limits and group guide rates under guide rate group control.
E100	GCONSUMP	to change group gas consumption rates.
E300	GRUPFUEL	to change group gas fuel rates.
	GRUPNET	to change the VFP table or ALQ value on network branches, or to change the pressure of an existing fixed pressure node.
	GRUPTARG	to change individual group rate limits or guide rates.
	GRUPTREE	to change the group hierarchy
	GSATINJE	to change injection rates of satellite groups.
	GSATPROD	to change production rates of satellite groups.
E100	NCONSUMP	to change gas consumption at nodes in the extended network model.
	NEXTSTEP	to limit the length of the next timestep, for example to reduce it after some wells have been opened.
	NODEPROP	to change nodal properties in the extended network model.
E300	RPTPRINT	to change switches for printed reports.
E100	RPTSCHED	to change switches for printed reports. The following report switches will be ignored here: <ul style="list-style-type: none"> <li>'RESTART' - restart files are only written at the end of a contract period</li> <li>'CPU' - the timer switch setting must not be altered within the annual scheduling file.</li> </ul>
E300	TSCRIT	to modify timestepping criteria.
	TUNING	to modify tuning parameters, for example maximum step size.
	WEFAC	to change well efficiency factors.
	WELDEBUG	to change well debug switches.
	WELOPEN	to open or close wells or connections.
	WELPRI	to change well priorities for prioritization group control.
	WELTARG	to change well operating limits.

Restriction	Keyword	Description
	WGRUPCON	to change well guide rates for guide rate group control.

## Example

For a contract year beginning on 1<sup>st</sup> September

Start the set of keywords to be placed on the annual scheduling file

```
GASBEGIN
```

Remove the summer downtime factor on well P2

```
WEFAC
P2 1.0 /
/
```

Set output switches so that only a well report will be generated

```
RPTSCHED
'WELLS=2' 'SUMMARY=2' 'WELSPECS' /
```

Advance the simulation to 1<sup>st</sup> Jan., and request a report

```
GASMONTH
JAN YES /
```

Advance the simulation to 1<sup>st</sup> June, without a report

```
GASMONTH
JUN NO /
```

From 1<sup>st</sup> June, impose a summer downtime factor on well P2

```
WEFAC
P2 0.8 /
/
```

Restore pressure and saturation switches for the end of contract year report

```
RPTSCHED
'PRES' 'SWAT' 'SGAS' 'WELLS=2' 'SUMMARY=2'
'WELSPECS'
```

End the annual scheduling file

```
GASEND
```

Simulate 3 contract years using this annual scheduling file

```
GASYEAR
3 100000 ACQ /
```

Subsequent years do not have the summer downtime factor on well P2, but still require a report on 1<sup>st</sup> January.

First remove the summer downtime factor imposed in the last contract

```
WEFAC
P2 1.0 /
/
```

Set up a new annual scheduling file with just the winter report

```
GASBEGIN
RPTSCHED
'WELLS=2' 'SUMMARY=2' 'WELSPECS' /
GASMONTH
JAN YES /
RPTSCHED
'PRES' 'SWAT' 'SGAS' 'WELLS=2' 'SUMMARY=2'
'WELSPECS' /
GASEND
```

Simulate 4 more contract years using the new annual scheduling file

```
GASYEAR
4 1* ACQ /
END
```

## GASCCMP

**GASSATC or GASCONC component number**

This keyword is used to specify a component number to be used with the [GASSATC](#) or the [GASCONC](#) keyword. If there is only one component (NCOMPS=1) the keyword is optional.

**Example**

```
GASCCMP
2 /
```

	<b>ECLIPSE 100</b>

## GASCONC Initial coal gas concentration

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by one real number for every matrix grid block, specifying the initial gas concentration in the coal. The data field should be terminated by a slash (/).

UNITS:  $\text{sm}^3/\text{m}^3$  (METRIC),  $\text{Mscf}/\text{ft}^3$  (FIELD),  $\text{scc}/\text{cc}$  (LAB)

Grid blocks are ordered with the X axis index cycling fastest (from 1 to NDIVIX), followed by the Y axis index (from 1 to NDIVIY), and finally the Z axis index (from 1 to NDIVIZ). NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword DIMENS. Repeat counts may be used for repeated values (for example 115\*0.22). Note that spaces must not be inserted on either side of the asterisk (\*). Data need only be supplied for the matrix cells, that is the upper half of the grid.

Both GASCONC and GCVD (ECLIPSE 100) are entirely optional. If neither of these keywords is present, the coal gas concentration is taken as the equilibrium concentration for the corresponding fracture pressure.

The initial coal gas concentration should not be set above the initial equilibrium value. ECLIPSE issues a warning if it is.

See the [GCVD](#) keyword.

ECLIPSE 100

ECLIPSE 300

GASCONC can only be used to specify the initial coal gas concentration for one component which is given by the keyword [GASCCMP](#). The keyword [GASADCO](#) can be used for the general case. Note that the keyword is not compatible with the instant adsorption model ([CBMOPTS](#)). Only values for coal cells are used. The keyword resets the coal concentration but YMF values still need to be specified. The YMF values are however only used if [GASADEC](#) or [GASSATC](#) are used. Note that the keyword cannot be used together with [GASADCO](#).

### Example

With NDIVIX=8, NDIVIY=6, NDIVIZ=10 specified in RUNSPEC keyword [DIMENS](#):

```
GASCONC
48*89.1 48*87.3 48*85.1 48*85.0 48*85.0 /
```

## GASEND

### Ends set of keywords for annual scheduling file

GASEND denotes the end of the set of keywords to be placed in the annual scheduling file, for use with the gas field operations model. This keyword has no associated data.

See keyword [GASBEGIN](#) for a more detailed description of the Annual Scheduling file.

## GASFCOMP Automatic compressors for standard network option

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

When the gas field operations model is run in conjunction with the standard network option, automatic compressors can be declared with this keyword. One compressor is allowed in each branch of the network. ECLIPSE switches on compression whenever necessary to enable the field to meet its gas production target. The compressors are turned off whenever the target rate decreases to see if the field can meet it without them. The automatic compressors are also turned on while calculating the field's delivery capacity.

The Simple option for automatic compressors has just two states: all compressors on and all compressors off. Each compressor is defined by a single record of data.

The Extended option allows each compressor to have up to five levels of compression. The compressors will be turned on or switched to a higher compression level individually in a predefined order until the field can make its production target. The order in which these events occur is determined by an action sequence number. Compression levels with sequence number 1 are switched on first, followed by levels with sequence number 2, and so on in ascending order until either the rate target is met or all compressors are operating at their highest defined levels. The current operating level of each compressor can be written to the Summary file with the [SUMMARY](#) section keyword [GMCPL](#). All compressors are switched to their highest defined level while calculating the field's delivery capacity. The Extended option requires a small amount of extra storage, which must be reserved by entering 'YES' in item 1 of keyword [GASFIELD](#) in the RUNSPEC section. Each compression level in each compressor is defined by a single record of data.

See "[Gas field operations model](#)" and "[Network option](#)" in the *ECLIPSE Technical Description* for further details.

---

**Note:** If you are using the Extended Network option (keyword [NETWORK](#) in the RUNSPEC section) then automatic compressors must be defined with the [NETCOMPA](#) keyword instead of [GASFCOMP](#). The Extended Network compressors defined with keyword [NETCOMPA](#) have most of the functionality of the extended compressors defined with [GASFCOMP](#).

---

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/). The set of records must end with a blank record, containing only a slash (/).

- Group name or group name root whose network pipeline contains the compressor
 

The compressor associated with this group influences the pressure drop in the pipeline between this group and its parent group.

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.
- VFP table number to use when the compressor is operating at the level specified in item 5
 

When the compressor is off, the table number specified in keyword [GRUPNET](#) is used.

A zero or negative number means that the same VFP table number specified in [GRUPNET](#) is used.

DEFAULT: 0
- Artificial Lift Quantity to use when the compressor is operating at the level specified in Item 5
 

When the compressor is off, the ALQ value specified in keyword [GRUPNET](#) will be used.

UNITS: These depend on what the ALQ was meant to represent when the table was created. Refer to section "[Record 6:ALQ values](#)" in the description of keyword [VFPPROD](#).

DEFAULT: 0.0

4. Compressor's gas consumption rate (used to fuel the compressor) when operating at the level specified in item 5

When the compressor is on, the extra gas consumption rate is added to the fixed value specified in [GCONSUMP](#), if any.

UNITS: sm<sup>3</sup>/day (METRIC), Mscf/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: 0.0

5. The compression level that items 2 - 4 represent

An integer between 1 and 5. A number greater than 1 may be entered only if you are using the extended compressor option (see keyword [GASFIELD](#) in the RUNSPEC section).

DEFAULT: 1

6. The action sequence number at which the compressor switches to this compression level

An integer  $\geq 0$ . A number greater than 1 may be entered only if you are using the extended compressor option (see keyword [GASFIELD](#) in the RUNSPEC section). A zero value makes this level inactive.

Two levels in the same compressor cannot share the same action sequence number.

DEFAULT: 1

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

See also the [COMPOFF](#) keyword.

## Examples

### Example 1

To place a single-level compressor in the pipeline from PLAT-A (simple compressor option):

```
GASFCOMP
-- GROUP  NEW VFP  NEW  GAS      COMP  SEQUENCE
-- NAME   TAB NO  ALQ  CONSUMP LEVEL  NUMBER
  PLAT-A   1*    50   1000   /
/
```

### Example 2

To declare a pair of two-level compressors in the pipelines from PLAT-A and PLAT-B, and have them turned on in sequence (extended compressor option):

```
GASFCOMP
-- GROUP  NEW VFP  NEW  GAS      COMP  SEQUENCE
-- NAME   TAB NO  ALQ  CONSUMP LEVEL  NUMBER
  PLAT-A   1*    50   1000   1     1     /
  PLAT-A   1*   100   1500   2     2     /
  PLAT-B   1*    50   1000   1     3     /
  PLAT-B   1*   100   1500   2     4     /
/
```

## GASFDECR Decrement for FIELD gas contract

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The GASFDECR keyword enables a monthly adjustment to be made to the field gas production rate for the second pass of the gas field operations model. The adjusted rate at which the field is produced is then  $DCQ \times PROFILE - DECREMENT$ .

The GASFDECR can be used in conjunction with the GASFTARG keyword in which case the field is produced at the lesser of  $DCQ \times PROFILE - DECREMENT$  and the rate specified by the GASFTARG data items.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC), Mscf/day (FIELD), scc/hr (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

(ECLIPSE 100 only) If item 1 of DCQDEFN is set to ' ENERGY ':

UNITS: kJ/day (METRIC), Btu/day (FIELD), J/hr (LAB), kJ/day (PVT-M)

See "Gas field operations model" in the *ECLIPSE Technical Description* for further details.

The GASFDECR keyword is followed by 12 numbers, terminating with a slash (/). The decrements for defaulted months are set to zero.

### Example

```
GASFDECR
-- JAN FEB MAR APR MAY JUN JUL AUG SEP OCT NOV DEC
  2*1000.0 3*          2*1000.0 3*          2*500.0 /
```

## GASFDEL C Delivery capacity definition for Gas Field Operations Model

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The delivery capacity is defined as the sales gas production rate that would ensue immediately after the removal of all group and field gas rate targets and limits, at current grid block conditions. The `GASFDEL C` keyword may be used to specify whether or not any group or field oil or water rate limits, and any rate limits on the wells themselves, should also be removed when calculating the delivery capacity.

The delivery capacity is calculated at every timestep after the first entry of the `SWINGFAC` keyword which effectively turns this facility on.

See "[Gas field operations model](#)" in the *ECLIPSE Technical Description* for further details.

The keyword is followed by a single integer (either 1 or 2), terminated with a slash (/).

1. Remove only the group and field gas rate targets and limits.  
Honor all other limits, including any well rate and pressure limits.
2. Remove all well, group and field rate limits.
3. Honor only the well BHP and THP limits. (If the wells have drawdown limits, these will be honored too if `YES` has been entered in item 4 of keyword `WELDRAW`.)

If this keyword is not used, definition number 1 will be assumed.

---

**Note:** Definition 2 is not allowed when there are any contract groups using the `FIX2` option in item 3 of keyword `GDCQ`, for multiple contract groups.

---

### Example

```
GASFDEL C
2 /
```

## GASFIELD Enables special options in the Gas Field Operations Model

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is required if the gas field operations model is to be used with:

- either the extended compressor option (see keyword [GASFCOMP](#)),
- or multiple contract groups (defined with keyword [GSWINGF](#)),
- or the accelerated iteration scheme for calculating the DCQ in the first pass of the contract period (see "[Calculating the DCQ value](#)" in the *ECLIPSE Technical Description*, and item 8 of keyword [GASYEAR](#) or item 9 of [GASPERIO](#)).

The keyword may be omitted if the gas field operations model is used without these options. (See "[Gas field operations model](#)" in the *ECLIPSE Technical Description* for further details.)

---

**Note:** The extended compressor option need **not** be requested when the extended network option is being used (see "[The extended network model](#)" in the *ECLIPSE Technical Description*). Compressors in the extended network option (defined with keyword [NETCOMPA](#)) contain most of the functionality of the extended compressor option.

---

The keywords should be followed by some or all of the following items to indicate whether these special options are going to be used, followed by a slash (/).

1. Flag to indicate whether or not the extended compressor option or multiple contract groups are required
  - YES The extended compressor option is required, and/or multiple contract groups are defined
  - NO Otherwise
  - DEFAULT: NO
2. Flag to indicate whether the accelerated iteration scheme for calculating the DCQ in the first pass of the contract period is to be used.
  - YES The accelerated iteration scheme is used.
  - NO The original (pre-96A) algorithm is used.
  - DEFAULT: NO

### Example

```
GASFIELD
YES YES /
```

## GASFTARG Production rate for FIELD gas contract

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The GASFTARG keyword specifies a gas rate at which the field is to be produced in the second pass of the gas field operations model.

For months in which a rate is specified in the GASFTARG keyword the field is produced at the lesser of  $DCQ \times PROFILE$  and the specified rate. For months in which GASFTARG is defaulted the field is produced at  $DCQ \times PROFILE$ . The GASFTARG keyword can also be used in conjunction with the [GASFDECR](#) keyword.

UNITS:  $sm^3/day$  (METRIC), Mscf/day (FIELD), scc/hr (LAB),  $sm^3/day$  (PVT-M)

In ECLIPSE 100 only. If item 1 of [DCQDEFN](#) is set to 'ENERGY':

UNITS: kJ/day (METRIC), Btu/day (FIELD), J/hr (LAB), kJ/day (PVT-M)

See "[Gas field operations model](#)" in the *ECLIPSE Technical Description* for further details.

The GASFTARG keyword is followed by 12 numbers, terminating with a slash (/).

### Example

```

GASFTARG
-- JAN  FEB  MAR  APR  MAY  JUN  JUL  AUG  SEP  OCT  NOV  DEC
   2*50000.0  3*                2*20000.0  3*                2*50000.0  /

```

## GASMONTH Sets month pointer in annual scheduling file

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

GASMONTH is used in the annual scheduling file of the gas field operations model, to set the time of the next set of operations specified by the subsequent keywords. It can also be used to request a printed report to be written at specified times each year.

See keyword [GASBEGIN](#) for a more detailed description of the annual scheduling file.

The GASMONTH keyword should be followed by two items, terminated with a slash (/):

1. Name of month - three letters

JAN, FEB, MAR, APR, MAY, JUN, JUL, AUG, SEP, OCT, NOV, DEC

The operations defined by the subsequent keywords will be performed at the beginning of the specified month.

(JLY is an acceptable alternative to JUL.)

2. Write a printed report? - YES or NO

(The word may be abbreviated, only the first character is significant)

YES A report for the timestep ending at the start of the specified month will be written to the Print file. The contents will depend on the current values of the [RPTSCHED](#) or [RPTPRINT](#) switches.

NO No report will be written to the Print file at this time.

DEFAULT: NO

The GASMONTH keyword is only valid when bracketed by the keywords [GASBEGIN](#) and [GASEND](#). If more than one GASMONTH keyword is present, they must be in the correct order within the year starting from the beginning of the first contract period.

### Example

For a contract year beginning on the 1<sup>st</sup> September:

```
GASBEGIN
GASMONTH
SEP Y /
```

(The GASMONTH keyword was not necessary here. The pointer is already at 1<sup>st</sup> September, the beginning of the contract year. A report is always printed at the end of each contract period. This keyword therefore has no effect here.)

Enter actions to be performed on 1<sup>st</sup> September.

```
Scheduling keywords...
```

Advance pointer to 1<sup>st</sup> December, the beginning of the winter quarter. No report is required.

```
GASMONTH
DEC N
```

Enter actions to be performed on 1<sup>st</sup> December.

```
Scheduling keywords...
```

Advance pointer to 1<sup>st</sup> March, the beginning of the spring quarter. Print a report for the timestep ending 1<sup>st</sup> March, the end of the winter quarter.

```
GASMONTH  
MAR Y /
```

Enter actions to be performed on 1<sup>st</sup> March.

```
Scheduling keywords...
```

Advance pointer to 1<sup>st</sup> June, the beginning of the summer quarter. No report is required.

```
GASMONTH  
JUN N /
```

Enter actions to be performed on 1<sup>st</sup> June.

```
Scheduling keywords...
```

End the annual scheduling file.

```
GASEND
```

---

**Note:** In this example, the last valid GASMONTH date is AUG, as the contract year ends at the end of that month. A SEP entry is interpreted as the beginning of the contract year, and would be out of order at the end of the annual scheduling file.

---

## GASPERIO Advances simulator over ‘n’ gas field contract periods

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The GASPERIO keyword can be used instead of [DATES](#), [TIME](#) or [TSTEP](#) to advance the simulation over an integral number of contract periods, when running the gas field operations model (see "[Gas field operations model](#)" in the *ECLIPSE Technical Description*). The contract period is the time over which the DCQ must remain fixed until the next review; it may be a year, or any number of months that is a factor of 12 (that is 1, 2, 3, 4 or 6). The keyword [GASYEAR](#) may be used instead of GASPERIO if the contract period is a year.

The GASPERIO keyword activates two features of the model:

- Generation of the annual production profile from the profile factors set in keyword [SWINGFAC](#) or [GSWINGF](#).
- Automatic reduction of the DCQ when necessary to obey the swing factor requirement, using the swing factors set in keyword [SWINGFAC](#) or [GSWINGF](#).

The [SWINGFAC](#) or [GSWINGF](#) keyword must have been entered previously to activate the gas field operations model.

The keyword should be followed by some or all of these data items, terminated with a slash (/):

1. Number of contract periods to simulate.

The contract period begins at the current date when the GASPERIO keyword is read. An error will be flagged if this is not the first day of a month. At the end of each contract period, ECLIPSE writes an output report and dumps a Restart file if required.

2. Number of months in a contract period.

This must be 1, 2, 3, 4, 6 or 12.

DEFAULT: 12

3. The initial DCQ (Daily Contracted Quantity).

When there is a single gas supply contract on the FIELD (keyword [SWINGFAC](#)), the initial DCQ must be specified in the first entry of the GASPERIO keyword. It should be defaulted in subsequent entries, unless you wish to reset its value.

When there are separate gas supply contracts on different groups (that is keyword [GSWINGF](#) has been used to activate the multiple contract group facility; see "[Applying separate gas supply contracts to individual groups](#)" in the *ECLIPSE Technical Description*), this item should be defaulted. Any value entered here is ignored. Instead, the initial DCQs of the contract groups must be set with keyword [GDCQ](#) before the GASPERIO keyword is read.

UNITS: sm<sup>3</sup>/day (METRIC), Mscf/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

*ECLIPSE 100 only*

If item 1 of [DCQDEFN](#) is set to 'ENERGY':

UNITS: kJ/day (METRIC), Btu/day (FIELD), J/hr (LAB), kJ/day (PVT-M)

DEFAULT: Current value of DCQ

4. Swing requirement for automatic reduction of the DCQ

PER or YES The field (or each contract group) must be able to produce at the DCQ multiplied by the monthly swing factor, for the whole contract period.

PRO The field (or contract group) must be able to raise its production rate from  $DCQ \times \text{profile}$  to  $DCQ \times \text{swing}$  for an instant at any time in the contract period.

PCQ The field (or contract group) must be able to produce at the DCQ multiplied by the monthly swing factor continuously until it has produced its contracted quantity (= no. of days in period  $\times$  DCQ).

NO The swing requirement is not tested. The DCQ remains at its current value, even if the field (or contract group) cannot produce at its target rate.

Items 5 - 8 of this keyword are ignored.

DEFAULT: PER

If any option except NO is requested, each contract period is solved twice. The first pass is a test calculation, which has the purpose of deciding how much the DCQ needs to be reduced in order to obey the swing requirement for the current contract period. The second pass simulates the actual performance of the field, with the sales gas rate target set each month to the new value of the DCQ multiplied by the monthly profile factor.

PER is a suitable option for cases where the monthly swing factors are the same as the profile factors, as it ensures the production profile fits underneath the delivery capacity decline curve. But for cases where the swing factors exceed the profile factors, the PRO or PCQ options may be more suitable. For more discussion of these options, see "[Interpretations of the swing requirement](#)" in the *ECLIPSE Technical Description*.

When using the multiple contract groups facility (initiated with keyword [GSWINGF](#)), only the options PER and NO are allowed if there is more than one variable-DCQ contract group (see keyword [GDCQ](#)). If all contract groups except one have fixed DCQs, all the above options are allowed.

---

**Note:** If the [GASPERIO](#) keyword is used with the PCQ option and a 12 month contract period, the results may be marginally different to those obtained using the ACQ option in the [GASYEAR](#) keyword. This is because a 12 month contract period has either 365 or 366 days as opposed to the average 365.25 days used with the [GASYEAR](#) keyword.

---

5. Should the timesteps be limited so that each month starts with a new timestep? - YES or NO

(The word may be abbreviated, only the first character is significant)

YES ECLIPSE automatically limits each timestep so that it does not go beyond the end of the current month. This ensures that there is at least one Summary file entry per month, and that the network (if using the Network option) is balanced at least once per month.

NO ECLIPSE only limits the timestep to the end of the month if the production rate target changes, or if there is an operation on the Annual Scheduling file. All other means of limiting the timestep (see keyword [TUNING](#)) still remain in force.

DEFAULT: YES

6. Limiting DCQ reduction factor, FLIM, allowed in a single iteration of the first pass of the contract year.

This restricts the amount by which the DCQ can be reduced in a single iteration of the first pass of the contract period. If the DCQ needs to be reduced to a fraction less than the value specified here, it is reduced only to this specified fraction ( $DCQ \times FLIM$ ) and the first pass of the contract period is solved again, subject to the upper limit in item 7 on the number of iterations.

If you are using the accelerated iteration scheme (this is always the case for ECLIPSE 300 and controlled by item 2 of RUNSPEC section keyword `GASFIELD` for ECLIPSE 100), it is not necessary to have a limiting reduction factor. Although a small value (for example 0.1) could be useful when the field or a contract group is getting close to the end of its life. This would stop the iteration immediately jumping to a DCQ of zero when it may still be able to operate with a small value of the DCQ.

ECLIPSE 100

If you are **not** using the accelerated iteration scheme, the DCQ reduction must be limited more strictly to obtain accurate results, to prevent it from substantially overshooting the correct value (it will not increase again). The nearer the reduction factor is to 1.0 the more accurate will be the result, but at the expense of requiring more iterations of the first pass to converge it.

RANGE: 0.0 to 0.99

DEFAULT: 0.0 (Allowing unlimited reduction)

See "[Calculating the DCQ value](#)" in the *ECLIPSE Technical Description*.

7. Anticipated annual DCQ reduction factor.

Once the DCQ has been reduced automatically below the specified initial value, the DCQ is multiplied by the anticipated reduction factor at the start of each contract period.

If you are using the accelerated iteration scheme (this is always the case for ECLIPSE 300 and controlled by item 2 of RUNSPEC section keyword `GASFIELD` for ECLIPSE 100), it is not necessary to have an anticipated reduction factor, as the scheme chooses a starting value based on the previous period's reduction in DCQ. This item should therefore be defaulted in general. If a value is specified here then it is used instead of the value calculated by ECLIPSE.

ECLIPSE 100

If you are **not** using the accelerated iteration scheme, an anticipated reduction factor could help reduce the number of iterations required to converge the DCQ by bringing the starting value nearer to the final value. For example, during the first pass of the contract period ECLIPSE calculates that the DCQ must be reduced to a value  $DCQ_2$ . The second pass is solved with the DCQ at this value. If an anticipated reduction factor, `FANT`, has been set, ECLIPSE starts the first pass of the next contract period with an initial  $DCQ = DCQ_2 \times FANT$ .

RANGE: 0.01 to 1.0

DEFAULT: 1.0 (Giving no anticipated reduction)

See "[Calculating the DCQ value](#)" in the *ECLIPSE Technical Description*.

8. Maximum allowed number of iterations of the first pass of each contract period to calculate the DCQ.

This takes effect if you are using the accelerated iteration scheme (this is always the case for ECLIPSE 300 and controlled by item 2 of RUNSPEC section keyword `GASFIELD` for ECLIPSE 100) or if there is a limiting DCQ reduction factor defined in item 5. A warning will be issued if the DCQ has not converged within the maximum number of iterations.

ECLIPSE 100

If you are **not** using the accelerated iteration scheme, and there is no limiting DCQ reduction factor, the first pass is only performed once to calculate the DCQ. The resulting value of the DCQ will be pessimistic if there has been a significant reduction.

DEFAULT: 3

9. Convergence tolerance for the DCQ calculation when using the accelerated iteration scheme.

The value must lie between 0.0 and 1.0. A value of 0.1, for example, accepts the DCQ as converged when its change in value over an iteration is 10% or less. The minimum of the two DCQ values is chosen, so that the DCQ is on the safe side of the true result. A warning is issued if the DCQ has not converged after the maximum number of iterations specified in item 7.

This item is ignored if you are not using the accelerated iteration scheme.

RANGE: 0.0 to 1.0

DEFAULT: 0.1

End the data with a slash (/)

**CAUTION:** If an Annual Scheduling file (ASF) is being used with contract periods of varying length some caution must be exercised. It is allowable, for example, to perform a 6 month contract period followed by 3 quarterly contract periods. The first two quarters take the ASF to the end of its year and it then starts again for the third quarter. However, it is not allowable to do 3 quarterly contract periods followed by a half year contract period; the ASF does not wrap around within a contract period. Essentially, the end of an ASF year **must** coincide with the end of a contract period. To achieve the second scenario it would be necessary to redefine the ASF starting at the appropriate month before the second use of GASPERIO.

## Examples

To advance the simulation through three and a half years using quarterly contract periods, with the DCQ initially 100,000 but reduced when necessary to obey the swing requirement, and a new timestep starting on the first of each month. For ECLIPSE 100, the accelerated iteration scheme has been selected in RUNSPEC section keyword GASFIELD. A small limiting DCQ reduction factor is applied (0.1), and 4 iterations of the first pass are allowed for convergence to 5% accuracy.

### Example 1

```
GASPERIO
-- No of   Period   Initial   Swing   Monthly   Lim DCQ   Ant DCQ   Max no   Conv
-- periods Length   DCQ      req     t/steps   reduc     reduc     DCQ its  tol
      10      3      100000   PER     1*        0.1      1*        4       0.05 /
```

### Example 2

To continue the simulation for another year with the same DCQ iteration parameters but using two six month contract periods. The initial DCQ should be defaulted now.

```
GASPERIO
-- No of   Period   Initial   Swing   Monthly   Lim DCQ   Ant DCQ   Max no   Conv
-- periods Length   DCQ      req     t/steps   reduc     reduc     DCQ its  tol
      2      6      1*        PER     1*        0.1      1*        4       0.05 /
```

## GASSATC

## Initial saturated coal gas concentration

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by one real number for every matrix grid block, specifying the initial saturated gas concentration in the coal. The data field should be terminated by a slash (/).

UNITS:  $\text{sm}^3/\text{m}^3$  (METRIC),  $\text{Mscf}/\text{ft}^3$  (FIELD),  $\text{scc}/\text{cc}$  (LAB)

Grid blocks are ordered with the X axis index cycling fastest (from 1 to NDIVIX), followed by the Y axis index (from 1 to NDIVIY), and finally the Z axis index (from 1 to NDIVIZ). NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword [DIMENS](#). Repeat counts may be used for repeated values (for example 115\*0.22). Note that spaces must not be inserted on either side of the asterisk (\*). Data need only be supplied for the matrix cells, that is the upper half of the grid.

In ECLIPSE 100. This information is used to scale the Langmuir isotherm, as specified by the [LANGMUIR](#) keyword, at the initial pressure in the reservoir. This is an alternative to the [MLANG](#) keyword, which provides scaling of the Langmuir isotherm at the maximum fracture pressure entry in each of the [LANGMUIR](#) tables. Both GASSATC and [MLANG](#) are entirely optional. If neither of these keywords is present, the information provided in the [LANGMUIR](#) keyword is used without any scaling.

In ECLIPSE 300. This information is used to scale the Langmuir isotherm, as specified by the [LANGMEXT](#) or [LANGMUIR](#) keyword, at the initial pressure and composition in the reservoir for one chosen component. The component used is specified by the [GASCCMP](#) keyword. The same scaling factor is used for all the components. For the general case the keyword [GASADEC](#) can be used.

Note that the keyword cannot be used together with [LANGMULT](#), [LANGMULC](#) or [GASADEC](#).

Only values for coal cells are used. Note that the composition (YMF) and pressure value of the coal cell is used and not the connected pore volume (fracture) composition and pressure.

### Example

With NDIVIX=8, NDIVIY=6, NDIVIZ=10 specified in RUNSPEC keyword [DIMENS](#):

```
GASSATC
48*89.1 48*87.3 48*85.1 48*85.0 48*85.0 /
```

## GASSOL

## Specify number of gas components to dissolve in the aqueous phase

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword turns on the general specification of compositional gas, for example a flue gas, for gas injection, allowing a specified number, NCMPHW, of gas components to dissolve in the aqueous phase. This remains isothermal and there is no water in the gas phase. This keyword cannot be used if directional saturation table end-point scaling is used (switched on by setting the first item of keyword [ENDSCALE](#) to [DIRECT](#)).

This keyword is read in the RUNSPEC section to define the number of components allowed to dissolve in the aqueous phase in a compositional run. GASSOL contains one item, the number of components, NCMPHW, to be allowed to dissolve in the aqueous phase. The total number of components in a compositional run is specified by keyword [COMPS](#) in the RUNSPEC section. If present it is read, and an error message is produced if the item's value is less than zero or greater than specified with the [COMPS](#) keyword. There are several optional associated keywords:

[SOLUAQA](#) Defines the solubility data.

[RSWVD](#) This specifies the initial variation of the aqueous gas-water ratio versus depth for each component.

[RSW](#) This specifies the initial variation of the aqueous gas-water ratio by enumeration for each component.

[AMF](#) This specifies the initial composition of the aqueous gas system for each component.

[VISCAQA](#) This specifies coefficients of Ezrokhi's method for aqua viscosity for each component.

[DENAQA](#) This specifies coefficients of Ezrokhi's method for aqua density for each component.

For further information see "[GASSOL solution in the aqueous phase](#)" in the *ECLIPSE Technical Description*.

### Example

Confirm that five components (NCMPHW=5) are allowed to dissolve in the aqueous phase:

```
GASSOL
5 /
```

## GASVISCF Gas viscosity function

x	<b>ECLIPSE 300</b>
x	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can only be used with the [THERMAL](#) option.

For the  $i^{\text{th}}$  oil component, the gas viscosity is fitted according to the equation:

$$\mu_{g_i} = A \cdot T^B$$

where T is the temperature (K (METRIC), °R (FIELD), K (LAB), K (PVT-M)).

The gas phase viscosity is calculated as

$$\mu_g = \sum_{i=1}^{N_c+1} \mu_{g_i} Y_i$$

where  $Y_i$  are the component mole fractions in the gas phase.

The keyword is followed by two records, each containing  $N_c$  columns of data, described below, followed by a blank record, containing only a slash.

1. *A* coefficients

A set of  $N_c$  values is entered, one for each hydrocarbon component

UNITS: cP (METRIC), cP (FIELD), cP (LAB), cP (PVT-M)

2. *B* coefficients

A set of  $N_c$  values is entered, one for each hydrocarbon component

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as the 9<sup>th</sup> parameter of [TABDIMS](#).

### Example

```
GASVISCF
-- SGAS HEAVY
0.5E-4 1.0E-4
0.9 0.9
/
```

## GASVISCT Gas viscosity versus temperature table

x	<b>ECLIPSE 300</b>
x	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can only be used with the [THERMAL](#) option.

The data comprises NTPVT tables (the item 2 of keyword [TABDIMS](#)) of gas phase component viscosities versus temperature for each pressure table. Each table consists of  $N_c + 1$  columns of data (described below), and is terminated by a slash (/).

1. Temperature values.

The values should increase monotonically down the column.

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

2. The corresponding values of gas component viscosity.

The values should increase or stay level down the column.

UNITS: cP (METRIC), cP (FIELD), cP (LAB), cP (PVT-M)

For temperature values outside the interval specified, constant value extrapolation is performed.

The gas phase viscosity is calculated as

$$\mu_g = \sum_{i=1}^{N_c+1} \mu_{g_i} Y_i$$

where  $\mu_{g_i}$  are the gaseous component viscosities and  $Y_i$  are the component mole fractions in the gas phase.

### Example

```
GASVISCT
 75 0.0143 0.0180
100 0.0149 0.0188
150 0.0161 0.0203

The GASWAT option provides a method of modeling gas phase/aqueous phase equilibriums using an equation of state. The Peng Robinson equation of state is modified following the suggestions of Soreide and Whitson to obtain accurate gas solubilities in the aqueous phase.

This option is described in detail in "[GASWAT option](#)" in the *ECLIPSE Technical Description*.

The keyword GASWAT contains no items.

## GASYEAR Advances simulator over ‘n’ gas field contract years

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The GASYEAR keyword can be used instead of [DATES](#), [TIME](#) or [TSTEP](#) to advance the simulation over an integral number of contract years, when running the gas field operations model. For contract periods that are less than a year, keyword [GASPERIO](#) must be used instead. The GASYEAR keyword activates two features of the model:

- Generation of the annual production profile from the profile factors set in keyword [SWINGFAC](#) or [GSWINGF](#).
- Automatic reduction of the DCQ when necessary to obey the swing factor requirement, using the swing factors set in keyword [SWINGFAC](#) or [GSWINGF](#).

The SWINGFAC or GSWINGF keyword must have been entered previously to activate the Gas Field Operations Model.

The keyword should be followed by some or all of these data items, terminated with a slash (/):

1. Number of contract years to simulate.

The contract year begins at the current date when the GASYEAR keyword is read. An error will be flagged if this is not the first day of a month. At the end of each contract year, ECLIPSE writes an output report and dumps a restart file if required.

2. The initial DCQ (Daily Contracted Quantity).

When there is a single gas supply contract on the FIELD (keyword [SWINGFAC](#)), the initial DCQ must be specified in the first entry of the GASYEAR keyword. It should be defaulted in subsequent entries, unless you wish to reset its value.

When there are separate gas supply contracts on different groups (that is keyword [GSWINGF](#) has been used to activate the multiple contract group facility; see "[Applying separate gas supply contracts to individual groups](#)" in the *ECLIPSE Technical Description*), this item should be defaulted. Any value entered here is ignored. Instead, the initial DCQs of the contract groups must be set with keyword [GDCQ](#) before the GASYEAR keyword is read.

UNITS: sm<sup>3</sup>/day (METRIC), Mscf/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

*ECLIPSE 100 only*

If item 1 of [DCQDEFN](#) is set to 'ENERGY':

UNITS: kJ/day (METRIC), Btu/day (FIELD), J/hr (LAB), kJ/day (PVT-M)

DEFAULT: Current value of DCQ

3. Swing requirement for automatic reduction of the DCQ

YEAR or YES The field (or each contract group) must be able to produce at the DCQ multiplied by the monthly swing factor, for the whole contract year.

PRO The field (or contract group) must be able to raise its production rate from DCQ × profile to DCQ × swing for an instant at any time in the contract year.

ACQ The field (or contract group) must be able to produce at the DCQ multiplied by the monthly swing factor continuously until it has produced its annual contracted quantity (= 365.25 × DCQ).

JAN, FEB, MAR, APR, MAY, JUN, JUL, AUG, SEP, OCT, NOV, DEC

The field (or contract group) must be able to produce at the DCQ multiplied by the monthly swing factor continuously, until it has produced a fraction of its annual contracted quantity proportional to the sum of profile factors up to the end of the specified month.

(JLY is an acceptable alternative to JUL.)

NO The swing requirement is not tested. The DCQ remains at its current value, even if the field (or contract group) cannot produce at its target rate.

items 5 - 8 of this keyword will be ignored

DEFAULT: YEAR

YEAR is a suitable option for cases where the monthly swing factors are the same as the profile factors, as it ensures the production profile fits underneath the delivery capacity decline curve. But for cases where the swing factors exceed the profile factors, the PRO or ACQ options may be more suitable. For more discussion of these options, see "[Interpretations of the swing requirement](#)" in the *ECLIPSE Technical Description*.

When using the multiple contract groups facility (initiated with keyword [GSWINGF](#)), only the options YEAR and NO are allowed if there is more than one variable-DCQ contract group (see keyword [GDCQ](#)). If all contract groups except one have fixed DCQs, all the above options are allowed.

4. Should the timesteps be limited so that each month starts with a new timestep? - YES or NO

(The word may be abbreviated, only the first character is significant)

YES ECLIPSE automatically limits each timestep so that it does not go beyond the end of the current month. This ensures that there is at least one Summary file entry per month, and that the network (if using the Network option) will be balanced at least once per month.

NO ECLIPSE only limits the timestep to the end of the month if the production rate target changes, or if there is an operation on the annual scheduling file. All other means of limiting the timestep (see keyword [TUNING](#)) still remain in force.

DEFAULT: YES

5. Limiting DCQ reduction factor, FLIM, allowed in a single iteration of the first pass of the contract year.

This restricts the amount by which the DCQ can be reduced in a single iteration of the first pass of the contract year. If the DCQ needs to be reduced to a fraction less than the value specified here, it is reduced only to this specified fraction ( $DCQ \times FLIM$ ) and the first pass of the contract year is solved again, subject to the upper limit in item 7 on the number of iterations.

If you are using the accelerated iteration scheme (this is always the case for ECLIPSE 300 and controlled by item 2 of RUNSPEC section keyword [GASFIELD](#) for ECLIPSE 100), it is not necessary to have a limiting reduction factor. Although a small value (for example 0.1) could be useful when the field or a contract group is getting close to the end of its life. This would stop the iteration immediately jumping to a DCQ of zero when it may still be able to operate with a small value of the DCQ.

ECLIPSE 100

If you are **not** using the accelerated iteration scheme, the DCQ reduction must be limited more strictly to obtain accurate results, to prevent it from substantially overshooting the correct value (it will not increase again). The nearer the reduction factor is to 1.0 the more accurate will be the result, but at the expense of requiring more iterations of the first pass to converge it.

RANGE: 0.0 to 0.99

DEFAULT: 0.0 (Allowing unlimited reduction)

See "[Calculating the DCQ value](#)" in the *ECLIPSE Technical Description*.

6. Anticipated annual DCQ reduction factor.

Once the DCQ has been reduced automatically below the specified initial value, the DCQ is multiplied by the anticipated reduction factor at the start of each contract year.

If you are using the accelerated iteration scheme (this is always the case for ECLIPSE 300 and controlled by item 2 of RUNSPEC section keyword [GASFIELD](#) for ECLIPSE 100), it is not necessary to have an anticipated reduction factor, as the scheme chooses a starting value based on the previous year's reduction in DCQ. This item should therefore be defaulted in general. If a value is specified here then it is used instead of the value calculated by ECLIPSE.

ECLIPSE 100

If you are **not** using the accelerated iteration scheme, an anticipated reduction factor could help reduce the number of iterations required to converge the DCQ by bringing the starting value nearer to the final value. For example, during the first pass of the contract year ECLIPSE calculates that the DCQ must be reduced to a value DCQ2. The second pass is solved with the DCQ at this value. If an anticipated reduction factor, FANT, has been set, ECLIPSE will start the first pass of the next contract year with an initial  $DCQ = DCQ2 \times FANT$ .

RANGE: 0.01 to 1.0

DEFAULT: 1.0 (Giving no anticipated reduction)

See "[Calculating the DCQ value](#)" in the *ECLIPSE Technical Description*.

7. Maximum allowed number of iterations of the first pass of each contract year to calculate the DCQ.

This takes effect if you are using the accelerated iteration scheme (this is always the case for ECLIPSE 300 and controlled by item 2 of RUNSPEC section keyword [GASFIELD](#) for ECLIPSE 100) or if there is a limiting DCQ reduction factor defined in item 5. A warning will be issued if the DCQ has not converged within the maximum number of iterations.

ECLIPSE 100

If you are **not** using the accelerated iteration scheme, and there is no limiting DCQ reduction factor, the first pass is only performed once to calculate the DCQ. The resulting value of the DCQ is pessimistic if there has been a significant reduction.

DEFAULT: 3

8. Convergence tolerance for the calculation DCQ when using the accelerated iteration scheme.

The value must lie between 0.0 and 1.0. A value of 0.1, for example, accepts the DCQ as converged when its change in value over an iteration is 10% or less. The minimum of the two DCQ values is chosen, so that the DCQ is on the safe side of the true result. A warning is issued if the DCQ has not converged after the maximum number of iterations specified in item 7.

ECLIPSE 100

If you are not using the accelerated iteration scheme this item is ignored.

RANGE: 0.0 to 1.0

DEFAULT: 0.1

End the data with a slash (/).

See also the [GASPERIO](#) keyword.

## Examples

### Example 1

To advance the simulation through four years, with the DCQ initially 100,000 but reduced when necessary to obey the swing requirement, and a new timestep starting on the first of each month. For ECLIPSE 100, the accelerated iteration scheme has been selected in RUNSPEC section keyword GASFIELD. A small limiting DCQ reduction factor is applied (0.1), and 4 iterations of the first pass are allowed for convergence to 5% accuracy.

```
GASYEAR
-- No of      Initial   Swing   Monthly   Lim DCQ   Ant DCQ   Max no   Conv
-- years      DCQ         req     t/steps   reduc     reduc     DCQ its  tol
--           4      100000   YEAR    1*        0.1      1*       4      0.05 /
```

### Example 2

To continue the simulation for another two years with the same DCQ iteration parameters. The initial DCQ should be defaulted now.

```
GASYEAR
-- No of      Initial   Swing   Monthly   Lim DCQ   Ant DCQ   Max no   Conv
-- years      DCQ         req     t/steps   reduc     reduc     DCQ its  tol
--           2      1*       YEAR    1*        0.1      1*       4      0.05 /
```

### Example 3

To advance the simulation through one year with the DCQ fixed at 50000, and timesteps limited just by rate changes.

```
GASYEAR
-- No of      Initial   Swing   Monthly   Lim DCQ   Ant DCQ   Max no   Conv
-- years      DCQ         req     t/steps   reduc     reduc     DCQ its  tol
--           1      50000   NO      NO        /
```

## GCALECON Energy and calorific value economic limit data for groups

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword allows minimum economic limits to be set for the energy rate and/or the mean calorific value of individual groups and the field, when running the gas calorific value control option (see "[Gas calorific value control](#)" in the *ECLIPSE Technical Description*).

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/). The set of records must end with a blank record, containing only a slash (/).

1. Group name or group name root,

or FIELD (for field economic limit data)

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. Minimum energy production rate

UNITS: kJ/day (METRIC), Btu/day (FIELD), J/hr (LAB), kJ/day (PVT-M)

DEFAULT: 0.0

If the group's energy production rate falls below the specified minimum, all the producers in the group are shut or stopped (see item 9 in keyword [WELSPECS](#)). A zero or negative value switches off this limit.

3. Minimum calorific value

UNITS: kJ/sm<sup>3</sup> (METRIC), Btu/Mscf (FIELD), J/scc (LAB), kJ/sm<sup>3</sup> (PVT-M)

DEFAULT: 0.0

If the group's mean calorific value falls below the specified minimum, all the producers in the group are shut or stopped (see item 9 in keyword [WELSPECS](#)). A zero or negative value switches off this limit.

4. End run flag

YES The run stops at the next report time if all the producers in the group are shut or stopped for any reason, provided the group has had at least one producer open previously

NO The run continues regardless

DEFAULT: NO

---

**Note:** If the [GECON](#) keyword is entered subsequently to GCALECON, item 8 of the GECON keyword overwrites the end run flag defined here.

---

End each data record with a slash (/).

End the set of records with a blank record, containing just a slash.

## Example

```
GCALECON  
G1 1.0E7 28000 YES/  
/
```

## GCONCAL **Calorific value controls for groups**

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The GCONCAL keyword sets a target mean calorific value for the gas produced by a group (or the field), when running the gas calorific value control option. The group's gas production rate must simultaneously be under guide rate group control (keyword [GCONPROD](#)). Mean calorific value targets are met by adjusting the guide rates to obtain a suitable mix of gases of different calorific values. See "[Adjusting guide rates to control mean calorific value](#)" in the *ECLIPSE Technical Description* for further information.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/). The set of records must end with a blank record, containing only a slash (/).

1. Group name or group name root,

or FIELD (for field calorific value controls)

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. Target mean calorific value of the produced gas

UNITS: kJ/sm<sup>3</sup> (METRIC), Btu/Mscf (FIELD), J/scc (LAB), kJ/sm<sup>3</sup> (PVT-M)

DEFAULT: Infinity (1.0E20), which will turn off the calorific value control

3. Action if the calorific value target cannot be met after all available production rule actions have been tried (because there are no wells under group control whose calorific values straddle the target)

NONE Take no further action; allow the mean calorific value to drift.

RATE Cut the group's gas rate target successively, by the rate reduction factor in item 4, until wells with calorific values straddling the target are brought back under group control.

See "[Action when calorific value target cannot be met](#)" in the *ECLIPSE Technical Description* for further details.

DEFAULT: NONE

4. Rate reduction factor for the RATE action in item 3

DEFAULT: 0.9

End each data record with a slash (/).

End the set of records with a blank record, containing just a slash.

### Example

```
GCONCAL
FIELD 35000.0 RATE 0.95 /
/
```

## GCONENG Energy production rate control for groups

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The GCONENG keyword sets a target or limiting energy production rate for groups (or the field), when running the gas calorific value control option. A group's energy production target is apportioned between its subordinate wells according to their energy guide rates. See "[Controlling the energy production rate](#)" in the *ECLIPSE Technical Description* for further information.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/). The set of records must end with a blank record, containing only a slash (/).

1. Group name or group name root,

or FIELD (for field energy production rate control)

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. Energy production rate target or upper limit

UNITS: kJ/day (METRIC), Btu/day (FIELD), J/hr (LAB), kJ/day (PVT-M)

DEFAULT: Infinity (1.0E20)

End each data record with a slash (/).

End the set of records with a blank record, containing just a slash.

### Example

```
GCONENG
FIELD 1.0E9 /
```

## GCONINJE Injection rate controls/limits for groups/field

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies the injection targets and limits for groups.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The records may be terminated at any item after item 1. The remaining items assume their default values. Default values can be specified before the slash by a null repeat count of the form  $n^*$ , where  $n$  is the number of consecutive items to be defaulted.

The set of records must end with a blank record, containing only a slash (/).

1. Group name or group name root  
or FIELD (for field rate control data)

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. Phase to which the following controls/limits apply

WATER Water injection controls.

GAS Gas injection controls.

ECLIPSE 300

When running in compositional mode, the nature of the injected gas must also be specified with keyword **GINJGAS**, unless the group is under control of a higher level group with gas injection controls where the injection fluid is defined.

ECLIPSE 100 only

OI Oil injection controls.

Injection controls and limits can be applied to one or more phases in any group. A separate data record is needed for each phase.

3. Injection rate control mode

NONE No immediate control of injection rate.

RATE The group/field surface injection rate of the phase in item 2 is controlled to meet the target specified in item 4.

RESV The group/field reservoir volume injection rate of the phase in item 2 will be controlled so that the **total** reservoir volume injection rate of the group/field meets the target specified in item 5.

REIN The group/field surface injection rate of the phase in item 2 is controlled to equal the group/field production rate of the phase times the reinjection fraction specified in item 6.

VREP The group/field reservoir volume injection rate of the phase in item 2 is controlled so that the **total** reservoir volume injection rate of the group/field equals its production voidage rate times the voidage replacement fraction specified in item 7.

ECLIPSE 300 only

WGRA The group/field wet gas injection rate of the phase in item 2 is controlled to meet the target specified in item 13.

FLD The group is immediately under control from a higher level group or the field, injecting its share of the higher group's or field's target rate, according to its guide rate (which must be set in items 9 and 10 in this keyword).

DEFAULT: NONE

4. Surface injection rate target or upper limit for the phase in item 2. User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

UNITS: sm<sup>3</sup>/day (METRIC), stb/day for oil or water (FIELD), Mscf/day for gas (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: No target or limit

5. Total reservoir volume injection rate target or upper limit. User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

If a non-default value is specified here, the phase in item 2 is declared the top-up phase. Its target or limiting reservoir volume injection rate will be equal to the value specified here minus the reservoir volume injection rate of the other phases. The phase injection rate is calculated to top up the total group or field injection to the required reservoir volume rate, after allowing for any injection of the other phases. There can be only one top-up phase at any given time in the simulation run.

UNITS: rm<sup>3</sup>/day (METRIC), rb/day (FIELD), rcc/hr (LAB), rm<sup>3</sup>/day (PVT-M)

DEFAULT: No target or limit

6. Reinjection fraction target or upper limit for the phase in item 2. User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

The reinjection fraction is applied to the group or field production rate of the phase in item 2.

ECLIPSE 100

For gas, the consumption rate of the group and any subordinate groups is subtracted from the production rate, and the gas import rate is added to it, before multiplying by the reinjection fraction (see keyword [GCONSUMP](#)).

ECLIPSE 300

For gas, the reinjection fraction is applied to the group's available gas. The available produced gas rate of a group is by default equal to the group's gas production rate minus its fuel rate (keyword [GRUPFUEL](#)) minus its sales target (keyword [GRUPSALE](#)); however, this definition can be altered using keyword [WTAKEGAS](#). Any advance gas allocated to the group (keyword [GADVANCE](#)) is also added to the available gas. This limit ignores makeup gas (keyword [GINJGAS](#), item 4); it should not be applied if makeup gas is available, which is treated as an infinite resource. In the case of a reinjection fluid defined by a stream or mixture, the specified fraction of the available surface gas production rate is applied as a wet gas reinjection rate target.

The reinjection fraction can be applied to the production rate of a different group by entering the required group's name in item 11.

ECLIPSE 100

DEFAULT: No target or limit

ECLIPSE 300

DEFAULT: 1 (if the injection rate control mode is REIN), otherwise no target or limit.

7. Total voidage replacement fraction target or upper limit. User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

If a non-default value is specified here, the phase in item 2 is declared the 'top-up' phase. Its target or limiting reservoir volume injection rate will be equal to the value specified here times the group/field

production voidage rate, minus the reservoir volume injection rate of the other phases. The phase injection rate is calculated to 'top up' the total group or field injection to the required voidage replacement fraction, after allowing for any injection of the other phases. There can be only one 'top-up' phase at any given time in the simulation run.

The voidage replacement fraction can be applied to the reservoir volume production rate of a different group by entering the required group's name in item 12.

ECLIPSE 100

DEFAULT: No target or limit

ECLIPSE 300

DEFAULT: 1 (if the injection rate control mode is VREP), otherwise no target or limit.

8. Is the group free to respond to a higher level injection rate target?

YES Injection from the group is cut back as necessary to meet any rate target/limit imposed at a higher level

NO The group injects at its own capacity or target irrespective of any higher level rate target or limit

This item is ignored if the data record applies to the FIELD.

DEFAULT: YES

9. Group's injection guide rate for the phase in item 2, a dimensionless number governing the group's share of a higher level injection target

A group needs a guide rate only if it is required to inject a specified proportion of a higher level rate target. The group is then placed under rate control, with a target rate set in proportion to its guide rate. The definition of this guide rate is specified in item 10. It can either be set to a fixed surface rate or reservoir volume rate, or adjusted each timestep to reflect the group's voidage replacement requirements.

If no guide rate is specified, the group's share of a higher level injection target is governed by the guide rates of its subordinate injection wells, or any subordinate groups with injection guide rates. (The well guide rates are set by default equal to the wells' injection potentials, but can be specified directly by using the keyword WGRUPCON). The group will essentially be transparent to higher level injection targets, which will be apportioned directly down to its subordinate wells or groups with guide rates.

Set this item to a positive value if you wish to give the group a fixed injection guide rate for this phase (with RATE or RESV set in item 10).

Default this item if the group is to have no injection guide rate for this phase, or if the guide rate definition in item 10 is VOID or NETV.

ECLIPSE 300

If a zero guide rate is specified, the group's guide rate is set at the beginning of each timestep to be equal to the group's injection potential - that is, the sum of the injection potentials of all of its subordinate open injectors.

This item is ignored if the data record applies to the FIELD.

DEFAULT: No fixed guide rate

10. Definition of the guide rate in item 9.

RATE The guide rate applies to group's surface injection rate (so the surface injection rate target will be in proportion to the guide rate).

	RESV	The guide rate applies to group's reservoir volume injection rate (so the reservoir volume injection target is in proportion to the guide rate).
ECLIPSE 100 only	VOID	The guide rate is set at the beginning of each timestep equal to the group's voidage production rate. This setting can be used to apportion an injection target between groups in proportion to their voidage production rates. The entry in item 9 is ignored.
ECLIPSE 100 only	NETV	The guide rate is set at the beginning of each timestep equal to the group's net voidage rate (that is its voidage production rate minus the reservoir volume injection rate of any other phases). This setting can be used to apportion an injection target between groups in proportion to their top-up needs for voidage replacement. It can only be applied if the phase in item 2 is the 'top-up' phase. The entry in item 9 is ignored.

' ' The group has no injection guide rate for this phase.

Higher level injection targets is apportioned directly down to its subordinate wells, or any subordinate groups with injection guide rates.

The item is ignored if the data record applies to the FIELD.

DEFAULT: ' ' (The group has no injection guide rate.)

11. Name of the group whose production rate the reinjection fraction in item 6 should be applied to.

The group in item 1 can be made to reinject a fraction of **another** group's production rate, by entering the name of this other group here.

DEFAULT: The group in item 1 reinjects a fraction of its **own** production rate

12. Name of the group whose reservoir volume production rate the voidage replacement fraction in item 7 should be applied to.

The group in item 1 can be made to replace a fraction of **another** group's voidage, by entering the name of this other group here.

DEFAULT: The group in item 1 replaces a fraction of its **own** voidage

- ECLIPSE 300 only 13. Wet gas injection rate target or upper limit for the phase in item 2  
(this should only be set if the phase in item 2 is GAS)

Wet gas rate is related to the hydrocarbon moles injected using a unity Z-factor at surface conditions.

UNITS: sm<sup>3</sup>/day (METRIC), Mscf/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: No target or limit

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

---

**Note:** Setting non-default values in item 5 or 7, or entering NETV in item 10, causes the phase in item 2 to become the top-up phase. Its injection target depends not only on the production flows but also on the injection flows of any other injected phases. Thus the top-up phase flows must be calculated after all other injection phases have been processed. There can only be one 'top-up' phase in the simulation at any one time. Two groups cannot have different 'top-up' phases. However, the top-up phase can be changed during the run. If for example you initially inject water to replace the voidage, but wish to change to voidage

replacement with gas later in the run, it is first necessary to remove all top-up phase controls and limits from the water phase. Thus GCONINJE must first be used for the water phase to reset items 5 and 7 to their default values, and item 10 must not be set to NETV, before specifying voidage replacement controls for the gas phase. In this situation, the simplest way to remove the limits from the water phase is to change the injection rate control mode for the water phase to NONE.

### Examples

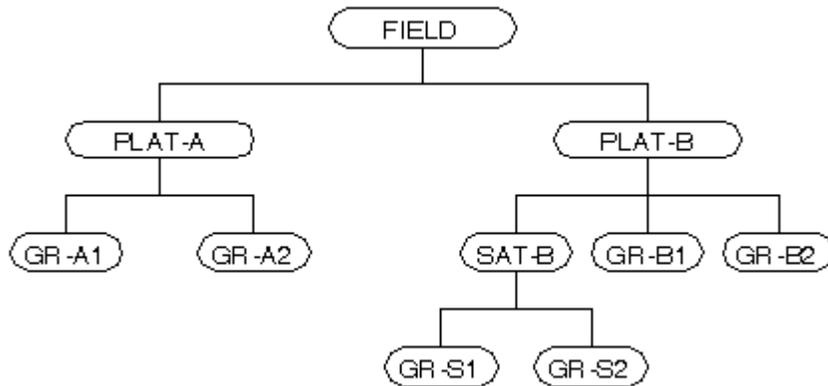

Figure 3.6. A five level hierarchy

#### Example 1

The field reinjects all of its available gas, to be shared between the injection wells in proportion to their guide rates or potentials, subject to their individual rate and pressure limits.

```

GCONINJE
FIELD GAS REIN 2* 1.0 /
/
    
```

#### Example 2

The field injects 30,000 Mscf/day of gas, subject to PLAT-A and PLAT-B not injecting more than their available gas. SAT-B has a gas injection limit of 10,000 Mscf/day.

```

GCONINJE
FIELD GAS RATE 30000 /
'PLAT*' GAS NONE 2* 1.0 /
SAT-B GAS NONE 10000 /
/
    
```

#### Example 3

As Example 2, but the injected gas is to be distributed between each bottom-level group in proportion to its voidage production (subject to the platform constraints and the group's injection potentials). Since the bottom-level groups are given guide rates, they are placed under rate control from a higher level.

```

GCONINJE
FIELD GAS RATE 30000 /
'PLAT*' GAS NONE 2* 1.0 /
SAT-B GAS NONE 10000 /
'GR-*' GAS FLD 6* VOID /
/
    
```

### Example 4

The field injects water to replace half its production voidage. The water injection is shared between the injection wells in proportion to their guide rates or potentials, subject to their individual rate and pressure limits.

```
GCONINJE
  FIELD  WAT  VREP  3* 0.5 /
/
```

### Example 5

As Example 1, but with the remainder of the field's voidage replacement needs being met by water injection.

```
GCONINJE
  FIELD  GAS  REIN  2* 1.0 /
  FIELD  WAT  VREP  3* 1.0 /
/
```

### Example 6

ECLIPSE 100

As Example 3, but with the remainder of the field's voidage replacement needs being met by water injection, subject to a maximum rate of 6000 stb/day on PLAT-A and PLAT-B. The water injection is to be distributed, whenever possible, between the bottom-level groups in proportion to their net voidage rates after allowing for gas injection.

```
GCONINJE
  FIELD  GAS  RATE  30000 /
  'PLAT*' GAS  NONE  2*      1.0 /
  SAT-B  GAS  NONE  10000 /
  'GR-*' GAS  FLD   6*      VOID /
  FIELD  WAT  VREP  3*      1.0 /
  'PLAT*' WAT  NONE  6000 /
  'GR-*' WAT  FLD   6*      NETV /
/
```

## GCONPRI

## Group/field production limits for prioritization

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword sets the production rate limits for groups using the prioritization option. The option must be activated with the keyword `PRIORITY`. See the `PRIORITY` keyword for a description of this option, and how it can be mixed with the guide rate method of group control.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

---

**Note:** When switching between group prioritization and group production rate control methods `WELOPEN` can be used to open wells temporarily closed under prioritization control.

---

The set of records must end with a blank record, containing only a slash (/).

- Group name or group name root  
or `FIELD` (for field rate limits)  
  
A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.
- Oil production rate upper limit. User defined arguments can be set with keywords `UDQ` and `UDADIMS`.

UNITS:  $\text{sm}^3/\text{day}$  (`METRIC`),  $\text{stb}/\text{day}$  (`FIELD`),  $\text{scc}/\text{hr}$  (`LAB`),  $\text{sm}^3/\text{day}$  (`PVT-M`)

DEFAULT: No limit

- Procedure on exceeding oil rate limit
  - `NONE` Do nothing
  - `CON` Shut worst-offending connection in worst-offending well
  - `+CON` Shut worst-offending connection and all below it in worst-offending well (see keyword `COMPORD`)
  - `WELL` Shut or stop worst-offending well  
(item 9 in keyword `WELSPECS`)

*ECLIPSE 100 only*

`PLUG` Plug back worst-offending well (see keyword `WPLUG`)

`PRI` Control group/field production rate by prioritization (using the first priority formula if two have been defined).

*ECLIPSE 100 only*

`PR2` Control group/field production rate by prioritization using the second priority formula.

(In ECLIPSE 300, `CON+` is interpreted as `+CON` for back-compatibility)

DEFAULT: `NONE`

*ECLIPSE 300*

Wells and connections are closed or plugged back at the end of the timestep in which the limit is exceeded (but see keyword `WLIMTOL`). The worst-offending well or connection here is the one producing the highest ratio of the violating phase to the well's preferred phase (item 6 of keyword `WELSPECS`). See also keywords `COMPLUMP` and `WORKLIM`.

If a preferred phase is not defined, the worst offending well or connection here is the one producing the highest rate of the violating phase.

4. Water production rate upper limit. User defined arguments can be set with keywords `UDQ` and `UDADIMS`.  
  
UNITS:  $\text{sm}^3/\text{day}$  (`METRIC`),  $\text{stb}/\text{day}$  (`FIELD`),  $\text{scc}/\text{hr}$  (`LAB`),  $\text{sm}^3/\text{day}$  (`PVT-M`)  
  
DEFAULT: No limit
5. Procedure on exceeding the water rate limit in item 4  
  
The choices are as defined in item 3.  
  
DEFAULT: NONE
6. Gas production rate upper limit. User defined arguments can be set with keywords `UDQ` and `UDADIMS`.  
  
UNITS:  $\text{sm}^3/\text{day}$  (`METRIC`),  $\text{Mscf}/\text{day}$  (`FIELD`),  $\text{scc}/\text{hr}$  (`LAB`),  $\text{sm}^3/\text{day}$  (`PVT-M`)  
  
DEFAULT: No limit
7. Procedure on exceeding the gas rate limit in item 6  
  
The choices are as defined in item 3.  
  
DEFAULT: NONE
8. Liquid production rate upper limit. User defined arguments can be set with keywords `UDQ` and `UDADIMS`.  
  
UNITS:  $\text{sm}^3/\text{day}$  (`METRIC`),  $\text{stb}/\text{day}$  (`FIELD`),  $\text{scc}/\text{hr}$  (`LAB`),  $\text{sm}^3/\text{day}$  (`PVT-M`)  
  
DEFAULT: No limit
9. Procedure on exceeding the liquid rate limit in item 8  
  
The choices are as defined in item 3.  
  
DEFAULT: NONE
10. Reservoir fluid volume production rate upper limit. User defined arguments can be set with keywords `UDQ` and `UDADIMS`.  
  
The procedure on exceeding this limit is `PRI`.  
  
UNITS:  $\text{rm}^3/\text{day}$  (`METRIC`),  $\text{rb}/\text{day}$  (`FIELD`),  $\text{rcc}/\text{hr}$  (`LAB`),  $\text{rm}^3/\text{day}$  (`PVT-M`)  
  
DEFAULT: No limit
11. Reservoir volume production balancing fraction upper limit. User defined arguments can be set with keywords `UDQ` and `UDADIMS`.  
  
This limits the group's reservoir fluid volume production rate to the specified fraction (or multiple) of the group's reservoir fluid volume injection rate.  
  
The procedure on exceeding this limit is `PRI`.  
  
DEFAULT: No limit
12. ECLIPSE 300 only: Wet gas production rate upper limit. User defined arguments can be set with keywords `UDQ` and `UDADIMS`.

Wet gas rate is related to the hydrocarbon moles produced using a unity Z-factor at surface conditions.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC), Mscf/day (FIELD), scc/hr (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

DEFAULT: No limit

13. ECLIPSE 300 only: Procedure on exceeding the wet gas rate limit in item 12

The choices are as defined in item 3.

DEFAULT: NONE

14. ECLIPSE 300 only: Surface gas volume production balancing fraction upper limit. User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

This limits the group's surface gas volume production rate so that the available gas (production gas minus fuel gas minus sales gas) is the specified fraction (or multiple) of the group's surface gas volume injection rate. (Setting [item 104](#) in `OPTIONS3` to a non-zero value modifies the balancing so that it is the surface gas volume **production** which is limited to the specified fraction (or multiple) of the group's surface gas volume injection rate.)

The procedure on exceeding this limit is `PRI`.

DEFAULT: No limit

15. ECLIPSE 300 only: Surface water volume production balancing fraction upper limit. User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

This limits the group's surface water volume production rate to the specified fraction (or multiple) of the group's surface water volume injection rate.

The procedure on exceeding this limit is `PRI`.

DEFAULT: No limit

16. Linearly combined rate target or upper limit. Linear combination coefficients must be set with keyword [LINCOM](#). User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

UNITS: determined by keyword [LCUNIT](#)

DEFAULT: No target or limit

17. Procedure on exceeding the linearly combined rate limit in item 16

The choices are as defined in item 3.

DEFAULT: NONE

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

See also keywords [GRUPTARG](#) and [PRIORITY](#).

## Notes

For temperature values outside the interval specified, constant value extrapolation is performed. If a non-default limit is specified for any of the production balancing targets/limits (that is, any of items [11](#), [14](#) and [15](#)), ECLIPSE will solve all the injectors before the producers at each timestep, instead of the other way round. While any group has a production balancing fraction upper limit, the following controls are not allowed because these facilities require the producers to be solved before the injectors.

- Group reinjection or voidage replacement targets/limits
- Well reinjection or voidage replacement targets/limits
- Guide rate definitions VOID or NETV in keyword `GCONINJE` item 10
- Sales gas control (keyword `GCONSALE`), which uses reinjection.
- Advanced or Make-up gas (keywords `GADVANCE` or `GINJGAS`)
- Injection limited by availability (keyword `WAVAILIM`).

ECLIPSE 100 only

ECLIPSE 100 only

ECLIPSE 300 only

ECLIPSE 300 only

ECLIPSE 300

If the composition of the injected gas stream is defined by the produced vapor from a group or well (keywords `GINJGAS` or `WINJGAS`), the composition will be taken from the previous converged Newton iteration.

### Example

The field has an oil production rate limit of 10,000 stb/day. All groups with a name beginning with PLAT have liquid production rate limits of 6,000 stb/day. Wells will be brought on in decreasing order of priority until these limits are reached. The platforms also have gas rate limits of 20,000 Mscf/day. If these limits are exceeded the worst-offending wells will be worked over.

```
GCONPRI
FIELD 10000 PRI /
'PLAT*' 4*          20000 CON 6000 PRI /
/
```

2. Production rate control mode

NONE No immediate control of production rate

ORAT Group/field oil production rate is controlled to meet the target specified in item 3

WRAT Group/field water production rate is controlled to meet the target specified in item 4

GRAT Group/field gas production rate is controlled to meet the target specified in item 5

LRAT Group/field liquid production rate is controlled to meet the target specified in item 6

CRAT Group/field linearly combined production rate is controlled to meet the target specified in item 20

RESV Group/field reservoir fluid volume production rate is controlled to meet the target specified in item 14

PRBL Group/field reservoir fluid volume production rate is controlled to meet the target production balancing fraction specified in item 15

*ECLIPSE 300 only*

WGRA Group/field wet gas production rate is controlled to meet the target specified in item 16

*ECLIPSE 300 only*

CVAL Group/field calorific rate is controlled to meet the target specified in item 17. Molar calorific values must be specified with the [CALVAL](#) keyword before this control mode may be used.

*ECLIPSE 300 only*

PBGS Group/field surface gas production rate is controlled to meet the target specified in item 18

*ECLIPSE 300 only*

PBWS Group/field surface water production rate is controlled to meet the target specified in item 19

FLD Group is immediately under control from a higher level group or the field, producing its share of the higher group's or field's target rate, according to its guide rate (which must be set in items 9 and 10 in this keyword).

DEFAULT: NONE

3. Oil production rate target or upper limit. User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

UNITS: sm<sup>3</sup>/day (METRIC), stb/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: No target or limit

4. Water production rate target or upper limit. User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

UNITS: sm<sup>3</sup>/day (METRIC), stb/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: No target or limit

5. Gas production rate target or upper limit. User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

UNITS: sm<sup>3</sup>/day (METRIC), Mscf/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: No target or limit

6. Liquid production rate target or upper limit. User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

UNITS: sm<sup>3</sup>/day (METRIC), stb/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: No target or limit

7. Procedure on exceeding a maximum rate limit

NONE Do nothing

CON Shut worst-offending connection in worst-offending well

+CON Shut worst-offending connection and all below it in worst-offending well (see keyword [COMPORD](#))

WELL Shut or stop worst-offending well (item 9 in keyword [WELSPECS](#))

ECLIPSE 100 only

PLUG Plug back worst-offending well (see keyword [WPLUG](#))

RATE Control group/field production rate to equal the violated upper limit

(In ECLIPSE 300, CON+ is interpreted as +CON for back-compatibility)

DEFAULT: NONE

Wells and connections are closed or plugged back at the end of the timestep in which the limit is exceeded (but see keyword [WLIMTOL](#)). The 'worst-offending' well or connection here is the one producing the highest ratio of the violating phase to the well's preferred phase (item 6 of keyword [WELSPECS](#)). See also [COMPLUMP](#) and [WORKLIM](#) for ECLIPSE 100.

ECLIPSE 300

If a preferred phase is not defined, the ‘worst offending’ well or connection here is the one producing the highest rate of the violating phase.

The procedure specified here applies to the four rate limits set in items 3 - 6, except for a rate limit that is a control target as specified in item 2. For control targets, the procedure is always RATE. The procedure can be reset for individual rate limits in items 11 - 13.

8. Is the group free to respond to a higher level production rate target?

YES production from the group is cut back as necessary to meet any rate target imposed at a higher level

NO the group produces at its own capacity or target irrespective of any higher level rate target

This item is ignored if the control data record applies to the FIELD.

DEFAULT: YES

9. Group’s production guide rate

A dimensionless number governing the group’s share of a higher level production rate target

A group needs a guide rate only if it is required to produce a specified proportion of a higher level rate target. The group is then placed under rate control, with a target rate set in proportion to its guide rate. The definition of this guide rate is specified in item 10. It can either be set for a specified phase, or calculated from the group’s production potentials or (in ECLIPSE 100) its injection rate. If the guide rate phase in item 10 differs from the phase under control, the guide rate is translated into a guide rate for the controlled phase using the group’s production ratios at the beginning of each timestep.

If no guide rate is specified, the group’s share of a higher level rate target is governed by the guide rates of its subordinate wells, or any subordinate groups with guide rates. (The well guide rates are set by default equal to the wells’ production potentials, but can be specified directly by using the keyword [WGRUPCON](#)). The group is essentially ‘transparent’ to higher level production rate targets, which will be apportioned directly down to its subordinate wells or groups with guide rates.

Set this item to a positive value if you wish to give the group a fixed guide rate for a particular phase (OIL, WAT, GAS, LIQ, RES, WGA or CVAL) defined in item 10.

Default this item if the group is to have no guide rate, or if the guide rate definition in item 10 is INJV, POTN, or FORM.

If a zero guide rate is specified, this has the same effect as setting item 10 to POTN. (This option of setting the guide rate is only included for back-compatibility with old datasets. It should not be encouraged for new datasets.)

This item is ignored if the data record applies to the FIELD.

10. Definition of the group's guide rate in item 9.

OIL The group’s guide rate applies to the oil phase.

WAT The group’s guide rate applies to the water phase.

GAS The group’s guide rate applies to the gas phase.

LIQ The group’s guide rate applies to the liquid phase.

COMB The group’s guide rate applies to the linearly combined phase.

<i>ECLIPSE 300 only</i>	WGA The group's guide rate applies to the wet gas production.
<i>ECLIPSE 300 only</i>	CVAL The group's guide rate applies to the calorific value production.
<i>ECLIPSE 100 only</i>	<p>INJV The group's guide rate is set at the beginning of each timestep equal to the group's reservoir volume injection rate. This can be useful when the field has a production balancing target that is apportioned among the groups in proportion to their injection rates. See item 15. The entry in item 9 is ignored.</p> <p>POTN The group's guide rate is set at the beginning of each timestep equal to the group's production potential - which is the sum of the production potentials of all its subordinate open producers; see "Well potentials" in the <i>ECLIPSE Technical Description</i>. The entry in item 9 is ignored. (This option is primarily intended for use with master groups in the ECLIPSE 100 Reservoir Coupling facility. It is not recommended for general use outside this facility, as similar results can be obtained more efficiently by defaulting the well and group guide rates.)</p> <p>FORM The group's guide rate is calculated at specified intervals from a formula involving its production potentials, defined with the keyword GUIDERAT. This option can be used to decrease the contribution from groups with high GOR or water cut. The entry in item 9 will be ignored. (As with the POTN option, the FORM option is primarily intended for use with master groups in the ECLIPSE 100 Reservoir Coupling facility. Outside this facility, similar results may be obtained more efficiently by applying the guide rate formula directly to the wells.)</p> <p>' ' The group has no production guide rate. Higher level production targets will be apportioned directly down to its subordinate wells, or any subordinate groups with guide rates.</p>

The item will be ignored if the data record applies to the FIELD.

DEFAULT: ' ' (The group has no production guide rate)

11. Procedure on exceeding the water rate limit in item 4.

The choices are as defined in item 7.

If this item is defaulted, the procedure specified in item 7 is applied.

12. Procedure on exceeding the gas rate limit in item 5.

The choices are as defined in item 7.

If this item is defaulted, the procedure specified in item 7 is applied.

13. Procedure on exceeding the liquid rate limit in item 6.

The choices are as defined in item 7.

If this item is defaulted, the procedure specified in item 7 is applied.

14. Reservoir fluid volume production rate target or upper limit.

The procedure on exceeding this limit is always RATE.

UNITS:  $\text{rm}^3/\text{day}$  (METRIC),  $\text{rb}/\text{day}$  (FIELD),  $\text{rcc}/\text{hr}$  (LAB),  $\text{rm}^3/\text{day}$  (PVT-M)

DEFAULT: No target or limit

15. Reservoir volume production balancing fraction target or upper limit.

This limits the group's reservoir fluid volume production rate to the specified fraction (or multiple) of the group's reservoir fluid volume injection rate.

DEFAULT: No target or limit

The procedure on exceeding this limit is always RATE.

*ECLIPSE 300 only*

16. Wet gas production rate target or upper limit

Wet gas rate is related to the hydrocarbon moles produced using a unity Z-factor at surface conditions.

UNITS: sm<sup>3</sup>/day (METRIC), Mscf/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: No target or limit

The procedure on exceeding this limit is always RATE.

*ECLIPSE 300 only*

17. Calorific rate target or upper limit

UNITS: kJ/day (METRIC), Btu/day (FIELD), J/hr (LAB), kJ/day (PVT-M)

DEFAULT: No target or limit

The procedure on exceeding this limit is always RATE.

*ECLIPSE 300 only*

18. Surface gas production balancing fraction target or upper limit.

This limits the group's surface gas volume production rate so that the available gas (production gas minus fuel gas minus sales gas) is the specified fraction (or multiple) of the group's surface gas volume injection rate. (Setting OPTIONS3 item 104 to a non-zero value modifies the balancing so that it is the surface gas volume *production* which is limited to the specified fraction (or multiple) of the group's surface gas volume injection rate.)

DEFAULT: No target or limit

The procedure on exceeding this limit is always RATE.

*ECLIPSE 300 only*

19. Surface water production balancing fraction target or upper limit

This limits the group's surface water volume production rate to the specified fraction (or multiple) of the group's surface water volume injection rate.

DEFAULT: No target or limit

The procedure on exceeding this limit is always RATE.

20. Linearly combined rate target or upper limit. Linear combination coefficients must be set with keyword LINCOM. User defined arguments can be set with keywords UDQ and UDADIMS.

UNITS: determined by keyword LCUNIT

DEFAULT: No target or limit

21. Procedure on exceeding the linearly combined rate limit in item 20.

The choices are as defined in item 7.

If this item is defaulted, the procedure specified in item 7 is applied.

End each data record with a slash (/).

End the set of records with a blank record, containing just a slash.

See also keywords [GRUPTARG](#) and [WGRUPCON](#), and also [GUIDERAT](#) and [PRORDER](#) in ECLIPSE 100.

## Notes

If a non-default value is specified for any of the production balancing targets/limits (that is, any of items [15](#), [18](#) and [19](#)), or if in ECLIPSE 100 an INJV guide rate is specified in item [10](#), ECLIPSE solves all the injectors are solved before the producers at each timestep, instead of the other way round. While any group has a production balancing fraction target or limit, the following controls are not allowed:

- Group reinjection or voidage replacement targets/limits
- Well reinjection or voidage replacement targets/limits
- Guide rate definitions (VOID or NETV in keyword [GCONINJE](#)) item 10
- Sales gas control (keyword [GCONSALE](#)), which uses reinjection
- Advanced or Make-up gas (keywords [GADVANCE](#) or [GINJGAS](#))
- Injection limited by availability (keyword [WAVAILIM](#)), because these facilities require the producers to be solved before the injectors.

*ECLIPSE 100 only*

*ECLIPSE 100 only*

*ECLIPSE 300 only*

*ECLIPSE 300 only*

*ECLIPSE 300*

If the composition of the injected gas stream is defined by the produced vapor from a group or well (keywords [GINJGAS](#) or [WINJGAS](#)), the composition will be taken from the previous converged Newton iteration.

The use of a production balancing control mode (that is, [PRBL](#), [PBGS](#) or [PBWS](#) in item 2 of this keyword) only allows balancing of the production from a group with the injection from the same group. This behavior is in contrast with that of [GCONINJE](#) in which items 11 and 12 allow the injection to a group from the production from another group.

When a group which was operating under a rate target for one phase, switches to rate control by another phase, the guide rates for any children of this group are not allowed to be zero as explained in the note in "[Group production rate limits](#)" in the *ECLIPSE Technical Description*. Instead, a small positive guide rate is imposed on such wells to force them to stay open and operate at their potential. **Unfortunately, sometimes this means that the original group gas rate target is exceeded.** Because of this, it is strongly recommended that [RATE](#) is not used to control breakthrough in this way. Two possible alternatives are

- use an alternative procedure such as [WELL](#) or [CON](#) under [GCONPROD](#) in items 11 onwards, or:
- use a [GUIDERAT](#) formula than penalizes wells that see breakthrough.

## Examples

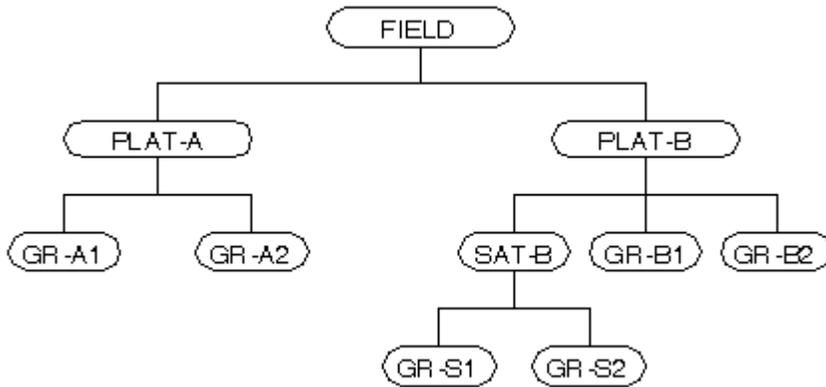

Figure 3.7. A five level hierarchy

### Example 1

The field has a target oil rate of 10,000 stb/day of oil, to be shared between the wells in proportion to their guide rates or potentials, subject to their individual rate and pressure limits.

```

GCONPROD
FIELD ORAT 10000 /
/
    
```

### Example 2

As Example 1, but PLAT-A, PLAT-B and SAT-B have water and gas production limits. If these limits are exceeded, the worst-offending wells are to be worked over.

```

GCONPROD
FIELD ORAT 10000 /
'PLAT*' NONE 1* 6000 20000 1* CON /
SAT-B NONE 1* 4000 10000 1* CON /
/
    
```

### Example 3

As Example 2, but PLAT-A and PLAT-B are required to produce equal amounts of liquid, if possible. They are given equal guide rates for the liquid phase, set to an arbitrary value of 1000, say. Since they have been given guide rates, they are placed under rate control from the higher (field) level.

```

GCONPROD
FIELD ORAT 10000 /
'PLAT*' FLD 1* 6000 20000 1* CON 1* 1000 LIQ /
SAT-B NONE 1* 4000 10000 1* CON /
/
    
```

### Example 4

As Example 3, but GR-A1 is required to produce as much as it can. The group is declared unable to respond to a higher level rate target. Its wells then produce as much as they can according to their own rate and pressure limits.

```

GCONPROD
FIELD 'ORAT' 10000 /
'PLAT*' FLD 1* 6000 20000 1* CON 1* 1000 LIQ /
SAT-B NONE 1* 4000 10000 1* CON /
GR-A1 NONE 5* NO /
/

```

### Example 5

As Example 4, but in addition GR-B1 is required to produce 2000 stb/day of oil, irrespective of any higher level rate target. It is declared unable to respond to a higher level rate target, and placed under oil rate control with a target rate of 2000.

```

GCONPROD
FIELD ORAT 10000 /
'PLAT*' FLD 1* 6000 20000 1* CON 1* 1000 LIQ /
SAT-B NONE 1* 4000 10000 1* CON /
GR-A1 NONE 5* NO /
GR-B1 ORAT 2000 4* NO /
/

```

### Example 6

ECLIPSE 100

The field is set to produce at a reservoir volume rate equal to the total reservoir volume injection rate of the field. The reservoir volume production rate target is to be shared between PLAT-A and PLAT-B in proportion to their individual reservoir volume injection rates.

```

GCONPROD
FIELD PRBL 12* 1.0 /
'PLAT*' FLD 7* INJV /
/

```

## GCONSALE Sales gas production controls for groups/field

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword provides a means of controlling the export of associated gas from an oil field, which may at the same time have controls on the oil production rate. It is not intended for use when simulating gas fields, as it relies on gas injection to control the sales gas rate.

The sales gas production rate of a group is defined as

$$(\text{sales gas production rate}) = (\text{total gas production rate}) - (\text{gas injection rate}) + (\text{gas import rate to the group and any subordinate groups}) - (\text{gas consumption rate of the group and any subordinate groups})$$

The gas consumption and import rates are set with the keyword [GCONSUMP](#).

The sales gas production rate is controlled by reinjecting the surplus gas not required for sale. Sales gas control can be applied independently of any other production controls on the group or field, provided that there is enough injection capacity to inject the surplus gas. There must be one or more gas injectors subordinate to each group with a sales gas target. The group or field is automatically placed under gas reinjection control, and its target reinjection fraction is determined dynamically at each timestep to inject the surplus gas. Other limits on gas injection for the group or field (for example maximum surface rate) can be simultaneously applied using the keyword [GCONINJE](#): place the group under REIN control, with any value for the reinjection fraction, and supply the values for any other gas injection limits. The distribution of the injected gas between any subordinate groups can also be controlled by giving these groups upper rate limits and guide rates for gas injection, with the keyword [GCONINJE](#).

If the group or field is producing more surplus gas than the injectors can handle, the drilling queue will be scanned for a new gas injector to open. Failing this, a choice of actions can be performed at the end of the timestep to reduce the gas production in the next timestep. The choice is governed by item 5 in this keyword. If on the other hand the group or field is not producing enough gas to fulfil the sales requirements, corrective action is taken at the end of the timestep, as described under item 4.

The keyword is followed by any number of records, each containing the following items of data and terminated with a slash (/).

The set of records must end with a blank record, containing only a slash.

1. Group name or group name root

or FIELD (for field sales gas control data)

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. Sales gas production rate target. User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

A negative value switches off sales gas control (and reinjection) for the group. If you wish to continue reinjection, or impose other forms of group gas injection control, you must initiate this by subsequent use of the keyword [GCONINJE](#).

UNITS:  $\text{sm}^3/\text{day}$  (METRIC), Mscf/day (FIELD), scc/hr (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

3. Maximum permitted sales gas production rate. User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

This value should be greater than the target rate in item 2.

If the maximum rate is exceeded, the action requested in item 5 is taken at the end of the timestep.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC), Mscf/day (FIELD), scc/hr (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

DEFAULT: Infinity (1.0E20)

4. Minimum permitted sales gas production rate. User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

UNITS: sm<sup>3</sup>/day (METRIC), Mscf/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

This value should be less than the target rate in item 2.

If the rate falls below the minimum, the corrective action described below is taken at the end of the timestep:

If The group is limited by a maximum gas production rate, increase its gas rate limit by the amount necessary to reach the sales gas target

Else If There is a special gas producer (see keyword [WGASPROD](#)) open subordinate to the group and able to increase its production rate, increase the target gas rate of the special gas producer by its incremental rate set in keyword [WGASPROD](#)

Else If There are more special gas producers in the drilling queue, open the next special gas producer in the drilling queue that is subordinate to the group needing more sales gas, and not subordinate to a group under gas rate control or a prioritization group, and set the well's initial gas rate target equal to its incremental rate

Else If There are no suitable special gas producers in the drilling queue, open the next ordinary producer in the drilling queue that is subordinate to the group needing more sales gas, and not subordinate to a group under gas rate control or a prioritization group.

DEFAULT: Minus infinity (-1.0E20)

---

**Note:** Prior to 2007.1, the default for this item was 0 (Zero). If a non-positive lower limit value was specified, then this was interpreted as “no lower limit”. This was changed at 2007.1 in order to allow negative lower limit values to be specified. The pre-2007.1 behavior can be recovered by setting [item 103](#) in [OPTIONS](#) to a positive value.

---

5. Procedure on exceeding a maximum rate limit

NONE Do nothing

CON Shut worst-offending connection in worst-offending well

+CON Shut worst-offending connection and all below it in worst-offending well

WELL Shut or stop worst-offending well

(item 9 in keyword [WELSPECS](#))

PLUG Plug back worst-offending well (see keyword [WPLUG](#))

RATE Reduce the group's gas production rate target/limit to a value that meets the sales gas target after allowing for any consumption and the current rate of reinjection. Place the group on gas production rate control.

MAXR As RATE, but maximize the future production rate by setting the reinjection fraction limit to 1 (or 100 in cases with a net sales, import and consumption target of zero) so that if the

injection capacity subsequently increases the gas production target increases correspondingly. (See "Sales gas production control" in the *ECLIPSE Technical Description*.)

Pre-2007.1, the reinjection limit was set to 1 instead of 100 in cases where the net sales, import and consumption was zero. This had caused the MAXR algorithm to stagnate and not take advantage of any increases in injection capacity. The old behavior can be recovered by setting [item 103](#) in OPTIONS to a positive value.

The new "zero net sales, import and consumption" target gas reinjection fraction limit value of 100 can be modified by setting OPTIONS item 103 to a negative value.

END Stop the simulation at the end of the report step

DEFAULT: NONE

The 'worst-offending' well or connection here is the one producing the highest ratio of gas to the well's preferred phase (item 6 of keyword WELSP ECS). See also keywords [COMPLUMP](#) and [WORKLIM](#).

The MAX option overwrites the group's gas production rate limit with a value equal to the sales gas target plus the injection rate plus any gas consumption minus any import rate, while the group is operating on gas production rate control. Any user-defined limit on this quantity is erased.

The RATE and MAXR options are not allowed in groups using the prioritization option for production rate control (see keywords [GCONPRI](#) and [PRIORITY](#)).

## Examples

### Example 1

The field gas sales target is 50,000 Mscf/day. The surplus gas is to be reinjected by the gas injectors in proportion to their guide rates or injection potentials. If the surplus is too much for the injectors to handle, the worst-offending well will be shut in.

```
GCONSALE
FIELD 50000 55000 45000 WELL /
/
```

### Example 2

As example 1, but the field is subject to a gas injection limit of 30,000 Mscf/day. The rate limit is imposed with the keyword GCONINJE. The field is placed under reinjection control (since this is the control mode for sales gas control), but the reinjection fraction set here will be ignored. The field will switch to gas production rate control if it is unable to reinject all the surplus gas.

```
GCONSALE
FIELD 50000 55000 45000 RATE /
/
GCONINJE
FIELD GAS REIN 30000 1* 1.0 /
/
```

### Example 3

As example 1, but the keyword GCONINJE is used to control the distribution of reinjected gas. The grouping hierarchy is the same as that given in the examples for the GCONINJE keyword. The injected gas

is to be distributed between the bottom-level groups in proportion to their voidage production, subject to PLAT-A and PLAT-B not injecting more than their own available gas.

```
GCONSALE
FIELD  50000 55000 45000  WELL /
/
GCONINJE
'PLAT*'  GAS  NONE  2*    1.0    /
'GR-*'   GAS  FLD   6*           VOID /
/
```

## GCONSUMP Gas consumption and import rates for groups

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used to specify the rate of gas consumption and the gas import rate for individual groups. The gas consumption rate may represent, for example, gas used for power generation at a platform. The gas import rate can be used to take account of gas imported from outside the group.

Gas consumption and import rates are taken into account for group reinjection control (see keyword [GCONINJE](#)) and sales gas control (see keyword [GCONSALE](#)).

Under gas reinjection control, the gas injection rate is (gas injection rate of group) = (the group's reinjection fraction) \* [(the group's gas production rate) + (the gas import rate to the group and any subordinate groups) - (the gas consumption rate of the group and any subordinate groups)]

The sales gas production rate is calculated as (sales gas production rate) = (gas production rate) - (gas injection rate) + (gas import rate) - (gas consumption rate)

Gas consumption and import rates are also taken into account by the network model (gas consumed is subtracted from the pipeline flows, gas imported is added - but see also item 4 below), and the gas field operations model (group/field target gas rates apply to sales gas rather than gross production from the formation).

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Group name or group name root

or FIELD (if gas is consumed or imported at the field level)

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. Gas consumption rate for the group

If a negative value between 0.0 and -1.0 is specified, it is interpreted as minus the fraction of the group's gas production. Thus for example a value of -0.1 sets the gas consumption rate for the group to one tenth of its total gas production rate. A negative value is not allowed when running the gas field operations model. A user defined argument can be set with keywords [UDQ](#) and [UDADIMS](#).

UNITS: sm<sup>3</sup>/day (METRIC), Mscf/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: Zero

3. Gas import rate for the group. The value must be greater than or equal to zero. A user defined argument can be set with keywords [UDQ](#) and [UDADIMS](#).

UNITS: sm<sup>3</sup>/day (METRIC), Mscf/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: Zero

4. Name of the network node from which the group's consumption should also be removed or import added

This item is only relevant if you are using the extended network model. It is ignored otherwise. The item defines the point in the network where the gas consumption should be subtracted from (or import added to) the network flow. This is necessary because the extended network structure is distinct from the group hierarchy, and in general there is no correspondence between groups and network nodes (except at the source-groups that supply production into the network, for example well-groups).

If this item is defaulted when the extended network model is active, the result is as follows. If the group in item 1 is a source-group, then the default node is the node with the same name as the source-group. If the group in item 1 is **not** a source-group, then the default is that the consumption or import will **not** be taken into account in the network flows. If the group is a source-group but it is desired that the consumption or import rates are not accounted for anywhere in the network, then the character string 'NO-NODES' must be entered here.

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

Groups not specified in this keyword will have their gas consumption and import rates defaulted to zero.

## Example

```
GCONSUM
  PLAT-A  20 50  /
  PLAT-B  15   /
/
```

## GCONTROL Tolerance for group control targets

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword provides a means of controlling the accuracy to which group production and injection calculations are performed. There are three issues concerning the accuracy:

- The number of Newton iterations of each timestep for which the well rate targets are calculated to meet the group targets (see notes 1 and 2).
- When the injection gas composition in ECLIPSE 300 depends on the injection rate, the composition must be calculated using an accurate estimate of the injection rate (see note 3).
- The number of injection iterations in ECLIPSE 300. For example, when the [WAVAILIM](#) keyword is entered in ECLIPSE 300 and a limited source of gas is shared between two or more injection groups, the injection calculation may have to be iterated a number of times to match the groups' share of the available gas with their injection capability (see note 4).

**Note:** In ECLIPSE 300, the default values for items 3 and 4 are NOT the same as the defaults when GCONTROL is not included in this dataset. Use of this keyword with defaults for items 3 and 4 may change the simulation behavior for both gas and water injection. See note 5 for more details.

The keyword is followed by a line containing some or all of the following items, terminated with a slash (/).

*ECLIPSE 100 only*

1. Tolerance fraction to which group/field flow targets must be met (see note 2).

If a target is not met to within the tolerance fraction times the target value, when there is sufficient potential to meet the target, the well flow rates are recalculated to meet the target regardless of the value of NUPCOL.

The tolerance fraction does not apply to ECLIPSE 300, which ignores this value.

DEFAULT: Infinity.

2. Value of NUPCOL, the number of Newton iterations in each timestep during which the well flow rates are recalculated to meet any collective control targets (see note 1).

A value entered here overrides any value entered previously with keyword GCONTROL or NUPCOL.

DEFAULT: Unchanged.

*ECLIPSE 300 only*

3. Tolerance fraction to which the most rapidly changing well gas injection rate estimate or well available gas fraction must be met (see notes 3 and 4).

The injection calculation is repeated until the largest fractional change of all the well gas injection rate estimates lies within this tolerance, or the maximum number of iterations is reached (see item 4). If availability limits apply (see keyword [WAVAILIM](#)), this tolerance must also be met for the largest change of all the wells' available gas fractions.

DEFAULT: 1.0E-3.

*ECLIPSE 300 only*

4. Maximum number of iterations over the injection calculation (see notes 3 and 4).

DEFAULT: 5.

### Notes

1. When any form of group control option is being used (for example keywords [GCONPROD](#), [GCONINJE](#) and [GCONSALE](#)), the flow targets of certain wells are directly influenced by the behavior of other

wells in the field. For example, the target rates of producers under group control must allow for the production from wells that are under other modes of control within the group. Also injection wells performing reinjection or voidage replacement have flow targets that depend on the behavior of the production wells.

For the group targets to be met exactly, the flow targets of the wells under group control must be recalculated at every Newton iteration. But when the well flow targets change at each iteration, the convergence rate of the iterations is reduced. This is because the Jacobian matrix calculation does not include the terms representing the mutual dependency of the well rates.

As a compromise, the well flow targets are updated in the first NUPCOL Newton iterations of each timestep, and are kept constant for any subsequent iterations. (This can be set at any time in the simulation with the keyword [NUPCOL](#) or item 2 of keyword [GCONTOL](#).) Thus the group/field flow target is met exactly if the timestep converges within NUPCOL iterations. Any changes in the solution after the first NUPCOL iterations may cause the group/field flow rates to drift slightly away from their targets. In general, larger values of NUPCOL result in the group/field flow targets being met more accurately, but perhaps at the expense of requiring more Newton iterations to achieve convergence.

- ECLIPSE 100*
2. The discrepancy between a group/field flow target and its actual flow rate can be limited to lie within a tolerance fraction set in item 1 of this keyword. If at any Newton iteration a flow target is not met to within this tolerance, when there is sufficient capacity to meet the target, the well flow rates are recalculated to meet that target regardless of the value of NUPCOL. Since recalculating the well targets may retard the convergence of the Newton iterations, it is best not to make the tolerance too small. A lower limit of 0.01 is suggested.

The tolerance fraction does not apply when using the prioritization option (see keywords [GCONPRI](#) and [PRIORITY](#)). Also, the tolerance fraction currently does not apply to ECLIPSE 300.

- ECLIPSE 300*
3. The composition of the injected gas may vary with the injection rate when advance gas has been specified for the source group or well, or make-up gas has been specified for the injecting group or well (see keywords [GINJGAS](#) and [WINJGAS](#)), or when the injection gas is made up of a mixture defined by [WINJORD](#). Thus an estimate of the injection rate is required in order to calculate the injection gas composition, before the injection calculation is performed. The actual injection rate may, in turn, depend on the composition of the gas, and whether additional constraints (for example, a well BHP limit) prevent a group from achieving its injection target. The injection calculation may have to be iterated a number of times until the actual injection rates agree with the estimates used to determine the composition, to a tolerance fraction specified in item 3. An upper limit to the number of these iterations can be set in item 4. An indication that the injection calculation has not yet converged would, for example, be a significant excess gas rate value reported for a group which is required to inject all its produced gas and some make-up gas in order to meet a reinjection target.

- ECLIPSE 300*
4. An iterative loop over the injection calculation is also required to obtain an accurate solution when two or more injection groups take their gas from the same source and are limited by availability (see keyword [WAVAILIM](#)). Each injection group is assigned a certain fraction of the available gas from the source. These fractions are initially calculated in proportion to the groups' gas injection potentials. After each pass through the injection calculation loop, these fractions are recalculated using the actual gas injection rates. Thus, if a particular injection group injects significantly less than its allocated share of available gas, its unused share of available gas is reallocated to the other groups. It may take several loops around the injection calculation before the available gas fractions converge; items 3 and 4 may be used to control this iteration process.

- ECLIPSE 300*
5. items 3 and 4 control how the injection system is solved. The default values shown for items 3 and 4 are also the values adopted for the iterative loop solving the injection system if [GCONTOL](#) is absent and
    - advance gas is used, or

- make-up gas is used, or
- a WINJORD mixture has been specified, or
- availability limits have been requested.

If none of these conditions are met, the injection calculation is only performed once per Newton iteration. If GCONTOL items 3 and 4 are defaulted, the limit on the number of Newton iterations is increased to 5.

## Example

To set a two percent tolerance on group rate targets in ECLIPSE 100:

```
GCONTOL  
0.02 3 /
```

To limit the number of injection calculation iterations in ECLIPSE 300 to 2:

```
GCONTOL  
3* 2 /
```

## GCUTBACK Group cutback limits

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

Default values can be specified by “null value” indicators (n\*, where n is the number of consecutive items to be defaulted).

The set of records must end with a blank record, containing only a slash (/).

1. Group name or group name root

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. Water cut upper limit for group rate cutback

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: Infinity (1.0E20)

(A value of 0.0 or > 1.0 switches off this check)

3. Gas-oil ratio upper limit for group rate cutback

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), Mscf/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: Infinity (1.0E20)

(A value of 0.0 or > 1E19 switches off this check)

4. Gas-liquid ratio upper limit for group rate cutback

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), Mscf/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: Infinity (1.0E20)

(A value of 0.0 or > 1E19 switches off this check)

5. Water-gas ratio upper limit for group rate cutback

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/Mscf (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: Infinity (1.0E20)

(A value of 0.0 or > 1E19 switches off this check)

6. Rate cutback factor (fraction)

This is the ratio of the reduced flow rate to the current flow rate. It should be less than 1.0.

DEFAULT: same as item 2 in the [GCUTBACK](#) keyword, if that has been entered previously, otherwise no default is allowed.

7. Control phase, to which the reduced rate applies

OIL Reduced oil rate

WAT Reduced water rate

GAS Reduced gas rate

LIQ Reduced liquid rate

RESV Reduced reservoir fluid volume rate

COMB Reduced linearly combined rate (coefficients must be set with [LINCOM](#))

You are advised to choose a phase that does not have a user defined rate limit, as it would be overwritten whenever a cutback or cutback reversal occurs.

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

Whenever the group violates one of the cutback limits given in items 2 to 5, it is set to produce at a reduced target rate of the control phase specified in item 7. The target rate of the control phase is set equal to the group's current flow rate of that phase, multiplied by the cutback factor specified in item 6. The group's production rate target is met by guide rate control (see keyword [GCONPROD](#)), unless the group has been placed under prioritization with keyword [GCONPRI](#).

See also keyword [WLIMTOL](#).

## Example

```
GCUTBACK
G1 0.6 3* 0.9 LIQ /
G2 1* 3.0 2* 0.9 RESV /
/
```

## GCUTBACT Tracer cutback limits for groups

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

GCUTBACT is followed by any number of records, described below, each record terminated by a slash (/). The keyword is not compatible with the reservoir coupling option. A record may be terminated early at any item; the remaining items assume their default values. Default values can be specified before the slash by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted. There are two types of record; one describes the connection and the second lists the tracers and their limits.

The set of records must end with a blank record, containing only a slash (/).

Records of the first kind can contain some or all of the following items:

1. Group name or group name root.

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. Rate cutback factor (fraction).

This is the ratio of the reduced flow rate to the current flow rate. It should be less than 1.0. The same rate cutback factor applies to both this keyword and the [GCUTBACK](#) keyword. If GCUTBACK has been entered previously, this item overwrites item 6 in that keyword. If GCUTBACT is entered subsequently, its item 6 overwrites this item.

DEFAULT: same as item 6 in the GCUTBACK keyword, if that has been entered previously; otherwise no default is allowed.

3. Control phase, to which the reduced rate applies

OIL Reduced oil rate

WAT Reduced water rate

GAS Reduced gas rate

LIQ Reduced liquid rate

RESV Reduced reservoir fluid volume rate

COMB Reduced linearly combined rate (coefficients must be set with [LINCOM](#))

You are advised to choose a phase that does not have a user defined rate limit, as it would be overwritten whenever a cutback or cutback reversal occurs. See also Note 5 in the [WCUTBACT](#) keyword.

End the record with a slash (/)

There can follow a maximum of three subsequent records for each group. These records have some or all of the following items.

1. Tracer name (Use PLY for a polymer and BRI for brine).

2. Total tracer rate upper limit for well rate cutback

DEFAULT: No limit

3. Total tracer rate lower limit for well rate cutback reversal

DEFAULT: No limit

4. Total tracer concentration upper limit for well rate cutback (not available for partitioned tracers).  
 DEFAULT: No limit

5. Total tracer concentration lower limit for well rate cutback reversal (not available for partitioned tracers)  
 DEFAULT: No limit

End the record with a slash (/).

End the data for this well with a blank line containing just a slash(/).

Note that this means that the keyword will end with two blank lines containing just slashes.

## Notes

- No units are given for the tracer rates. The rates are those of the carrier flow.
- Since the tracers are solved after the main reservoir simulation, if it is subsequently discovered that a limit is violated the timestep is always repeated, with the action enforced from the start of the timestep. Even with doing this it may be that the 'action' lags the violation by a timestep.
- This keyword needs to end with two lines containing only slashes. See the example below.
- Whenever the group violates one of the cutback reversal limits, **and** if the group is currently operating under rate control of the phase selected in item 3 of record 1, the target rate of the phase is increased by dividing it by the factor specified in item 2. This essentially reverses the cutback process.

## Example

```

GCUTBACT
  GRP1  0.8 WAT  /
TR1 1000.0 3*/
TR2 2* 0.5 0.001 /
TR3 1500.0 10.0 0.5 /

## GCVD

## Initial coal gas concentration versus depth tables

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTEQUL (keyword [EQLDIMS](#) in the RUNSPEC section) tables of initial gas concentration versus depth, one for each equilibration region. The keyword should only be used when the Coal Bed Methane option is active (keyword [COAL](#) in RUNSPEC section). Each table consists of 2 columns of data, and must be terminated by a slash (/).

1. Depth values. The values should increase monotonically down the column.  
UNITS: m (METRIC), ft (FIELD), cm (LAB)
2. The corresponding values of gas concentration in the coal.  
UNITS:  $\text{sm}^3/\text{m}^3$  (METRIC),  $\text{Mscf}/\text{ft}^3$  (FIELD),  $\text{scc}/\text{cc}$  (LAB)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NDRXVD (keyword [EQLDIMS](#) in the RUNSPEC section).

Both GASCONC and GCVD are entirely optional. If neither of these keywords is present, the coal gas concentration is taken as the equilibrium concentration for the corresponding fracture pressure.

The initial coal gas concentration should not be set above the initial equilibrium value; ECLIPSE issues a warning if it is. If the coal gas concentration is below the equilibrium value, the non-reversible diffusion model is recommended (set item 2 in keyword [DIFFCOAL](#) to 0.0).

See also the [GASCONC](#) keyword.

### Example

With NTEQUL=1 and NDRXVD  $\geq$  2

```
GCVD
 7000 74.0
10000 74.0 /
```

## GDCQ

## Initial DCQs for multiple contract groups

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword must be used to set the initial DCQ values for each contract group, when running the Gas Field Operations Model in the multiple contract groups mode (initiated with keyword [GSWINGF](#)). The keyword must be entered after the contract groups have been defined with keyword [GSWINGF](#), but before the first [GASYEAR](#) or [GASPERIO](#) keyword. The DCQ values can subsequently be reset at any time in the simulation by further use of the GDCQ keyword.

See "[Applying separate gas supply contracts to individual groups](#)" in the *ECLIPSE Technical Description* for further details.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/). The set of records must end with a blank record, containing only a slash (/).

1. Group name or group name root

The group must previously have been defined as a contract group with keyword [GSWINGF](#).

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. The initial DCQ (Daily Contracted Quantity) of the group

UNITS:  $\text{sm}^3/\text{day}$  (METRIC), Mscf/day (FIELD), scc/hr (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

If item 1 of [DCQDEFN](#) is set to 'ENERGY':

UNITS: kJ/day (METRIC), Btu/day (FIELD), J/hr (LAB), kJ/day (PVT-M)

DEFAULT: The group's current DCQ

3. Is the group's DCQ variable or fixed?

**VAR** ECLIPSE reduces the group's DCQ as necessary to obey the swing requirement as defined in item 3 of keyword [GASYEAR](#) or item 4 of [GASPERIO](#). (If there is more than one VAR contract group, only the options YEAR or PER and NO are allowed. The option YEAR or PER must be selected if you wish ECLIPSE to reduce the DCQs automatically.)

**FIX1** The group's DCQ remains at the value set in item 2, even if the group cannot produce its target rate. During the first pass of each contract period, the group's target rate is its DCQ  $\times$  Swing Factor; or DCQ  $\times$  Profile Factor if item 3 in keyword [GASYEAR](#) or item 4 in [GASPERIO](#) is PRO. During the second pass of each contract period, the group's target rate is its DCQ  $\times$  Profile Factor.

**FIX2** Same as for **FIX1**, but in addition a maximum gas production rate of DCQ  $\times$  Swing Factor is imposed on the group while the delivery capacities are being calculated.

DEFAULT: VAR

End each data record with a slash (/).

End the set of records with a blank record, containing just a slash.

## Example

```
GDCQ
  PLAT-A 60000 VAR /
```

```
PLAT-B 40000 FIX2 /  
/
```

## GDCQECON Minimum economic DCQ limit for contract groups

	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword sets a minimum economic DCQ for contract groups, when running the Gas Field Operations Model (see "Gas field operations model" in the *ECLIPSE Technical Description*).

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/). The set of records must end with a blank record, containing only a slash (/).

1. Contract group name or name root,  
or FIELD (if the FIELD is the contract group)

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. Minimum economic DCQ value

If the DCQ falls below the specified minimum value, all the producers subordinate to the contract group will be shut or stopped (see item 9 in keyword [WELSPECS](#)). If the contract group is the FIELD, the run is terminated.

A zero value switches off this limit.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC), Mscf/day (FIELD), scc/hr (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

*ECLIPSE 100 only*

If item 1 of [DCQDEFN](#) is set to 'ENERGY':

UNITS: kJ/day (METRIC), Btu/day (FIELD), J/hr (LAB), kJ/day (PVT-M)

DEFAULT: 0.0

## GDFILE

## Imports a grid file

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword allows the grid geometry to be defined by an external Grid file. Typically, this could be a grid file generated by ECLIPSE, and it must have the required format of an ECLIPSE Grid file.

The external Grid file is composed of a set of topologically cuboidal cells, with the (X,Y,Z) position of each of the 8 corners specified independently. This allows a more flexible definition of the grid geometry than is available with the `ZCORN` and `COORD` keywords. The keyword also supports reading an EGRID format file.

See also the `IMPORT` keyword.

The keyword should be followed by the name of grid file to be imported and a file formatting flag:

1. Name of Grid file to be imported.

This argument should include the file extension and is case sensitive, that is the string entered should exactly match the name of the file to be read. The complete file name, including extension, should not exceed 72 characters in length.

2. Formatted flag (optional).

There are 2 choices:

`FORMATTED` Formatted file

`UNFORMATTED` Unformatted file

The word may be shortened to `F` or `U`.

DEFAULT: `UNFORMATTED`

The data should be terminated by a slash (/).

**CAUTION:**

- This keyword should be used with care and is not recommended for general use. It is not possible to use it in radial geometry option, or with auto refinement.
- In ECLIPSE 100, the geometric data in the imported Grid file is skipped for any local grids
- In ECLIPSE 100, this keyword is also not recommended for use with the Vertical Equilibrium option.

## ECLIPSE 100

**Note:** If [item 134](#) in `OPTIONS` is set to 1, a wider range of global cells is used as reference when calculating the geometry of the LGR cells. This can provide better output to the `.EGRID` file for visualization purposes.

## ECLIPSE 300

Prior to the 2012.1 version, ECLIPSE 300 accepted the filename without its extension and then proceeded to search for either a matching `.EGRID` or `.GRID` file in this order. The file name was additionally converted to upper case. Whilst this is not the recommended usage of the keyword, the behavior is retained for backwards compatibility and is triggered by providing a string without a period ‘.’ as the first argument to the keyword. This is illustrated by Example 2.

## Examples

For the examples which follow, the simulator reads the geometric grid data from the file specified, after which it switches back to the next keyword in the current file.

### Example 1

For ECLIPSE 100 and ECLIPSE 300 where the file to be read is ModelGrid.eGrid:

```
GDFILE  
ModelGrid.eGrid /
```

### Example 2

For ECLIPSE 300 exercising the legacy behavior where the file to be read is either MODELGRID.EGRID or MODELGRID.GRID

```
GDFILE  
ModelGrid /
```

## GDIMS

## Specify the dimensions for the instantaneous gradient option

	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies the dimensions for the instantaneous gradient option, see the "[Instantaneous gradients](#)" section in the *ECLIPSE Technical Description*. The keyword is followed by a single item of data, terminated by a slash (/). The instantaneous gradient option requires an unencoded gradient license since the results are accessed as summary quantities.

1. The maximum number of well gradient parameters defined by the [GWRTWCV](#) keyword in the SCHEDULE section.

DEFAULT: 0

### Example

```
GDIMS
 3 /
```

## GDORIENT **Grid orientation**

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This is an optional keyword which data generation applications (and manually generated decks) can use to indicate to ECLIPSE and to post-processing software the orientations of the grid and the data prescribed on it. ECLIPSE itself will not use this information in its calculations, but it will attempt to verify that the Z-direction and handedness, values 4 and 5, are consistent with the grid. It will not modify or override the grid geometry specified with for example COORD or ZCORN regardless of the outcome of the verification.

Following the keyword line, there is a single record containing five items of data, ending with a slash (/):

1. Indicates property ordering, taking the value INC if properties such as PORO or PERMX are input in order of increasing I, otherwise it takes the value DEC.

DEFAULT: INC

2. Indicates property ordering, taking the value INC if properties such as PORO or PERMX are input in order of increasing J, otherwise it takes the value DEC.

DEFAULT: INC

3. Indicates property ordering, taking the value INC if properties such as PORO or PERMX are input in order of increasing K, otherwise it takes the value DEC.

DEFAULT: INC

4. The Z-direction

DEFAULT: DOWN

5. The handedness of the grid.

DEFAULT: RIGHT

If the keyword is not supplied the simulator will assume default values for items 1-3 and attempt to determine items 4 and 5 directly from the grid.

Note that some pre- and post-processors do not support left-handed grids.

### Example

```
GDORIENT
  INC INC INC DOWN RIGHT /
```

## GDRILPOT Group minimum potential rates for drilling

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies a minimum potential flow rate for a group (see "Well potentials" in the *ECLIPSE Technical Description*). If the group's production or injection potential falls below this limit the drilling queue (set up with either keyword `QDRILL` or `WDRILPRI`) will be scanned for a new well, of the appropriate type, to open to restore the group's potential.

This feature allows the drilling process to be started in good time before the well is required to maintain a group production or injection target set with keyword `GCONPROD` or `GCONINJE`, by setting the group's minimum potential rate sufficiently greater than its actual flow target, if the well has a non-zero drilling time set in item 2 of keyword `WDRILTIM`.

**Note:** If wells are treated as closed while being drilled (see item 3 of keyword `WDRILTIM`), ECLIPSE continues to drill new wells because the group potential will not increase immediately. This can be avoided by using the `QDRILL` option in the `WDRILTIM` keyword.

The GDRILPOT keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Group name or group name root

or FIELD (for field minimum potential rates)

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. Quantity to which the rate in item 3 applies

OPR Oil production potential

WPRD Water production potential

GPRD Gas production potential

OINJ Oil injection potential

WINJ Water injection potential

GINJ Gas injection potential

*ECLIPSE 100 only*

**Note:** Only one production quantity can be active at any one time for each group, but injection limits may be defined simultaneously by entering multiple records for the same group.

3. Minimum potential rate of the quantity in item 2

The value must be greater than or equal to zero.

UNITS: sm<sup>3</sup>/day (METRIC), stb/day for oil or water (FIELD), Mscf/day for gas (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: Zero

A zero or negative value implies that there is no minimum potential rate, for the quantity specified in item 2, applying to this group.

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

## Example

```
GDRILPOT
-- group
-- name      phase      rate
GR-A        OPRD        7520      /
GS-A        GPRD        17760     /
GR-A        WINJ        3000      /
GR-A        GINJ        35000     /
/
```

## GECON

## Economic limit data for groups and the field

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The records may be terminated at any item after item 1. The remaining items assume their default values. Default values can be specified before the slash by a null repeat count of the form  $n^*$ , where  $n$  is the number of consecutive items to be defaulted.

The set of records must end with a blank record, containing only a slash (/).

1. Group name or group name root

or FIELD (for field economic limit data)

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. Minimum oil production rate. User defined arguments can be set with keywords UDQ and UDADIMS.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC),  $\text{stb}/\text{day}$  (FIELD),  $\text{scc}/\text{hr}$  (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

DEFAULT: 0.0

If the group (or field) oil production rate falls below the specified minimum, all the producers in the group (or field) are shut or stopped (see item 9 in keyword WELSPECS). A zero or negative value switches off this constraint.

3. Minimum gas production rate. User defined arguments can be set with keywords UDQ and UDADIMS.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC),  $\text{Mscf}/\text{day}$  (FIELD),  $\text{scc}/\text{hr}$  (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

DEFAULT: 0.0

If the group (or field) gas production rate falls below the specified minimum, all the producers in the group (or field) are shut or stopped (see item 9 in keyword WELSPECS). A zero or negative value switches off this constraint.

4. Maximum group or field water cut (water-liquid ratio). User defined arguments can be set with keywords UDQ and UDADIMS.

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC),  $\text{stb}/\text{stb}$  (FIELD),  $\text{scc}/\text{scc}$  (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: No limit

(A value of 0.0 switches off this constraint).

5. Maximum group or field gas-oil ratio. User defined arguments can be set with keywords UDQ and UDADIMS.

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC),  $\text{Mscf}/\text{stb}$  (FIELD),  $\text{scc}/\text{scc}$  (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: No limit

(A value of 0.0 switches off this constraint)

6. Maximum group or field water-gas ratio. User defined arguments can be set with keywords UDQ and UDADIMS.

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC),  $\text{stb}/\text{Mscf}$  (FIELD),  $\text{scc}/\text{scc}$  (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: No limit

(A value of 0.0 switches off this constraint)

7. Workover procedure on exceeding water cut, GOR or WGR limit

NONE Do nothing

CON Shut worst-offending connection in worst-offending well

+CON Shut worst-offending connection and all below it in worst-offending well (see keyword [COMPORD](#))

WELL Shut or stop worst-offending well (item 9 in keyword [WELSPECS](#))

ECLIPSE 100 only

PLUG Plug back worst-offending well (see keyword [WPLUG](#))

ECLIPSE 300 only

ALL Shut all producers subordinate to the group

DEFAULT: NONE

8. End run flag

YES The run stops at the next report time if all the producers in the group (or the field) are shut or stopped for any reason, provided the group has had at least one producer open previously

NO The run continues regardless

DEFAULT: NO

ECLIPSE 100

---

**Note:** If the [GCALECON](#) keyword of the gas calorific value control option is entered subsequently to the [GECON](#) keyword, item 4 of the [GCALECON](#) keyword overwrites the 'end run flag' defined here.

---

ECLIPSE 100 only

9. Maximum allowed number of open wells subordinate to this group

DEFAULT: 0 (Which implies no limit)

This option prevents wells from being opened automatically (AUTO in keywords [WCONPROD](#), [WCONINJE](#), [WELOPEN](#)) or from the drilling queue (keyword [QDRILL](#)) or swapped from one group to this one (keyword [WREGROUP](#)) if the number of subordinate wells would violate this limit. The limit does not prevent wells being opened manually ('OPEN' in keywords [WCONPROD](#) and [WCONINJE](#) for example), but a warning message is issued if they violate this limit.

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

---

**Note:** The actions taken as a result of the [GECON](#) keyword are applied at the end of the timestep. The run normally continues with the next timestep. However, the [WLIMTOL](#) keyword may be used to instruct the simulator to redo the timestep if an economic limit has been violated by more than a specified tolerance.

---

See also the ECLIPSE 100 keywords [COMPLUMP](#) and [WORKLIM](#).

## Example

```
GECON
GRUP1 2000 1* 0.8 10.0 1* CON Y /
GRUP2 1000 /

## Tracer economic limits for groups

GECONT is used to set tracer economic limits for groups, including polymer and brine. The keyword is not compatible with the reservoir coupling option.

GECONT is followed by any number of records, described below, each record terminated by a slash (/). A record may be terminated early at any item; the remaining items assume their default values. Default values can be specified before the slash by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted. There are two types of record; one describes the connection and the second lists the tracers and their limits.

The set of records must end with a blank record, containing only a slash (/).

Records of the first kind can contain some or all of the following items:

1. Group name or group name root

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. Workover procedure when a limit is violated

NONE No action to be taken

CON Shut worst-offending connection

+CON Shut worst-offending connection and all those below it (see keyword [COMPORD](#))

WELL Shut or stop the worst-offending well (item 9 in keyword [WELSPECS](#))

PLUG Plug back the worst offending well (see keyword [WPLUG](#))

DEFAULT: NONE

3. End run flag

YES The run stops at the next report time if the well is shut or stopped for any reason after being opened

NO The run continues regardless

DEFAULT: NO

4. Maximum allowed number of open wells subordinate to this group

DEFAULT: 0 (which implies no limit)

This option prevents wells from being opened automatically (AUTO in keywords [WCONPROD](#), [WCONINJE](#), [WELOPEN](#)) or from the drilling queue (keyword [QDRILL](#)) or swapped from one group to this one (keyword [WREGROUP](#)) if the number of subordinate wells would violate this limit. The limit does not prevent wells being opened manually ('OPEN' in keywords [WCONPROD](#) and [WCONINJE](#) for example), but a warning message is issued if they violate this limit.

End the record with a slash (/).

A maximum of three subsequent records can follow, for each group. These records can contain some or all of the following items.

1. Tracer name (Use PLY for a polymer and BRI for brine)
2. Maximum total tracer rate  
DEFAULT: No limit
3. Maximum total tracer concentration (not available for partitioned tracers)  
DEFAULT: No limit  
The following are only available for two-phase tracers.
4. Maximum free tracer rate  
DEFAULT: No limit
5. Maximum free tracer concentration  
DEFAULT: No limit
6. Maximum solution tracer rate  
DEFAULT: No limit
7. Maximum solution tracer concentration  
DEFAULT: No limit.

End the record with a slash (/).

End the data for this well with a blank line containing just a slash(/).

Note that this means that the keyword will end with two blank lines containing just slashes.

## Notes

- No units are given for the tracer rates. The rates are those of the carrier flow.
- Due to the tracers being solved after the main reservoir simulation if it is subsequently discovered that a limit is violated the timestep is always repeated with the action being enforced from the start of the timestep. Even with doing this it may be that the 'action' lags the violation by a timestep.
- This keyword needs to end with two lines containing only slashes. See the examples.

See also keyword [WLIMTOL](#) and the ECLIPSE 100 keyword [WORKLIM](#).

## Examples

## GEFAC

## Sets group efficiency factors (for downtime)

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword allocates efficiency factors to groups, rather than individual wells. Group efficiency factors may be applied when all the wells subordinate to a group have their downtimes synchronized, so that the group either flows with its full rate or not at all. If the wells are taken down individually, rather than all together, efficiency factors should be allocated to the wells (with keyword [WEFAC](#)) instead of the group.

The GEFAC keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Group name or group name root

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

---

**Note:** The FIELD cannot have an efficiency factor.

---

2. Efficiency factor for the group

This is the fractional time for which the group is operational. For example, if the group is down for 10 percent of the time, its efficiency factor is 0.9.

The efficiency factor must be greater than zero.

DEFAULT: 1.0

3. Should the group's efficiency factor be automatically transferred to its corresponding node in the Extended Network option? (See "[Well and group efficiency factors](#)" in the *ECLIPSE Technical Description*).

**YES** The node's flow contribution to the flow rate of its parent node in the network will be multiplied by the group's efficiency factor. Thus the branch pressure losses downstream of the parent node reflects the time-averaged contribution of this group. (Note that the pressure losses in the outlet branch of this group's node still reflect the full, or reported, group flow rate.)

**NO** The node's contribution to the flow rate of its parent node in the network is **not** multiplied by the group's efficiency factor. Thus all downstream branch pressure losses reflect the full flow rate of this group.

This flag applies only to the Extended Network Model. If the Standard Network Model is being run, the groups' **reported** flows are always used to calculate the pressure losses in the branch to their parent group.

The flag also applies only if there is a node in the extended network that has the same name as the group. Otherwise, the [NEFAC](#) keyword can be used to apply efficiency factors directly to the network nodes.

DEFAULT: YES

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

The efficiency factors for groups not specified with this keyword are defaulted to 1.0.

## Treatment of group downtime

If wells are brought down individually on a regular basis for short periods of maintenance, each should be given its own efficiency factors with keyword **WEFAC**. The treatment of well downtime is described in the **WEFAC** keyword documentation.

If all the wells in a group are brought down together for regular maintenance, then the efficiency factor should be applied to the group. The treatment of group downtime is entirely analogous to the treatment of well downtime. The group is solved with its full flow rate, which is the sum of its wells' full flow rates (unless any wells or subordinate groups also have efficiency factors allocated). The group's flow rates reported in the Print and Summary files also reflect its full flow rate. Any flow targets and limits for the group will apply to its full flow rate. But the group rates are multiplied by the group efficiency factor when summing the group's contribution to its parent group in the hierarchy. Thus the flows of any superior groups will reflect this group's time-averaged flow rate.

Below the group, the flows of the wells and any subordinate groups reflect the full flowing rates (subject to any efficiency factors applied at a lower level). But the well and group flows are multiplied by the efficiency factor when incrementing their cumulative flows over the timestep, and the group efficiency factor is also applied to the subordinate well connections when determining the source/sink terms in the reservoir grid blocks.

If the Standard Network option is in use, the groups' **reported** flows are always used to calculate the pressure losses in the branch to their parent group. Thus if a group (but none of its subordinate groups or wells) has an efficiency factor set  $< 1.0$ , the flow in the branch to its parent group, and any branches below it in the group tree, reflects the full flow rate, while the flow in its parent group's network branch and any branches above it in the group tree reflects the group's time-averaged rate.

The Extended Network option has more flexibility in handling downtime. If an efficiency factor is applied to a group that has the same name as a node in the network, by default the efficiency factor is also applied to the corresponding node. The node's flow rates are multiplied by the efficiency factor when adding them to the flow in its parent node. The pressure drop in a node's outlet branch is calculated from the node's flow rate. Thus the node's outlet branch and the branches upstream of the node reflects the full flow rates, while the branches downstream of its parent node reflects the time-average flows. (This is equivalent to the Standard Network Model's treatment of group efficiency factors.) However, by setting item 3 of this keyword to 'NO' it is possible to specify that the group's full flow rates should be used for calculating all downstream pressure losses, by not assigning the group's efficiency factor to the corresponding network node.

If the wells are receiving gas lift, their gas lift injection rates reflects the full flows. But the group's contribution to the lift gas supply rate of its superior groups are multiplied by its efficiency factor to reflect the time-averaged rate.

---

**Note:** It is not normal for efficiency factors to be allocated on more than one level of the well/group hierarchy. If they are, then the efficiency factors are multiplicative. That is, if a group has an efficiency factor of 0.9 (implying that all its wells are down together for 10 percent of the time), and also one of its wells is given an efficiency factor of 0.9 in **WEFAC**, then that well's contribution to the field's production rate and its cumulative totals is reduced to 81 percent of its full rate. A well's efficiency factor product (multiplied with the efficiency factors of all its superior groups) may be written to the Summary file using the **SUMMARY** section keyword **WEFFG**.

---

**Note:** If you are using the Reservoir Coupling option, there are some subtle issues related to the use of the group efficiency factor.

Due to possible differences in timestepping between the Master and Slave simulations, the actual mechanism for passing rates from the Slave to the Master is to pass the cumulative flow, then the Master calculates the difference in cumulative flow over its timestep to work out the flow rates. The efficiency factor from the Slave group is also passed to the Master so that its effect can be removed, allowing the master group to calculate the peak flow. The Master group cumulative values are subsequently calculated from the calculated peak flow, the Master group efficiency factor and the Master group timestep.

**If you want the Master group's time averaged rate to be based on the same efficiency factor as the Slave, you need to re-specify the Slave group efficiency in the Master group.**

In some situations, you may need to specify different efficiency factors for the Master group and Slave group, for example if you have an efficiency factor in the group hierarchy *above* the Master group, then this can be specified for the Slave group so that it reports the correct peak and averaged flows.

One further issue to be aware of is that Master group cumulative quantities will revert to the Slave cumulative quantity if a Master timestep is chopped.

---

A rock stress (force) conservation in each coordinate direction is calculated in addition to the fluid mass and energy conservation.

The keyword is followed by a single record that contains options on the frequency of running the coupled geomechanics calculation and the type of calculation.

1. This item is not used.
2. A character specifying how often the coupled geomechanics calculation is run

R run the geomechanics calculation at each report step

T run the geomechanics calculation at the end of each timestep

DEFAULT: R

3. A character string requesting the stress calculation method

FE requests a finite element stress calculation

DEFAULT: FE

4. A character string specifying the porosity-stress relationship model

RVBAL requests that rock volume be conserved

RMBAL requests that rock mass be approximately conserved

RCOMP requests that porosity is determined from a [ROCKCOMP](#) model

DEFAULT: RVBAL

---

**Note:** The rock volume conservation model is implemented with the relation  $V^{n+1}(1-\varphi^{n+1}) = V^n(1-\varphi^n)$ , which can also be written  $\delta\varphi = -(1-\varphi)\delta\varepsilon_b$ , where  $V$  is the bulk volume,  $\varphi$  is the porosity,  $n$  is the timestep number and  $\delta\varepsilon_b$  is the change in volumetric strain. The approximate rock mass conservation model is implemented following the relation

$$\delta\varphi = -\left(1 - \varphi - \frac{C_r}{C_{bc}}\right)(\delta\varepsilon_b - C_r\delta P)$$

where  $C_r$  is the rock or matrix compressibility,  $C_{bc}$  is the bulk compressibility,  $\varepsilon_b$  is the bulk volumetric strain, and the symbol  $\delta A$  denotes  $A^{n+1} - A^n$  where  $A$  is any quantity that changes from timestep  $n$  to timestep  $n + 1$ . Further details of this second relationship can be found in the discussion of the keyword [ROCK](#) and see also [\[Ref. 46\]](#) and [\[Ref. 134\]](#).

---

5. A character string specifying the initial equilibration method

INIT will preserve initial pore volumes and pressures after application of traction, stress or velocity boundary conditions.

NOINIT allows the reservoir to compress and change these quantities.

DEFAULT: INIT

6. A character string specifying the sign of compressive stresses. All boundary tractions and stresses will follow this convention.

COMPN Compressive stress is negative:  $\sigma^T = \sigma^e - \alpha P$

COMPP Compressive stress is positive:  $\sigma^T = \sigma^e + \alpha P$

DEFAULT: COMPN

7. A character string specifying an initial thermal stress calculation

INITH

NOINITH

DEFAULT: NOINITH

The record can be terminated early with a slash (/), the remaining items taking default values.

Geomechanics in ECLIPSE 300 is discussed in the "Geomechanics" chapter of the *ECLIPSE Technical Description*.

---

**Note:** Some data must be entered in order for the coupled geomechanics calculation to proceed. The minimum data required is Young's modulus as discussed in the keyword [YOUNGMOD](#) and the Poisson ratio as discussed in [POISSONR](#).

---

## Example

```
-- Run the coupled geomechanics finite element stress calculation,  
-- update at each report step  
-- rock volume conservation porosity-stress relation  
-- initialize the solution to preserve specified pressures,  
-- pore volumes and FIP  
  
GEOMECH  
/
```

## GEOYCAP **Geomechanics cap model parameters**

	<b>ECLIPSE 100</b>
x	<b>ECLIPSE 300</b>
x	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is used to specify the extended Sandler-Rubin cap model to simulate the plastic deformation having a shear failure surface together with a cap shaped yield in compression.

The keyword is only valid if **GEOMECH** is specified in the **RUNSPEC** section. It allows the user to specify the cap model parameters region by region. Every record line corresponds to a geomechanical material region defined in **YLDNUM**, each of which is terminated by a slash (/). Each record consists of some or all of the following items:

1. Initial rock cohesive stress  $C_0$   
This must be a positive quantity.
2. Internal friction angle  
UNITS: degrees (METRIC), degrees (FIELD), degrees (LAB), degrees (PVT-M)  
DEFAULT: 30 degrees
3. UCS - Uniaxial Compression Strength  
This must be a positive quantity
4. Material parameter K that defines the ratio of the yield stress in triaxial extension to the yield stress in triaxial compression.  
DEFAULT: 1.0
5. Ratio of principal ellipse radii R for cap surface  
DEFAULT: 1.0
6. Material parameter W for hardening law  
This must be a positive quantity.
7. Material parameter D1 for hardening law  
This must be a positive quantity.
8. Material parameter D2 for hardening law  
This must be a positive quantity.  
DEFAULT: 0.0
9. Initial cap position X0  
This must be a non-positive quantity.  
DEFAULT: 0.0

### Example

```

-- FIELD units
GEOYCAP
-- Co  PHI  UCS  K    R    W    D1
   1450 30  3600 1.0  3.2  0.13  9.79E-5  2*/

```

## GEOYLDF Geomechanics yield function parameters

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword is only valid if **GEOMECH** is specified in the **RUNSPEC** section. It allows the user to specify the yield function parameters region by region. Every record line corresponds to a geomechanical material region defined in **YLDNUM**, each of which is terminated by a slash (/). The data is terminated by a null record (that is a record with no data before the terminating slash). Each record consists of some or all of the following items:

1. Initial rock cohesive strength,  $C_{o_i}$   
This must be a positive quantity.
2. The angle of internal friction  
UNITS: degrees (METRIC), degrees (FIELD), degrees (LAB), degrees (PVT-M)  
DEFAULT: 30 degrees
3. The failure model  
This must be one of:  
  
MC indicating the Mohr-Coulomb model  
  
DP indicating the Drucker-Praeger model.  
  
DEFAULT: MC (Mohr-Coulomb)
4. UCS - uniaxial compressive strength  
This must be a positive quantity
5. Type of hardening law.  
This must be one of:  
  
'HYP' indicating a hyperbolic law  
  
'POW' indicating a power hardening law  
  
'PER' which selects perfect plasticity.  
  
DEFAULT: 'PER'
6. 'a' parameter for hardening - see equations below
7. 'b' parameter for hardening - see equations below

The hardening laws are implemented as a change in the shear cohesive strength,  $C_o$ , with change in generalized plastic strain  $\bar{\epsilon}_p$ .

Generalized plastic strain is defined as  $\bar{\epsilon}_p = \sum_{i,j} \frac{\epsilon_{ij}^p \cdot \sigma_{ij}}{F}$

where

$\varepsilon_{ij}^p$  is the plastic strain vector,

$\sigma_{ij}$  is the effective stress tensor and

$F$  is a norm of the stress tensor.

The power law takes the form  $Co = a\bar{\varepsilon}_p^b + Co_i$  while the hyperbolic law follows the relation

$$Co = \frac{\bar{\varepsilon}_p}{a + b\bar{\varepsilon}_p} + Co_i.$$

---

**Note:** Only one of Initial Rock Cohesive Strength or Uniaxial Compressive Strength is necessary to define the yield function. If UCS is entered, it will be converted to Initial Rock Cohesive Strength. If both are entered, the value of Initial Rock Cohesive Strength will be used.

---

## Example

In the PROPS section:

```
-- FIELD units
GEOYLDF
1450 30 'MC' 3600 'HYP' 1 1 /
```

## GETDATA **Read named array data from an ECLIPSE restart or init file**

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
x	EDIT
x	PROPS
x	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

The GETDATA keyword allows ECLIPSE to read named arrays from previously generated initial or restart files. The keyword should be followed by four items of data:

1. Full name of the file from which to import.  
The file name should not exceed 72 characters in length.
2. Flag indicating whether the import file is formatted or unformatted (binary).  
A single word, either FORMATTED or UNFORMATTED.  
The word may be shortened to F or U.  
DEFAULT: UNFORMATTED
3. Name of the array (ZNAME) that you wish to construct by importing data from the import file.  
ZNAME must be a valid ECLIPSE array name for the current section of the dataset.
4. Name of the corresponding array (ZALT) in the import file.  
The array ZALT in the import file is imported into the simulation as the array ZNAME.  
DEFAULT: The same name as in item 3.

The data should be terminated by a slash (/).

### Example

In this example, we want to input the SWCR array from the run `old_run.init` as SWATINIT in the current realization:

```
GETDATA
old_run.init UNFORMATTED SWATINIT SWCR /
```

### Note

In order to obtain the correct information from the restart or init file, this keyword also requires the Grid file.

The “standard” Grid file is required (see [GRIDFILE](#) keyword). By default, GRIDFILE will produce an extensible Grid file ( `.EGRID` ) but not the “standard” Grid file. Before GETDATA is used, the base run, from which the restart files are obtained, must contain the GRIDFILE keyword with the first item set to 2. This will produce the correct Grid file needed to process the GETDATA keyword. This information needs to be read in or imported for the current run. Refer to keywords [ACTNUM](#) and [GDFILE](#).

## GETGLOB **Read only the global restart data**

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used to instruct ECLIPSE to read in just the global grid data from a restart file of a previous run that had local grids present. Any data for local grids on the restart file are ignored. This may be useful, for example, if the local grids are no longer needed in the restart run.

The keyword has no associated data.

ECLIPSE 100. If the restart run has any local grids present, then these are treated as being added at the restart time. The run is initialized by inheriting the solutions from the global host cells at the restart time.

### Example

```
GETGLOB
```

## GETSOL

## Obtain initial solution arrays from restart file

	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword enables explicit initial state data, such as PRESSURE, SWAT, SGAS, XMF, YMF, RS, RV and PDEW, to be obtained from an ECLIPSE 100 type Restart file. The mnemonic required, the Restart file name and the report step index required, should be specified. The result of a GETSOL operation is exactly the same as specifying the same data with the corresponding keyword. The RPTRST keyword in ECLIPSE 100 may be used to request that bubble and dew points are written to the Restart file. (The fifth item in RPTRST should be set to 1). The Restart files to be read may be multiple or unified. If multiple Restart files are to be read the MULTIN keyword should be used.

Possibilities are:

PRESSURE	Pressures
SWAT	Water saturations
SGAS	Gas saturations
RS	Bubble point pressures
RV	Vapor oil-gas ratios
PDEW	Dew point pressures
XMF	Liquid mole fractions
YMF	Vapor mole fractions
TEMP	Temperatures (for the Thermal option)

Mole fractions can only be obtained from a Restart file produced by ECLIPSE 300, using the RPTRST keyword. Usually, when using ECLIPSE 100 Restart files, the mole fractions are supplied using the XMF or XMFVP and YMF or YMFVP keywords.

## Example

```
GETSOL
  PRESSURE BASE 1 /
  SWAT BASE 1 /
  SGAS BASE 1 /
  /
```

## Note

In order to obtain the correct information from the restart file, this keyword also requires the Grid file.

The “standard” Grid file is required (see GRIDFILE keyword). By default, GRIDFILE will produce an extensible Grid file (.EGRID) but not the “standard” Grid file. Before GETSOL is used, the base run, from which the restart files are obtained, must contain the GRIDFILE keyword with the first item set to 2. This will produce the correct Grid file needed to process the GETSOL keyword.

ECLIPSE 100

## G

## Initial Gi values for enumeration

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

The keyword may be used when the initial conditions are set by enumeration, to specify the initial Gi values in each grid block. If the keyword is not present, the initial Gi values will be set to zero by default.

The keyword cannot be used when the initial conditions are set by equilibration (keyword [EQUIL](#)). In equilibrated starts, the initial Gi values are all set to zero.

The keyword should be followed by one real number for every grid block, specifying the initial Gi value. The set of numbers must be terminated with a slash (/).

UNITS:  $\text{sm}^3/\text{rm}^3$  (METRIC), Mscf/rb (FIELD), scc/rcc (LAB)

Grid blocks are ordered with the X axis index cycling fastest (from 1 to NDIVIX), followed by the Y axis index (from 1 to NDIVIY), and finally the Z axis index (from 1 to NDIVIZ). NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword [DIMENS](#). Repeat counts may be used for repeated values (for example 115\*7200). Note that spaces must not be inserted on either side of the asterisk (\*).

See also the keywords [PRESSURE](#), [RS](#), [RV](#), [SWAT](#), [PRVD](#) and [SGAS](#) in the SOLUTION section.

See section entitled "[Gi pseudo-compositional model](#)" in the *ECLIPSE Technical Description* for more information.

### Example

With NDIVIX=10, NDIVIY=1, NDIVIZ=1 specified in RUNSPEC keyword [DIMENS](#):

```
GI
10*0.2 /
```

## GIALL

## Variation of saturated properties with pressure and Gi

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is an alternative method of specifying the variation of  $R_v$ ,  $R_s$ ,  $B_g$  and  $B_o$  with pressure and  $G_i$ . GIALL replaces the [RSGI](#), [RVGI](#), [BOGI](#) and [BGGI](#) keywords with the constraint that for all four properties the same pressure nodes are used. This can be a more convenient format when the data is supplied by the PVT  $i$  package.

The data comprises NTPVT (item 2 in keyword [TABDIMS](#)) tables of multiplier functions, each terminated by a slash(/), describing the variation of saturated  $R_v$ ,  $R_s$ ,  $B_g$  and  $B_o$  with pressure and  $G_i$  value. Each table consists of up to NPPVT sets of data records (item 4 in keyword [TABDIMS](#)). Each set of records within a table consists of up to NPPVT sets of four values.

These four columns define two-dimensional (P,  $G_i$ ) functions that multiply the saturated values of  $R_v$ ,  $R_s$ ,  $B_g$  and  $B_o$  at (P,  $G_i=0$ ) to give the true saturated value at (P,  $G_i$ ).

The first record of each elementary set of records contains the following items of data:

- The oil pressure value.  
The values should increase monotonically down the column.  
UNITS: barsa (METRIC), psia (FIELD), atma (LAB)
- The gas  $R_v$  multiplying factor at a  $G_i$  value specified as the first item in the [GINODE](#) table.
- The oil  $R_s$  multiplying factor at a  $G_i$  value specified as the first item in the [GINODE](#) table.
- The gas  $B_g$  multiplying factor at a  $G_i$  value specified as the first item in the [GINODE](#) table.
- The oil  $B_o$  multiplying factor at a  $G_i$  value specified as the first item in the [GINODE](#) table.

For record 2 and all subsequent records up to a maximum of NPPVT, there should be only 4 data item in the record. These items define the corresponding factors for the  $G_i$  values specified in the [GINODE](#) keyword.

See "[Gi pseudo-compositional model](#)" in the *ECLIPSE Technical Description* for further information.

### Example

With NTPVT =1 and NPPVT =2

```

--      RV      RS      BG      BO
GIALL
100.0   1.0     1.0     1.0     1.0
        0.97    0.93    0.98    0.93   /
200.0   1.0     1.0     1.0     1.0
        0.952  0.941  0.927  0.898  /
/

```

The keyword has no associated data.

## GINJGAS

## Specify the nature of the injected gas

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies the nature of the gas to be injected by a group. This should be used if [GCONINJE](#) or [GPMAINT](#) is used to specify group gas injection control data in compositional models. However, it is not necessary to use GINJGAS for groups subordinate to a higher level group having gas injection controls for which the nature of its injected gas is defined; this ensured that the injection stream is that defined for the higher level group.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash, the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. The name of the group.

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. A character string specifying the nature of the injected gas.

**GAS** The composition of the injected gas is set to that of the field separator gas. However, it is generally better to specify the injected gas composition more precisely.

From 2007.1, GAS is internally converted to GV (for the field separator) which has better reinjection and gas accounting behavior. [item 113](#) in [OPTIONS3](#) can be used to recover the pre-2007.1 behavior.

**STREA** The molar composition of the injected fluid has been defined using the [WELLSTRE](#) keyword. The name of the stream must be entered in item 3.

**MIX** The molar composition of the injected fluid has been defined as a mixture using either keyword [WINJMIX](#) or [WINJORD](#). The name of the mixture must be entered in item 3.

**GV** The injected fluid is to be taken from the vapor production of a nominated group. The name of the group must be entered in item 3.

**WV** The injected fluid is to be taken from the vapor production of a nominated well. The name of the well must be entered in item 3.

**GRUP** The injected fluid is that defined for a superior group.

DEFAULT: GRUP

Only the first two characters are significant.

3. A character string is required if the composition of the injection fluid was specified using [STREAM](#), [MIX](#), [GV](#) or [WV](#) in item 2.

In these cases this item is a character string specifying the name of the wellstream, mixture, group or well that defines or supplies the injection stream.

The available gas supply from a source group (or well) may be augmented by advance gas defined in keyword [GADVANCE](#) (or [WADVANCE](#)). Gas used for fuel ([GRUPFUEL](#)) and sales ([GRUPSALE](#)) is by

default subtracted from a source group's available gas supply for reinjection, but keyword [WTAKEGAS](#) may be used to alter the priorities for reinjection, fuel and sales.

4. The mnemonic for a wellstream to be used as make-up gas.

This is only required if make-up gas is to be used to make up the injection target of the group named in item 1, if insufficient injection gas is available from the source defined in items 2 and 3.

If make-up gas is used, the injection calculation may have to be iterated to match the injection gas composition with the injection rate (see keyword [GCONTROL](#)).

5. The stage of the separator which defines the fluid composition for injection.

The vapor from any stage of the separator may act as a source of injection fluid. The default value of 0 results in the use of the vapor from the whole separator as the injection fluid.

Note that the choice of separator stage also affects the available produced gas supply rate from the source group or well (item 3) if the source is GV or W (item 2).

DEFAULT: 0

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

See also keyword [WAVAILIM](#), and items 3 and 6 of keyword [GCONINJE](#), which can be used to control the rate of gas injection.

## Notes

For accurate group gas accounting, there is a limitation that re-injection control and any sales gas or fuel gas requirements must all be specified for the same group, usually the FIELD group, and not split across the group hierarchy. This limitation only applies if the injection gas contains group vapor, with the vapor taken from a separator stage (that is **not** from the whole separator).

## Example

The gas injection groups are to use the vapor produced by the FIELD group.

```
GINJGAS
'GI*' GV FIELD /
/
```

## GINODE

## Gi nodal values

The data comprises NTPVT (item 2 in keyword [TABDIMS](#)) tables of Gi values, each terminated by a slash (/), describing the nodal values for Gi to be used in the calculation of the oil and gas properties. Each table consists of up to NPPVT real entries.

The Gi nodal values within each table should be positive and strictly increasing.

UNITS:  $\text{sm}^3/\text{rm}^3$  (METRIC), Mscf/rb (FIELD), scc/rcc (LAB)

The number of entries in each table must correspond to the number of multiplier values entered under each of the [RSGI](#), [RVGI](#), [BGGI](#) and [BOGI](#) keywords.

See "[Gi Pseudo-compositional model](#)" in the *ECLIPSE Technical Description* for further information.

## Example

With NTPVT=2 and NPPVT  $\geq$  4

```
GINODE
  0.0
  10.0
  50.0
100.0 /
  0.0
100.0 /
```

## GLIFTLIM

## Maximum group capacity for artificial lift

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword can be used to limit the number of wells that are automatically switched to artificial lift (see keyword [WLIFT](#) and [PRORDER](#)). Limits can be set for individual groups or the field as a whole. A well will not be switched to artificial lift if it would exceed the lift capacity of its superior groups (including the field). Lift capacity limits will not prevent retubing from being carried out (see item 4 in keyword [WLIFT](#)). No action will be taken if wells already placed on artificial lift exceed these limits.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Group name or group name root

or FIELD (if the limits apply to the field as a whole)

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. Maximum total lift capacity.

This acts as a limit on the sum of the artificial lift quantity (ALQ) values of all subordinate open producers multiplied by their efficiency factors. If the ALQ refers to the pump power, this item limits the total pump power that can be applied in the group. For gas lift, if the ALQ refers to the lift gas injection rate, this item limits the group's total lift gas injection rate.

---

**Note:** If you wish to omit the efficiency factors from the sum of the well ALQ values, set [item 49](#) in [OPTIONS](#) to > 0. This restores back-compatibility with pre-96A versions of ECLIPSE, in which efficiency factors are not taken into account. Alternatively, group efficiency factors could be applied instead (see keyword [GEFAC](#)).

---

If the item is defaulted or set to zero, this limit will not be applied.

UNITS: These depend on what the ALQ was meant to represent when the table was created. Refer to section "[Record 6:ALQ values](#)" in the description of keyword [VFPPROD](#).

3. Maximum number of wells on artificial lift. This acts as a limit on the number of subordinate open producers that have a non-zero value for their artificial lift quantity.

If the item is defaulted or set to zero, this limit is not applied.

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

### Example

```
GLIFTLIM
PLAT-A 800.0 /
PLAT-B 1* 20 /

## GLIFTOPT

## Group lift gas limits for gas lift optimization

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The GLIFTOPT keyword may be used to set group lift gas supply limits for the Gas lift optimization facility (see "Gas lift optimization" in the *ECLIPSE Technical Description*). Keyword **LIFTOPT** must be entered before GLIFTOPT, to activate the facility.

The keyword is followed by any number of records, each containing the following items of data and terminated with a slash (/). The set of records must end with a blank record, containing only a slash.

- Group name or group name root, or FIELD to set a lift gas supply limit for the field
 

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.
- Maximum lift gas supply limit for the group
 

The group's lift gas supply is the sum of the lift gas injection rates of its subordinate wells or groups, multiplied by the wells' or groups' efficiency factors.

A default or negative value implies there is no limit for the group.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC), Mscf/day (FIELD), scc/hr (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)
- Maximum **total** gas rate for the group
 

The group's total gas rate is the sum of the lift gas plus the gas produced from the formation for each subordinate well or group, multiplied by the well's or group's efficiency factor. Lift gas increments are not allocated to wells below this group if they would cause this limit to be exceeded.

A default or negative value implies there is no limit for the group.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC), Mscf/day (FIELD), scc/hr (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

End the data record with a slash (/).

End the set of records with a blank record containing just a slash (/).

## Example

```

GLIFTOPT
-- group      max lift   max total
-- name       gas rate   gas rate
--           SM3/DAY
-- 'PL-*'     1E6 /
/

```

## GLTHEX

## Geomechanical linear thermal expansion coefficient

	ECLIPSE 100
x	ECLIPSE 300

	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword may only be used when the [GEOMECH](#) keyword is specified in the RUNSPEC section together with one of [THERMAL](#), [TEMPI](#) or [TEMPVD](#).

The keyword should be followed by one non-negative real number for every grid block in the current input box, specifying the rock linear thermal expansion coefficient. The data must be terminated by a slash (/).

UNITS: 1/K (METRIC), 1/°R (FIELD), 1/K (LAB), 1/K (PVT-M)

An additional term is included in the elastic stiffness matrix,  $(2G + 3\lambda)\alpha_T(T - T_r)$  if the [THERMAL](#) option is used or  $(2G + 3\lambda)\alpha_T T$  if the [THERMAL](#) option is not used. In these relations,  $G$  is the modulus of rigidity,  $\lambda$  is the Lamé constant,  $\alpha_T$  is the coefficient of linear expansion defined by this keyword and  $T_r$  is a reference temperature. Temperature  $T$  in the above calculation is predicted when using the [THERMAL](#) option and is set with the keywords [TEMPI](#) or [TEMPVD](#) if not.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y- and Z-axis indices. Repeat counts may be used for repeated values (for example 115\*1.25E-5). Note that spaces may not be inserted on either side of the asterisk.

### Example

## Displacement boundary conditions for coupled rock and stress calculations

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies displacement boundary conditions when a coupled rock stress and fluid flow calculation is specified with the keyword [GEOMECH](#) in the RUNSPEC section.

This keyword allows displacement boundary conditions to be specified on all boundaries. If a particular boundary is not specified by this keyword or by [GMTRABC](#) or [GMPSTBC](#) keywords, that boundary is defaulted to a rigid boundary.

This keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. A character string specifying the boundary to which the displacement boundary condition is applied

This must be one of the following:

X+ Specify the boundary condition on the outer X+ edge

X- Specify the boundary condition on the outer X- edge

Y+ Specify the boundary condition on the outer Y+ edge

Y- Specify the boundary condition on the outer Y- edge

Z+ Specify the boundary condition on the outer Z+ edge

Z- Specify the boundary condition on the outer Z- edge

The Z- boundary is the top boundary of the simulation, Z+ is the bottom.

2. An integer specifying the type of boundary condition on this face

This must be one of the following:

1. A normal rock displacement is specified on the boundary denoted in item 1.

2. A rock displacement with X, Y, Z components. A single X, Y, Z displacement component is set in item 3 and the component name must be set in item 4. Separate lines are needed to set different components.

For boundary condition type 2, the X, Y, Z components conform to the X, Y, Z directions as specified in the [COORD](#) keyword for corner point geometry.

DEFAULT: 2

3. A normal rock displacement on this boundary if the boundary condition type in item 2 is 1, or an X, Y, Z component of a rock displacement if the boundary condition type in item 2 is 2.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: 0

4. A character string that gives the component of displacement if the boundary type in item 2 is 2. This must be one of 'X', 'Y' or 'Z'.

DEFAULT: None. It must be specified if item 2 is 2

5. First block to be modified in the X direction

DEFAULT: 1 if an X- face

6. Last block to be modified in the X direction

DEFAULT: NX if an X+ face

7. First block to be modified in the Y direction

DEFAULT: 1 if a Y- face

8. Last block to be modified in the Y direction

DEFAULT: NY if a Y+ face

9. First block to be modified in the Z direction

DEFAULT: 1 if a Z- face

10. Last block to be modified in the Z direction

DEFAULT: NZ if a Z+ face

## Example

```
-- set a normally rigid boundary in the x and y-directions
GMDISBC
-- side type displacement
  'X+' 1 /
  'X-' 1 /
  'Y+' 1 /
  'Y-' 1 /
/
```

## GMDISBCL Displacement boundary conditions for coupled rock and stress calculations in a Local Grid Refinement

	ECLIPSE 100
x	ECLIPSE 300

This keyword specifies displacement boundary conditions when a coupled rock stress and fluid flow calculation is specified with the keyword [GEOMECH](#) in the RUNSPEC section.

Use of this keyword allows displacement boundary conditions to be specified on all boundaries of a local grid refinement. If a particular boundary is not specified in this keyword or the [GMTRABCL](#) or [GMPSTBCL](#) keywords, that boundary is defaulted to a rigid boundary.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form  $n^*$ , where  $n$  is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. A character string specifying the boundary to which the velocity boundary condition is applied

This must be one of the following:

X+ Specify the boundary condition on the outer X+ edge

X- Specify the boundary condition on the outer X- edge

Y+ Specify the boundary condition on the outer Y+ edge

Y- Specify the boundary condition on the outer Y- edge

Z+ Specify the boundary condition on the outer Z+ edge

Z- Specify the boundary condition on the outer Z- edge

DEFAULT: There is no default for this item; it must be specified.

The Z- boundary is the top boundary of the simulation, Z+ is the bottom.

2. An integer specifying the type of boundary condition on this face

This must be one of the following:

- a. A normal rock displacement is specified on the boundary denoted in item 1.

- b. A rock displacement with X, Y, Z components.

A single X, Y, Z component is set in item 4 and the component name must be set in item 5. Separate lines are needed to set different components.

For boundary condition type 2, the X, Y, Z components conform to the X, Y, Z directions as specified in the [COORD](#) keyword for corner point geometry.

DEFAULT 2

3. Name of the Local Grid Refinement

4. A normal rock displacement on this boundary, if the boundary condition type in item 2 is 1, or an X, Y, Z component of a rock displacement, if the boundary condition type in item 2 is 2.  
UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)  
DEFAULT: 0
5. A character string that gives the component of displacement or velocity if the boundary type in item 2 is 2. This must be one of 'X', 'Y' or 'Z'.  
DEFAULT: None. It must be specified if item 2 is 2
6. First block to be modified in the X direction in the LGR box specified in item 3.  
DEFAULT: 1 if an X- face
7. Last block to be modified in the X direction in the LGR box specified in item 3.  
DEFAULT: NX if an X+ face
8. First block to be modified in the Y direction in the LGR box specified in item 3.  
DEFAULT: 1 if a Y- face
9. Last block to be modified in the Y direction in the LGR box specified in item 3.  
DEFAULT: NY if a Y+ face
10. First block to be modified in the Z direction in the LGR box specified in item 3.  
DEFAULT: 1 if a Z- face
11. Last block to be modified in the Z direction in the LGR box specified in item 3.  
DEFAULT: NZ if a Z+ face

## Example

```

-- set a normally rigid boundary in the x and y-
directions for the local grid refinement LGR1
GMDISBCL
-- side type velocity
  'X+' 1 'LGR1' /
  'X-' 1 'LGR1' /
  'Y+' 1 'LGR1' /
  'Y-' 1 'LGR1' /
/

```

## GMPSTBC

## Principal stress boundary conditions coupled stress and fluid flow

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies principal stress boundary conditions when a finite volume or finite element rock stress calculation is specified. It is only applicable when the keyword [GEOMECH](#) has been specified in the RUNSPEC section.

This keyword allows the full set of three principal stress vectors to be specified on all boundaries. This is sufficient information to fully define the stress tensor at the chosen boundary. Alternatively, tractions or displacements may be specified using the [GMTRABC](#) or [GMDISBC](#) keywords.

Note that the principal stress vectors should, by definition, be mutually orthogonal. If non-orthogonal vectors are provided, ECLIPSE 300 issues a warning message and orthogonalizes the vectors provided using the Gram-Schmidt process.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form  $n^*$ , where  $n$  is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. A character string specifying the boundary to which the principal stress boundary condition is applied

This must be one of the following:

X+ Specify the boundary condition on the outer X+ edge

X- Specify the boundary condition on the outer X- edge

Y+ Specify the boundary condition on the outer Y+ edge

Y- Specify the boundary condition on the outer Y- edge

Z+ Specify the boundary condition on the outer Z+ edge

Z- Specify the boundary condition on the outer Z- edge

The Z- boundary is the top boundary of the simulation, Z+ is the bottom.

2. The X component of the first principal stress vector.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

DEFAULT: 0

3. The Y component of the first principal stress vector.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

DEFAULT: 0

4. The Z component of the first principal stress vector.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

- DEFAULT: 0
5. The X component of the second principal stress vector.  
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

## GMPSTBCL Principal stress boundary conditions for coupled stress and fluid flow in a Local Grid Refinement

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies principal stress boundary conditions when a finite volume or finite element rock stress calculation is specified. It is only applicable when the keyword [GEOMECH](#) has been specified in the RUNSPEC section.

This keyword allows the full set of three principal stress vectors to be specified on all boundaries in a local grid refinement. This is sufficient information to fully define the stress tensor at the chosen boundary. Alternatively, tractions or displacements may be specified using the [GMTRABCL](#) or [GMDISBCL](#) keywords.

Note that the principal stress vectors should, by definition, be mutually orthogonal. If non-orthogonal vectors are provided, ECLIPSE 300 issues a warning message and orthogonalizes the vectors provided using the Gram-Schmidt process.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form  $n^*$ , where  $n$  is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. A character string specifying the boundary to which the principal stress boundary condition is applied

This must be one of the following:

X+ Specify the boundary condition on the outer X+ edge

X- Specify the boundary condition on the outer X- edge

Y+ Specify the boundary condition on the outer Y+ edge

Y- Specify the boundary condition on the outer Y- edge

Z+ Specify the boundary condition on the outer Z+ edge

Z- Specify the boundary condition on the outer Z- edge

DEFAULT: There is no default for this item; it must be specified.

The Z- boundary is the top boundary of the simulation, Z+ is the bottom.

2. Name of local grid refinement
3. The X component of the first principal stress vector.  
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)  
DEFAULT: 0
4. The Y component of the first principal stress vector.  
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)  
DEFAULT: 0

5. The Z component of the first principal stress vector.  
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)  
DEFAULT: 0
6. The X component of the second principal stress vector.  
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)  
DEFAULT: 0
7. The Y component of the second principal stress vector.  
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)  
DEFAULT: 0
8. The Z component of the second principal stress vector.  
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)  
DEFAULT: 0
9. The X component of the third principal stress vector.  
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)  
DEFAULT: 0
10. The Y component of the third principal stress vector.  
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)  
DEFAULT: 0
11. The Z component of the third principal stress vector.  
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)  
DEFAULT: 0
12. First block to be modified in the X direction  
DEFAULT: 1 if an X- face
13. Last block to be modified in the X direction  
DEFAULT: NX if an X+ face
14. First block to be modified in the Y direction  
DEFAULT: 1 if a Y- face
15. Last block to be modified in the Y direction  
DEFAULT: NY if a Y+ face
16. First block to be modified in the Z direction  
DEFAULT: 1 if a Z- face
17. Last block to be modified in the Z direction  
DEFAULT: NZ if a Z+ face

## Example

```
-- Principal stress vectors:

## GMTRABC Traction boundary conditions

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword allows traction boundary conditions to be specified on all boundaries. A traction at a boundary surface is a force/unit area. If a particular boundary is not specified, that boundary is defaulted to a rigid boundary unless a displacement condition is given with the keyword [GMDISBC](#) or a principal stress boundary condition is given with keyword [GMPSTBC](#).

This keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. A character string specifying the boundary to which the traction boundary condition is applied

This must be one of the following:

X+ Specify the boundary condition on the outer X+ edge

X- Specify the boundary condition on the outer X- edge

Y+ Specify the boundary condition on the outer Y+ edge

Y- Specify the boundary condition on the outer Y- edge

Z+ Specify the boundary condition on the outer Z+ edge

Z- Specify the boundary condition on the outer Z- edge

DEFAULT: There is no default for this item; it must be specified.

The Z- boundary is the top boundary of the simulation, Z+ is the bottom.

2. An integer specifying the type of boundary condition on this face

This must be one of the following:

- 1 A total normal traction is specified on the boundary denoted in item 1. The magnitude of this normal traction is set in item 3.

- 2 A given traction with X, Y, Z components. A single X, Y, Z traction component is set in item 3 and the component name is set in item 4. Separate lines are needed to set different components.

DEFAULT: If a boundary of a cell or face is not specified with traction, stress or displacement boundary conditions, default is a rigid boundary as specified in [GMDISBC](#) item 2.

3. A normal traction on this boundary, if the boundary condition type in item 2 is 1, or an X or Y or Z component of a given traction, if the boundary condition type in item 2 is 2. The component direction is set in item 4 below.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

DEFAULT:0

*Finite Element*

4. Finite element: A character string that gives the component of traction if the boundary type in item 2 is 2. This must be one of 'X', 'Y' or 'Z'.  
DEFAULT: None. It must be specified if item 2 is 2
5. First block to be modified in the X direction  
DEFAULT: 1 if an X- face
6. Last block to be modified in the X direction  
DEFAULT: NX if an X+ face
7. First block to be modified in the Y direction  
DEFAULT: 1 if a Y- face
8. Last block to be modified in the Y direction  
DEFAULT: NY if a Y+ face
9. First block to be modified in the Z direction  
DEFAULT: 1 if a Z- face
10. Last block to be modified in the Z direction  
DEFAULT: NZ if a Z+ face

## Example

```

-- set a 3000 psi total compressive traction on the X+, X-, Y+ and Y- boundaries
-- set a 3000 psi overburden pressure (compressive stress is -ve)
-- note that the 'Z-' direction is positive downwards
GMTRABC
-- side type total
--          traction
'X+'  1  -3000 /
'X-'  1  -3000 /
'Y+'  1  -3000 /
'Y-'  1  -3000 /
'Z-'  1  -3000 /
/

```

## GMTRABCL Traction boundary conditions in a Local Grid Refinement

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies traction boundary conditions when a coupled stress calculation is specified with the keyword [GEOMECH](#) in the `RUNSPEC` section.

This keyword allows traction boundary conditions to be specified on all boundaries of a local grid refinement. A traction at a boundary surface is a force/unit area. If not specified, that boundary is defaulted to a rigid boundary unless a displacement condition is given with the keyword [GMDISBCL](#) or a principal stress boundary condition is given with keyword [GMPSTBCL](#).

This keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form  $n^*$ , where  $n$  is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. A character string specifying the boundary to which the traction boundary condition is applied

This must be one of the following:

X+ Specify the boundary condition on the outer X+ edge

X- Specify the boundary condition on the outer X- edge

Y+ Specify the boundary condition on the outer Y+ edge

Y- Specify the boundary condition on the outer Y- edge

Z+ Specify the boundary condition on the outer Z+ edge

Z- Specify the boundary condition on the outer Z- edge

DEFAULT: There is no default for this item; it must be specified.

The Z- boundary is the top boundary of the simulation, Z+ is the bottom.

2. An integer specifying the type of boundary condition on this face

This must be one of the following:

a. A total normal traction is specified on the boundary denoted in item 1. The magnitude of this normal traction is set in item 4.

b. A given traction with X, Y, Z components. A single X, Y, Z traction component is set in item 4 and the component name is set in item 5. Separate lines are needed to set different components.

DEFAULT: If a boundary of a cell or face is not specified with traction, stress or displacement boundary conditions, default is a rigid boundary as specified in [GMDISBC](#) item 2.

3. Name of the Local Grid Refinement
4. A normal traction on this boundary, if the boundary condition type in item 2 is 1, or an X or Y or Z component of a given traction, if the boundary condition type in item 2 is 2. The component direction is set in item 5 below.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

DEFAULT:0

5. A character string that gives the component of traction if the boundary type in item 2 is 2. This must be one of 'X', 'Y' or 'Z'.

DEFAULT: None. It must be specified if item 2 is 2

6. First block to be modified in the X direction

DEFAULT: 1 if an X- face

7. Last block to be modified in the X direction

DEFAULT: NX if an X+ face

8. First block to be modified in the Y direction

DEFAULT: 1 if a Y- face

9. Last block to be modified in the Y direction

DEFAULT: NY if a Y+ face

10. First block to be modified in the Z direction

DEFAULT: 1 if a Z- face

11. Last block to be modified in the Z direction

DEFAULT: NZ if a Z+ face

## Example

```

--
  For the local grid refinement LGR1 set a 3000 psi total compressive traction on the X
+, X-, Y+ and Y- boundaries
-- set a 3000 psi overburden pressure (compressive stress is -ve)
-- note that the 'Z-' direction is positive downwards
GMTRABCL
-- side type total
--      traction
  'X+'  1  'LGR1'  -3000 /
  'X-'  1  'LGR1'  -3000 /
  'Y+'  1  'LGR1'  -3000 /
  'Y-'  1  'LGR1'  -3000 /
  'Z-'  1  'LGR1'  -3000 /
/

```

## GNETDP

## Controls the dynamic changing of fixed pressures

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword may be used to adjust the pressure of a fixed-pressure group or node in the network option (see "Network option" in the *ECLIPSE Technical Description*), with the aim of maintaining its production flow rate within specified maximum and minimum limits. Whenever the flow into the fixed-pressure group or node falls below the minimum rate specified in item 3, ECLIPSE adjusts its pressure value by subtracting a pressure increment specified in item 5, then rebalances the network. This process continues until either the flow exceeds the minimum value or the pressure falls to the minimum allowed pressure specified in item 7. Similarly, whenever the flow into the fixed-pressure group or node rises above the maximum rate specified in item 4, ECLIPSE adjusts its pressure value by adding a pressure increment specified in item 6, then rebalances the network. This process continues until either the flow falls below the maximum value or the pressure increases to the maximum allowed pressure specified in item 8.

The facility is available with both the Standard Network Model (for fixed-pressure groups) and the Extended Network Model (for fixed-pressure nodes). Subordinate groups or nodes cannot have their pressure adjusted with this facility.

This facility predates automatic chokes (see "Automatic chokes" in the *ECLIPSE Technical Description*), which offer a more versatile means of controlling a group's flow rate by adjusting the network nodal pressures. However, automatic chokes are available only in the Extended Network Model (see "The extended network model" in the *ECLIPSE Technical Description*).

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/). The set of records must end with a blank record, containing only a slash (/).

1. Name of the fixed-pressure group, for a standard production network,  
or  
name of the fixed-pressure node, for an extended network
2. Phase whose rates items 3 and 4 refer to  
OIL, WAT, GAS, or LIQ  
DEFAULT: GA
3. Minimum rate (into the group/node of item 1) that triggers a pressure adjustment when violated.  
UNITS: sm<sup>3</sup>/day (METRIC), stb/day for oil, water or liquid (FIELD), Mscf/day for gas (FIELD),  
scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)  
DEFAULT: 0.0 (there will be no pressure adjustment to increase the flow)
4. Maximum rate (into the group/node of item 1) that triggers a pressure adjustment when violated.  
UNITS: sm<sup>3</sup>/day (METRIC), stb/day for oil, water or liquid (FIELD), Mscf/day for gas (FIELD),  
scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)  
DEFAULT: infinity (1.0E20) (there will be no pressure adjustment to decrease the flow)
5. Pressure increment to be **subtracted** from the fixed pressure when the flow rate falls below the minimum in item 3.  
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)  
DEFAULT: 0.0
6. Pressure increment to be **added** to the fixed pressure when the flow rate exceeds the maximum in item 4.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

DEFAULT: 0.0

7. Minimum allowable pressure at the group/node.

The pressure is not adjusted below this value.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: 0.0

8. Maximum allowable pressure at the group/node.

The pressure is not adjusted above this value.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: Infinity (1.0E20)

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

---

**Note:** The network has to be rebalanced each time the pressure is adjusted so that the flows may be recalculated at the new pressure. The smaller the increment sizes are in items 5 and 6, the number of times the pressure is adjusted is correspondingly greater, increasing the computing time.

If both minimum and maximum rate limits are set in items 3 and 4, the pressure increments must be made small enough to find pressure values at which the rate lies between these limits. The minimum and maximum limits must not lie too close together.

---

## Example

```

GNETDP
-- Node   Phase   Min      Max      DP      DP      Min      Max
-- Name   Rate    Rate    Subt    Add    Pres    Pres
  FIELD   GAS     5000.0  15000.0  10.0   10.0   300.0   600.0 /
/

```

In this example the fixed pressure group/node FIELD has its fixed pressure changed according to how much gas is flowing into it. If the rate falls below 5000 then the fixed pressure is reduced in increments of 10 psi until the constraint is satisfied. If the rate goes above 15000 then the fixed pressure is raised in increments of 10 psi until the constraint is satisfied. The fixed pressure is not allowed to fall below 300 psi, or rise above 600 psi, regardless of the rates into the group/node.

## GNETINJE Defines the structure of the injection network

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword defines the structure of an injection network in the Network option (see "Network option" in the *ECLIPSE Technical Description*). Injection networks exist independently of the production network (if present), and separate networks can be defined for water and gas injection.

In ECLIPSE 300, if you are using the Extended Network keywords ([NODEPROP](#) and [BRANPROP](#)) to define the production network, you must also use those keywords instead of GNETINJE to define any injection networks; extended and standard network models cannot be mixed. In ECLIPSE 100, you must use GNETINJE to define any injection networks irrespective of the model used for the production network.

The keyword is followed by any number of records, each containing the following items of data and terminated with a slash (/). The set of records must end with a blank record, containing only a slash.

- Group name or group name root,  
or FIELD (to set a fixed pressure for the field node)  
  
A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.
- Phase of the injection network in which this group is a node  
  
WAT or GAS
- Fixed pressure for the group corresponding to the terminal node of the network  
  
Default this item, or set it negative, if the group is not a fixed-pressure terminal node in the network.  
  
UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)
- Injection VFP table number for the pipeline between the group and its parent group  
  
A value of 9999 can be entered to indicate that there is no pressure loss in the network branch between the group and its parent group. Otherwise, if a non-zero table number is entered, the corresponding injection VFP table must have been set up for the phase named in item 2.  
  
If the group is a fixed-pressure node (that is if a positive value is set for item 3) this item must be defaulted, since a fixed-pressure group is a terminal node and cannot have a pipeline connection to a higher group.  
  
If this item is defaulted for a group that is not a fixed-pressure node, the group is not part of the network.  
  
Two or more network pipelines may share the same VFP table if they have similar pressure loss characteristics.  
  
DEFAULT: 0 Implies the group has no pipeline connection to its parent group.

End the data record with a slash (/).

End the set of records with a blank record containing just a slash.

### Example

```
GNETINJE
PLAT-A  WAT  14.7  /
GR-B2   WAT  1*   1  /
/
```

## GNETPUMP Automatic pump/compressor switching in a standard network

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword defines automatic compressors or pumps in a standard production network in the network option (see "Network option" in the *ECLIPSE Technical Description*). If you are using the extended network model (keyword `NETWORK` in the `RUNSPEC` section), you should define automatic compressors or pumps with keyword `NETCOMP` instead.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The records may be terminated at any item after item 1. The remaining items assume their default values. Default values can be specified before the slash by a null repeat count of the form  $n^*$ , where  $n$  is the number of consecutive items to be defaulted.

The set of records must end with a blank record, containing only a slash (/).

1. Group name or group name root

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. Production rate below which the pump/compressor is to be switched on

UNITS:  $\text{sm}^3/\text{day}$  (METRIC),  $\text{stb}/\text{day}$  for oil (FIELD),  $\text{Mscf}/\text{day}$  for gas (FIELD),  $\text{scc}/\text{hr}$  (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

DEFAULT: 0.0

A zero or negative value will disable this option.

3. Phase to which the production rate in item 2 refers

OIL or GAS

DEFAULT: OIL

4. New VFP table number

(When the pump/compressor is switched on this replaces the table number previously specified in keyword `GRUPNET`.)

A zero or negative number will leave the original VFP table number unchanged.

DEFAULT: 0

5. New artificial lift quantity (ALQ)

(When the pump/compressor is switched on this replaces the artificial lift quantity previously specified in keyword `GRUPNET`.)

The artificial lift quantity may be regarded as the pump or compressor power, according to the definition used in the VFP table.

UNITS: These depend on what the ALQ was meant to represent when the table was created. Refer to section "Record 6:ALQ values" in the description of keyword `VFPPROD`.

DEFAULT: 0.0

6. New gas consumption rate for the group

(When the pump/compressor is switched on this replaces any consumption rate previously specified with keyword `GCONSUMP`, to account for the increase in gas demand for power generation.)

A zero or negative value leaves the original gas consumption rate unchanged (that is, zero if `GCONSUMP` is not specified).

The gas consumption is subtracted from the flow rate through the pipeline when interpolating the VFP table to calculate the pressure loss. Gas consumption is also taken into account for group reinjection control (see keyword `GCONINJE`) and sales gas control (see keyword `GCONSALE`). But the total gas production rates reported for the groups and the field will not be reduced.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC),  $\text{Mscf}/\text{day}$  (FIELD),  $\text{scc}/\text{hr}$  (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

DEFAULT: 0.0

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

The pump/compressor is switched on at the end of the timestep in which the group's production rate falls below the set limit. A network balancing calculation is performed at the beginning of the next timestep, regardless of the interval set in keyword `NETBALAN`. However, if a limit tolerance fraction has been set with keyword `WLIMTOL`, the timestep in which the rate fell below the limit is recalculated with the pump/compressor switched on if the limit is violated by more than this fraction.

---

**Note:** An automatic compressor cannot be present if the pipeline's ALQ is equated to the oil or gas surface density in item 7 of keyword `GRUPNET`.

---

## Example

Pumps to boost the flow through the network pipelines from platforms PLAT-A and PLAT-B are started if their oil production rates fall below 1000 stb/day. An artificial lift quantity of 100 is used to interpolate the VFP table that calculates the pressure loss in the pipeline from PLAT-A, keeping the same VFP table number. The pipeline from PLAT-B changes to a new table number 3, interpolated with a zero artificial lift quantity. There is no change to any gas consumption rate, if specified.

```

GNETPUMP
PLAT-A  1000  OIL  0 100 /
PLAT-B  1000  OIL  3 /
/

```

This keyword may be used to instruct a group to adjust its production or injection rate so as to maintain the average pressure in a particular fluid-in-place region at a specified target.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Group name or group name root

or FIELD (to adjust the field's production or injection rate)

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

The specified group maintains the average pressure in the selected region, by adjusting its production or injection rate as chosen in item 2. Obviously the group's wells must be able to influence the region's pressure, preferably being completed inside the region. It is possible to specify more than one group to maintain the pressure in a particular region. The groups' flow rate targets are set in proportion to the proportionality constant in item 6.

2. Flow target that ECLIPSE calculates to control the pressure

PROD The group's production RESV rate is adjusted.

*ECLIPSE 100 only*

OINJ The group's oil injection RESV rate is adjusted.

WINJ The group's water injection RESV rate is adjusted.

GINJ The group's gas injection RESV rate is adjusted.

*ECLIPSE 100 only*

OINS The group's oil injection surface rate is adjusted.

WINS The group's water injection surface rate is adjusted.

GINs The group's gas injection surface rate is adjusted.

*ECLIPSE 300 only*

WGIN The group's wet gas injection rate is adjusted.

NONE The group's flow is no longer adjusted to maintain pressure.

If PROD is selected, the group must **not** be under prioritization group control (see keyword [GCONPRI](#)), as only guide rate group control (keyword [GCONPROD](#)) can be used to control the pressure.

---

**Note:** When running ECLIPSE 300 in compositional mode, if one of the gas flow targets (that is, GINJ, GINS or WGIN) are selected in this item, then the nature of the injected gas must also be specified with keyword [GINJGAS](#), unless the group is under control of a higher level group with gas injection controls where the injection fluid is defined.

---

---

**CAUTION:** Additional injection or production rate limits may be set for the group with keyword `GCONINJE` or `GCONPROD`. These limits are not removed by using the `GPMAINT` keyword, except for the limit that corresponds to the control target that is adjusted to maintain the pressure, which is overwritten at each timestep by the target calculated for pressure maintenance. If the flow quantity selected in item 2 is at a later date no longer required to be adjusted for pressure maintenance, its rate target must be reset or removed with an appropriate group control keyword, otherwise the latest calculated target is retained as a limit.

---

ECLIPSE 100

3. Region number, whose pressure this group controls.

This **fluid-in-place** region should be identified by an integer between 0 and `NTFIP` (see keyword `REGDIMS` in the `RUNSPEC` section). Region 0 refers to the whole field. Fluid-in-place regions are defined with the keyword `FIPNUM` in the `REGIONS` section (or keyword `FIP` if a different family of regions is requested in item 4).

ECLIPSE 300

This **pressure maintenance** region should be identified by an integer between 1 and `NUMPMA` (set in item 14 of keyword `TABDIMS` in the `RUNSPEC` section). The default value for the pressure maintenance region is 1. Pressure maintenance regions are defined with the keyword `PMANUM` in the `REGIONS` section.

ECLIPSE 100 only

4. The fluid-in-place region family, to which the specified region belongs.

The family name should be up to 5 characters long.

A default (1\*) or blank ( ' ') entry refers to the standard set of fluid-in-place regions defined with the keyword `FIPNUM`.

Additional families of fluid-in-place regions may optionally be defined, using the keyword `FIP`. The family name is string of up to 5 characters that makes up the second segment of the keyword name (characters 4 - 8). Each family can divide up the field in different ways. Thus, for example, the standard `FIPNUM` family may divide the field into layers, and an additional family can be defined to divide the field into areal sectors. Pressure maintenance may be selected for any region in any family.

5. The target pressure for the region

The group attempts to maintain the region's average hydrocarbon pressure at this value.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

ECLIPSE 300

---

**Note:** The field pressure `FPRP` shown in the screen output and in the Print file is a pore-volume weighted pressure and may not correspond exactly to the hydrocarbon pore-volume weighted target pressure, `FPR`.

---

6. The proportionality constant, for controlling the group's flow rate

At each timestep, the group's target rate is set equal to the proportionality constant multiplied by the region's pressure error term.

UNITS:  $\text{rm}^3$  or  $\text{sm}^3/\text{day}/\text{bars}$  (METRIC),  $\text{rb}$  or  $\text{stb}/\text{day}/\text{psi}$  (FIELD),  $\text{rcc}$  or  $\text{sc}/\text{hr}/\text{atm}$  (LAB),  $\text{rm}^3$  or  $\text{sm}^3/\text{day}/\text{atm}$  (PVT-M)

7. The integral time constant, for controlling the group's flow rate

The integral of the region's pressure error over time, divided by the integral time constant, is added to the current pressure error.

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

## Example

```

GPMAINT
-- Group      Inj      FIP      FIP      Targ  Prop  Inte
-- Name      Phase    Reg      Fam      Pres  Const Tcon
      PLAT-A    WINJ     2        1*      3900  30   70 /
      SP-C      WINJ     6        1*      3800  30   70 /
      SP-B      PROD     3        1*      3600  50   70 /
/

```

## Control strategy

The control strategy applied to the group's flow target is that of a proportional + integral controller from elementary control theory. However, because of the discrete nature of the timesteps, the integral is replaced by a summation over the timesteps.

The group's flow target for the quantity specified in item 2 (for example RESV) is set at each timestep equal to

$$V = V_i + K \left[ e + \frac{\Sigma e \cdot \delta t}{T_i} \right] \quad \text{Eq. 3.76}$$

where:

$V_i$  is the initial rate at the time the keyword is entered

$K$  is the proportionality constant (item 6)

$T_i$  is the integral time constant (item 7)

$e$  is the region's pressure error  $P_{\text{targ}} - P_{\text{reg}}$  at the end of the previous timestep

$\Sigma(e \cdot \delta t)$  is the cumulative sum of the pressure error times the timestep length, up to the previous timestep, starting from the time the keyword was most recently entered.

The purpose of the  $V_i$  term is to help stabilize cases where a pressure maintenance target is set (or re-set with a subsequent GPMAINT keyword) when the flow rate of the controlled quantity is already adequate to maintain pressure. If the pressure error is small the flow should remain approximately at its initial value. But if pressure maintenance by injection is specified at the start of injection,  $V_i$  will be zero and the injection will build up from zero in response to the sum of the error and integral terms.

Increasing the proportionality constant  $K$  in item 6 helps the region's pressure to reach its target value more quickly. But values of  $K$  that are too high result in oscillations in the pressure. A suitable order of magnitude to try initially for  $K$  would be the expected steady state flow rate (of the targeted quantity) of the group divided by a transient pressure error that you are prepared to tolerate.

Increasing the time constant  $T_i$  in item 7 helps to reduce the tendency for the pressure to oscillate, but will slow down the rate at which the pressure reaches its target value.

Each timestep acts as a "delay" in the control loop, as the pressure error is measured at the end of the previous timestep. The longer the timesteps are, the greater is the tendency for the pressure to oscillate for given values of  $K$  and  $T_i$ .  $T_i$  should be set to a value at least as big as the maximum timestep size.

The resulting value of the flow target is applied as a target production or injection rate for the group. The group's actual flow rate may still be limited by additional constraints set with keyword [GCONPROD](#) or [GCONINJE](#).

## GPMAINT3 Data for pressure maintenance groups

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword may be used to instruct a group to adjust its production or injection rate so as to maintain the average pressure in a particular pressure maintenance region at a specified target. It is retained for back compatibility with pre-2000A ECLIPSE 300 data files; however, you are encouraged to use keyword [GPMAINT](#) instead, which is compatible with both simulators.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records is ended by a blank record, containing only a slash.

1. The name of the group.

A character string of up to 8 letters.

This must be supplied, and a group of this name must exist.

The specified group will maintain the average pressure in the selected region, by adjusting its production or injection rate as chosen in item 2. Obviously the group's wells must be able to influence the region's pressure, preferably being completed inside the region. It is possible to specify more than one group to maintain the pressure in a particular region. The groups' flow rate targets are set in proportion to the proportionality constant in item 6.

2. Flow target that ECLIPSE 300 calculates to control the pressure.

This may be one of the following:

NONE The group's flow is no longer adjusted to maintain pressure

PROD The group's production RESV rate is adjusted

WINJ The group's water injection RESV rate is adjusted

GINJ The group's gas injection RESV rate is adjusted (black oil mode only)

WINS The group's water surface injection rate is adjusted

GINs The group's gas surface injection rate is adjusted (black oil mode only)

WAT Water is injected, and the control target specified in item 9 is adjusted

GAS Gas is injected, and the control target specified in item 9 is adjusted. In a compositional run the composition of the injected gas is set to that of the field separator gas. However, it is generally better to specify the injected gas composition more precisely.

ST The molar **composition** of the injected fluid has been defined using the [WELLSTRE](#) keyword. The name of the injection stream must be specified in item 8. The control target specified in item 9 is adjusted.

MIX The molar **composition** of the injected fluid has been defined as a mixture using either the [WINJMIX](#) or [WINJORD](#) keywords. The name of the mixture must be specified in item 8. The control target specified in item 9 is adjusted.

- WV The molar **composition** of the injected fluid is to be taken from the vapor production of a nominated well. The name of the well must be specified in item 8. The control target specified in item 9 is adjusted.
- GV The molar **composition** of the injected fluid is to be taken from the vapor production of a nominated group. The name of the group must be specified in item 8. The control target specified in item 9 is adjusted.

If PROD is selected, the group must not be under prioritization group control, as only guide rate group control can be used to control the pressure.

If any of WAT, GAS, ST, MIX, WV or GV are selected, the required pressure maintenance target rate will be assigned according to the specified control mode in item 9.

---

**CAUTION:** If there is a user-specified rate limit for the flow quantity selected here, it is overwritten by the target calculated for pressure maintenance.

If the selected flow quantity is subsequently no longer required to be adjusted for pressure maintenance, its rate target must be reset with the appropriate group control keyword, otherwise the latest calculated target is retained.

---

3. Pressure maintenance region number, whose pressure this group controls.

This should be an integer between 1 and NUMPMA (see keyword [TABDIMS](#)). The default value for the pressure maintenance region is 1.

Pressure maintenance regions are defined with the [PMANUM](#) keyword.

4. This item is not used in ECLIPSE 300; it is retained for compatibility with ECLIPSE 100. The item must be defaulted.
5. The target pressure for the region

The group attempts to maintain the region's average hydrocarbon pore-volume weighted pressure at this value.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

---

**Note:** The field pressure FPRP in screen output and in the Print file is a pore-volume weighted pressure and may not correspond exactly to the hydrocarbon pore-volume weighted target pressure, FPR.

---

6. The proportionality constant, for controlling the group's flow rate

At each timestep, the group's target rate is set equal to the proportionality constant multiplied by the region's pressure error term.

UNITS:  $\text{rm}^3/\text{day}/\text{bars}$  (METRIC),  $\text{rb}/\text{day}/\text{psi}$  (FIELD),  $\text{rcc}/\text{hr}/\text{atm}$  (LAB),  $\text{rm}^3/\text{day}/\text{atm}$  (PVT-M)

7. The integral time constant, for controlling the group's flow rate

The integral of the region's pressure error over time, divided by the integral time constant, is added to the current pressure error.

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

---

8. A character string is required if the composition of the injection fluid was specified in item 2 using the ST , MIX , WV or GV methods.

In these cases this item is a character string specifying the name of the wellstream, mixture, well or group that defines or supplies the injection stream.

9. A character string specifying the control target which is adjusted to maintain the pressure.

This is required if item 2 was set to WAT, GAS, ST, MIX, WV or GV. It is one of the following:

WA Water surface injection rate

GA Gas surface injection rate

RV Reservoir volume injection rate

WG Wet gas rate

10. The maximum reinjection fraction

This item provides an upper limit on the rate at which the group in item 1 may inject, with this rate limit defined as the reinjection fraction multiplied by the water or available gas rate of the group or well named in item 12. The available produced gas rate of a group is by default equal to the group's gas production rate plus the rate of any advanced gas associated with the group (keyword [GADVANCE](#)) minus its fuel rate (keyword [GRUPFUEL](#)) minus its sales target (keyword [GRUPSALE](#)); however, this definition can be altered using keyword [WTAKEGAS](#). In the case of a reinjection fluid defined by a stream or mixture, the specified fraction of the available surface gas production rate is applied as a wet gas reinjection rate limit.

An alternative interpretation of this reinjection fraction may be activated by setting item 14 of this keyword to 'PROD', whereby the reinjection fraction limits the amount of available produced gas in the injection stream and not the overall rate of injection. This facility is only available when make-up gas has been specified to provide sufficient injection gas over and above the limited reinjection of produced gas for pressure maintenance (see item 13).

DEFAULT: 0.0, giving no restriction on the reinjection fraction.

11. The type of production that the reinjection fraction multiplies.

This need only be supplied if a reinjection fraction has been set in item 10. It should be one of the following:

W The production rate of the **well** named in item 12

G The production rate of the **group** named in item 12

DEFAULT: W if item 2 is WVG otherwise

12. The name of the group or well that controls the reinjection limit.

This need only be supplied if a reinjection fraction has been set in item 10. If item 11 is W it should be the name of a production well. If item 11 is G it should be the name of a group.

If this name is not specified, it defaults to the fluid composition source name (item 8) for injection fluids WV or GV in item 2, and to the name of the group in item 1 for the other cases.

13. The mnemonic for a wellstream to be used as make-up gas.

This is only required if make-up gas is to be used when there is insufficient available gas from the source group or well to supply the injection gas for pressure maintenance.

14. This item defines the interpretation of the reinjection fraction defined in item 10 for gas injection:

TOT The gas injection rate of the group is limited by the reinjection fraction multiplied by the available produced gas rate of the group.

PROD When make-up gas has been defined (see item 13), the reinjection fraction limits the amount of produced gas used for injection, with any additional injection gas required for pressure maintenance being supplied from the make-up gas stream.

DEFAULT: TOT

## Notes

Additional injection limits may be set for the group with the `GRUPINJE` keyword (or in the case where pressure is maintained by controlling the group's production rate, additional production rate limits can be set with keyword `GRUPPROD`). These limits are not removed by using the `GPMAINT3` keyword, except for the limit that corresponds to the control target that is adjusted to maintain the pressure.

See also notes 2, 3 and 4 of keyword `GRUPINJE`.

## Examples

### Example 1

Basic pressure maintenance by water injection

```
GPMAINT3
-- Group   Inj   PMA           Targ   Prop   Inte
-- Name    Phase Reg         Pres   Const  TCon
   GR-B2   WINJ   0   1*   3500   100   30 /
/
```

### Example 2

Pressure maintenance by gas injection, with only half the group's produced gas used for this purpose. The make-up stream `MUGAS` provides an additional source of gas for injection should reinjection of the limited produced gas be insufficient to maintain the target pressure.

```
GPMAINT3
-- Group Inj PMA           Targ   Prop   Time   Srce   Cont   Reinj   M-U   Re-Inj
-- Name  Fld Reg         Pres   Cons   Cons   Grp    Targ   Frc    Gas   Usage
   GR1   GV  1   1*   5000   100   30    GR1   GA    0.5   2*   MUGAS  PROD /
/
```

## GPTABLE Tables of gas plant recovery factors

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword enables tables to be entered to control gas plants. (See "Gas plants and NGLs" in the *ECLIPSE Technical Description*.)

The keyword contains the following items of data.

1. The gas plant table number.  
This should lie between 1 and the maximum number of gas plant tables, specified using the [GPTDIMS](#) keyword in the RUNSPEC section.
2. The lower component index used to define the heavy fractions.  
This defaults to the last component.
3. The upper component index used to define the heavy fractions.  
This defaults to the last component.
4. A table of recovery fractions versus heavy mole fraction.

Each value of the heavy mole fraction should be followed by  $N_c$  values (where  $N_c$  is the number of components in the run). The set of  $N_c$  values lists the liquid recovery fractions for each hydrocarbon component (that is the number of moles of liquid per unit mole of feed for each component).

Thus there should be  $N_c + 1$  numbers for each value of the heavy mole fraction.

The table should be terminated with a slash.

The defaults for items 2 and 3 imply that the gas plant table is normally of recovery fractions against the mole fraction of the last component in the feed.

If the recoveries do not vary with the heavy mole fraction, it is only necessary to enter data for a single value of that heavy mole fraction.

### Example

The first column contains the heavy component mole fractions, for the tenth component. The remaining columns are the recovery fractions of components 1 to 10.

```
GPTABLE
1 10 10

## GPTABLE3 Gas plant table with oil, NGL and gas recoveries

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword enables tables to be entered to control gas plants with recovery factors specified for oil, NGL and gas. (See "Gas plants and NGLs" in the *ECLIPSE Technical Description*.)

The keyword contains the following items of data.

1. The gas plant table number  
This should lie between 1 and the maximum number of gas plant tables, specified using the [GPTDIMS](#) keyword in the RUNSPEC section.
2. The lower component index used to define the 'heavy' fractions  
This defaults to the last component.
3. The upper component index used to define the 'heavy' fractions  
This defaults to the last component.
4. A table of recovery fractions versus heavy mole fraction.

Each value of the heavy mole fraction should be followed by 3  $N_c$  values (where  $N_c$  is the number of components in the run). The first set of  $N_c$  values lists the oil recovery fractions for each hydrocarbon component (that is the number of moles of oil per unit mole of feed for each component). The second set of  $N_c$  values lists the NGL recovery fractions and the third set of  $N_c$  values lists the gas recovery fractions. The sum of these recovery fractions for each component need **not** equal unity

Thus there should be  $3 N_c + 1$  numbers for each value of the heavy mole fraction.

The table should be terminated with a slash.

The defaults for items 2 and 3 imply that the gas plant table is normally of recovery fractions against the mole fraction of the last component in the feed.

If the recoveries do not vary with the heavy mole fraction, it is only necessary to enter data for a single value of that heavy mole fraction.

### Example

The first column contains the heavy component mole fractions, for the ninth component. The remaining columns are the recovery fractions of components 1 to 9.

The data consists of the following items, describing the dimensions of the gas plant and recovery plant table data to be used in the run.

- Maximum number of gas plant tables.  
This includes both tables specified with [GPTABLE](#), [GPTABLEN](#) and [GPTABLE3](#).  
DEFAULT: 1
- Maximum number of rows of gas plant table data.  
DEFAULT: 1
- Maximum number of rows of recovery plant table data.  
This specifies the maximum number of rows in item 3 of keyword [RECOVERY](#).  
DEFAULT: 2

See "[Gas Plants and NGLs](#)" in the *ECLIPSE Technical Description* for further information.

## Example

Two gas plant tables, each with a maximum of twenty rows.

```
GPTDIMS
2 20 /
```

## GQUALITY **Set group gas quality target**

	<b>ECLIPSE 100</b>
x	<b>ECLIPSE 300</b>
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

In GASWAT mode it is possible to set a target for the quality of gas produced by a group. The quality is in terms of calorific value/mole. Calorific value is determined by summing the component rates multiplied by their calorific values set with the keyword **CALVAL**, and then dividing by the total molar rate. (See "**GASWAT option**" in the *ECLIPSE Technical Description* for further information.)

The group must have a target such as a gas rate, which is distributed between the sons using guide rates. By modifying these guide rates we can weight the production between low and high quality wells so that a required group quality is obtained as well as satisfying the group production target. The quality target is only satisfied if:

1. At least two sons are under group control.
2. At least one son must be producing gas with a higher quality than the GQUALITY value.
3. At least one son must be producing gas with a lower quality than the GQUALITY value.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The set of records is ended by a blank record, containing only a slash.

1. Group name or name root, or **FIELD** (to set the field quality target)

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. Gas quality target

UNITS: kJ/kg-M (**METRIC**), Btu/lb-M (**FIELD**), J/gm-M (**LAB**), kJ/kg-M (**PVT-M**)

### Example

```
GQUALITY
FIELD 1.51 /
/
```

## GRADGRUP Specify field and group quantities to be output to HMD file

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to specify which field and group quantities are written to the HMD file.

The keyword must be followed by a set of records specifying mnemonics associated with derivatives. Each record should be terminated with a slash (/) and the set of records must end with a slash.

The available mnemonics are:

GOPR Surface group oil rate

GWPR Surface group water rate

GGPR Surface group gas rate

GWCT Group water cut

GGOR Group gas-oil ratio

GOPT Surface group oil production cumulative total

GWPT Surface group water production cumulative total

GGPT Surface group gas production cumulative total

The keyword is optional. If it is not specified, no group of field derivatives is produced. If the keyword is used more than once, only mnemonics from the most recent invocation are used so that the list may be specified again at a restart or during the run.

Output from ECLIPSE is for any groups specified using the [RPTHMG](#) keyword.

### Example

Output derivatives only for group oil and water rates:

```
GRADGRUP
  'GWPR' /
  'GOPR' /
/
```

## GRADRESV Specify derivatives of solution quantities to be output to the restart file

x	ECLIPSE 100

	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to specify which gradients of solution data are output to the restart files. The keyword is entirely optional. If it is not specified then no gradients of solution data are written to the restart file.

---

**Note:** The `eclipse4d` license feature is required to use this keyword. If this feature is not available then no output will be generated. Please contact your SIS account manager to obtain a license.

---

The keyword must be followed by a set of records specifying mnemonics associated with derivatives. Each record should be terminated with a slash (/) and the set of records must end with a slash.

The available mnemonics are currently:

PRES output gradients of grid block oil pressures

SOIL output gradients of grid block oil saturation

SGAS output gradients of grid block gas saturation

SWAT output gradients of grid block water saturation

DENO output gradients of grid block oil phase density

DENG output gradients of grid block gas phase density

DENW output gradients of grid block water phase density

PORO output gradients of grid block reservoir porosity

RS output gradients of solution GOR

ACIP output gradients of grid block pressure-wave impedance

ACIS output gradients of grid block shear-wave impedance

POIS output gradients of grid block Poisson's ratio

Additional mnemonics (for example for fluid properties or a combination of fluid and rock properties) could easily be output if requested, for instance effective densities. Please contact SIS with any requests or suggestions.

---

**Note:** The gradients output will be encoded unless the `UNCODHMD` keyword is used. The use of this keyword requires the `uncodedhmd` license feature to be available. Your Schlumberger account manager will be pleased to help you in obtaining a license.

---

### Example

This example shows how to request the output of gradients of pressure, water saturation and pressure-wave impedance for all gradient parameters in the study.

```
GRADRESV
 'PRES' /
 'SWAT' /
 'ACIP' /
 /
```

## Formats

A record 'GRADRESV' is written to the HMD and Restart files to list the mnemonics. For example, referring to the above example

```
'GRADRESV'          3 'CHAR'
'GPRES'  'GSWAT'  'GACIP'  /
/
```

or

```
'GRADRESV'          4 'CHAR'
'GPRES'  'GSOIL'  'GSWAT'  'GSGAS'  /
/
```

The solution gradient data is written to the Restart file in the following manner (see the *ECLIPSE File Formats Reference Manual* for details of how restart data is written from ECLIPSE).

Header GRADSOL indicates a solution gradient mnemonic:

For example

```
'GRADSOL'          5 'CHAR'
'HMTRANZ'  'GRADZONE'  '1'  '1'  '3'  /
/
```

The record GRADSOL contains some or all of the following items:

1. Parameter name
2. Keyword name, associated with parameter:
  - 'GRADZONE' for regional parameters defining gradzones
  - 'FAULTS' for faults
  - 'AQUCTS' / 'AQUFET' for aquifers
  - 'SATNUM' relative permeability shape parameters
  - 'PVTNUM' / 'SATNUM' / 'ROCKNUM' for rock parameters
  - 'MULTNUM' for inter-region transmissibility multipliers
3. Feature name
  - Blank for regional parameters
  - Name of fault for fault parameters
  - Blank for all other parameters
4. Parameter type
  - This is described under HMHEAD in ["Output from the Gradient option"](#) in the *ECLIPSE Technical Description*

5. Region ID or Feature number
  - This is the subregion number for regional parameters
  - Fault number for fault parameters
  - Aquifer number for aquifer parameters
  - Saturation table number for relative permeability shape parameters
  - Rock table number for rock parameters
  - First region number for inter-region connection parameters
6. Associated phase
  - This is a pointer internal to ECLIPSE and should not be used by an external application.
7. region ID
  - This is the second region number for inter-region connection parameters
  - Set to zero for all other parameters
8. Not used at present. This is for forward extensibility.
9. Not used at present. This is for forward extensibility.
10. Not used at present. This is for forward extensibility.

Following each 'GRADSOL' record, the solution gradients are written in the following form:

```

'GRADSOL'      6 'CHAR'
'HMTRNXY' 'GRADZONE' ' ' '3' ' ' '3' ' ' '1' ' '
'GPRES_13'      300 'REAL'
  0.45278375E+03  0.40524387E+03  0.35893173E+03 -0.87420359E+01
-0.12985765E+02 -0.22687635E+02 -0.40819241E+02 -0.70829422E+02
-0.11564088E+03 -0.16381274E+03  0.19503807E+03  0.19354639E+03
  0.18682153E+03 -0.16461343E+01 -0.25963242E+01 -0.47793212E+01

```

The 'GPRES\_nn' mnemonic indicates oil pressures. The names in GRADRESV are preceded by the letter 'G' so they are distinct from names 'SGA', 'SWAT' which ECLIPSE and GRAF use for the solution values.

The header is usually of the form 'G' //name(1:4)//number; except when the 'name' is less than four characters, for example, the solution gas-oil ratio, RS. For this exception, additional underscores are used.

Characters 5 to 8 in the header just make a unique number such that GRAF does not get confused by several headers called 'GPRES' for example. The 'GRADSOL' header qualifies the actual solution gradients so that the last 3 letters of the header can be ignored. The {number} is required only because applications such as GRAF and FloViz have no special code to recognize these mnemonics.

## GRADRFT Request gradient output of RFT quantities

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

When using the Gradient option, it is possible to output gradients of RFT quantities to the RFT file for matching measured RFT. Normally, gradient information for well observations is written to the HMD file when the Gradient option is being used. The gradient data will normally be used by the SimOpt program.

The keyword must be followed by a set of records specifying mnemonics associated with derivatives. Each record should be terminated with a slash (/) and the set of records must end with a slash.

The available mnemonics are:

PRESSURE	Connection grid block pressure
SWAT	Connection grid block water saturation
SGAS	Connection grid block gas saturation
SOIL	Connection grid block oil saturation

The keyword is optional. If it is not specified, no RFT gradients will be output. The list of wells for which RFT gradients are required can be specified in the [GRADWELL](#) keyword.

When GRADRFT is specified, RFT output is automatically switched on at report timesteps for wells specified in the [RPTHMW](#) keyword, so that it is not necessary to specify the [WRFT](#) keyword in addition.

If the keyword is entered more than once, only mnemonics from the most recent entry are used, so that the list may be specified again at a restart or during the run.

Refer to "[Gradient option](#)" in the *ECLIPSE Technical Description* for further information.

### Example

Output derivatives only for connection block pressure (oil phase pressure), water saturation and gas saturation.

```
GRADRFT
  PRESSURE /
  SWAT /
  SGAS /
  /
```

## GRADWELL Specify well quantities to be output to HMD file

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to specify which well quantities are written to the HMD file.

The keyword must be followed by a set of records specifying mnemonics associated with derivatives. Each record should be terminated with a slash (/) and the set of records must end with a slash.

The available mnemonics are:

- WBP One-point pressure average - see keyword [WPAVE](#)
- WBP4 Four-point pressure average - see keyword [WPAVE](#)
- WBP5 Five-point pressure average - see keyword [WPAVE](#)
- WBP9 Nine-point pressure average - see keyword [WPAVE](#)

WOPR Surface oil rate

WWPR Surface water rate

WGPR Surface gas rate

WWCT Well water cut

WGOR Well gas-oil ratio

WBHP Bottom hole pressure

WOPT Surface oil production cumulative total

WWPT Surface water production cumulative total

WGPT Surface gas production cumulative total

The keyword is optional.

ECLIPSE 100

If this keyword is not specified, then the first 9 items listed above (WBP, WBP4, WBP5, WBP9, WOPR, WWPR, WGPR, WWCT, and WGOR) are output for each well.

ECLIPSE 300

If this keyword is not specified, then the six items (WOPR, WWPR, WGPR, WWCT, WGOR, and WBHP) are output for each well.

If the keyword is used more than once, only mnemonics from the most recent invocation are used so that the list may be specified again at a restart or during the run.

### Example

Output derivatives only for water rate, water cut and bottom hole pressure:

```
GRADWELL
'WWPR' /
'WWCT' /
'WBHP' /
/
```

## GRAVCONS Specify user defined gravity constant

	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This requests that gravity drainage and imbibition are modeled between the matrix and fracture cells in a dual porosity run.

If this option is used, then the vertical dimensions for blocks of matrix material should be entered with keywords [DZMTRX](#) or [DZMTRXV](#) in the GRID section.

See "[Dual porosity](#)" in the *ECLIPSE Technical Description* for further information. See also keyword [GRAVDRM](#).

The keyword has no associated data.

## GRAVD RB Use the vertical discretized gravity drainage model for dual porosity runs

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword requests that the vertical discretized gravity drainage and imbibition model should be used. If this option is used, then the geometry of the matrix sub-cell specified by keyword [NMATOPTS](#) must be vertical.

See "[Dual porosity](#)" in the *ECLIPSE Technical Description* for further information.

The keyword has no associated data.

In ECLIPSE 100, with this model, the minimum value for the number of global cells in the X direction (keyword [DIMENS](#)) is 2.

## GRAVDRM **Use the alternative gravity drainage model for dual porosity runs**

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword requests that the alternative gravity drainage and imbibition model should be used. (The GRAVDRM keyword may be used instead of the [GRAVDR](#) keyword; if both are present the GRAVDRM keyword supersedes GRAVDR.)

The keyword has one data item, terminated with a slash(/):

1. Allow re-infiltration

YES Oil flow is allowed both out of and into the matrix block.

NO Oil flow is only allowed out of the matrix block. With no re-infiltration the final recovery from the matrix is more predictable.

DEFAULT: YES

2. See "[Dual porosity](#)" in the *ECLIPSE Technical Description* for further information.

## GRAVITY

## Fluid gravities at surface conditions

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTPVT (see keyword [TABDIMS](#) in the RUNSPEC section) records, each terminated by a slash (/).

Each record consists of the following items of data:

1. Oil API gravity.  
DEFAULT: 45.5  
UNITS: °API
2. Water specific gravity (with reference to pure water).  
DEFAULT: 1.0
3. Gas gravity (with reference to air).  
DEFAULT: 0.7773

ECLIPSE 300

In compositional runs the oil and gas surface densities are obtained from the equation of state and the values entered under the GRAVITY keyword are not used. A dummy value may be entered in this case. The water specific gravity is always required. Note that GRAVITY always contains three items, even if not all three phases are present in the run.

ECLIPSE 100

---

**Note:** When using the API tracking option (keyword [API](#) in the RUNSPEC section), the set of records must be entered in decreasing order of oil API gravity.

---

Keyword [DENSITY](#) can be used as an alternative to GRAVITY.

See "[Units](#)" of the *ECLIPSE Technical Description* for conversion formulae between gravity and density.

## Example

With two PVT tables:

```
GRAVITY
40.1 1.16 0.852 /
36.5 1.16 0.852 /
```

## GRDREACH Defines location of grid blocks connecting to a river-bed

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword defines the location of the grid blocks connecting to a river and instructs ECLIPSE to allocate each 'completion' to a river reach. The river's reach structure must previously have been defined with the [REACHES](#) keyword. The location of each connected grid block is defined within the river by the branch name and the distance down the river to the start and end of the grid-block. This information must be supplied for **all** the grid-blocks connecting to the river that have been specified with the [COMPRIV](#) keyword. ECLIPSE allocates each grid block connection to the reach whose nodal point lies nearest to the center of the grid block. It is also possible to specify which reach a grid block belongs to.

The keyword can only be used on one river at a time, thus it must be specified more than once if there is more than one river.

The keyword is followed by a number of data records to define the location of all the grid block connections in the river. Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing just a slash.

The data items in each record are:

### Record 1

The first record consists of a single item of data that identifies the river.

1. Name of the river

End the data record with a slash (/).

### Each subsequent record

The subsequent records set the start and end of each grid block in terms of distance along the river from the river's zero reference point, and the branch number. The zero length reference point is defined relative to item 5 of the first record of keyword [REACHES](#). The grid blocks must previously have been defined with keyword [COMPRIV](#).

The grid blocks may either be specified individually, or in one or more "ranges". A "range" is a contiguous row or column of grid blocks that are connected to the same branch of the river. The river is assumed to go through each grid block in the specified direction. The distance along the river to the start and end of each grid block in the range is determined by summing the DX, DY or DZ thicknesses of the grid blocks in the range. **All** grid blocks in the river must have their distances set, either individually or within a range, working outwards along the main stem and each branch towards its source.

1. I - location of the individual grid block, or the grid block at the **start** of the range (nearest the river mouth)
2. J – location of the individual grid block, or the grid block at the **start** of the range (nearest the river mouth).
3. K - location of the individual grid block, or the grid block at the **start** of the range (nearest the mouth). This item will usually be 1.
4. Branch name on which this grid block (or range of grid blocks) is located.
5. Distance down the river from the river's zero reference point to the **start** of **this** grid block .

UNITS: m (METRIC), ft (FIELD), cm (LAB)

DEFAULT: Zero, for the first of these records, or the distance to the end of the previous grid block or range, for subsequent records

6. Distance down the river from the river's zero reference point to the **end** of **this** grid block .

This item, if set, must be greater than item 5.

UNITS: m (METRIC), ft (FIELD), cm (LAB)

DEFAULT: Value of item 5 + thickness of the grid block in the direction of penetration

7. Reach number the grid blocks connect to

Optional: If entered this value will override any value calculated by ECLIPSE. It is a particularly good idea to use this keywords if the grid blocks are dead grid blocks.

8. Direction of penetration through the grid block or the range.

X or I for horizontal penetration in the x-direction

Y or J for horizontal penetration in the y-direction

Z or K for vertical penetration

This item is used for calculating the distance to the end of the grid block (or the grid blocks in the range), where it defines which component of the grid block size to add (DX, DY or DZ). The item must be set if item 6 is defaulted, or if a range is specified in item 9. Otherwise it may be defaulted as it is not required.

9. Grid block I, J, or K coordinate at the **end** of the range, depending on the direction of penetration set in item 7. (For example the I-coordinate of the grid block at the end of the range, if the branch penetrates in the I-direction.)

This may be greater than, or less than, the corresponding grid block coordinate in item 1, 2 or 3, depending on whether the branch penetrates out towards the positive I, J or K direction.

If this item is set, the lengths are calculated for all the river's grid blocks that lie within the range. Should the range pass through an inactive grid block ECLIPSE prints a warning message and a thickness must be set.

If this item is defaulted, this record sets the data for the single grid block identified by items 1, 2 and 3.

10. Contact area of this grid block with the river (See item 17)

UNITS: m<sup>2</sup> (METRIC), ft<sup>2</sup> (FIELD), cm<sup>2</sup> (LAB)

11. Table number describing contact areas as a function of the depth of water in the river. (See [RBEDCONT](#))

One of items 10 or 11 must not be defaulted. If both are entered the table number will be ignored.

12. Productivity index of grid block with river (See item 17)

UNITS: m/day/bars (METRIC), ft/day/psi (FIELD), cm/hr/atm (LAB)

DEFAULT: 0.0

13. The length of a dead grid block in the penetration direction

UNITS: m (METRIC), ft (FIELD), cm (LAB)

14. Option to connect a REACH either to the cell center (default) or to cell top. A value of 1 connects this REACH to cell top, and a value of 0 connects this REACH to cell center.

DEFAULT: 0

15. Adjustment of REACH connection elevation with positive value pointing upward. This item allows a REACH to connect anywhere within a cell by introducing a shift to the connection point.

DEFAULT: 0

16. Remove capillary pressure from inflow equation? 'YES' or 'NO'

DEFAULT: 'NO'

17. Choice of infiltration equation? The choice of infiltration equation should either be zero or one depending on the choice of model. If the default is used you must enter items 10 and 12, otherwise items 18 and 19 must be entered. See "Rivers" in the *ECLIPSE Technical Description* for more details on the river infiltration equations.

DEFAULT: 0

18. Hydraulic conductivity (See item 17)

UNITS: m/day (METRIC), ft/day (FIELD), cm/hr (LAB)

DEFAULT: 0.0

19. Thickness of river bed (See item 17)

UNITS: m (METRIC), ft (FIELD), cm (LAB)

DEFAULT: 0.0

End the data record with a slash (/).

End the set of data records with a slash.

**Note:** River data can be complicated to enter. It is advisable to check your data by examining the output generated in the Print file.

The output is generated by setting `RPTSCHED` mnemonic `WELSPECS`.

## Example

```
GRDREACH

## Reference gravities for EoS

In a run with  $N_c$  components this keyword specifies the fluid gravities at the reference conditions with respect to that of water. The keyword can be used either in a run which uses the Zudkevitch Joffe equation or in a thermal run (keyword [THERMAL](#) in the RUNSPEC section). Alternatively the keyword [DREF](#) can be used.

The density of water is:

UNITS: 999.014 kg/m<sup>3</sup> (METRIC), 62.3664 lb/ft<sup>3</sup> (FIELD), 0.999014 gm/cc (LAB), 999.014 kg/m<sup>3</sup> (PVT-M)

There should be one value for each component.

DEFAULT: 1.0

If multiple equations of state are being used, a record should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

### Example

```
GRES
0.805 0.778 0.454 0.548 0.610 0.659 0.719 0.838 0.907 /
```

## Reference gravities for surface EoS

This optional keyword supplies component reference gravities for use in the surface calculations. The default, if this is not supplied, is for these to follow the reservoir values supplied with [GREF](#).

If multiple equations of state are being used, a set of data should be entered for each surface EoS. The number of surface equation of state regions is entered as item 10 of [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

## GRIDFILE

## Control output of the grid geometry file

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by up to two integers.

This value controls the amount of data written to the GRID geometry file. The possible values are:

1. Control of the GRID file output
  - 0 No GRID file is produced
  - 1 A standard GRID file is produced. (for active cells only).
  - 2 An extended GRID file is produced, containing:
    - Inactive cell data
    - Non-neighbor connection data
    - Local grid refinement data
    - Local grid coarsening data

DEFAULT: 0

If any local grid refinements or coarsening are present, then a value of 1 will be promoted to 2.

2. Control of the extensible grid file output (EGRID)
  - 0 No EGRID file is produced
  - 1 Output an extensible grid file, containing:
    - Inactive cell data
    - Non-neighbor connection data
    - Local grid refinement data
    - Local grid coarsening data

DEFAULT: 1

The data must be terminated by a slash (/).

If neither the GRIDFILE nor **NOGGF** keywords are used, then by default, an EGRID file will be produced.

If the NOGGF keyword is used then no GRID file of either form is output.

The Extensible Grid file (EGRID file) contains the same information as the standard grid file in corner point or block centered grids. The format is typically more efficient for generating a smaller file that is faster to load into post-processing programs. In addition the format is used to store unstructured grid data, where ECLIPSE does not know original grid geometry but just the processed pore volumes and transmissibilities.

The GRAF program can read the extensible EGRID file, the standard GRID file or the extended GRID file. However, an EGRID file or an extended GRID file is required if the grid displays are to include the local grid refinements.

---

**Note:** Setting the first item in GRIDFILE to 2 is recommended for correct display in 3D graphical applications.

---

## Examples

### Example 1

```
-- Extensible EGRID file only
GRIDFILE
0 1 /
```

### Example 2

```
-- Both EGRID and Extended GRID file
GRIDFILE
2 1 /
```

## GRIDOPTS Options to process grid data

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword requests additional options for processing the grid data. It should be followed by some or all of the following items, terminated with a slash (/).

1. Allow the alternative transmissibility multipliers including [MULTX-](#), [MULTY-](#), [MULTZ-](#) (which apply to the grid block faces X-, Y-, Z-) to be used in the GRID, EDIT or SCHEDULE sections. Similarly, the keyword is required if the alternative diffusivity multipliers, which include [DIFFMX-](#), [DIFFMY-](#), [DIFFMZ-](#), are used.

YES Keywords [MULTX-](#), [DIFFX-](#) and related keywords may be used

NO Otherwise

DEFAULT: NO

2. [NRMULT](#) The maximum number of [MULTNUM](#) regions entered in the GRID section, which apply either to inter-region transmissibility multipliers using the [MULTREGT](#) keyword, or pore volume multipliers using the [MULTREGP](#) keyword. For both cases, if this item is set to zero or defaulted then any multiplier is applied between flux regions entered using [FLUXNUM](#).

ECLIPSE 100

[MULTNUM](#) regions can similarly be used for diffusivity and thermal conductivity multipliers ([MULTREGD](#) and [MULTREGH](#)).

DEFAULT: 0

ECLIPSE 100 only

---

**Note:** If this value is defaulted or set to 0 and the 4th item of [REGDIMS](#) is also defaulted or set to 0, the simulator behaves as though all grid blocks are in [MULTNUM](#) region 1. This has no effect except that specifying multipliers for region 1 will not generate a warning or error, and is a side-effect of the default value for [MULTNUM](#) being 1.

---

ECLIPSE 100 only

3. [NRPINC](#) The maximum number of [PINCHNUM](#) regions entered in the GRID section, which apply to the calculation of pinchouts by region.

DEFAULT: 0

ECLIPSE 300

---

**Note:** Data item 3 is not available for use in this release. Any values read in for this item is ignored by the simulator.

---

ECLIPSE 100

---

**Note:** This keyword can be specified once only, unless [item 223](#) in [OPTIONS](#) is set to 1 for backward compatibility purposes. Users who do this should be aware that while respecifying it will overwrite the values, it does not undo options which were triggered by the first specification, in particular the choice of which region set will be used by default for [MULTREGT](#).

---

## Example

```
GRIDOPTS  
YES 0 3 /
```

This keyword is entirely optional; it is normally output by grid pre-processors.

The keyword should be followed by up to two items of data:

1. Unit of length for the grid data
2. A flag set to MAP or left blank

This is to indicate whether the grid data are measured relative to the map, or relative to the origin given by the [MAPAXES](#) keyword.

The data must be terminated by a slash (/).

This data is then available through the GRID file for post-processing.

### Example

```
GRIDUNIT
METRES MAP /
```

**Note:** ECLIPSE 100 checks if the units specified in the INCLUDE or IMPORT file are consistent with the units specified in the RUNSPEC section of the dataset. If necessary, it then does the appropriate conversion assuming an origin at (0,0,0). The conversion is only applied up to the end of the next INCLUDE / IMPORT file (so care needs to be taken if the data grid is split into separate files), or until the end of the GRID section. If this is not satisfactory, check that the GRIDUNIT keyword is correct. If necessary, export the data again from the gridding software using the correct units.

**Note:** ECLIPSE 300 checks if the units specified in the INCLUDE or IMPORT file are consistent with the units specified in the RUNSPEC section of the dataset. Unlike ECLIPSE 100, it does not convert the geometric grid and edit data. Export the data from the gridding software again using the correct units, and check that the GRIDUNIT keyword is correct.

## GRUPFUEL **Specifies group fuel rate**

	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies the amount of gas produced from a group that is burnt for fuel. This reduces the gas available for reinjection.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/). The set of records is ended by a blank record, containing only a slash.

1. Group name or name root

or FIELD (to set the field fuel rate)

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. The constant usage rate. This is summed with the quantity specified using item 3 to give the overall gas fuel requirement. A user defined argument can be set with keywords [UDQ](#) and [UDADIMS](#).

UNITS:  $\text{sm}^3/\text{day}$  (METRIC), Mscf/day (FIELD), scc/hr (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

DEFAULT: 0.0

3. The fractional gas rate. This is a fraction of the total gas production from the group (before any fuel, sales and re-injection requirements have been taken). This fractional part is calculated at each timestep and then summed with the quantity specified using item 2 to give the overall gas fuel requirement. A user defined argument can be set with keywords [UDQ](#) and [UDADIMS](#).

DEFAULT: 0.0

4. The component template.

This may be used to alter the composition of the gas removed for fuel.

One value is required for each component, the default being 1. If a value less than one is specified, the amount of that component used for fuel will be correspondingly reduced.

The method used to determine the amount of fuel burnt is:

- Sum the fuel requirements from any subgroups.
- If a fractional usage rate is defined (item 3), add the specified fraction of the remaining gas from the group, multiplying the volume rate of each component by its template value. Note that the template can alter the overall volume rate of gas used for fuel when a fractional usage rate is specified.
- If a constant usage rate is defined (item 2), add this to the fuel usage, subject to an upper limit equal to the remaining gas rate. The component template is used to multiply the contribution from each component. Note that the component template does not alter the constant usage rate, as the component volume rates are normalized again to obey the specified constant rate.
- The component rates used for fuel are now subtracted from the gas available for subsequent requests such as sales or reinjection. Note that using a component template can alter the composition of the remaining available gas.

In a multilevel group hierarchy the remaining available gas is reduced for all children of the group concerned. The same reduction fraction is used for all children as for the group concerned - the gas used for fuel is assumed to be evenly taken from the gas produced by the group.

By default, the group fuel requirement is satisfied prior to the sales requirement. This ordering may be changed using the [WTAKEGAS](#) keyword.

The fuel requirements are satisfied from the bottom of the group hierarchy to the top.

See also "[Group injection control options](#)" in the *ECLIPSE Technical Description*.

---

**Note:** For accurate group gas accounting, there is a limitation that reinjection control and any sales gas or fuel gas requirements must all be specified for the same group, usually the FIELD group, and not split across the group hierarchy. This limitation only applies if the injection gas contains group vapor, with the vapor taken from a separator stage (that is not from the whole separator).

---

## Example

Set field gas fuel rate of 1000 Mscf/day:

```
GRUPFUEL
FIELD 1000 /
/
```

## GRUPGR

## Specifies group guide rates

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies the user guide rates for a group.

The keyword is retained for back-compatibility; you are encouraged to use keywords [GCONPROD](#) and [GCONINJE](#) to set group controls and guide rates, which are compatible with both simulators.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. Group name or name root

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. A character specifying if group is available for group control.

This must be start with Y or N.

DEFAULT: Y

3. The guide rate value.
4. The type of guide rate being specified.

This must be one of the following:

OIL Oil production guide rate

WAT Water production guide rate

GAS Gas production guide rate

LIQ Liquid production guide rate

COM Linearly combined production guide rate (coefficients must be set with [LINCOM](#))

WG Wet gas production guide rate

VP Voidage production guide rate

IG Gas surface volume injection guide rate

IW Water surface volume injection guide rate

VG Gas voidage injection guide rate

VW Water voidage injection guide rate

VI Injection voidage guide rate (sets VG and VW)

RV Reservoir voidage guide rate (sets VP, VG and VW)

INJ Injection guide rate (sets IG and IW)

NONE No guide rate specified

POTN A group's guide rates will be set at the beginning of each timestep equal to the group's production and injection potentials - that is the sum of the production and injection potentials of all its subordinate open producers and injectors

ALL Set all guide rates

DEFAULT: NONE

In general, it is best to either specify all the guide rates for the children of a group (to specify the required distribution of targets explicitly), or to use POTN to instruct potential rates to be used as guide rates.

It is usual to set one production guide rate (one of OI, WA, GA, LI, WG, VP), one water injection guide rate (one of IG, VG) and one gas injection guide rate (one of IW, VW). The others in each of these three classes are set using flow ratios from the value specified. The VI, RV, INJ and ALL options allow several guide to be set explicitly.

See also "[Group production control options](#)" in the *ECLIPSE Technical Description* for further information.

## Example

```
GRUPGR
Z45 Y 100.0 INJ /
/
```

## GRUPINJE Specifies group injection targets

	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies the injection control data for a group. Both the nature of the fluid to be injected, and the target and limiting rates at which injection is to occur are defined.

The keyword is retained for back-compatibility; you are encouraged to use keyword [GCONINJE](#) instead, which is compatible with both simulators.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. Group name or name root

or `FIELD` (to set field injection controls)

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. A character string specifying the fluid to be injected.

In black oil mode this may only be `WAT` or `GAS`. In compositional mode, the nature of the injected fluid (that is the mole fraction of each component) must be known. This may be defined in one of the following ways:

- the injection stream has a user specified composition, defined with the [WELLSTRE](#), [WINJMIX](#) or [WINJORD](#) keyword
- the injection stream is taken from the production of a named well or group.

The fluid string must be one of the following:

`WAT` Water.

`GAS` Gas may be selected in either a black oil or a compositional run.

In a compositional run the composition of the injected gas is set to that of the field separator gas. However, it is generally better to specify the injected gas composition more precisely.

From 2007.1, in a compositional run, `GAS` is internally converted to `GV` (for the field separator) which has better reinjection and gas accounting behavior. [Item 113](#) in `OPTIONS3` can be used to recover the pre-2007.1 behavior.

`ST` Implies that the molar composition of the injected fluid has been defined using the `WELLSTRE` keyword.

`MIX` Implies that the molar composition of the injected fluid has been defined as a mixture using either the `WINJMIX` or `WINJORD` keywords.

`WV` Implies that the composition of the injected fluid is to be taken from the vapor production of a nominated well.

GV Implies that the composition of the injected fluid is to be taken from the vapor production of a nominated group.

Only the first two characters are significant.

The injection fluid string may only be defaulted if the group is under group control, in which case the injection fluid will be supplied by the parent group.

3. A character string is required if the composition of the injection fluid was specified using the ST, MIX, WV or GV methods.

In these cases this item is a character string specifying the name of the wellstream, mixture, well or group that defines or supplies the injection stream.

4. A character string specifying the method used to control the rate at which fluid is injected.

This must be one of the following:

NONE No immediate control of injection rate

WA Inject a target water volume rate set in item 6

GA Inject a target gas volume rate set in item 7

RV Inject the fluid to make up a target reservoir volume injection rate set in item 8

WG Inject the fluid at a target wet gas rate set in item 9

RE ReInjection or voidage replacement control, at a fraction set in item 10

GR Group is immediately under control from a higher level group, injecting its share of the higher group's target rate, according to its guide rate (which must be set in the GRUPGR keyword)

The character string determines the rate to be used as an initial target for group injection; other rates entered are interpreted as limits.

5. The target/limit oil volume rate.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC),  $\text{stb}/\text{day}$  (FIELD),  $\text{scc}/\text{hr}$  (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

6. The target/limit water volume rate.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC),  $\text{stb}/\text{day}$  (FIELD),  $\text{scc}/\text{hr}$  (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

7. The target/limit gas volume rate.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC),  $\text{Mscf}/\text{day}$  (FIELD),  $\text{scc}/\text{hr}$  (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

8. The target/limit reservoir volume rate.

UNITS:  $\text{rm}^3/\text{day}$  (METRIC),  $\text{rb}/\text{day}$  (FIELD),  $\text{rcc}/\text{hr}$  (LAB),  $\text{rm}^3/\text{day}$  (PVT-M)

9. The target/limit wet gas injection rate.

Wet gas rate is related to the moles injected using a unity Z-factor at standard conditions.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC),  $\text{Mscf}/\text{day}$  (FIELD),  $\text{scc}/\text{hr}$  (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

10. The target/limit reinjection fraction or voidage replacement fraction.

If item 15 is set to S, item 10 is interpreted as a reinjection fraction. When this is a target, the group attempts to inject the fluid specified in item 2 at a surface rate equal to the reinjection fraction multiplied by the water or available gas rate of the group or well named in item 12. The available gas rate of a group for reinjection is by default equal to the group's gas production rate plus the rate of any advanced gas associated with the group (keyword **GADVANCE**) minus its fuel rate (keyword **GRUPFUEL**) minus its sales target (keyword **GRUPSALE**); however, the ordering of this definition can be altered using keyword **WTAKEGAS**. In the case of a reinjection fluid defined by a stream or mixture, the specified fraction of the available surface gas production rate is applied as a wet gas reinjection rate target.

If item 15 is set to R, item 10 is interpreted as a voidage replacement fraction. When this is a target, the group attempts to inject the fluid specified in item 2 to make up a total reservoir volume injection rate equal to the voidage replacement fraction multiplied by the total reservoir volume production rate of the group or well named in item 12.

A make-up gas stream may be specified in item 14, which is mixed with the injection stream if the gas injection rate exceeds the available gas rate.

DEFAULT: 1.0 if item 4 is RE, 0.0 otherwise

11. The type of production used to define the rate under reinjection or voidage replacement control.

This is required for reinjection or voidage replacement control. It may be one of the following:

W Implies the reinjection or voidage replacement depends on the production of the **well** named in item 12.

G Implies the reinjection or voidage replacement depends on the production of the **group** named in item 12.

DEFAULT: W if item 2 is WV, G if item 2 is GV

12. The name of the production well or group that controls the reinjection or voidage replacement rate.

This is required for reinjection or voidage replacement control. If item 11 is W it should be the name of a production well. If item 11 is G it should be the name of a group.

If this name is not specified, it defaults to the fluid composition source name (item 3) for injection fluids WV or GV in item 2, and to the name of the group in item 1 for the other cases (WA, GA, ST or MIX in item 2).

13. Not used at present.

14. The mnemonic for a wellstream to be used as make-up gas.

This is only required if make-up gas is to be used when the injected gas rate exceeds the advance and/or available produced gas from the source group or well.

15. The way in which reinjection or voidage replacement fraction in item 10 is to be interpreted.

S Reinject a fraction of **surface** volume production (that is reinjection)

R Replace a fraction of **reservoir** volume production (that is the voidage replacement)

DEFAULT: S

16. The stage of the separator that defines the fluid composition for injection.

The vapor from any stage of the separator may act as a source of injection fluid. The default value of 0 results in the use of the vapor from the whole separator as the injection fluid.

Note that the choice of separator stage also affects the available produced gas supply rate from the source group or well (item 3) if the source is GV or WV (item 2), and also that of the control group or well (item 12) for reinjection.

DEFAULT: 0

## Notes

1. To reinject one phase (for example gas) and top it up with another phase (for example water) to achieve voidage replacement, enter two records of GRUPINJE data. The first record sets a target injection rate or reinjection fraction on the first phase. The second record sets a target voidage replacement fraction (usually 1.0) on the second phase. But the target voidage replacement fraction is taken to apply to the total reservoir volume injection of both phases, that is the injection rate of the second phase is controlled to top up the total reservoir volume injection to achieve the voidage replacement target. The second phase is treated as the top-up phase. The top-up phase is taken to be the phase with a target voidage replacement fraction (item 10) or reservoir volume rate (item 8). ECLIPSE 300 will only allow one top-up phase amongst all groups. This is illustrated in Examples 4 and 5.
2. If the injection stream originates from a particular group or well, and the injection target exceeds the available produced gas, the extra gas required is taken from the make-up gas stream, if this is specified in item 14. If no make-up gas is specified, the behavior of the injection controls depends on whether the keyword `WAVAILIM` is entered. Without this keyword, the injection target is honored by injecting more gas than is available, resulting in a negative excess rate in the gas accounting table. If the `WAVAILIM` keyword is entered, the injection rate is limited by the amount of gas available for injection from the source group or well. See keyword `WAVAILIM` for further details.
3. For gas injection wells under group control, it is best to default the fluid injection type defined in items 2 and 3 of their `WELLINJE` keywords (as illustrated in example 5). This ensures that the injection stream will be that defined by the group. If a gas injection well under group control has its own fluid set, then this fluid, and not that defined by the group, is injected at a rate determined by the group.
4. For water injection wells under group control, the injection fluid `WATER` must be set in item 2 of their `WELLINJE` keywords (as illustrated in example 5). If this is not done, then the well defaults to a gas injector and will not contribute to an overall group controlled water injection rate.
5. The reinjection fraction limit (item 10, if item 15 is set to S) ignores makeup gas (item 14). It should not be applied if makeup gas is available, which is treated as an infinite resource.

## Examples

### Example 1

Replace the voidage produced by the group GRP1 with injected water. The defaulted voidage replacement fraction will automatically be set to 1.0 in this case.

```
GRUPINJE
GRP1 WATER ' ' RE 10* R /
/
```

### Example 2

Water is to be injected by the group at a rate of 1000 stb/day.

```
GRUPINJE
G1 Water ' ' Water 1* 1000.0 /
/
```

### Example 3

The hydrocarbon defined by wellstream MixB is to be injected so as to replace the voidage produced by group PGC.

```
GRUPINJE
PLATA Stream MixB Reij 5* 1.0 Group PGC 2* R /
/
```

### Example 4

Gas is reinjected from field production at a rate of half the surface production rate. Water tops up the gas to achieve 100% voidage replacement.

```
GRUPINJE
--group fluid name ctrl rates reinj reinj reinj misc Reservoir/
-- mode frac type contr Surface
FIELD STREAM SOLV RE 5* 0.5 G 1* 2* S /
FIELD WAT 1* RE 5* 1.0 G 1* 2* R /
/
```

### Example 5

Gas is reinjected from field production at a fixed rate.

Water tops up the gas to achieve a fixed reservoir voidage target.

The [WELLINJE](#) keyword defines water and gas injectors, with group controlled rates.

```
GRUPINJE
-- Group Phase Name Mode Rates
FIELD GV Field GA 2* 1000 /
FIELD Water ' ' RV 3* 1000 /
/
WELLINJE
IG1 2* GR /
IG2 2* GR /
IW1 WA 1* GR /
IW2 WA 1* GR /
/
```

## GRUPLIM

# Specifies group economic limits

GRUPLIM is an alias for [GECON](#).

## GRUPMAST Identifies the master groups and their slaves

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword must be used in a reservoir coupling master run to identify the master groups and to indicate which slaves they are associated with (see "Reservoir coupling" in the *ECLIPSE Technical Description*).

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/). The set of records must end with a blank record, containing only a slash (/).

1. The master group's name or group name root

A group name root, ending with an asterisk (\*), can be used to refer to several groups in one record.

The master groups must previously have been declared with the keyword `GRUPTREE`. They must not contain any wells or have subordinate groups.

2. The name of the slave reservoir containing the group's associated slave group

The slave reservoir must previously have been declared and activated with keyword `SLAVES`. The slave reservoir name is entered as item 1 in that keyword.

Alternatively, if a default (1\*) or blank name (') is entered, the group's flow rates will be read from the input reservoir coupling file instead of being calculated from the slave reservoir simulation. In this case, the `USECUPL` keyword must be entered to identify the input Reservoir Coupling file, and the group's slave reservoir should not be included in the `SLAVES` keyword.

3. The name of the master group's associated slave group in the slave reservoir

The associated slave group may have a different name from its master group. For example, the slave group may be the top level group in its slave reservoir, and thus must be called `FIELD`.

If a default (1\*) or blank name (') is entered, ECLIPSE assumes the associated slave group has the same name as its master group.

4. The limiting fraction by which the group's flow rate may change in a single timestep

DEFAULT: infinity

A value may optionally be entered here to limit the fraction by which the group's flow rate (that is the reservoir fluid volume production rate and its phase injection rates) can change over a single timestep. ECLIPSE does this by restricting the length of the master run's timestep, based on the previous timestep's flow rate changes. The restriction takes place retrospectively, and the timestep is **not** chopped if a sudden rate change causes the limit to be exceeded.

If the slave groups' flow rates change significantly over a single timestep of the master run, the group flow rate targets imposed in the master reservoir may not be accurately obeyed. This is because the flow rate targets are apportioned among the master groups according to their slave groups' flow capabilities at the **start** of each timestep, while the reported flows are those occurring at the **end** of the timestep. Reducing the limiting flow change fraction increases the accuracy of the group controls. However, it is also advisable to set a minimum timestep length that this restriction can impose (see keyword `RCMASTS`), as the fractional flow changes can be large when the flows are small and wells are being opened or closed in the slave reservoirs.

A value entered here has no effect if the group's flows are to be read from the Reservoir Coupling file (that is item 2 is defaulted).

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

## Example

```
GRUPMAST
-- master      slave      associated  limiting
-- group      reservoir  slave      rate change
-- name        name        group      fraction
  LOWER-A     LOWER      PL-A       0.1 /
  LOWER-B     LOWER      PL-B       0.1 /
  UPPER-A     UPPER      PL-A       /
  UPPER-B     UPPER      PL-B       /
/
```

## GRUPNET **Defines the standard production network structure**

x	ECLIPSE 100
x	ECLIPSE 300
x	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword defines the structure of a standard production network, when using the network option (see "[Network option](#)" in the *ECLIPSE Technical Description*). If you are using the extended network model (keyword [NETWORK](#) in the RUNSPEC section), you should define the production network with keywords [BRANPROP](#) and [NODEPROP](#) instead.

The GRUPNET keyword is followed by any number of records, each containing the following items of data and terminated with a slash (/). The set of records must end with a blank record, containing only a slash.

- Group name or group name root,  
or FIELD (to set a fixed pressure for the field node)  
  
A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.
- Fixed pressure for the group corresponding to the terminal node of the network  
  
Default this item, or set it negative, if the group is not a fixed-pressure terminal node in the network.  
  
UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)
- Production VFP table number for the pipeline from the group to its parent group  
  
A value of 9999 can be entered to indicate that there is no pressure loss in the network branch between the group and its parent group.  
  
If the group is a fixed-pressure node (that is if a positive value is set for item 2) this item must be defaulted, since a fixed-pressure group is a terminal node and cannot have a pipeline connection to a higher group.  
  
If this item is defaulted for a group that is not a fixed-pressure node, the group is not part of the network.  
  
Two or more network pipelines may share the same VFP table if they have similar pressure loss characteristics.  
  
DEFAULT: 0 Implying the group has no pipeline connection to its parent group.
- Artificial Lift Quantity (ALQ) used in the pressure loss calculations for the group's pipeline.  
  
This quantity is used as a look-up parameter for the VFP table in item 3. It may be regarded as the pump or compressor power, according to the definition used in the construction of the table.  
  
UNITS: These depend on what the ALQ was meant to represent when the table was created. Refer to section "[Record 6:ALQ values](#)" in the description of keyword [VFPPROD](#).  
  
DEFAULT: 0
- Flag indicating whether the group is a sub-sea completion manifold, so that a group production target will be met by adjusting its wells' THP limits instead of by the standard method of flowing the wells in proportion to their guide rates.  
  
YES A group production target is met by adjusting its wells' THP limits, so that all wells may operate at the same THP

NO A group production target is met by the standard method of group control, and the wells may operate with different THP values

Any manifold groups that are subordinate to higher level groups having production rate targets (or limits that become rate targets if violated) should be given guide rates in keyword `GCONPROD`, otherwise their wells will not operate at the same THP.

ECLIPSE 100

Only well-groups can be manifolds, not higher level groups that are parents to other groups.

ECLIPSE 100

The convergence tolerance and iteration limit for the calculation of the manifold group's THP are set in keyword `NETBALAN`. The THP value input in item 10 of keyword `WCONPROD` for the first well in the group is used as the initial guess for the manifold group's THP in the first timestep. A suitable value entered for this quantity speeds the convergence of the first calculation.

ECLIPSE 300

The treatment in ECLIPSE 300 differs from that in ECLIPSE 100. Entering YES indicates that the group's outlet branch acts as an automatic choke, and that any production rate target applied to the group is met by adjusting the pressure loss across the choke. **The group's outlet pipeline must be given a VFP table number of 9999 in item 3**, so that its only pressure drop is that of the choke. Groups at any level in the tree may be selected, except for the terminal node which has no outlet pipeline.

DEFAULT: NO

6. Flag indicating whether gas-lift gas from the subordinate wells flows through this group's pipeline.

NO No liftgas flows along the pipeline, only formation gas.

FLO Add the lift gas flows of the subordinate producers to the gas flow rate along the pipeline. The lift gas flow is assumed to be equal to the sum of the ALQ values of the subordinate producers, multiplied by their efficiency factors.

ALQ Set the ALQ value for this pipeline equal to the sum of the ALQ values of the subordinate producers, multiplied by their efficiency factors. The entry in item 4 is ignored.

If the FLO or ALQ option is selected, the Artificial Lift Quantity for the wells (`WCONPROD` item 12) and the pipeline must be defined as the rate of lift gas injection. This definition must be selected in the VFP *i* program if it is used to construct the VFP tables.

ECLIPSE 300

If FLO is entered for a well group in ECLIPSE 300, the lift gas flows of its wells are included in the network source term and are included in the network flows up to the terminal node irrespective of the item 6 setting for superior groups. (In ECLIPSE 100 FLO must be entered for all the groups through which the lift gas is to flow.)

DEFAULT: NO

ECLIPSE 100 only

7. Equivalence the pipeline's ALQ to the surface density?

The pipeline's ALQ may optionally be made equivalent to the average surface density of either the oil phase or the gas phase flowing along it. ECLIPSE then automatically sets it equal to this value when it looks up the VFP table. The VFP table must have been prepared using the same definition of the ALQ (see keyword `VFPPROD`), and should span the expected range of surface density values. This option is useful when a mixture of oil or gas with different surface densities flows into the network. Obviously the ALQ cannot then also be used to represent a pump or compressor, or to represent the lift gas flow rate in item 6 above, and the pipeline cannot contain an automatic pump/compressor.

DENO Set the ALQ equal to the average surface density of the **oil** flowing along the pipeline.

DENG Set the ALQ equal to the average surface density of the **gas** flowing along the pipeline.

NONE Do not equate the ALQ to the oil or gas density. Leave it at the value entered in item 4 (or allow it to be used to represent lift gas or an automatic pump/compressor).

DEFAULT: NONE

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/). End the data record with a slash (/).

End the data record with a slash (/).

## Example

```
GRUPNET
FIELD 200 /
PLAT-A 1* 1 /
PLAT-B 1* 2 100 /
'GR-A*' 1* 3 1* YES /
GR-B1 1* 6 1* YES FLO /
GR-B2 1* 7 1* YES FLO /
/
```

## GRUPPROD Specifies group production target/limits

x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies the production targets and limits for a group.

The keyword is retained for back-compatibility; you are encouraged to use keyword [GCONPROD](#) instead, which is compatible with both simulators.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form  $n^*$ , where  $n$  is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. Group name or group name root

or `FIELD` (to specify field production controls)

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. A character string specifying the method used to control the rate at which fluid is produced.

This must be one of the following:

`NONE` No immediate control of production rate

`OIL` Oil volume rate

`WAT` Water volume rate

`GAS` Gas volume rate

`LIQ` Liquid (oil + water) volume rate

`COM` Linearly combined volume rate (coefficients must be set with [LINCOM](#))

`RV` Reservoir volume rate

`WGV` Wet gas volume rate

`GR` Group is immediately under control from a higher level group, producing its share of the higher group's target rate, according to its guide rate (which must be set in the [GRUPGR](#) keyword)

3. The target/limit oil volume rate.

UNITS:  $\text{sm}^3/\text{day}$  (`METRIC`),  $\text{stb}/\text{day}$  (`FIELD`),  $\text{scc}/\text{hr}$  (`LAB`),  $\text{sm}^3/\text{day}$  (`PVT-M`)

4. The target/limit water volume rate.

UNITS:  $\text{sm}^3/\text{day}$  (`METRIC`),  $\text{stb}/\text{day}$  (`FIELD`),  $\text{scc}/\text{hr}$  (`LAB`),  $\text{sm}^3/\text{day}$  (`PVT-M`)

5. The target/limit gas volume rate.

UNITS:  $\text{sm}^3/\text{day}$  (`METRIC`),  $\text{Mscf}/\text{day}$  (`FIELD`),  $\text{scc}/\text{hr}$  (`LAB`),  $\text{sm}^3/\text{day}$  (`PVT-M`)

---

**Note:** If, in compositional mode, a group is controlled by gas volume rate, surface volumes are obtained by  $Q_g^m RT_{\text{ref}} / P_{\text{ref}}$ , where  $Q_g^m$  is the molar gas rate,  $R$  the gas constant,  $P_{\text{ref}}$  the standard pressure and  $T_{\text{ref}}$  the standard temperature.

---

6. The target/limit liquid (oil + water) volume rate.  
UNITS: sm<sup>3</sup>/day (METRIC), stb/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)
  7. The reservoir volume rate.  
UNITS: rm<sup>3</sup>/day (METRIC), rb/day (FIELD), rcc/hr (LAB), rm<sup>3</sup>/day (PVT-M)
  8. The target/limit wet gas rate. (Compositional Only)  
UNITS: sm<sup>3</sup>/day (METRIC), Mscf/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)
  9. The target/limit linearly combined rate  
UNITS: determined by keyword `LCUNIT`.
- 

**Note:** The rate to be used as an initial target for group production is selected by the mode string (item 2); other rates entered are interpreted as limits. If these are exceeded the group changes control mode, the limit becoming a new target and the target a new limit.

---

See also "[Group production control options](#)" in the *ECLIPSE Technical Description* for further information.

## Example

```

## GRUPRIG Assigns workover and drilling rigs to groups

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used to assign workover rigs and drilling rigs to individual groups. Each group may have up to five workover rigs and five drilling rigs allocated to it. Several groups may share the same rig, if required. A rig allocated to a high-level group (or the Field) will be available for use by all the wells in its subordinate groups.

A workover rig is necessary to perform automatic workovers if the time taken to perform workovers has been set to a value greater than zero in keyword [WORKLIM](#). The availability of workover rigs will then determine the rate at which automatic workovers can be performed. For each automatic workover on a well, a workover rig is assigned and is made unavailable for other workovers for the duration entered in keyword [WORKLIM](#). A workover on a particular well is postponed if all the workover rigs that can be assigned to it are already occupied until the end of the timestep.

- In ECLIPSE 100, a workover refers to the automatic closure, plug-back or opening of a well connection resulting from instructions specified in keywords [WECON](#), [CECON](#), [GECON](#), [GCONPROD](#), [GCONPRI](#), [GCONSALE](#), [PRORDER](#) and [WORKTHP](#).
- In ECLIPSE 300, a workover refers only to the automatic closure of a well connection as a result of an economic or rate limit being broken.

Connection changes specified manually (for example with [COMPDAT](#)) are not affected by rig availability, and do not occupy any rigs. If item 3 of keyword [WDRILTIM](#) is set to YES for a given well, the well is treated as closed for the duration of the workover. This is done by temporarily reducing the well's efficiency factor, so that its flows are not included in the group totals and cumulative totals while it is being worked over. If the [WORKLIM](#) keyword is absent, workovers take up no rig time, and workover rig availability is not a restriction.

A drilling rig is necessary to open a new well automatically if the time taken to drill the well has been set to a value greater than zero in item 2 of keyword [WDRILTIM](#). The availability of drilling rigs will then determine the rate at which new wells can be opened automatically. When a new well is to be drilled, a drilling rig is assigned and is made unavailable for drilling other wells for the duration entered in keyword [WDRILTIM](#). The drilling of a well is postponed if all the drilling rigs that can be assigned to it are already occupied until the end of the timestep. The drilling processes controlled by rig availability are:

- Wells opened from the Drilling Queue (see keywords [QDRILL](#) and [WDRILPRI](#))
- Wells on Automatic Opening (for example with item 2 in keyword [WCONPROD](#) set to AUTO)
- Wells that are opened on the closure of another well (see item 9 of keyword [WECON](#)).

*ECLIPSE 100 only*

Wells opened manually are not affected by rig availability, and do not occupy any rigs. If item 3 of keyword [WDRILTIM](#) is set to YES for a given well, the well is treated as closed for the duration of the drilling process. This is done by temporarily reducing the well's efficiency factor, so that its flows are not included in the group totals and cumulative totals while it is being drilled. If the [WDRILTIM](#) keyword is absent, drilling takes up no rig time, and drilling rig availability is not a restriction.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Group name or group name root

or FIELD (if the rig is being assigned to the whole field)

A group name root, ending with an asterisk (\*), can be used to refer to several groups in one record.

2. Workover rig number (between -2 and 99)
  - 1-99 A workover rig with this number is added to (or removed from) the group
  - 0 No change to existing workover rigs
  - 1 A workover rig with this number prevents workovers on any well subordinate to the group, regardless of the availability of other rigs
  - 2 This number causes the removal of all workover rigs currently belonging to the group (but not any belonging to subordinate or superior groups).

DEFAULT: 0

3. Drilling rig number (between -2 and 99)
  - 1-99 A drilling rig with this number is added to (or removed from) the group
  - 0 No change to existing drilling rigs
  - 1 A drilling rig with this number prevents any well subordinate to the group from being drilled, regardless of the availability of other rigs
  - 2 This number causes the removal of all drilling rigs currently belonging to the group (but not any belonging to subordinate or superior groups).

DEFAULT: 0

4. Add or remove these rigs
  - ADD Add the rig(s) to the group
  - REM Remove the rig(s) from the group

DEFAULT: ADD

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

If no workover rigs have been specified, a single workover rig (number 100) is automatically be created for the FIELD group. Similarly, if no drilling rigs have been specified, a single drilling rig (number 100) will automatically be created for the FIELD group. These default rigs are created for back-compatibility with pre-95A ECLIPSE 100 and pre-2002A ECLIPSE 300 releases that do not use the GRUPRIG keyword for both types of rig. They are removed automatically the first time GRUPRIG is used to add a rig to any group.

Rigs may be allocated to groups on different levels. A rig allocated to a group on any level will be available to all its subordinate wells. For example, let the FIELD contain two groups, PLAT-A and PLAT-B. If rigs 1 and 2 are allocated to the FIELD group, and rig 3 is allocated to group PLAT-A, then all three rigs are available to the wells subordinate to PLAT-A while only rigs 1 and 2 are available to the wells subordinate to PLAT-B. Thus, if more than five rigs of a given type are to be available to the whole field, the first five can be allocated to the FIELD group and the remainder (up to another five) can be allocated to all the groups on the next level down. ECLIPSE makes no attempt to optimize the use of multiple rigs; to find a rig for a well it searches up the group hierarchy from the well's group up to the FIELD and selects the first free rig that it finds.

The two types of rig operate independently of each other. For example, drilling rig number 1 and workover rig number 1 are separate rigs, and do not affect each other.

ECLIPSE 100 only

**CAUTION:** Pre-96A datasets experience a change in behavior if two or more rigs of either type are allocated to the same group (for example if a group changes its rig during the run). Before the 96A release, the second rig would replace the first one. Now, however, the second rig is added to the group and the first rig still remains available. If you wish to replace one rig with another, you must now remove the old rig then add the new one.

See also keywords [WORKLIM](#), [WDRILTIM](#), [QDRILL](#), [WDRILPRI](#) and [PRORDER](#).

## Examples

### Example 1

Drilling rigs 1 and 2 are allocated to the FIELD. Workover rigs 1 and 2 are allocated to groups PLAT-A and PLAT-B respectively.

```
GRUPRIG
-- group      workover  drilling  add or
-- name       rig       rig       remove
  FIELD        0         1 /
  FIELD        0         2 /
  PLAT-A       1         0 /
  PLAT-B       2         0 /
/
```

### Example 2

Drilling rig 2 is to be removed from the FIELD and just made available to group PLAT-B.

```
GRUPRIG
-- group      workover  drilling  add or
-- name       rig       rig       remove
  FIELD        0         2   REM /
  PLAT-B       0         2   ADD  /
/
```

## GRUPSALE Specifies group gas sales rate

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies the amount of gas produced from a group that is reserved for sale. This reduces the gas available for reinjection.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. Group name or name root

or FIELD (to set the field sales rate)

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. The constant sales rate. This is summed with the quantity specified using item 3 to give the overall gas sales requirement. A user defined argument can be set with keywords [UDQ](#) and [UDADIMS](#).

UNITS: sm<sup>3</sup>/day (METRIC), Mscf/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: 0.0

3. The fractional gas sales rate. This is a fraction of the total gas production from the group (before any fuel, sales and reinjection requirements have been taken). This fractional part is calculated at each timestep and then summed with the quantity specified using item 2 to give the overall gas sales requirement. A user defined argument can be set with keywords [UDQ](#) and [UDADIMS](#).

DEFAULT: 0.0

4. The component template

One value for each component, the default being 1 for all components.

By default, the group fuel requirement is satisfied prior to the sales requirement. This ordering may be changed using the [WTAKEGAS](#) keyword.

The treatment of the constant and fractional parts of the sales requirement, and the use of the component template, are the same as that described for fuel under keyword [GRUPFUEL](#).

See also "[Group injection control options](#)" in the *ECLIPSE Technical Description*.

---

**Note:** For accurate group gas accounting, there is a limitation that reinjection control and any sales gas or fuel gas requirements must all be specified for the same group, usually the FIELD group, and not split across the group hierarchy. This limitation only applies if the injection gas contains group vapor, with the vapor taken from a separator stage (that is not from the whole separator).

---

### Example

Set group gas sales rate of 1000 Mscf/day.

```
GRUPSALE  
FIELD 1000 /  
/
```

## GRUPLAV Identifies the slave groups in a slave reservoir

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword must be used in each reservoir coupling slave run to identify the slave groups and their associated master groups in the master run, and to set the filter flags that determine which rate constraints are to be imposed on them (see "Reservoir coupling" in the *ECLIPSE Technical Description*).

If the slave run is activated by the master run (see keyword [SLAVES](#)), the slave groups' rate constraints are transmitted from the master run by the message passing system, at each timestep of the master run.

Alternatively, the slave run may be activated on its own. In this case, the slave groups' rate constraints are read from the input Reservoir Coupling file, which must be specified with the keyword [USECUPL](#).

In either case, the slave run's timesteps are synchronized to coincide with the timesteps of the master run (either transmitted from the master run or read from the Reservoir Coupling file). The slave run may, however, take more than one timestep to reach the end of the master run's timestep.

The GRUPLAV keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. The slave group's name or group name root  
or `FIELD` (if the `FIELD` group is the slave group)

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record

The slave reservoir must contain one or more slave groups. They need not all be on the same level in the group tree, but a slave group cannot be subordinate to another slave group. The slave groups must not be subject to production or injection rate constraints applied to any superior group within the slave reservoir.

The groups must previously have been declared with the keyword [GRUPTREE](#) or [WELSPECS](#).

2. The name of the slave group's associated master group in the master reservoir

The slave group may have a different name from its master group. For example, the slave group may be the top level group in the slave reservoir, and thus must be called `FIELD`.

If a default (1\*) or blank name (' ') is entered, ECLIPSE assumes the associated master group has the same name as its slave group.

In slave runs activated by the master run, ECLIPSE checks that the master-slave group pairs specified in keywords [GRUPMAST](#) and [GRUPLAV](#) are consistent.

3. The filter flag for oil production rate constraints (up to 4 characters)

This determines the source of the oil rate constraints to be applied to the slave group: the master run (or the Reservoir Coupling file), the slave run's own data file, or both.

**MAST** Apply only the constraints transmitted from the master run or read from the Reservoir Coupling file. Ignore any rate constraints specified for this slave group in the slave run's own data file.

**SLAV** Apply only the constraints specified for this slave group in the slave run's own data file. Ignore any rate constraints transmitted from the master run or read from the Reservoir Coupling file.

BOTH Apply the rate constraints from both sources, taking the minimum of the two values.

DEFAULT: MAST

4. The filter flag for water and liquid production rate constraints  
The choices are the same as for item 3.
5. The filter flag for gas production rate constraints  
The choices are the same as for item 3.
6. The filter flag for reservoir fluid volume production rate constraints  
The choices are the same as for item 3.
7. The filter flag for oil injection rate constraints  
The choices are the same as for item 3.
8. The filter flag for water injection rate constraints  
The choices are the same as for item 3.
9. The filter flag for gas injection rate constraints  
The choices are the same as for item 3.

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

## Notes

- The SLAV option in items 3 - 9 is only intended for use when the slave run is performed on its own and reads the slave group rate constraints from the input Reservoir Coupling file. This allows you to see how the slave reservoir would perform in the absence of selected rate constraints imposed by the master run. The SLAV option should **not** be used when the slave run is activated by the master run as part of the coupled system. Ignoring rate constraints imposed by the master run would cause target or limiting rates imposed on the global system to be exceeded.
- If a rate constraint is applied to a phase that is not an active phase in the slave run, ECLIPSE transforms it into a constraint on an associated phase, using the latest available production ratios. This may happen in the following two circumstances:
  - Gas is an active phase in the master run, but not in the slave run that instead has a constant  $R_s$  specified with keyword [RSCONST](#) or [RSCONSTT](#).
  - Oil is an active phase in a gas condensate master run, but not in the slave run that instead has a constant  $R_v$  specified with keyword [RVCONST](#) or [RVCONSTT](#).

## Examples

Slave groups PL-A and PL-B take their rate constraints from the master run, but in addition PL-B observes its own limits on water injection rate.

```

.....
GRUPLAV
-- slave  assoc  oil    wat/liq  gas    resv   oil    wat    gas
-- group  master  prod  prod    prod   prod   inj    inj    inj
-- name   group  limits limits limits limits limits limits limits limits
.....

```

PL-A	UP-A	/			
PL-B	UP-B		5*		BOTH /

## GRUPTARG Resets a group production rate target or limit

x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to reset a group production rate target or limit, without the bother of specifying all the other quantities required by the group control keywords [GCONPROD](#) or [GCONPRI](#). These other quantities are left unchanged. The group control data should initially have been set using [GCONPROD](#) (for guide rate control) or [GCONPRI](#) (for prioritization), otherwise guide rate control is applied by default if a limit is exceeded.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Group name or group name root  
or [FIELD](#) (for field targets or limits)

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. Definition of the target or limit to be changed

ORAT Oil rate

WRAT Water rate

GRAT Gas rate

LRAT Liquid rate

CRAT Linearly combined rate (coefficients must be set with [LINCOM](#))

*ECLIPSE 300 only*

WGRA Wet gas rate

RESV Reservoir fluid volume rate

*ECLIPSE 300 only*

CVAL Calorific rate

PRBL Reservoir fluid volume production balancing fraction

*ECLIPSE 300 only*

PBGS Surface gas volume production balancing fraction

*ECLIPSE 300 only*

PBWS Surface water volume production balancing fraction

GUID Guide rate (see items 9 and 10 of the keyword [GCONPROD](#)).

The guide rate can only be set here if its definition has been set to OIL, WAT, GAS, LIQ, WGA or RES in item 10 of keyword [GCONPROD](#).

3. New value of this quantity.

The units depend upon the quantity chosen. The appropriate units are listed in the specification for keywords [GCONPROD](#) and [GCONPRI](#).

If an oil, water, gas or liquid rate limit is specified, and the procedure on exceeding the corresponding rate limit has not been set in [GCONPROD](#) or [GCONPRI](#), the procedure is defaulted to [RATE](#) (for guide rate control) or [PRI](#) (for prioritization).

DEFAULT: No target or limit

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

See also the ECLIPSE 100 keyword [GTMULT](#).

## Example

```

```

## GRUPTREE Sets up tree structure for multi-level group control

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is required only if you need a grouping structure with more than three levels in the hierarchy (that is field - groups - wells). A multi-level tree structure can be built up by using this keyword to specify the immediate parent of each group. The field itself occupies the top of the tree (Level 0). The groups immediately subordinate to the field are on Level 1. Other groups may be placed on Level 2 by giving them a parent on Level 1. Groups can be placed on any lower level in this way.

The keyword is followed by any number of records, each containing two group names and terminated with a slash (/). Group names may have up to 8 characters. Name roots (ending with an asterisk) **cannot** be used here.

1. The name of the child group
2. The name of its parent group

The record declares the second group to be the parent of the first group.

The set of records must end with a blank record, containing only a slash.

Groups on Level 1 need not have their parent declared, but optionally their parent can be declared as FIELD. Groups without a parent are automatically placed on Level 1.

ECLIPSE 100

The group hierarchy can have any number of levels. Groups that have other groups as children cannot also have wells. (Wells are assigned to groups in the keyword WELSPECS.) Thus a group either contains wells (that is a well-group) or has other groups as children (that is a node-group).

ECLIPSE 300

The group hierarchy can have any number of levels. However, group controls and guide rates can only be assigned to a maximum of four levels of groups down any branch of the hierarchy, including the FIELD. A group may have both wells and child groups, but this structure is incompatible with that allowed in ECLIPSE 100.

Groups can be reassigned to different parents during the simulation, and new groups can be inserted into the hierarchy, by using GRUPTREE to declare any changes in the parent-child relationships.

If this keyword is omitted, all the groups declared in WELSPECS are assigned to Level 1, giving the standard 3-level field-group-well hierarchy.

### Example

To define the hierarchy as shown in figure 3.8:

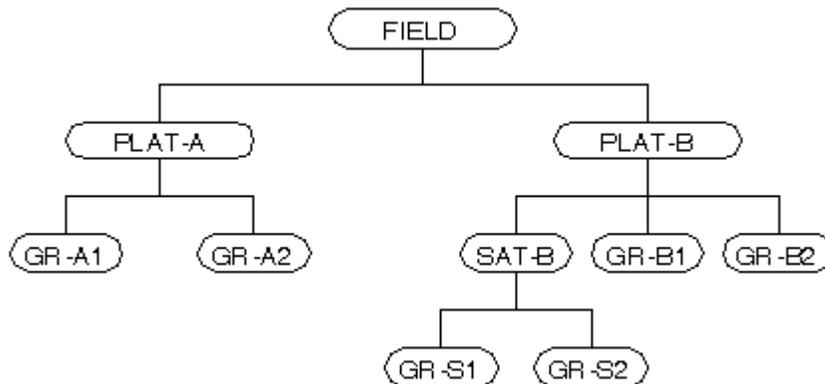

Figure 3.8. A five level hierarchy

It is assumed that groups GR-A1, GR-A2, GR-B1, GR-B2, GR-S1 and GR-S2 have wells declared as belonging to them in WELSPECS. PLAT-A and PLAT-B can optionally have FIELD declared as their parent.

```
GRUPTREE
-- child  parent
GR-A1    PLAT-A  /
GR-A2    PLAT-A  /
GR-B1    PLAT-B  /
GR-B2    PLAT-B  /
SAT-B    PLAT-B  /
GR-S1    SAT-B   /
GR-S2    SAT-B   /
/
```

## GSATCOMP Specify a composition for a satellite group

x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies the composition of the oil or gas to be injected or produced by a satellite group (see keywords [GSATINJE](#) and [GSATPROD](#)).

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. The set of records is ended by a blank record, containing only a slash.

1. Satellite group name or group name root.

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record. The group(s) must previously have been declared with keyword [GRUPTREE](#), to define their position in the grouping hierarchy.

2. Character string specifying type of composition to be defined.

This must be one of the following:

IG Set composition of injection gas

IO Set composition of injection oil

PG Set composition of produced gas

PO Set composition of produced oil

3. Mnemonic for a well stream defining the composition.

The stream must be defined with the keyword [WELLSTRE](#).

4. Oil density value at surface conditions.

This will set the assumed oil density for reporting of surface oil mass rate and mass total. If not specified, it will be estimated from an initial flash of the reservoir fluid.

UNITS: kg/m<sup>3</sup> (METRIC), lb/ft<sup>3</sup> (FIELD), gm/cc (LAB), kg/m<sup>3</sup> (PVT-M)

## GSATINJE Injection rate data for satellite groups

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies the rate at which oil, water and gas is to be injected by a satellite group.

Satellite groups provide a means of incorporating known production and injection flows from other reservoirs or regions that are not part of the simulation grid. They have no associated wells or subordinate groups, but act as sources of production flow and/or sinks of injection flow. The GSATINJE keyword is used to specify the injection rates of one or more satellite groups. These rates are held constant until they are reset in a subsequent GSATINJE keyword. If the satellite groups are also producing fluid, their production rates must be set with keyword GSATPROD. See keyword GSATPROD for further description of satellite groups.

When using ECLIPSE 300 for compositional runs, the composition of the injected oil or gas should be defined with keyword GSATCOMP. If the fluid compositions are left undefined, the injected oil and gas compositions will default to the compositions obtained by flashing the initial reservoir fluids-in-place through the field separator.

The GSATINJE keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

### 1. Satellite group name or group name root

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record. The groups must previously have been declared with keyword GRUPTREE, to define their position in the grouping hierarchy.

If a complete group name (without an asterisk) is entered, and the group has not been declared earlier, ECLIPSE creates a new group with that name and places it on level 1 directly subordinate to the FIELD.

Satellite groups cannot have wells or subordinate groups.

### 2. Phase to which the following rates apply

OIL, WAT or GAS

Satellite groups may inject more than one phase. A separate data record is needed for each phase.

### 3. Surface injection rate of the phase in item 2

The value must be greater than or equal to zero.

UNITS: sm<sup>3</sup>/day (METRIC), stb/day for oil, water or liquid (FIELD), Mscf/day for gas (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: Zero

### 4. Reservoir volume injection rate of the phase in item 2

You need to enter a value here only if you want the reservoir volume injection rate of the superior groups and the field to include that of the satellite group. If this quantity is left as zero for all the satellite groups, the field's reservoir volume injection rate will just represent the fluid injected into the simulation grid. The choice is important if a superior group has a reservoir volume injection rate target or a voidage replacement target, or a target production balancing fraction.

UNITS: rm<sup>3</sup>/day (METRIC), rb/day (FIELD), rcc/hr (LAB), rm<sup>3</sup>/day (PVT-M)

DEFAULT: Zero

The value must be greater than or equal to zero.

- ECLIPSE 100 only 5. Mean calorific value of gas injected by the group

A value need only be entered here if the gas calorific value control option is being used (see "[Gas calorific value control](#)" in the *ECLIPSE Technical Description*).

The value must be greater than or equal to zero.

UNITS: kJ/sm<sup>3</sup> (METRIC), Btu/Mscf (FIELD), J/scc (LAB), kJ/sm<sup>3</sup> (PVT-M)

DEFAULT: Zero

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

## Example

```
GSATINJE
-- group   inj      surf   resv
-- name    phase   rate   rate
  SAT-A    WAT      7520   7520  /
  SAT-A    GAS      17760  10240  /
/
```

## GSATPROD Production rate data for satellite groups

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies the rate at which oil, water and gas is produced by a satellite group.

Satellite groups provide a means of incorporating known production and injection flows from other reservoirs or regions that are not part of the simulation grid. They have no associated wells or subordinate groups, but act as sources of production flow and/or sinks of injection flow. The GSATPROD keyword is used to specify the production rates of one or more satellite groups. These rates are held constant until they are reset in a subsequent GSATPROD keyword. If the satellite groups are also injecting fluid, their injection rates must be set with keyword [GSATINJE](#).

In ECLIPSE 300. In compositional runs, the composition of the produced hydrocarbon fluids should be defined with keyword [GSATCOMP](#). If the fluid compositions are left undefined, the produced oil and gas compositions default to the compositions obtained by flashing the initial reservoir fluids-in-place through the field separator.

The group control facilities will take account of flows to and from satellite groups. If a superior group has a rate target, the flows from satellite groups, and any other groups declared unavailable for control from a higher level, will first be determined. Then the other subordinate groups or wells make up the remainder of the flow target, if they have sufficient potential.

The first time a group is referenced in either keyword GSATPROD or GSATINJE it is defined to be a satellite group. In a multilevel group hierarchy, the satellite group should previously be declared in keyword [GRUPTREE](#) to define its position in the grouping hierarchy, otherwise by default the group is placed on level 1 immediately subordinate to the `FIELD`. An error message is issued if the group has already been given wells or subordinate groups. Once defined as a satellite group, only keywords GSATPROD and GSATINJE should be used to set its flow rates; [GCONPROD](#) and [GCONINJE](#) should not be used.

When running the network option, satellite groups can be included in the production or injection network with the keyword [GRUPNET](#) or [GNETINJE](#) respectively. Nodal pressures will be calculated for these groups, as for all other groups in the network, but of course the satellite groups' flow rates are fixed at their specified values and do not depend on their nodal pressures. When running the extended network model, satellite groups are source groups and must therefore have a network node with the same name; they are included in the network with the keywords [NODEPROP](#) and [BRANPROP](#). When running the gas field operations model, satellite groups cannot be made contract groups.

The GSATPROD keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Satellite group name or group name root

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record. The groups must previously have been declared with keyword `GRUPTREE`, to define their position in the grouping hierarchy.

If a complete group name (without an asterisk) is entered, and the group has not been declared earlier, ECLIPSE creates a new group with that name and places it on level 1 directly subordinate to the `FIELD`.

Satellite groups cannot have wells or subordinate groups.

2. Oil production rate from the group

The value must be greater than or equal to zero.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC),  $\text{stb}/\text{day}$  (FIELD),  $\text{scc}/\text{hr}$  (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

DEFAULT: Zero

3. Water production rate from the group

The value must be greater than or equal to zero.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC),  $\text{stb}/\text{day}$  (FIELD),  $\text{scc}/\text{hr}$  (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

DEFAULT: Zero

4. Gas production rate from the group

The value must be greater than or equal to zero.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC),  $\text{Mscf}/\text{day}$  (FIELD),  $\text{scc}/\text{hr}$  (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

DEFAULT: Zero

5. Reservoir fluid volume production rate from the group

The value must be greater than or equal to zero.

You need to enter a value here only if you want the reservoir fluid volume rate of the superior groups and the field to include that from the satellite group. If this quantity is left as zero for all the satellite groups, the field's reservoir fluid volume rate will just represent the fluid produced from the simulation grid. The choice is important if a superior group has a reservoir fluid volume production rate target or production balancing fraction, or a voidage replacement injection target.

UNITS:  $\text{rm}^3/\text{day}$  (METRIC),  $\text{rb}/\text{day}$  (FIELD),  $\text{rcc}/\text{hr}$  (LAB),  $\text{rm}^3/\text{day}$  (PVT-M)

DEFAULT: Zero

6. Lift gas supply rate to the group

You need enter a value here only if lift gas is being supplied to the group and you are running the Network option (ECLIPSE 100 only) or the Gas Lift Optimization facility.

ECLIPSE 100

The lift gas is added to the production network flows, for the purpose of calculating the pressure drop along each network branch, in branches that have item 6 of the `GRUPNET` keyword set to FLO, or in extended network nodes that have item 4 of keyword `NODEPROP` set to YES (see the "Network option" in the *ECLIPSE Technical Description*).

When running the Gas Lift Optimization facility (see the "Gas lift optimization" in the *ECLIPSE Technical Description*), the group's lift gas supply rate is accounted against any superior group's lift gas supply limit set with keyword `GLIFTOPT`.

The value must be greater than or equal to zero.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC),  $\text{Mscf}/\text{day}$  (FIELD),  $\text{scc}/\text{hr}$  (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

DEFAULT: Zero

ECLIPSE 100 only

7. Mean calorific value of gas produced by the group

A value need only be entered here if the gas calorific value control option is being used (see "Gas calorific value control" in the *ECLIPSE Technical Description*).

The value must be greater than or equal to zero.

UNITS:  $\text{kJ}/\text{sm}^3$  (METRIC),  $\text{Btu}/\text{Mscf}$  (FIELD),  $\text{J}/\text{scc}$  (LAB),  $\text{kJ}/\text{sm}^3$  (PVT-M)

DEFAULT: Zero

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

## Notes

*ECLIPSE 300 only*

- Separators only act on the component molar rates produced from wells; the resultant phase surface volume rates from each well in a group are then summed to form the group's phase surface volume rates. This summation is also done for the gas volume rates at each stage of the separator to give group level stage gas volume rates. Satellite groups do not have any wells so, for reporting purposes, the satellite group stage 1 gas volume rate is set to the group gas production rate (so that the group rate and the sum of the group stage rates match).
- In complex separator chains, where the stage 1 separator gas is used as a feed further down the separator chain, the setting of the satellite group stage 1 gas volume rate to the group gas production rate may cause confusion, as it is not added to the latter feed. [Item 113](#) in `OPTIONS3` can be used to turn off the setting of satellite group stage 1 gas volume rate to the group gas production rate to avoid such confusion.

## Example

```
GSATPROD
-- group  oil      water    gas      void    lift
-- name   rate     rate     rate     rate    gas
  SAT-A   14500   2640    17600   /
  SAT-B   12700   3270    15800   /
/
```

## GSEPCOND Assigns separators to groups in ECLIPSE 100

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used to associate each separator, previously named in keyword `SEPVALS`, with a particular group. It is required if you wish to model the effects of changing separator conditions in ECLIPSE 100 runs. If a separator is assigned to a particular group, all wells subordinate to that group use that separator. If the separator's conditions are subsequently altered by redefining them with `SEPVALS`, the oil and gas flow rates of these wells are transformed to reflect the change in conditions. See keyword `SEPVALS` for a more detailed discussion on changing separator conditions.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Group name or group name root  
or `FIELD` (if the separator is at the field level)

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. Name of the separator associated with the group
3. (and its subordinate groups and wells).

The separator named here must already have been specified in keyword `SEPVALS`.

A blank name ( ' ') removes any previous association between the group and a separator.

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

### Examples

#### Example 1

To assign a separator to the whole field:

```
GSEPCOND
FIELD SEP1 /
/
```

#### Example 2

To assign different separators to two platforms:

```
GSEPCOND
PLAT-A SEP1 /
PLAT-B SEP2 /
/
```

## GSEPREPT Assign separator conditions to a group for group flash summary vectors

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword sets the separator, EoS and PVT region numbers for the flash calculation used for group level flash summary keywords. These keywords are listed in table 2.25 and end in G.

**Note:** If any of the summary section keywords ending in G are used then warnings will be issued for any groups with ambiguous equation of state or PVT region numbers. To eliminate these warning messages add a new GSEPREPT entry for the group which incurred the warning.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The records may be terminated at any item after item 1. The remaining items assume their default values. Default values can be specified before the slash by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records must end with a blank record, containing only a slash (/).

1. Group name or group name root

or FIELD (for field level flash calculation)

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. Separator name. This must either be 'FIELDSEP' or be defined by SEPCOND.

DEFAULT: The first separator assigned to a parent group by SEPCOND will be used.

3. The surface equation of state number.

This should only be specified if multiple equations of state are used. When this option is employed it may still be defaulted, in which case the fluid from a group is flashed using the equation of state used for the first well assigned to this group. If this group has no wells then the equation of state used by the first well assigned to the first group assigned to this group is used, followed by the first well assigned to the second group assigned to this group and so on through the group tree until such a well exists.

**Note:** A warning is given if wells contributing to this group use more than one equation of state. If such a warning is given it is not meaningful to compare the group level flash to the sum of the well level flashes.

If an equation of state index is specified, this forces the use of a given surface equation of state. The value must lie between 1 and the maximum number of equations of state for surface conditions, TABDIMS item 10. See also the discussion under "Equations of state regions" in the *ECLIPSE Technical Description*

*Thermal only*

4. The PVT table number.

This should be specified if multiple PVT regions are specified. When this option is employed it may still be defaulted, in which case the fluid from a group is flashed using the PVT table number used for the first well assigned to this group. If this group has no wells then the PVT table number assigned to the first well assigned to the first group assigned to this group is used, followed by the first well

assigned to the second group assigned to this group and so forth through the group tree until such a well exists.

---

**Note:** A warning is given if wells contributing to this group use more than one PVT table number. If such a warning is given it is not meaningful to compare the group level flash to the sum of the well level flashes.

---

### Example

```
GSEPREPT
  PLAT-A      FIELDSEP      1      1 /
  PLAT-B      SEP1          2      1 /
/
```

## GSF

## Gas saturation functions (GASWAT/CO2STORE cases)

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is used in conjunction with the [WSF](#) keyword in [GASWAT](#) or [CO2STORE](#) (non-thermal) cases.

The data specified consists of a number of tables of gas saturation data, each terminated with a slash (/). Each table consists of 3 columns of data. The number of tables should be equal to be number of saturation tables in the run, specified by the [TABDIMS](#) keyword, and defaulting to 1.

Column:

- The gas saturation.  
Values should be between 0 and 1 and should increase monotonically down the column.
- The corresponding gas relative permeability.  
Values should be between 0 and 1 and should be level or increasing down the column. The first value in the column must be 0.
- The corresponding gas-water capillary pressure.  
Values should be level or increasing down the column.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

There must be the same number of entries in each column of a given table, and the number of rows should be less than or equal to the maximum number of rows of saturation data specified with [TABDIMS](#).

### Example

```

GSF
.0000 .0000 .0000
.0400 .0000 .2000

## GSSCPTST Performs a sustainable capacity test

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword causes a sustainable capacity test to be carried out. The model is saved, and then run forward to establish whether a group of wells could sustain a certain gas or oil production rate for a certain period of time. Depending on the options selected, the test will then try to establish the maximum possible production rate sustainable for the test period by attempting to simulate the test period with different group production rates. After the test has been completed ECLIPSE will run on from the reservoir state before the test began.

The GSSCPTST keyword should be followed by the items described below, terminated with a slash (/):

1. Group name or group name root or FIELD (for field rate control)

DEFAULT: FIELD

2. Group production rate control mode

The group of wells may be placed under the control modes listed below

GRAT Gas rate control

ORAT Oil rate control

WRAT Water rate control

WGRA Wet gas rate control

DEFAULT: GRAT

3. Target production rate

UNITS:  $\text{sm}^3/\text{day}$  (METRIC), stb/day for oil or water (FIELD), Mscf/day for gas (FIELD), scc/hr (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

DEFAULT: No production

4. Target production period

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

DEFAULT: No period

5. Maximum production rate calculation flag

1 Run a single iteration at the target production rate until either the target period has been achieved or the group cannot sustain the production rate.

2 As for 1, but if target rate is not sustainable run further iterations to find the maximum rate which is sustainable for the target production period.

3 Run a number of iterations to try to find the maximum rate sustainable for the target production period. For this option, item 3 serves only as a first guess.

DEFAULT: Option 1

6. Convergence tolerance

*ECLIPSE 300 only*

If item 5 is set to 2 or 3, stop searching for a maximum sustainable rate if the maximum sustainable rate and minimum unsustainable rate are separated by this tolerance. A more generous tolerance will result in less time being spent on the test, but the result will be less informative. The maximum sustainable rate is the greatest production rate tested which can be maintained for the test period. The minimum unsustainable rate is the lowest production rate tested which cannot be maintained for the test period.

UNITS: sm<sup>3</sup>/day (METRIC), stb/day for oil or water (FIELD), Mscf/day for gas (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: No tolerance (use all iterations)

#### 7. Maximum number of iterations

If item 5 is set to 2 or 3, stop searching for a maximum sustainable rate after this many iterations.

DEFAULT: 6 iterations

#### 8. Subgroup control flag

The control of subgroups of the group named in element 1 will be set to GRUP. This flag specifies changes to rate limits for subgroups

0 No change to subgroup rate limits.

1 Any subgroup gas rate limits removed.

2 As option 1, but wet gas and calorific rate limits are also removed.

3 As option 2, but liquid, oil, water and voidage production rate limits are also removed.

DEFAULT: Option 0

The results of the sustainable capacity test are printed in the PRT file. [SUMMARY](#) section keywords FGSTP, FGSPR, FGSSP, FGSRU, FGSRL, GGSTP, GGSPR, GGSRU and GGSRL all give information on the most recent sustainable capacity test (SCT) for gas. The [SUMMARY](#) section keywords FOSTP, FOSPR, FOSSP, FOSRU, FOSRL, GOSTP, GOSPR, GOSRU and GOSRL do the same for an oil SCT. Similarly replacing O with W in these keywords provides the SCT for water.

If the user is interested in the accuracy of the time period outputs of GSSCPTST (for example FGSSP) then it may be advisable to set TSMAXZ using [TUNING](#) before any GSSCPTST calls. The time period outputs are only as accurate as the maximum timestep used. It may also be useful to increase [NUPCOL](#) to ensure that the well system converges in one timestep.

The first iteration will use item 3 as the target production rate for the nominated group. Subsequent iterations use the following algorithm to set the target rate:

- If no unsustainable rate has been found, double previous rate.
- If no sustainable rate has been found, halve previous rate.
- If only one unsustainable rate has been found, bisect the sustainable rate and the lowest unsustainable rate
- If two unsustainable rates have been found the following formula is used  $R = U_0 + \frac{(U_0 - U_1)(T_f - T_0)}{T_0 - T_1}$

where

ECLIPSE 300 only

- $R$  is the new rate
- $U_0$  is the previous minimum unsustainable rate
- $U_1$  is the previous next-to-minimum unsustainable rate
- $T_0$  is the time when rate  $U_0$  became unsustainable
- $T_1$  is the time when rate  $U_1$  became unsustainable
- and  $T_f$  is the time of the end of the sustained capacity test.

If the final method suggests a rate which is too high then the rate is set to  $R = U_0 - Tol$  where  $Tol$  is the tolerance specified in item 6. If  $T_0 = T_1$  then a bisection is used.

## Example

To see if group GP can produce gas at 50000 Mscf/day for a year use the following (assuming FIELD units):

```
GSSCPTST
GP  GRAT  50000.0  365.25  1  /
```

To see what gas rate could be maintained for a decade (to within 100 Mscf and again assuming FIELD units), use the following:

```
GSSCPTST
GP  GRAT  50000.0  3652.5  3  100.0  12  /
```

---

**Note:** This second example could require up to 120 years of simulated reservoir time, and is therefore likely to take some time to complete.

---

## GSWINGF

## Swing and profile factors for multiple contract groups

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The GSWINGF keyword is used in place of [SWINGFAC](#) to turn on the Gas Field Operations Model in the Multiple Contract Groups mode. This allows two or more separate groups to have their own independent gas supply contracts. Each contract group has its own set of swing factors and profile factors, and its own DCQ value which ECLIPSE will adjust independently to meet the swing requirement if requested to do so in the [GASYEAR](#), [GASPERIO](#) and [GDCQ](#) keywords.

The GSWINGF keyword is used to identify the contract groups and supply their swing and profile factors. The following features of the Gas Field Operations Model are also activated when either GSWINGF or SWINGFAC is first entered:

- Group and field gas rate targets are applied to **sales** gas rates instead of **gross** gas production rates.
- The delivery capacity is calculated at the beginning of each timestep.
- In ECLIPSE 100, any automatic compressors (specified with keyword [GASFCOMP](#) or [NETCOMPA](#)) will be turned on and off as required to meet the group or field gas targets.

The swing factors and profile factors themselves are used to set the group gas production targets and to adjust their DCQs when the simulation is advanced using the keyword [GASYEAR](#) or [GASPERIO](#) instead of [DATES](#), [TIME](#) or [TSTEP](#). Each contract group is automatically placed under Guide Rate Control to meet any gas rate targets imposed, unless Prioritization is requested with the keyword [GCONPRI](#).

## ECLIPSE 100

In order to use the Multiple Contract Groups facility, item 1 of the [GASFIELD](#) keyword in the RUNSPEC section must be set to YES.

The set of contract groups must obey the following restrictions:

- One contract group must not be subordinate to another contract group.
- The set of contract groups must cover the whole field, that is every production well must be subordinate to a contract group.
- There must be no gas consumption or import at any node downstream of a contract group (otherwise the contract group's sales gas targets would not be set correctly).

## ECLIPSE 100

See "[Applying separate gas supply contracts to individual groups](#)" in the *ECLIPSE Technical Description* for further details.

The GSWINGF keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/). The set of records must end with a blank record, containing only a slash (/).

1        Name or name root of the Contract Group(s) to which the following swing and profile factors apply

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2 - 13    Swing factors for each month in sequence from January to December.

Setting January's swing factor to a negative value causes the group to stop being a contract group.

14 - 25   Profile factors for each month in sequence from January to December.

A warning is printed if the profile factor for any month is greater than that month's swing factor. If this is so, obeying the swing requirement may not guarantee the group could produce its target rate profile.

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

## Normalized profile factors

In order to produce the required ACQ for a given DCQ, the profile factors should be normalized such that

- the sum over all months of {profile factor × number of days in month} = 365.25,
- with February allocated 28.25 days.

If this “normalization requirement” is obeyed, then when leap years are taken into account every fourth year, the average annual production at a constant DCQ will be DCQ × 365.25, which is the ACQ. A warning is printed if the profile factors are not normalized.

## Example

```

GSWINGF
-- GROUP  JAN  FEB  MAR  APR  MAY  JUN  JUL  AUG  SEP  OCT  NOV  DEC
  PLAT-A   2*1.5036  3*1.0024          3*0.5012          3*1.0024          1.5036
           2*1.5036  3*1.0024          3*0.5012          3*1.0024          1.5036 /
  PLAT-B   2*1.6551  3*1.0031          3*0.3511          3*1.0031          1.6551
           2*1.6551  3*1.0031          3*0.3511          3*1.0031          1.6551 /
/
    
```

## GTADD

## Adds to a group rate target or limit

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to add to a group production rate, or injection rate target or limit, by a specified amount. The group control data with the initial target or limit should first have been entered using [GCONPROD](#) (for guide rate production control), [GCONINJE](#) (for guide rate injection control) or [GCONPRI](#) (for prioritization).

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Group name or group name root  
or FIELD (for field targets and limits)

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. Definitions of the target or limit to be changed are listed below.

This item can be a user defined quantity (UDA) and can be set with the keywords [UDQ](#) and [UDADIMS](#). The values in the brackets are the corresponding values to identify the control quantity if UDA is used for this item.

ORAT [ 1 ] Oil surface production rate

WRAT [ 2 ] Water surface production rate

GRAT [ 3 ] Gas surface production rate

LRAT [ 4 ] Liquid surface production rate

CRAT [ 5 ] Linearly combined rate (coefficients must be set with [LINCOM](#))

RESV [ 6 ] Reservoir fluid volume production rate

PRBL [ 7 ] Reservoir fluid volume production balancing fraction

GUID [ 8 ] Production guide rate (see items 9 and 10 of the keyword [GCONPROD](#)).

The guide rate can only be modified here if its definition has been set to OIL, WAT, GAS, LIQ or RES in item 10 of keyword [GCONPROD](#).

WINJ [ 9 ] Water surface injection rate

GINJ [ 10 ] Gas surface injection rate

WINR [ 11 ] Water reservoir volume injection rate

GINR [ 12 ] Gas reservoir volume injection rate

*ECLIPSE 100 only* OINJ [ 13 ] Oil surface injection rate

*ECLIPSE 100 only* OINR [ 14 ] Oil reservoir volume injection rate

- ECLIPSE 300 only*      PBGS [ 13 ] Surface gas volume production balancing fraction
- ECLIPSE 300 only*      PBWS [ 14 ] Surface water volume production balancing fraction
- ECLIPSE 300 only*      CVAL [ 15 ] Calorific production rate.

Note that if the UDQ for this item starts with 'GUID', then the production guide rate control option will be switched on.

3. Amount to add for this quantity. This quantity can be a UDA and can be set with the keywords UDQ and UDADIMS.

UNITS: the units depend upon the quantity chosen. Negative numbers are allowed. The appropriate units are listed in the documentation for keyword [GCONPROD](#), [GCONINJE](#) and [GCONPRI](#).

4. Number of times addition will be performed. Note that addition will be performed at report timesteps only and this item is active only when a UDA is used for item 3. This item will be truncated to the greatest integer lower than or equal to its value. Also note that any value less than 1 will be defaulted to 1.

DEFAULT: 1

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

This keyword can be used to multiply a group production rate or injection rate target or limit by a specified factor. The group control data with the initial target or limit should first have been entered using [GCONPROD](#) (for guide rate production control), [GCONINJE](#) (for guide rate injection control) or [GCONPRI](#) (for prioritization).

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Group name or group name root

or FIELD (for field targets and limits)

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

2. Definitions of the target or limit to be changed are listed below. This item can be a user defined quantity (UDA) and can be set with the keywords [UDQ](#) and [UDADIMS](#). The values in the brackets are the corresponding values to identify the control quantity if UDA is used for this item.

ORAT [ 1 ] Oil surface production rate

WRAT [ 2 ] Water surface production rate

GRAT [ 3 ] Gas surface production rate

LRAT [ 4 ] Liquid surface production rate

CRAT [ 5 ] Linearly combined rate (coefficients must be set with [LINCOM](#))

RESV [ 6 ] Reservoir fluid volume production rate

PRBL [ 7 ] Reservoir fluid volume production balancing fraction

GUID [ 8 ] Production guide rate (see items 9 and 10 of the keyword [GCONPROD](#)).

The guide rate can only be modified here if its definition has been set to OIL, WAT, GAS, LIQ or RES in item 10 of keyword [GCONPROD](#)

WINJ [ 9 ] Water surface injection rate

GINJ [ 10 ] Gas surface injection rate

## GUIDECAL Scales guide rates according to calorific value

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword provides an additional way of influencing the mean calorific value of the produced gas, for use with the gas calorific value control option (see "Gas calorific value control" in the *ECLIPSE Technical Description*), by calculating the individual well guide rates (and any group guide rates) as a function of their calorific values. Well guide rates that are not set directly with keyword `WGRUPCON` are calculated at the start of each timestep as a function of their production potentials. By default the guide rates are set equal to their production potentials, but the keyword `GUIDERAT` can be used to specify the coefficients of a more general function of production potentials.

The keyword `GUIDECAL` can be used to make the guide rate calculation take account of calorific values also. It sets the coefficients A and B of a function  $B_W$  which depends on the calorific value  $C_{gW}$

$$\beta_W = (1 + A C_{gW})^B \quad \text{Eq. 3.77}$$

When a well W has its guide rate calculated from its production potentials (that is not set to a fixed value with keyword `WGRUPCON`), the resulting guide rate is multiplied by  $B_W$ . Thus by setting appropriate values for the coefficients A and B in keyword `GUIDECAL`, it is possible to either increase or decrease the well guide rates with increasing calorific value. For example, setting a positive value for B bias the production towards wells with higher calorific values, while negative values of B bias the production towards wells with lower calorific values.

If **groups** are given guide rates that are calculated from the guide rate formula in keyword `GUIDERAT` (that is item 10 in `GCONPROD` is set to `FORM`), their guide rates are also multiplied by  $B_G$ , which is calculated as for  $B_W$  but using the groups' mean calorific values.

The `GUIDECAL` keyword requires two items of data, terminated with a slash (/):

1. The coefficient A in equation 3.77  
This must not be negative.
2. The coefficient B in equation 3.77

### Example

```
GUIDECAL
0.001 1.0 /
```

## GUIDERAT Specifies general formula for guide rates

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to specify a general formula for calculating production guide rates used for group control (see keyword [GCONPROD](#)). Subsequently, the formula is used to calculate the production guide rates for:

- All production wells that do not have fixed guide rates set with keyword [WGRUPCON](#), and
- Any group whose guide rate definition is set to 'FORM' in item 10 of keyword [GCONPROD](#).

Group flow rate targets are apportioned between the individual wells in proportion to their guide rates (see "[Group production rate targets - guide rate control](#)" in the *ECLIPSE Technical Description*). By default, each well has its guide rate set equal to its potential flow rate (that is what it could flow immediately in the absence of any rate constraints, at the current grid block conditions) at the beginning of each timestep, subject to limits defined in the keyword [DGRDT](#) for ECLIPSE 300. But it could be advantageous to weight the guide rates to discriminate against wells with high GOR or water cut. This keyword provides a means of automatically weighting production well guide rates to take account of their production ratios.

Groups may also be given guide rates, but only if they are required to produce a particular proportion of a rate target applied to a superior group. The formula in this keyword can optionally be applied to calculate production guide rates for individual groups as a function of their potential production rates, if requested in item 10 of keyword [GCONPROD](#). Group potentials are the sum of the potentials of their subordinate open wells.

At the beginning of the next timestep, the guide rates ( $GR_p$ ) for a nominated phase  $p$  is calculated from the formula

$$GR_p = \frac{(POT_p)^A}{B + C(R_1)^D + E(R_2)^F} \quad \text{Eq. 3.78}$$

where

$POT_p$  is the well's or group's potential flow rate of the nominated phase  $p$  (see "[Well potentials](#)" in the *ECLIPSE Technical Description*)

A, B, C, D, E and F are user-supplied powers and coefficients

$R_1$  and  $R_2$  are ratios of phase potentials, which depend on the nominated phase  $p$  (see item 2).

For the rest of the simulation, the guide rates are recalculated at the beginning of each timestep that starts after a specified interval (item 1) has elapsed from the previous guide rate calculation. The interval defaults to zero, giving a guide rate calculation at the beginning of each timestep. However, a longer interval may be preferred if the guide rates oscillate due to rate-dependent coning, or alternatively a damping factor may be applied in item 10.

The denominator is not allowed to become negative. If the power D or F is negative, the ratio  $R_1$  or  $R_2$  is limited to be not less than 1.0E-6.

If the nominated phase  $p$  differs from the phase under group control,  $GR_p$  is converted into a guide rate for the controlled phase using the well's or group's production ratios at the beginning of the timestep.

The [GUIDERAT](#) keyword is followed by a line containing some or all of the following data items, terminated with a slash (/).

The items are:

1. The minimum time interval between guide rate calculations.

The guide rates are calculated from the formula above at the beginning of each timestep that starts after the specified interval has elapsed since the previous guide rate calculation.

A zero value causes the guide rates to be recalculated every timestep. A longer interval may be preferred if the guide rates oscillate due to rate-dependent coning phenomena, or alternatively a damping factor may be applied in item 10.

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

DEFAULT: 0.0

2. The nominated phase p

OIL  $GR_p$  is the oil phase guide rate.

The phase potential ratios are:

$R_1$  = water-oil ratio (dimensionless)

$R_2$  = gas-oil ratio

UNITS:  $sm^3/sm^3$  (METRIC), Mscf/stb (FIELD), scc/scc (LAB),  $sm^3/sm^3$  (PVT-M)

LIQ  $GR_p$  is the liquid phase guide rate (oil + water).

The phase potential ratios are:

$R_1$  = water cut (dimensionless)

$R_2$  = gas-liquid ratio

UNITS:  $sm^3/sm^3$  (METRIC), Mscf/stb (FIELD), scc/scc (LAB),  $sm^3/sm^3$  (PVT-M)

GAS  $GR_p$  is the gas phase guide rate.

The phase potential ratios are:

$R_1$  = water-gas ratio

$R_2$  = oil-gas ratio

UNITS:  $sm^3/sm^3$  (METRIC), stb/Mscf (FIELD), scc/scc (LAB),  $sm^3/sm^3$  (PVT-M)

RES  $GR_p$  is the reservoir fluid volume guide rate.

The phase potential ratios are:

$R_1$  = water-oil ratio (dimensionless)

$R_2$  = gas-oil ratio

UNITS:  $sm^3/sm^3$  (METRIC), Mscf/stb (FIELD), scc/scc (LAB),  $sm^3/sm^3$  (PVT-M)

COMB  $GR_p$  is the linearly combined phase guide rate (coefficients must be set with [LINCOM](#)).

The phase potential ratios are:

$R_1$  = water to linearly combined phase ratio (dimensionless)

UNITS:  $\text{sm}^3/\text{U}$  (METRIC),  $\text{stb}/\text{U}$  (FIELD),  $\text{scc}/\text{U}$  (LAB),  $\text{sm}^3/\text{U}$  (PVT-M) where U represents the units specified in LCUNIT.

$R_2$  = gas to linearly combined phase ratio

UNITS:  $\text{sm}^3/\text{U}$  (METRIC),  $\text{Mscf}/\text{U}$  (FIELD),  $\text{scc}/\text{U}$  (LAB),  $\text{sm}^3/\text{U}$  (PVT-M) where U represents the units specified in LCUNIT.

NONE The general formula is not applied.

The well guide rates is set equal to their production potentials at every timestep, with no damping, just as if this keyword had not been entered. An error is flagged if any group requires its guide rate to be calculated from the formula.

DEFAULT: NONE.

3. The power A of the phase potential rate.

This must lie between 3.0 and -3.0.

DEFAULT: 0.0

4. The constant B on the denominator.

This must not be negative.

DEFAULT: 0.0

5. The coefficient C of the phase ratio  $R_1$ .

DEFAULT: 0.0

6. The power D of the phase ratio  $R_1$ .

This must lie between 3.0 and -3.0.

DEFAULT: 0.0

7. The coefficient E of the phase ratio  $R_2$ .

DEFAULT: 0.0

8. The power F of the phase ratio  $R_2$ .

This must lie between 3.0 and -3.0.

DEFAULT: 0.0

9. Should guide rates be allowed to increase?

YES Guide rates are allowed to increase if the formula results in a higher value (for example due to a reduced water cut or GOR).

NO The guide rate of the nominated phase is only allowed to decrease. If the formula results in a higher value than the current one, the value remains unchanged. (This option decreases the tendency for guide rates to oscillate due to rate-dependent coning phenomena.)

DEFAULT: YES

10. Damping factor, GRDAMP

This must lie between 0.0 and 1.0. It provides a means (as an alternative to setting item 9 to NO) of damping guide rate oscillations that may result from rate-dependent water cut or GOR. Each time a new guide rate is calculated for a well or group, it is averaged with its previous value according to the formula

$$GR_{used} = GRDAMP \cdot GR_{calculated} + (1-GRDAMP)GR_{previous} \quad \text{Eq. 3.79}$$

A damping factor of 1.0 allows the guide rates to change instantaneously with the phase potentials. As the damping factor reduces towards 0.0, the guide rates will be weighted increasingly towards their previous values, reducing any tendency to oscillate.

DEFAULT: 1.0

ECLIPSE 100 only

11. Use free gas and not total gas potential rates in the phase potential ratio R<sub>2</sub>.

YES Only use free gas (at well-block conditions) in the potential ratio.

NO Use total (free and dissolved) gas in the potential ratio.

DEFAULT: NO

ECLIPSE 300 only

12. Minimum guide rate GR<sub>min</sub>. If the calculated guide rate GR<sub>p</sub> is less than the minimum GR<sub>min</sub>, it will be set to the minimum. Very small guide rates may cause a group to be ignored, particularly if the group flow is large. Setting a minimum value prevents this. The minimum should be chosen to ensure GR<sub>min</sub> > 10<sup>-19</sup> × flow

DEFAULT: 10<sup>-6</sup>

In the absence of keyword GUIDERAT, the well guide rates are set equal to the wells' potential rates at the beginning of each timestep (unless fixed values have been supplied with keyword WGRUPCON).

The keyword affects production guide rates only. Guide rates for injection wells are still by default set equal to their potential injection rates.

## Examples

### Example 1

To set the liquid phase guide rates equal to the liquid phase potentials at low water cut, and biased against high water cut wells, with a damping factor of 0.1:

```
GUIDERAT
-- interval phase  A  B  C  D  E  F  increase?  damp
   1*      LIQ  1.0 1.0 10.0 2.0 0.0 0.0      NO      0.1 /
```

### Example 2

To set the oil phase guide rates equal to the oil phase potentials, to be recalculated after 100 day intervals:

```
GUIDERAT
-- interval phase  A  B  C  D  E  F  increase?  damp
   100      OIL  1.0 1.0  /
```

## GUPFREQ

## Update frequency for the instantaneous gradient option

## GWRTWCV Instantaneous gradients with respect to well control variables

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies collections of wells corresponding to instantaneous gradient parameters, see the "Instantaneous gradients" section in the *ECLIPSE Technical Description*. ECLIPSE will proceed to compute the instantaneous gradients of particular well properties with respect to the well control variables in the associated parameters. The gradient data is available using the summary keywords WOFWCn, WWFWCn, WGFWCn and WBHWCn, where n is the parameter number requested.

Note that the gradient data is instantaneous in the sense that the derivatives approximate the change in well properties at the current simulation time with respect to a variation in the well control variable at the current simulation time. In contrast, the history matching approach generates gradient data at the current simulation time with respect to variations at the initial time. The gradients calculated are due to the response of the reservoir rather than the well group hierarchy and therefore the wells considered must be under either oil, water, gas rate or bottom hole pressure control.

The maximum number of gradient parameters is specified by the `GDIMS` keyword in the `RUNSPEC` section. The instantaneous gradient option can be activated and deactivated during the course of a simulation using the `GUPFREQ` keyword.

The `GWRTWCV` keyword should be followed by a data record for each gradient parameter. Each data record consists of one or more well names, and is terminated with a slash. The set of records terminates with a blank record containing just a slash (/).

Subsequent use of the `GWRTWCV` resets all the previous parameters.

---

**Note:** The current implementation of `GWRTWCV` is restricted to the standard well model and unrefined grids.

---

### Example

The following example will set the first gradient parameter to be the control variable for the well `PROD1`, generating the gradient in the phase flow rates and well bottom hole pressure for all wells with respect to variations in the control variable of `PROD1`. This gradient data is available via the mnemonics `WOFWC1`, `WWFWC1`, `WGFWC1` and `WBHWC1`. The second parameter will result in gradient data calculated with respect to simultaneously varying the control variables of both well `PROD1` and well `PROD2`.

```

GWRTWCV
  PROD1 / -- parameter 1, output available via W**WC1 mnemonics
  PROD1 PROD2 / -- parameter 2
  INJ1 / -- parameter 3
/

-- later in deck redefine parameter 1 and reset parameters 2 & 3

GWRTWCV
  PROD3 /
/

```

## **H**

This section contains an alphabetic listing of keywords starting with the letter H.

## H2SSOL

## Allow H<sub>2</sub>S to dissolve in the aqueous phase

This keyword turns on the H<sub>2</sub>S solution option. The H<sub>2</sub>S component is then allowed to exist in all three phases. This keyword cannot be used if directional saturation table end-point scaling is used (switched on by setting the first item of keyword [ENDSCALE](#) to DIRECT).

For further information see "[CO<sub>2</sub>/H<sub>2</sub>S solution in the aqueous phase](#)" in the *ECLIPSE Technical Description*.

	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The use of HALFTRAN implies that transmissibilities are calculated using half block permeabilities.

The half block permeabilities are not used directly in the simulator. The half block permeabilities and cell face transmissibility multipliers are assumed to have been processed into the `MULTX` and `MULTX-` arrays prior to exporting the data into ECLIPSE 100. This is implemented by overloading `MULTX` and `MULTX-` for example, to the ratio of half-block to block center permeabilities, which is performed in FloGrid.

See "[Transmissibility calculations](#)" in the *ECLIPSE Technical Description* for more information.

The HALFTRAN keyword has no associated data.

## HAxxxxxx

# Additive modifiers for gradient parameters

These keywords are used to specify additive cumulative modifiers to history matching parameters. Their use in the ECLIPSE data file is embedded within the [HMPROPS](#) keyword, where examples of their usage may also be found.

## Tracer mechanical dispersion data

The HDISP keyword inputs the tracer mechanical dispersivity; the longitudinal value and the transverse value. The model assumes that the relative importance of diffusion and advection are independent of flow velocity and so can be characterized by a length scale, the mechanical dispersivity. The keyword should be concatenated with the tracer name. HDISP cannot be used in parallel runs and is only compatible with the standard and TVD tracer solvers.

For example: HDISPXXX is the keyword required to input the dispersivity for tracer XXX as specified in the [TRACER](#) keyword.

The data comprises NTPVT (see keyword [TABDIMS](#)) tables of diffusion data, each terminated by a slash (/). Each table applies to its corresponding PVT region, defined by keyword [PVTNUM](#) (if NTPVT > 1).

Each table consists of the following items of data:

1. The tracer mechanical dispersivity in the longitudinal (streamwise) direction.  
UNITS: m (METRIC), ft (FIELD), cm (LAB)
2. The tracer mechanical dispersivity in the transverse direction (perpendicular to the stream).  
UNITS: m (METRIC), ft (FIELD), cm (LAB)

---

**Note:** The use of HDISP can cause some runs to become much slower. In such cases it may be worth using the [SAMG](#) keyword.

---

## Example

With NTPVT=2 for tracers WT1 and WT2

```

.....
HDISPWT1
100 3 /
35 1/
HDISPWT2
80 0/
35 0/
.....

```

	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can only be used with the [THERMAL](#) option.

HEATER specifies the position and properties of one or more heater connections. If the connection is in a local grid, then use keyword [HEATERL](#).

The maximum number of heater connections must be set using keyword [HEATDIMS](#).

This keyword is followed by any number of records, each containing the items of data described below, and each terminated by a / character.

The records can be terminated early using the / character, the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\* where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. The name of the heater, a character string of up to 8 letters
2. The I-index of the connection
3. The J-index of the connection
4. The K-index of the connection
5. The maximum heat injection rate,  $H_{max}$

UNITS: kJ/day (METRIC), Btu/day (FIELD), J/hr (LAB), kJ/day (PVT-M)

DEFAULT: 0

6. The maximum temperature of the connection cell,  $T_{max}$

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

7. Temperature-dependent heat injection rate,  $R$

UNITS: kJ/day/K (METRIC), Btu/day/°R (FIELD), J/hr/K (LAB), kJ/day/K (PVT-M)

The heater can operate in up to three different modes depending upon the values assigned to items 5, 6 and 7:

#### Mode 1: Constant energy injection rate

If only item 5 is specified and items 6 and 7 are defaulted, heat will be injected at a constant rate into the grid block according to:

$$H = H_{max}$$

where  $H_{max}$  is defined by item 5.

#### Mode 2: Energy density dependent injection rate

If items 5 and 6 are specified and item 7 is defaulted, heat will be injected at a rate determined by the product of the grid-block volume and the rate of change of energy density:

$$H = \min\left(H_{max}, V \cdot \frac{\Delta E}{\Delta t}\right)$$

where  $V$  is the grid-block volume,  $\Delta t$  is the timestep, and the estimated change in energy density

$$\Delta E \text{ is given by: } \Delta E = e_t(T_{max}) - e_{t-\Delta t}$$

where  $e_t(T_{max})$  is the grid-block energy density when its temperature is  $T_{max}$  and  $e_{t-\Delta t}$  is the grid-block energy density at the previous timestep.  $H_{max}$  and  $T_{max}$  are defined by items 5 and 6 respectively. If item 6 is set to a value greater than 1.0E+10, this will have the effect of defaulting item 6 such that the heat injection mechanism reverts to Mode 1, that is, a constant energy injection rate.

### Mode 3: Temperature difference dependent injection rate

If items 5, 6 and 7 are all defined, heat will be injected at a rate determined by the temperature difference between the maximum temperature of the connection  $T_{max}$  and the current grid-block temperature  $T_c$ .

$$H = \min[(T_{max} - T_c) \times R, H_{max}]$$

where  $H_{max}$ ,  $T_{max}$  and  $R$  are defined by items 5, 6 and 7 respectively.

---

**Note:** If item 5 is defaulted, the heater will be turned off irrespective of whether items 6 and 7 are specified or defaulted. If item 5 is specified and item 6 is defaulted, the heater will be deemed to be operating in Mode 1 irrespective of whether item 7 is specified or defaulted.

---

---

**Note:** If items 5, 6 and 7 are defined with item 7 set to zero, then  $H = \min[0, H_{max}]$ . If  $H_{max}$  (item 5) is greater than 0, then the heater will be deemed to be operating in Mode 1 and turned off.

---

The output of heater performance data to the print file can be controlled by using item 14 of the `RPTPRINT` keyword.

Summary vectors WHTR and WHTT contain the energy rate and energy total for individual heaters and require a list of heater names. Vectors FHTR and FHTT contain the energy rate and energy total for all heaters.

### Example

```
HEATER
HEAT1 16 8 2 3.E+6 500.0 /
HEAT1 16 8 3 5.E+6 500.0 /
HEAT2 22 45 5 1.E+6 1* /

```

## HEATERL LGR heater data

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can only be used with the [THERMAL](#) option.

HEATERL specifies the position and properties of one or more heater connections in a local grid refinement. If the connection is not in a local grid, then use keyword [HEATER](#).

The maximum number of heater connections must be set using keyword [HEATDIMS](#).

This keyword is followed by any number of records, each containing the items of data described below, and each terminated by a / character.

The records can be terminated early using the / character, the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\* where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. The name of the heater, a character string of up to 8 letters
2. The name of the local grid
3. The I-index of the connection
4. The J-index of the connection
5. The K-index of the connection
6. The maximum heat injection rate,  $H_{max}$

UNITS: kJ/day (METRIC), Btu/day (FIELD), J/hr (LAB), kJ/day (PVT-M)

DEFAULT: 0

7. The maximum temperature of the connection cell,  $T_{max}$

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

8. Temperature-dependent heat injection rate,  $R$

UNITS: kJ/day/K (METRIC), Btu/day/°R (FIELD), J/hr/K (LAB), kJ/day/K (PVT-M)

The heater can operate in up to three different modes depending upon the values assigned to items 6, 7 and 8:

### Mode 1: Constant energy injection rate

If only item 6 is specified and items 7 and 8 are defaulted, heat will be injected at a constant rate into the grid block according to:

$$H = H_{max}$$

where  $H_{max}$  is defined by item 6.

### Mode 2: Energy density dependent injection rate

If items 6 and 7 are specified and item 8 is defaulted, heat will be injected at a rate determined by the product of the grid-block volume and the rate of change of energy density:

$$H = \min\left(H_{max}, V \cdot \frac{\Delta E}{\Delta t}\right)$$

where  $V$  is the grid-block volume,  $\Delta t$  is the timestep, and the estimated change in energy density  $\Delta E$  is given by:

$$\Delta E = e_t(T_{max}) - e_{t-\Delta t}$$

where  $e_t(T_{max})$  is the grid-block energy density when its temperature is  $T_{max}$  and  $e_{t-\Delta t}$  is the grid-block energy density at the previous timestep.  $H_{max}$  and  $T_{max}$  are defined by items 6 and 7 respectively. If item 7 is set to a value greater than 1.0E+10, this will have the effect of defaulting item 7 such that the heat injection mechanism reverts to Mode 1, that is, a constant energy injection rate.

### Mode 3: Temperature difference dependent injection rate

If items 6, 7 and 8 are all defined, heat will be injected at a rate determined by the temperature difference between the maximum temperature of the connection  $T_{max}$  and the current grid-block temperature  $T_c$ .

$$H = \min[(T_{max} - T_c) \times R, H_{max}]$$

where  $H_{max}$ ,  $T_{max}$  and  $R$  are defined by items 6, 7 and 8 respectively.

---

**Note:** If item 6 is defaulted, the heater will be turned off irrespective of whether items 7 and 8 are specified or defaulted. If item 6 is specified and item 7 is defaulted, the heater will be deemed to be operating in Mode 1 irrespective of whether item 8 is specified or defaulted.

---

**Note:** If items 6, 7 and 8 are defined with item 8 set to zero, then  $H = \min[0, H_{max}]$ . If  $H_{max}$  (item 6) is greater than 0, then the heater will be deemed to be operating in Mode 1 and turned off.

The `RPTPRINT` keyword can be used to output heater status to the Print file.

# HEATVAP Heat of vaporization

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can only be used with the [THERMAL](#) option.

HEATVAP specifies the constant part of the heat of vaporization of each oil component. This keyword should only be used for thermal runs with volatile oils; it should not be used with [DEADOIL](#).

The data record contains one value for each component:

UNITS: kJ/kg (METRIC), Btu/lb (FIELD), J/gm (LAB), kJ/kg (PVT-M)

DEFAULT: 0.0

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

The enthalpy of a gaseous oil component may be calculated by first determining the enthalpy of the component in its liquid state, then adding a heat of vaporization of the form

$$\Delta H = A \cdot (1 - T / T_{crit})^B \quad \text{Eq. 3.80}$$

where

*A* Constant part of  $\Delta H$  entered with this keyword

*B* Exponent entered with keyword [HEATVAPE](#) (normally default)

*T* Temperature

$T_{crit}$  Critical temperature of the component, keyword [TCRIT](#).

Heats of vaporization are often obtained at the normal boiling point. Hence the constant *A* above would be entered as

$$A = \frac{\Delta H_{nb}}{(1 - T_{nb} / T_{crit})^B} \quad \text{Eq. 3.81}$$

where  $\Delta H_{nb}$  is the heat of vaporization at the normal boiling point, and  $T_{nb}$  is the normal boiling point.

The exponent *B*, entered with keyword [HEATVAPE](#), is usually defaulted to 0.38.

---

**Note:** Only two of the three keywords [SPECHG](#), [SPECHA](#) and [HEATVAP](#) should be specified. For further information please see "[Enthalpy](#)" in the *ECLIPSE Technical Description*.

---

## Example

For 4 components of molecular weight 16, 134, 394, 539

```
FIELD
HEATVAP

## HMAQUCT

## Specify gradients for Carter-Tracy aquifers

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

The keyword can be used to obtain gradients of the solution with respect to parameters defining the performance of a Carter-Tracy aquifer. The analytic aquifer should previously have been defined using keywords [AQUCT](#) and [AQUANCON](#) or [AQUANCONL](#) in the SOLUTION section.

The keyword should be followed by a number of records defining the aquifers and gradient parameters for each aquifer.

The number of derivative calculations for analytic aquifers must not exceed MHAQUF specified in keyword [HMDIMS](#).

The set of records must end with a single line containing only a slash (/).

Each record refers to a separate Carter-Tracy aquifer, and contains the following items of data:

1. Aquifer identification number

The identification number is specified as item 1 [AQUCT](#).

2. Calculate derivatives with respect to a permeability multiplier for the aquifer:

YES derivatives with respect to a multiplier on the aquifer permeability

NO do not evaluate derivatives with respect to a multiplier on the aquifer permeability

DEFAULT: NO

3. Calculate derivatives with respect to a multiplier on the aquifer opening angle

YES derivatives with respect to a multiplier on the aquifer opening angle are evaluated:

NO do not evaluate derivatives with respect to a multiplier on the aquifer opening angle

DEFAULT: NO

4. Calculate derivatives with respect to the aquifer depth:

YES derivatives with respect to the aquifer depth are evaluated

NO do not evaluate derivatives with respect to the aquifer depth

DEFAULT: NO

If the initial aquifer pressure is not defaulted in keyword [AQUCT](#) then the initial derivative of aquifer pressure with respect to depth is set to zero; if the aquifer pressure is defaulted, the initial derivative is calculated from the assumption that the aquifer is in equilibrium with the reservoir. In this case the gradients with respect to aquifer depth will be insensitive and hence redundant in a regression.

In the absence of brine, the above parameters constitute a set of independent parameters defining the aquifer inflow performance. See "[Aquifer modeling facilities](#)" in the *ECLIPSE Technical Description*.

## Example

With MHAQUF $\geq$ 2 specified using [HMDIMS](#)

```

.....
AQUCT
--Aq. Datum Initial Perm Poro Ct Ro Thick- Angle Water AQU TAB Salt
.....

```

```

--no. depth pressure          ness of inf. table table conc.

HMAQUCT
-- Aquifer Derivative w.r.t.      Derivative w.r.t.
-- number permeability multiplier opening angle multiplier
   1          YES                  YES /
/

```

## HMAQUFET Specify gradients for Fetkovich aquifers

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

The keyword can be used to obtain gradients of the solution with respect to parameters defining the performance of a Fetkovich aquifer. The analytic aquifer should previously have been defined using either keyword [AQUFET](#) or both keywords [AQUFETP](#) and [AQUANCON](#) or [AQANCONL](#) in the SOLUTION section.

The keyword should be followed by a number of records defining the aquifers and gradient parameters for each aquifer.

The number of derivative calculations for analytic aquifers must not exceed MHAQUF specified in keyword [HMDIMS](#).

Each record is terminated by a slash (/). The set of records must be terminated with a blank record containing just a slash.

Each record refers to a separate Fetkovich aquifer, and contains the following items of data:

1. Aquifer identification number

If the [AQUFETP/AQUANCON](#) or [AQUFETP/ AQANCONL](#) combination is used to define Fetkovich aquifers, the identification number is specified in [AQUFETP](#) item 1. Otherwise, the aquifer is identified by its record number in [AQUFET](#).

2. Calculate derivatives with respect to a multiplier on the initial volume of water in the aquifer

YES derivatives with respect to a multiplier on the initial aquifer volume are evaluated

NO do not evaluate derivatives with respect to multiplier on the initial aquifer volume

DEFAULT: NO

3. Calculate derivatives with respect to aquifer productivity index multiplier

YES derivatives with respect to the productivity index multiplier are evaluated

NO do not evaluate derivatives with respect to the productivity index multiplier

DEFAULT: NO

4. Calculate derivatives with respect to the aquifer depth

YES derivatives with respect to the aquifer depth are evaluated

NO do not evaluate derivatives with respect to the aquifer depth

DEFAULT: NO

If the initial aquifer pressure is not defaulted in keyword [AQUFET](#) then the initial derivative of aquifer pressure with respect to depth is set to zero; if the aquifer pressure is defaulted, the initial derivative is calculated from the assumption that the aquifer is in equilibrium with the reservoir. In this case the gradients with respect to aquifer depth will be insensitive and hence redundant in a regression.

In the absence of brine, the above parameters constitute a set of independent parameters defining the aquifer inflow performance. See "[Aquifer modeling facilities](#)" in the *ECLIPSE Technical Description*.

The keyword must not be used in restarted runs, as the aquifer specification data cannot be changed.

## HMAQUNUM Calculate gradients for numerical aquifers

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword can be used to obtain gradients of the solution with respect to parameters defining the performance of a numerical aquifer. The aquifer should previously have been defined using keywords [AQUNUM](#) and [AQUCON](#) in the GRID section.

The keyword should be followed by a number of records defining the aquifers and gradient parameters for each aquifer.

The number of derivative calculations defined for all analytic and numerical aquifers must not exceed MHAQUF specified in item 5 of keyword [HMDIMS](#).

The set of records must end with a single line containing only a slash (/).

Each record refers to a separate numerical aquifer, and contains the following items of data (and is followed by a slash):

1. Aquifer identification number  
The identification number is specified as item 1 in keyword [AQUNUM](#).
2. Calculate derivatives with respect to a pore volume multiplier for the aquifer  
YES Derivatives with respect to a multiplier on the aquifer pore volume are evaluated  
NO Do not evaluate derivatives with respect to a multiplier on the aquifer pore volume  
  
DEFAULT: NO
3. Calculate derivatives with respect to a multiplier on the aquifer permeability  
YES Derivatives with respect to a multiplier on the aquifer permeability are evaluated  
NO Do not evaluate derivatives with respect to a multiplier on the aquifer permeability
4. Calculate derivatives with respect to the aquifer-grid connection transmissibility  
YES Derivatives with respect to the aquifer transmissibility are evaluated  
NO Do not evaluate derivatives with respect to the aquifer transmissibility  
  
DEFAULT: NO

---

**Note:** The pore volume parameter acts over **all** cells comprising a single aquifer. The permeability parameter relates to a multiplier on the permeability of **all** cells representing the aquifer. The transmissibility parameter relates to a multiplier on the transmissibilities **only** of the aquifer-grid connections and **not** for the aquifer-aquifer connections when an aquifer is represented by several cells. This acts like the transmissibility multiplier specified with item 9 in the [AQUCON](#) keyword.

---

**Note:** The pore volume of a numerical aquifer cell is calculated from  $PORV = Length \times Area \times Poro$  using data entered in the [AQUNUM](#) keyword, where the porosity *Poro* is taken from the grid block value if defaulted. The transmissibilities of numerical aquifer connections are calculated from the permeability entered in the [AQUNUM](#) keyword. The regional parameter [HMPORVM](#) may include aquifer cells to obtain sensitivities, but any values of [HMMULTPV](#) will be ignored for numerical aquifer cells during a regression

from SimOpt because the aquifer *PORV* always uses the above formula and ignores pore volume modifiers. Keyword `HMMLAQUN` should be used to modify the aquifer pore volume during a regression run. The regional parameters, for example `HMPERMx`, return zero sensitivities for any aquifer cells because the aquifer permeability is taken directly from `AQUNUM` and not from the grid values or permeability. ECLIPSE will remove all numerical aquifer cells from regions defined by `HMPORVM`, `HMPERMx` and related keywords, because `HMAQUNUM` should be used instead. Sensitivities for transmissibilities between different numerical aquifers or for groups of numerical aquifer to grid connections can be obtained using the inter-region transmissibility parameter `HMMULRGT` by defining `MULTNUM` for the aquifer cells specified in `AQUNUM`.

For further information on the treatment of numerical aquifers, see "[Aquifer modeling facilities](#)" in the *ECLIPSE Technical Description*.

## Example

With `MHAQUF` ≥ 1 specified in `HMDIMS`.

```

AQUNUM
--Aq. IX IY IZ Area Length Poro. Perm. Depth Pressure PVT Sat.
  1  7  1  1 1.0E+5 2000 1* 200.0 1* 1* 1 1 /
  1  8  1  1 1.0E+5 2000 1* 200.0 1* 1* 1 1 /
  1  9  1  1 1.0E+5 2000 1* 200.0 1* 1* 1 1 /
  1 10  1  1 1.0E+5 2000 1* 200.0 1* 1* 1 1 /
/
HMAQUNUM
-- Aquifer PoreV parameter Perm. parameter Trans. parameter
  1 YES YES NO /
/

```

## HMDIMS

	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

## Specify the dimensions for the gradient option

This keyword specifies the dimensions for the gradient option, and is followed by some or all of the following items, terminated by a slash (/)

1. The maximum number of gradient regions defined by keywords HMxxxxxxx in the REGIONS section  
DEFAULT: 0

2. The maximum subregion number occurring in any Gradient region  
DEFAULT: 0

3. The maximum number of gradients required for Gradient region keywords.

DEFAULT: If this is not specified, it defaults to MHISTM \* NMHSTR, where MHISTM is the maximum number of Gradient regions specified by item 1 of this keyword and NMHSTR the maximum subregion number occurring in any Gradient region specified by item 2 of this keyword.

When NMHSTR is large, the memory required can therefore be reduced by specifying NHRPAR, which is actual maximum number of active 'gradzone' parameters.

- ECLIPSE 100 only*
4. The maximum number of faults for which gradients are required, specified by keyword [HMFAULTS](#) in the GRID section, and also the maximum number of inter-region connection gradients specified using keyword [HMMULRGT](#) in the GRID section.  
DEFAULT: 0

- ECLIPSE 100 only*
5. The maximum number of parameters declared for aquifers for which gradients are required specified by keywords [HMAQUCT](#) or [HMAQUFET](#) in the SOLUTION section or by keyword [HMAQUNUM](#) in the GRID section.  
DEFAULT: 0

- ECLIPSE 100 only*
6. The maximum number of well parameters specified using keyword [HMWPIMLT](#) in the SCHEDULE section.  
DEFAULT: 0

7. Not used at present

- ECLIPSE 100 only*
8. The maximum number of parameters declared for gradients with respect to rock parameters (keywords [HMROCK](#) and [HMROCKT](#) in the PROPS section).  
DEFAULT: 0

- ECLIPSE 100 only*
9. The maximum number of parameters declared for gradients with respect to well connection parameters (that is, using the keyword [HMWELCON](#) in the SOLUTION section).  
DEFAULT: 0

*ECLIPSE 100 only*

---

**Note:** ECLIPSE requires additional memory, which is a minimum of approximately 3 double precision words per cell for each gradient parameter. Hence, to make best of the available memory, it is not advisable to set the maximum number of gradient parameters greater than the actual number to be used in each case.

---

See "[Gradient option](#)" in the *ECLIPSE Technical Description* for further information.

## Examples

### Example 1

In the following ECLIPSE 100 example there is a maximum of 3 gradient regions, each with up to 4 subregions with only 6 gradients required and 5 faults (with gradients required for two faults). There are two analytic aquifers with up to 100 grid block connections each and a default influence table.

```

FAULTDIM
--MFSEGS
  5 /
AQUDIMS
--MXNAQN  MXNAQC  NIFTBL  NRIFTB  NANAQU  NCAMAX
  0         0       1       36      2       100 /
HMDIMS
--MHISTM  NHMSTR  NHRPAR  MFHIST  MHAQUF
  3        4       6       2       2 /

```

### Example 2

In the following example there is a maximum of 4 gradient regions, each with up to 5 subregions with only 8 gradients required.

```

HMDIMS
--MHISTM  NHMSTR  NHRPAR
  4        5       8 /

```

## HMFAULTS Specify gradients for faults

	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword may be used in runs in which the gradient option is required.

The keyword can be used to obtain gradients of the solution with respect to transmissibilities across faults which have been previously defined by the [FAULTS](#) keyword in the GRID section.

The keyword should be followed by a number of records defining names of fault segments for which solution gradients are required.

The set of records must end with a single line containing only a slash (/). The set of records must be terminated with a blank record containing just a slash.

The number of gradients for faults must not exceed MFHIST specified in RUNSPEC keyword [HMDIMS](#).

### Example

This keyword applies multipliers to properties determining the performance of a numerical aquifer defined in keyword [AQUNUM](#). It is intended to be used as a modifier on the base data specified in the [AQUNUM](#) keyword during history matching.

The keyword should be followed by a number of records defining the aquifers and multipliers for each aquifer.

The set of records must end with a single line containing only a slash (/). The set of records must be terminated with a blank record containing just a slash.

Each record refers to a separate numerical aquifer, and contains the following items of data:

1. Aquifer identification number

The identification number is specified in [AQUNUM](#) item 1.

2. Multiplier on aquifer pore volume

DEFAULT: 1.0

3. Multiplier on aquifer permeability

DEFAULT: 1.0

---

**Note:** The aquifer-grid connection transmissibility is also modified when the aquifer permeability multiplier is used. For further information on the transmissibility calculation see "[Aquifer modeling facilities](#)" in the *ECLIPSE Technical Description*.

---

4. Multiplier on aquifer-grid connection transmissibility

DEFAULT: 1.0

See also the [HMAQUNUM](#) keyword.

---

**Note:** The aquifer pore volume cannot be modified by editing [PORV](#) for the aquifer cells or by specifying [MULTPV](#). See the [AQUNUM](#) keyword.

---

### Example

```

AQUNUM
--Aq. IX IY IZ Area Length Poro. Perm. Depth Pressure PVT Sat.

This keyword applies multipliers to properties determining the performance of the Fetkovich aquifer defined using either keyword [AQUFET](#), or keywords [AQUFETP](#) and [AQUANCON](#) or [AQANCONL](#). It is intended to be used as a modifier on the base data specified in the [AQUFET](#) keyword during history matching.

The keyword should be followed by a number of records defining the aquifers and multipliers for each aquifer.

The set of records must end with a single line containing only a slash (/). The set of records must be terminated with a blank record containing just a slash.

Each record refers to a separate Fetkovich aquifer, and contains the following items of data:

1. Aquifer identification number. The identification number is specified in [AQUFETP](#) item 1 or is the number in the list if keyword [AQUFET](#) is used.
2. Multiplier on initial volume of water in the aquifer.  
DEFAULT: 1.0
3. Multiplier on aquifer Productivity Index.  
DEFAULT: 1.0
4. Multiplier on aquifer depth  
DEFAULT: 1.0

See also the [HMAQUFET](#) keyword.

### Example

Obtain gradients for one aquifer, on the bottom of a 10 x 10 x 5 grid

```

AQUFET

```

## HMMLTWCN Modifies well connection transmissibility factor and skin factor

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used in runs in which the gradient option is required.

The keyword can be used to modify the connection transmissibility factor and skin factor for well connections that are defined using the `COMPDAT` (or `COMPDATL` or `COMPDATM`) keyword in the `SCHEDULE` section.

The multipliers specified are applied cumulatively, so if a well connection is specified more than once, or in more than one `HMMLTWCN` keyword, the multipliers will be cumulated.

The keyword is followed by any number of records, described below, each record terminated by a slash (/). A record can be terminated early using a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form `n*`, where `n` is the number of consecutive items to be defaulted.

The set of records must end with a blank record, containing only a slash (/).

### 1. Well name

This item cannot be defaulted. It should be the name of a single well which is defined in the `SCHEDULE` section. You cannot use a wildcard character to refer to more than one well at a time, and you cannot use a well list (that is, as defined using the keyword `WLIST`).

### 2. Grid name

If the well connection is not in a local grid, then you should specify `'FIELD'` for this item. If the well connection is in a local grid, this item should specify the name of the local grid refinement, and it should correspond to the local grid specified for the well connection in the `SCHEDULE` section.

DEFAULT: `'FIELD'`

### 3. I - location of the connecting grid block

This specifies the I-location of the well connection on the grid specified in item 2. It should correspond to the I-location of the connection specified in the `SCHEDULE` section.

This item cannot be defaulted.

### 4. J - location of the connecting grid block

This specifies the J-location of the well connection on the grid specified in item 2. It should correspond to the J-location of the connection specified in the `SCHEDULE` section.

This item cannot be defaulted.

### 5. K - location of the connecting grid block

This specifies the K-location of the well connection on the grid specified in item 2. It should correspond to the K-location of the connection specified in the `SCHEDULE` section.

This item cannot be defaulted.

### 6. Modifier for the connection transmissibility factor.

The connection transmissibility factor for the well connection will be multiplied by this value. It should be set to a value greater than zero.

DEFAULT: 1.0

7. Modifier for the skin factor.

The skin factor for the well connection will be multiplied by this value. It should be set to a value greater than zero.

DEFAULT: 1.0

## Example

This example assumes that the local grid, wells and connections are defined in the SCHEDULE section.

```
HMMLTWCN
-- Well  Grid  I  J  K  CTF  Skin
  PROD1  CARF1  6  4  1  1.01  0.95 /
  PROD1  CARF1  6  4  2  1*    1.40 /
  PROD1  CARF1  6  4  3  1.50  /
  PROD3   1*    4  5  2  1.00  1.00 /
  PROD3   1*    4  5  3  2.50  1*  /
/
```

## HMMLT<sub>xxx</sub>

# Cumulative multipliers for gradient parameters

	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This is analogous to [MULTREGT](#) except the effect is cumulative.

The keyword is followed by any number of records, each terminated with a slash (/).

Each record contains the following items of data:

1. From region number (I)
2. To region number (J)
3. Additional transmissibility multiplier (TMLT) for all connections between [FLUXNUM](#) or [MULTNUM](#) regions I and J.

The set of records must end with a single line containing only a slash (/). The set of records must be terminated with a blank record containing just a slash.

The options specified in [MULTREGT](#) items 4 and 5 apply. If the regions I and J have not previously been declared using [MULTREGT](#), then TMLT is applied to all connections between I and J (that is, items 4 and 5 of [MULTREGT](#) are assumed defaulted).

### Example

```
HMMMREGT
 1 2 1.1 /
 3 4 1.5 /

```

## HMMROCK Specify cumulative multipliers on rock compressibility

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword can be used to specify modifiers to the rock compressibility entered via keyword `ROCK`, in each `PVTNUM` or `SATNUM` region.

The keyword should be followed by up to `NTPVT` (see item 2 of keyword `TABDIMS`) records defining the gradient calculations for each PVT region, or by up to `NTSFUN` (see item 1 in keyword `TABDIMS`) records if the `ROCK` keyword refers to saturation regions as requested in the `ROCKOPTS` keyword.

The set of records must end with a single line containing only a slash (/). The set of records must be terminated with a blank record containing just a slash.

Each record consists of two items:

1. PVT or saturation table number.

This should be in the range 1 to `NTPVT` (or in the range 1 to `NTSFUN` if rock data is entered by saturation region).

2. The compressibility multiplier  $\lambda$  for this table.

DEFAULT: 1.0

The pore volume is calculated as

$$PV = PV_{ref}(1 + X + X^2)$$

with

$$X = C(p - p_{ref})$$

and where  $C$  and  $p_{ref}$  are the rock compressibility and reference pressure entered in the `ROCK` keyword.

ECLIPSE calculates derivatives with respect to  $\lambda$ , a multiplier on  $C$ , so that

$$X = \lambda C(p - p_{ref})$$

---

**Note:** By default, rock compressibility data is entered by `PVTNUM` region. But if item 3 in keyword `ROCKOPTS` is set to `SATNUM`, the rock compressibility data is entered according to `SATNUM` region.

---

### Example

```
HMMROCK
 2 1.03 /
 4 1.04 /
 /
```

## HMMROCKT Specify cumulative modifiers for rock compaction parameters

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword can be used to specify modifiers to rock compaction parameters entered via keyword `ROCKTAB` or `ROCKTABH` in each `ROCKNUM` region.

The pore volume is calculated as a multiplier on the reference pore volume using data supplied in the `ROCKTAB` or `ROCKTABH` tables:

$$PV = PV_{ref} M(p)$$

where  $p$  is the reservoir pressure. If the `OVERBURD` keyword has been entered,

$$P = P_{eff} = P_{fluid} - P_{overburden}$$

If the `STRESS` option is selected in item 1 of the `ROCKOPTS` keyword,

$$P = P_{eff} = P_{overburden} - P_{fluid}$$

ECLIPSE calculates gradients with respect to two parameters using the functional form

$$PV = PV_{ref} M(p) \left( \lambda_1 + \lambda_2 \frac{(P - P_{ref})}{P_{dim}} \right)$$

where  $p_{ref}$  is the reference pivot pressure entered in keyword `HMRREF` for the `ROCKNUM` region and  $p_{dim}$  is a reference scale pressure used to make the parameter  $\lambda_2$  dimensionless.

Derivatives are calculated with respect to the dimensionless parameters  $\lambda_1$  and  $\lambda_2$ .

The keyword should be followed by up to `NTROCC` (item 2 of keyword `ROCKCOMP`) records defining the gradient calculations for each `ROCKNUM` region. Each record consists of three items and is followed by a slash(/). The set of records should be terminated by a single slash.

1. Rock table number

This should be in the range 1 to `NTROCC` (item 2 of keyword `ROCKCOMP`).

2. Modifier  $\lambda_1$  (multiplicative parameter)

DEFAULT: 1.0

3. Modifier  $\lambda_2$  (additive parameter)

DEFAULT: 0.0

### Example

```
HMMROCKT
 2 1.0 1.13 /
 4 1.0 1.05 /
/
```

## HMMULRGT Calculate gradients for inter-region transmissibility multipliers

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword can be used to obtain gradients of the solution with respect to inter-region transmissibility multipliers declared using keyword [MULTREGT](#) in the GRID section.

The keyword is followed by any number of records, each terminated with a slash (/). The set of records must be terminated with a blank record containing only a slash.

Each record contains the following items of data:

- From region number (I)
 

A non-positive or defaulted value acts as a wildcard on all regions.

DEFAULT: Negative
- To region number (J)
 

A non-positive or defaulted value acts as a wildcard on all regions.

DEFAULT: Negative
- Direction(s) in which to apply the multiplier:
 

Either X, Y, Z, XY, YZ, XZ or XYZ.

DEFAULT: XYZ
- Flag governing application of the multiplier to non-neighbor connections:
 

NNC Apply the transmissibility multiplier only to non-neighbor connections between regions I and J

NONNC Do not apply the transmissibility multiplier to any non-neighbor connections between regions I and J

ALL Apply the transmissibility multiplier to all connections between regions I and J

NOAQUNNC Do not apply the transmissibility multiplier to numerical aquifer connections.

DEFAULT: ALL

The set of records must end with a single line containing only a slash (/).

The total number of gradients for inter-region transmissibility parameters as well as fault transmissibility parameters (specified using keyword [HMFAULTS](#)) must not exceed MFHIST specified in item 4 of keyword [HMDIMS](#).

See also keywords [MULTREGT](#) and [HMMMREGT](#).

### Example

```
HMMULRGT
 1 2 /
 3 4 /
/
```

## HMMULTxx Cumulative multipliers for gradient parameters

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
x	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

These keywords set cumulative pore volume or transmissibility multipliers for Gradient runs.

HMMULTX	Cumulative X-transmissibility multiplier
HMMULTY	Cumulative Y-transmissibility multiplier
HMMULTZ	Cumulative Z-transmissibility multiplier
HMMULTXY	Cumulative X and Y transmissibility multiplier
HMMULTPV	Cumulative pore volume multiplier

These keywords are analogous to [MULTPV](#) and [MULTX](#), [MULTY](#), [MULTZ](#) etc. except that HMMULTX etc. act as a multiplier on any values of MULTX that have been previously specified in either the GRID or EDIT sections. It is cumulative.

For modifications to permeability parameters, the following keywords are also recognized only in the GRID section:

HMMLTPX	X-permeability multiplier
HMMLTPY	Y-permeability multiplier
HMMLTPZ	Z-permeability multiplier
HMMLTPXY	XY-permeability multiplier

The correspondence with the MULTx keywords is shown below:

Cartesian	Radial alias
MULTX / HMMULTX	MULTR / HMMULTR
MULTY / HMMULTY	MULTTHT / HMMULTTH
MULTZ / HMMULTZ	MULTZ / HMMULTZ
MULTPV / HMMULTPV	MULTPV / HMMULTPV

Table 3.15: Correspondence between MULTxx and HMMULTxx keywords

Additionally, the keyword HMMLTPXY (HMMLTRTH in radial geometry) specifies both HMMULTX and HMMULTY.

The keyword should be followed by one non-negative real number for every grid block in the current input box. The values specified for HMMULTX act as cumulative multipliers on the transmissibilities calculated by ECLIPSE for the +X face of each grid block or specified directly using TRANX in the EDIT section. Thus, a value for HMMULTX specified for block (I,J,K) multiplies the transmissibility between blocks (I,J,K) and (I+1,J,K). The treatment of HMMULTY and HMMULTZ is analogous. Any non-neighbor connections due to faults have transmissibilities that reflect the HMMULTX/Y/Z values.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0). Note that spaces must not be inserted on either side of the asterisk.

The set of records must end with a single line containing only a slash (/). The set of records must be terminated with a blank record containing just a slash.

Each keyword may also be used in conjunction with the [BOX](#) and [EQUALS](#) keywords. Within the GRID section it is also possible to use them together with the [COPYBOX](#) and [EQUALREG](#) keywords.

## Notes

- Use in conjunction with HMTRANXn etc. keywords

Since the transmissibilities calculated by ECLIPSE for a base dataset (in the absence of any HMMULTX data) depend on existing MULTX values, the derivatives calculated by ECLIPSE for the transmissibility multiplier HMTRANXn are with respect to HMMULTX and not with respect to MULTX. This ensures all the derivatives consistently refer to additional multipliers on the base dataset.

- Use in the GRID section

If any keyword HMMULTX/HMMULTYHMMULTZ etc. (or HMMULTPV) is entered in the GRID section, then it applies only to the transmissibilities (or pore volumes) calculated by ECLIPSE using the information in the GRID section and **not** to any transmissibilities entered directly in the EDIT section using the TRANX/TRANY/TRANZ (or PORV) keyword. Any MULTX/Y/Z (MULTPV) values that are not specified when the end of the GRID section is reached default to 1.0.

- Use in the EDIT section

If any keyword HMMULTX/HMMULTYHMMULTZ etc. (or HMMULTPV) is entered in the EDIT section then it acts as an additional multiplier on the transmissibilities (or pore volumes) after reading any modified transmissibilities (pore volumes) from the EDIT section. Any non-neighbor connections not entered explicitly are modified to reflect the edited values of HMMULTX/HMMULTY/HMMULTZ.

- In *ECLIPSE 100* only, use with the Local Grid Refinement option

By default, any HMMULTxx data is inherited in local cells from the corresponding global host cells. Alternatively, modifiers can be defined for local cells between [REFINE](#) and [ENDFIN](#) pairs.

You should be aware that HMMULTX etc. (exactly analogous to [MULTX](#) etc.) from the global grid translates into a multiplier between local cells which share a boundary of the global grid to which HMMULTX etc. is applied, and **not** between local cells which share a boundary completely internal to a global cell. You should define HMMULTX etc. between a [REFINE](#) and [ENDFIN](#) pair if it is required to apply to all local cells within a box.

---

**Note:** The same rules described above in notes "[Use in the GRID section](#)" and "[Use in the EDIT section](#)" apply to **all** local grids.

---

## Examples

### Example 1

```

EQUALS
'MULTX'  0.5  1 10 1 1 1 4 /
'MULTY'  0.8  1 1  1 5 5 8 /
/

```

### Example 2

After any MULTX/Y/Z keywords

```
EQUALS  
'HMMULTX ' 0.4 1 5 1 1 2 3 /  
'HMMULTY ' 0.7 1 1 2 3 6 7 /  
'HMMULTPV' 0.35 4 5 2 5 2 4 /  
/
```

### Example 3

```
EQUALS  
'HMMULTPV' 0.35 4 5 2 5 2 4 /  
/
```

## HMMULTFT **Modifies the transmissibility across the named fault**

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The HMMULTFT keyword can be used to modify the transmissibility across a fault previously defined using the [FAULTS](#) keyword. It has the same effect as the [MULTFLT](#) keyword except the multiplier is applied cumulatively.

If MULTFLT is not entered for the named fault, then HMMULTFT has the same effect as MULTFLT. If MULTFLT has been previously entered, then HMMULTFT multiplies the existing fault transmissibility multiplier.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The records may be terminated after item 2. The remaining item assumes its default value.

The set of records must end with a blank record containing only a slash (/).

1. Fault name (as specified in the [FAULTS](#) keyword) or fault name root  
A fault name root, ending with an asterisk (\*), can be used to refer to several faults in one record.
2. Transmissibility Multiplier  
DEFAULT: 1.0
3. Diffusivity Multiplier (used if the Molecular Diffusion option is active)  
DEFAULT: 1.0

### Notes

- Use of the [MULTFLT](#) keyword in the GRID section modifies the MULTX, MULTY and MULTZ arrays along the fault trajectory. If the [MULTX](#), [MULTY](#) or [MULTZ](#) keyword is used for some cells, in addition to the HMMULTFT keyword, then the resultant transmissibility multiplier is the product of the two input multipliers.
- If two faults with different names run along the same face of a cell, then both transmissibility multipliers are applied.

See also the [FAULTS](#) and [RPTGRID](#) keywords.

### Example

(See the [FAULTS](#) keyword example)

```

MULTFLT
--          Multiplier
'zigzag'   0.2      /
/
HMMULTFT
--          Multiplier
'zigzag'   0.8      /
/

```

## HMMULTSG Dual porosity sigma factor modifiers

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This multiplies the dual porosity sigma factor, analogously to the [HMSIGMA](#) keyword in the [REGIONS](#) section.

The keyword should be followed by one non-negative real number for every grid block in the current input box.

Grid blocks are ordered with the *X* axis index cycling fastest, followed by the *Y* and *Z* axis indices. Repeat counts may be used for repeated values (for example 115\*0). Note that spaces must not be inserted on either side of the asterisk.

The data must be terminated by a slash. The set of records must end with a single line containing only a slash (/).

The keyword may also be used in conjunction with the [BOX](#) and [EQUALS](#) keywords.

### Example

```
EQUALS
'HMMULTSG' 10.0 1 10 1 1 1 4 /
/
```

## HMPROPS

## Section heading for end-point scaling modifiers

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is used to supply modifiers to the end-points by the SimOpt program.

The keyword acts as a section heading, and must occur just before the SOLUTION section (that is at the end of the REGIONS section, or at the end of the PROPS section when there is no REGIONS keyword). (Clearly, modifiers can only be supplied once the SATNUM values are known from the regions section and after all end-point arrays have been specified in the PROPS section; hence HMPROPS should occur after reading PROPS and REGIONS data.)

HMPROPS directs ECLIPSE to treat ensuing keywords as modifiers to any allowable [HMxxxxxxx](#) keywords pertaining to end-points. The modifier keywords [BOX](#), [EQUALS](#), [COPY](#), [MINVALUE](#), [MAXVALUE](#) and [ADD](#) may be used with the [HMxxxxxxx](#) keywords.

When the keyword to be modified occurs without the [ADD](#), [COPY](#), [MINVALUE](#), or [MAXVALUE](#) qualifiers, the initial two letters direct ECLIPSE whether to add or multiply the given array: keywords beginning with [HM](#) are multiplied, while those beginning with [HA](#) are added.

When using Local Grid Refinement, modifiers can be specified between the [REFINE](#) / [ENDFIN](#) pairs for local grids. By default, ECLIPSE takes the endpoints from the host global cells unless specified for local cells.

The processed end-points can be output using mnemonics [SWCR](#) and [SOWCR](#), for example in the [RPTSOL](#) keyword in the SOLUTION section.

The allowable [HA](#) array keywords that may occur in the HMPROPS section are of the form [HASWCR](#) and [HASOWCR](#) for example. Generally, any keyword of the form [HAXxxxxxx](#) can be used where [xxxxxxx](#) is an allowable saturation end point (such as [SWCR](#) or [SOWCR](#)).

The allowable [HM](#) array keywords that may occur in the HMPROPS section are in the form [HMKRW](#) and [HMKRG](#). Generally, any keyword of the form [HMxxxxxxx](#) can be used where [xxxxxxx](#) is an allowable relative permeability end point (such as [KRW](#) or [KRG](#)). For instance,

[HASOWCR](#) Specifies critical oil-in-water saturation modifiers.

[HASOGCR](#) Specifies critical oil-in-gas saturation modifiers.

[HASWL](#) Specifies connate water saturation modifiers.

[HMKRW](#) Specifies maximum water relative permeability modifiers.

[HMKRG](#) Specifies maximum gas relative permeability modifier.

[HMKRO](#) Specifies maximum oil relative permeability modifier.

[HMKRWR](#) Specifies maximum displacing water relative permeability modifier.

[HMKRGR](#) Specifies maximum displacing gas relative permeability modifier.

[HMKRORG](#) Specifies maximum displacing oil-in-gas relative permeability modifier.

[HMKRORW](#) Specifies maximum displacing oil-in-water relative permeability modifier.

[HASWLP](#) Specifies modifier on lower water saturation used for water capillary pressure.

[HASGLP](#) Specifies modifier on lower gas saturation used for gas capillary pressure.

HMPCW Specifies modifier on water capillary pressure.

HMPCG Specifies modifier on gas capillary pressure.

## Calculate gradients for rock compressibility

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword can be used to obtain gradients of the solution with respect to multipliers on the rock compressibility entered via keyword `ROCK` in each PVT or saturation region. See "Gradient option" in the *ECLIPSE Technical Description* for further information.

If the `ROCK` data refers to PVTNUM regions (see item 3 in keyword `ROCKOPTS`) then the keyword should be followed by up to NTPVT records (see keyword `TABDIMS`) defining the gradient calculations for each PVT region.

If the `ROCK` data refers to SATNUM regions then the keyword should be followed by up to NTSFUN records (see keyword `TABDIMS`) defining the gradient calculations for each saturation region.

The total number of rock gradient parameters specified using either the `HMROCK` or `HMROCKT` keywords must not exceed the maximum specified by item 8 of the `HMDIMS` keyword.

Each record must be terminated by a slash (/). The set of records must end with a single line containing only a slash (/).

Each record consists of two items:

1. PVT or saturation table number

This should be in the range 1 to NTPVT if PVTNUM regions are referenced, or in the range 1 to NTSFUN if SATNUM regions are referenced.

2. Calculate gradients with respect to the multiplier on the rock compressibility

1 calculate

0 do not calculate

DEFAULT: 0

The pore volume is calculated as

$$PV = PV_{ref}(1 + X + X^2) \quad \text{Eq. 3.83}$$

with

$$X = C(p - p_{ref})$$

where  $C$  and  $p_{ref}$  are the rock compressibility and reference pressure entered in the `ROCK` keyword.

ECLIPSE calculates derivatives with respect to  $\lambda$ , a multiplier on  $C$  (at  $\lambda = 1.0$ ), so that

$$X = \lambda C(p - p_{ref}) \quad \text{Eq. 3.84}$$

## Calculate gradients for rock compaction tables

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword can be used to obtain gradients of the solution with respect to multipliers on the rock compaction pore volume modifiers entered via keyword [ROCKTAB](#) or [ROCKTABH](#) in each [ROCKNUM](#) region. See "[Gradient option](#)" in the *ECLIPSE Technical Description* for further information.

The pore volume is calculated as a multiplier on the reference pore volume using data supplied in the [ROCKTAB](#) or [ROCKTABH](#) tables:

$$PV = PV_{ref}M(p) \quad \text{Eq. 3.85}$$

where  $p$  is the reservoir pressure. If the [OVERBURD](#) keyword has been entered,

$$p = P_{eff} = P_{fluid} - P_{overburden} \quad \text{Eq. 3.86}$$

If the [STRESS](#) option is selected in item 1 of the [ROCKOPTS](#) keyword,

$$p = P_{eff} = P_{overburden} - P_{fluid} \quad \text{Eq. 3.87}$$

ECLIPSE calculates gradients with respect to two parameters using the functional form

$$PV = PV_{ref}M\left(p\right)\left(\lambda_1 + \lambda_2 \frac{(p - P_{ref})}{P_{dim}}\right) \quad \text{Eq. 3.88}$$

where  $p_{ref}$  is the reference pivot pressure entered in keyword [HMRREF](#) for the [ROCKNUM](#) region and  $p_{dim}$  is a reference scale pressure used to make  $\lambda_2$  dimensionless.

Derivatives are calculated with respect to the dimensionless parameters  $\lambda_1$  and  $\lambda_2$ .

The keyword should be followed by up to [NTROCC](#) (item 2 of keyword [ROCKCOMP](#)) records defining the gradient calculations for each rock region. The set of records must end with a single line containing only a slash (/).

The total number of rock gradient parameters specified using either the [HMROCK](#) or [HMROCKT](#) keywords must not exceed the maximum specified by item 8 of the [HMDIMS](#) keyword.

Each record consists of three items followed by a slash:

1. Rock table number
  - This should be in the range 1 to [NTROCC](#) (item 2 of keyword [ROCKCOMP](#))
2. Calculate gradients with respect to  $\lambda_1$  (at  $\lambda_1 = 1.0$ )
  - 1 calculate
  - 0 do not calculate
3. Calculate gradients with respect to  $\lambda_2$  (at  $\lambda_2 = 0.0$ )
  - 1 calculate
  - 0 do not calculate

## Example

```
HMROCKT  
 2 0 1 /  
 4 1 0 /  
 /
```

## HMRREF

## Reference pressure for rock table modifications

This keyword must be used to supply reference pressures if any gradients with respect to rock compaction parameters in the [ROCKTAB](#) or [ROCKTABH](#) tables are requested, or if any modifications are to applied to these tables.

The keyword should be followed by NTROCC records, each terminated by a slash (/). NTROCC refers to the number of rock tables, entered in item 2 of keyword [ROCKCOMP](#).

Each record specifies the reference pressures  $p_{ref}$  and  $p_{dim}$  in [HMMROCKT](#). Each refers to a separate [ROCKNUM](#) region and contains the reference pressure for that region. The reference pressures are used to modify the rock tables via the [HMMROCKT](#) keyword.

Each record consists of two items:

1.  $p_{ref}$   
 UNITS: barsa (METRIC), psia (FIELD), atma (LAB)  
 DEFAULT: Error if not specified
2.  $p_{dim}$   
 UNITS: barsa (METRIC), psia (FIELD), atma (LAB)  
 DEFAULT: Error if not specified

Items  $p_{ref}$  and  $p_{dim}$  are described in the [HMMROCKT](#) keyword.

### Example

```

--With NTROCC=4 and p_eff = p_fluid
HMRREF
449.0 500.0 /
500.0 500.0 /
345.0 500.0 /
400.0 500.0 /

```

## HMWELCON Specify gradients for well connection parameters

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used in runs in which the gradient option is required.

The keyword can be used to obtain gradients of the solution with respect to well connection transmissibility factors and skin factors for well connections that are defined using the [COMPDAT](#) (or [COMPDATL](#) or [COMPDATM](#)) keyword in the [SCHEDULE](#) section.

The keyword is followed by any number of records, described below, each record terminated by a slash (/). A record can be terminated early using a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records must end with a blank record, containing only a slash (/).

### 1. Well name

This item cannot be defaulted. It should be the name of a single well which is defined in the [SCHEDULE](#) section. You cannot use a wildcard character to refer to more than one well at a time, and you cannot use a well list (that is, as defined using the keyword [WLIST](#)).

### 2. Grid name

If the well connection is not in a local grid, then you should specify 'FIELD' for this item. If the well connection is in a local grid, this item should specify the name of the local grid refinement, and it should correspond to the local grid specified for the well connection in the [SCHEDULE](#) section.

DEFAULT: 'FIELD'

### 3. I - location of the connecting grid block

This specifies the I-location of the well connection on the grid specified in item 2. It should correspond to the I-location of the connection specified in the [SCHEDULE](#) section.

This item cannot be defaulted.

### 4. J - location of the connecting grid block

This specifies the J-location of the well connection on the grid specified in item 2. It should correspond to the J-location of the connection specified in the [SCHEDULE](#) section.

This item cannot be defaulted.

### 5. K - location of the connecting grid block

This specifies the K-location of the well connection on the grid specified in item 2. It should correspond to the K-location of the connection specified in the [SCHEDULE](#) section.

This item cannot be defaulted.

### 6. Flag specifying whether connection transmissibility factor gradients are required.

This item should be set to 'YES' if connection transmissibility factor gradients are required, and 'NO' otherwise.

DEFAULT: 'NO'

### 7. Flag specifying whether skin factor gradients are required.

This item should be set to 'YES' if skin factor gradients are required, and 'NO' otherwise.

DEFAULT: 'NO'

The total number of well connection gradients requested (that is, the number of connection transmissibility factor gradients plus the number of skin factor gradients) must not exceed the value specified in item 9 of the RUNSPEC keyword [HMDIMS](#).

## Example

The example below requests well connection gradients for connections on three layers for well PROD1 in local grid CARF1. These gradients are for skin factor in layer 1, both connection transmissibility factor and skin factor in layer 2, and just connection transmissibility factor in layer 3. It also requests well connection gradients on two layers for well PROD3 on the global grid. These gradients are for both connection transmissibility factor and skin factor in layer 2, and just connection transmissibility factor in layer 3.

This example assumes that the local grid, wells and connections are defined in the SCHEDULE section. It also assumes that item 9 of the [HMDIMS](#) keyword in the RUNSPEC section has been set to at least 7 (that is, the total number of gradients requested).

```

HMWELCON
-- Well  Grid  I  J  K  CTF  Skin
  PROD1  CARF1  6  4  1  'NO'  'YES' /
  PROD1  CARF1  6  4  2  'YES'  'YES' /
  PROD1  CARF1  6  4  3  'YES'  /
  PROD3   1*   4  5  2  'YES'  'YES' /
  PROD3   1*   4  5  3  'YES'  'NO'  /
/

```

## HMWPIMLT Calculate gradients with respect to well productivity index

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword can be used to obtain gradients of the solution with respect to the productivity index of a nominated well. Derivatives will be calculated with respect to a multiplier applied to all connection flow rates.

The keyword should be followed by a number of records defining the wells to be used. The number of wells specified must not exceed the number specified by item 6 in the [HMDIMS](#) keyword.

For a well under BHP control, the derivative calculated by HMWPIMLT is equivalent to the derivative with respect to a multiplier on the connection transmissibility factor calculated by ECLIPSE or entered directly using keyword [COMPDAT](#) (or [COMPDATL](#)).

For a well under rate control, the derivative calculated by HMWPIMLT is equivalent to the derivative with respect to a multiplier on the limiting flow rate.

The keyword should be followed by a number of records to declare wells to add to the list of gradients. Wells declared as special history matching wells using keyword [WCONHIST](#) should **not** be included in keyword HMWPIMLT.

Each record consists of a well name or well name root. A well name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several wells in one record.

Each record must be terminated with a slash (/).

The set of records must end with a single line containing only a slash (/).

### Example

```
HMWPIMLT
  PROCUCER /
  'SOUTH*' /
/
```

## Gradient regions

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is used in runs in which the Gradient option is required.

The keyword should be followed by an integer between zero and NMHSTR for every grid block in the current input box to indicate the gradient sub-region associated with the keyword to which the cell belongs. A zero indicates that the cell belongs to no subregion, while a positive number defines the sub-region to which the cell belongs.

For each gradient region keyword, ECLIPSE then computes gradients of the solution with respect to the gradient parameters within each user- defined sub-region possessing active cells.

The number of gradient region keywords specified in the run must not exceed MHISTM, and the number of subregions within any gradient region cannot be greater than NMHSTR; these are specified in RUNSPEC keyword [HMDIMS](#).

The following parameters are currently recognized by ECLIPSE:

HMTRANX X-direction transmissibility multipliers

HMTRANY Y-direction transmissibility multipliers

HMTRANZ Z-direction transmissibility multipliers

HMTRNXY X and Y-direction transmissibility multipliers

HMPORVM Pore volume multipliers

HMSIGMA Dual porosity sigma factor multipliers (*ECLIPSE 100* only)

HMPERMX X-direction permeability multipliers

HMPERMY Y-direction permeability multipliers

HMPRMXY X and Y-direction permeability multipliers
