HMPERMZ Z-direction permeability multipliers

In addition, for *ECLIPSE 100* only, it is possible to calculate sensitivities with respect to saturation table end-point parameters. The relevant keywords are of the form HMzzzzzz where zzzzzz is any allowable end-point scaling grid array (dependent on the fluid combination in the run). Allowable values for HMzzzzzz are:

- Critical end-points: HMSWCR, HMSGCR, HMSOWCR, HMSOGCR. Derivatives are calculated with respect to SWCR, SGCR and forth.
- Water connate end-point: HMSWL. Derivatives are calculated with respect to SWL.
- End-points used for vertical scaling of the relative permeability: HMKRW, HMKRO, HMKRG, HMKRWR, HMKRGR, HMKRORW, HMKRORG. Derivatives are calculated with respect to multipliers (scale factors) on KRW, KRO, KRG and so on. Note that the alternative forms such as KRWR may be used even if the alternative three point scaling is not activated by keyword [SCALECRS](#).
- End-points used for vertical scaling of capillary pressure curves: HMPCW, HMPCG. Derivatives are calculated with respect to a multiplier (scale factor) on PCW and PCG.

At present sensitivities cannot be obtained when directional or reversible end-point scaling is present.

For a fuller description of the end-point scaling keywords, see "[Saturation table scaling](#)" in the *ECLIPSE Technical Description*.

## Transmissibility sensitivities: use of HMTRANX and related keywords

The keywords applying to the transmissibility modifiers will account for variations in transmissibility for any transmissibilities calculated by ECLIPSE using information given in the GRID section or entered directly in the EDIT section. The contributions to the gradient for non-neighbor connections are calculated for all non-neighbor connections calculated by ECLIPSE in the GRID section or modified in the EDIT section. The contribution from any non-neighbor connections entered explicitly using the [NNC](#) keyword in the GRID section is ignored. The behavior is exactly analogous to the treatment on non-neighbor connections using [MULTX](#) and related keywords.

Well connection factors are not varied with these keywords because these depend on permeability (unless explicitly specified).

## Permeability sensitivities: use of HMPERM and related keywords

The sensitivity of the solutions calculated by ECLIPSE depend on permeabilities in two ways.

Firstly the transmissibilities calculated from information in the GRID section depend on permeability, but any transmissibilities overwritten in the EDIT section do not contribute to these sensitivities. The contributions to the gradient of transmissibility for non-neighbor connections is accounted for all non-neighbor connections calculated by ECLIPSE in the GRID section or modified in the EDIT section. The contribution from any non-neighbor connections entered explicitly using the [NNC](#) keyword in the GRID section is ignored.

Secondly, well connection factors calculated in the SCHEDULE section depend on permeabilities using Peaceman's equation for example; if the connection factor or permeability thickness is specified in [COMPDAT](#) then these terms do not contribute towards the permeability sensitivities.

## Dual porosity sensitivities: use of HMSIGMA

The keyword accounts for variation of the matrix-fracture coupling transmissibility whatever the recovery mechanism. Therefore, if the Gravity Drainage Model is active, then the derivatives calculated by ECLIPSE also account for variations in [SIGMAGDV](#) (the sigma factor for gravity drainage) as well as for [SIGMAV](#). The keyword HMSIGMA will be ignored if the dual porosity model is inactive ([RUNSPEC](#) keyword [DUALPORO](#)).

## Local grid refinement and coarsening options

By default, cells in local grid systems will be assigned HMxxxxxxx values from their parent global grid cells, unless explicitly defined for local cells between a [REFINE](#) / [ENDFIN](#) pair.

The correct gradients can only be obtained at present when all local grids are run in-place using keyword [LGRLOCK](#) in the SCHEDULE section. An error will be reported if this is not the case.

The gradient calculation is compatible with the Grid Coarsening option. You should ensure that the same HMxxxxxxx region numbers are assigned to all fine grid cells within a single coarse cell, and that any [HMMULTxx](#) modifiers apply equally to all fine grid cells within a single coarse cell.

The gradient calculation is also compatible with the Auto refinement option.

At present, it is not possible to obtain permeability sensitivities with the Local Grid Refinement option.

## Examples

### Example 1

ECLIPSE 100 only

With `NDIVIX=3`, `NDIVIY=3` and `NDIVIZ=3` specified in RUNSPEC keyword `DIMENS` and `MHISTM=1` and `NMHSTR=3` specified in RUNSPEC keyword `HMDIMS`. To set two Z-direction transmissibility multiplier parameters, set the appropriate keywords in the REGIONS section:

```
HMTRANZ
 3*0 3*1 3*2 /
HMTRANZ
 1 0 0 1 0 0 1 0 0
 2 0 0 2 0 0 2 0 0
 3 0 0 3 0 0 3 0 0 /
```

### Example 2

ECLIPSE 100 only

To specify zones within a local grid;

```
REFINE
'GAMMA' /
EQUALS
'HMPORVM' 2 1 24 1 8 3 3 / layer 2
'HMTRANX' 1 1 24 1 8 2 2 / layer 3
'HMTRANZ' 1 1 24 1 8 2 2 / layer 2
'HMTRANX' 2 1 24 1 8 3 3 / layer 3
'HMPORVM' 1 1 24 1 8 2 2 / layer 2
'HMSOWCR' 1 1 24 1 8 1 6 / layers 1 to 6
/
ENDFIN
```

and in the SCHEDULE section, specify;

```
LGRLOCK
'*' /
/
```

### Example 3

With `NDIVIX=3`, `NDIVIY=3`, `NDIVIZ=3`, `MHISTM=1`, and `NMHSTR=3`, to set two pore volume multiplier parameters, set the appropriate keywords in the REGIONS section:

```
HMPORVM
 3*0 3*1 3*2 /
HMPORVM
 1 0 0 1 0 0 1 0 0
 2 0 0 2 0 0 2 0 0
 3 0 0 3 0 0 3 0 0 /
```

## Radial grid DRV ratios

The keyword `HRFIN` can be used to dictate the size ratios of `DRV` values within radial local grids. The keyword should be placed after the keyword introducing the local grid (`RADFIN` or `RADFIN4`) and before the local grid data is terminated with `ENDFIN`.

`HRFIN` should be followed by `NR-1` values terminated with a slash (/), where `NR` is the number of cells in the refined grid in the radial direction as specified in keyword `RADFIN` (item 6) or `RADFIN4` (item 8). ECLIPSE sets the `DR` values for the refined cells in proportion to their respective ratios, scaling them to fit within the host cell and honoring the outer radius specified by `OUTRAD`.

If `HRFIN` is not specified, radial refinements are automatically given geometrically (ECLIPSE 100), or logarithmically (ECLIPSE 300), increasing `DR` values, unless the `DR` (or `DRV`) values are specified explicitly.

Local grid refinement is described in "[Local Grid Refinement and Coarsening](#)" in the *ECLIPSE Technical Description*.

### Example

Set up `DR` ratios for 5 radial sectors:

```

INRAD
0.25 /

OUTRAD
1000.0 /

HRFIN
2.0 3.0 4.0 7.0 /

```

## HSGRO

	SCHEDULE

The HWKRO keyword specifies the value of oil relative permeability at the maximum oil saturation within each grid block for scaling the (high salinity) water-wet oil relative permeability saturation tables.

The HWKRO keyword should only be used if oil is present in the model and if the end-point scaling, low salinity and surfactant wettability options have been selected via the RUNSPEC keywords [ENDSCALE](#), [LOWSALT](#) and [SURFACTW](#) respectively.

The HWKRO keyword should be followed by one real number for each grid block in the current input box specifying the maximum oil relative permeability. The data must be terminated by a slash (/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If the keyword HWKRO is omitted for some or all of the grid blocks in a model where it could be specified, the oil relative permeabilities at maximum oil saturation will default to the values defined in the appropriate relative permeability tables.

See "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for details of the end-point scaling procedure.

## HWPCW

## Scaled (high salinity) water-wet maximum oil-water capillary pressure

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The HWPCW keyword specifies the maximum value of oil-water capillary pressure for scaling the (high salinity) water-wet water-oil capillary pressure saturation tables.

The HWPCW keyword should only be used if water and oil are present in the model and if the end-point scaling and surfactant options have been selected via the RUNSPEC keywords [ENDSCALE](#) and [SURFACT](#) (or [SURFACTW](#)) respectively.

The HWPCW keyword should be followed by one real number for each grid block in the current input box specifying the maximum oil-water capillary pressure. The data must be terminated by a slash (/).

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If the keyword HWPCW is omitted for some or all of the grid blocks in a model where it could be specified, the maximum oil-water capillary pressures at connate water saturation will default to the values defined in the appropriate capillary pressure tables.

See "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for details of the end-point scaling procedure.

### Notes

- The HWPCW keyword should not be used in combination with the J-function option specified by the keywords [JFUNC](#) or [JFUNCR](#) because the J-function calculation is used to define the water capillary pressure scaling and any values defined by the input LPCW keyword will be ignored. In this case the maximum capillary pressure for each cell is reported in the INIT file.
- The HWPCW values used to scale the oil-water capillary pressure must be consistent with the capillary pressure values in the tables. In particular both must possess the same sign.

### Example

```

-- In the RUNSPEC section :
DIMENS
 1 7 3 /

## HWSNUM

**(High salinity) water-wet saturation function region numbers**

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by one integer for every grid block specifying the (high-salinity) water-wet saturation function region to which it belongs. The region number should not be less than 1 or greater than NTSFUN (see item 1 of keyword [TABDIMS](#)). The data must be terminated by a slash (/).

The (high salinity) water-wet saturation function region number specifies the saturation table (input using [SWFN](#), [SOF3](#) and related keywords in the PROPS section) to be used to calculate relative permeabilities and capillary pressures in each grid block.

If the [LOWSALT](#) option has also been specified, the water-wet curves are computed as a weighted average between the low salinity water-wet saturation functions ([LWSNUM](#) region numbers) and the high salinity water-wet saturation functions (HWSNUM region numbers). In this case, the salinity weighting factors are taken from the [LSALTFNC](#) keyword according to the region numbers specified by the [LSNUM](#) keyword.

The table number specified here also defines the associated table number for the [SURFADDW](#) keyword. This specifies the weighting between immiscible water-wet and oil-wet saturation functions as a function of adsorbed surfactant concentration. The HWSNUM keyword can be used only if the [SURFACTW](#) keyword has been entered in the RUNSPEC section.

Grid blocks are ordered with the X-axis index cycling fastest, followed by the Y- and Z-axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

---

**Note:** The HWSNUM keyword is an alias for the [SURFNUM](#) keyword. One of these keywords must be specified if the [SURFACTW](#) option has been specified.

The [LWSNUM](#) keyword is an alias for the [LSLTWNUM](#) keyword. One of these keywords must be specified if the [LOWSALT](#) and [SURFACTW](#) options have been specified.

The [LSNUM](#) keyword is an alias for the [LWSLTNUM](#) keyword. One of these keywords must be specified if the [LOWSALT](#) option has been specified.

---

**Example**

With NTSFUN=2 specified in keyword [TABDIMS](#) and NDIVIX=8, NDIVIY=6 and NDIVIZ=5 specified in RUNSPEC keyword [DIMENS](#):

```
HWSNUM
144*1 96*2 /
```

## HWSOGCR Scaled (high-salinity) water-wet critical oil-in-gas saturations

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The HWSOGCR keyword specifies the critical oil in gas saturation (that is, the largest oil saturation for which the oil relative permeability to gas is zero) within each grid block for scaling the (high-salinity) water-wet oil relative permeability to gas saturation tables.

The tabulated oil relative permeability to gas functions are scaled between the critical oil in gas saturation defined by the HWSOGCR keyword and the maximum oil saturation defined in terms of the minimum water and gas saturations using the [LSWL](#) and [SGL](#) keywords respectively.

The HWSOGCR keyword should only be used if gas is present in the model and if the end-point scaling and surfactant options have been selected via the RUNSPEC keywords [ENDSCALE](#) and [SURFACT](#) (or [SURFACTW](#)) respectively.

The HWSOGCR keyword should be followed by one real number for each grid block in the current input box specifying the critical oil in gas saturation. The saturation should be in the range 0.0 to 1.0 inclusive. The data must be terminated by a slash (/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If the keyword HWSOGCR is omitted for some or all of the grid blocks in a model where it could be specified, the critical oil in gas saturations for the (high salinity) water-wet oil relative permeability to gas calculations will default to the values defined in the appropriate relative permeability tables.

See "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for details of the end-point scaling procedure.

## HWSWL

## Scaled (high salinity) water-wet connate water saturations

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The HWSWL keyword specifies the connate water saturation (that is, the smallest water saturation in a water saturation function table) within each grid block for scaling the (high salinity) water-wet oil-water capillary pressure and oil relative permeability to water tables.

The tabulated oil-water capillary pressure functions are scaled linearly between the connate water saturation defined using the HWSWL keyword and the maximum water saturation defined using the [HWSWU](#) keyword.

The HWSWL keyword is also used for scaling the oil relative permeability curves.

If the connate water saturation has additionally been specified using the [HWSWLPC](#) keyword, this saturation end-point will be used instead for scaling the oil-water capillary pressure curves. The connate water saturation entered using HWSWL will then only be used to scale the oil relative permeability curves.

The HWSWL keyword should only be used if water is present in the model and if the end-point scaling and surfactant options have been selected via the RUNSPEC keywords [ENDSCALE](#) and [SURFACT](#) (or [SURFACTW](#)) respectively.

The HWSWL keyword should be followed by one real number for each grid block in the current input box specifying the connate water saturation. The saturation should be in the range 0.0 to 1.0 inclusive. The data must be terminated by a slash (/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If the keyword HWSWL is omitted for some or all of the grid blocks in a model where it could be specified, the connate water saturations for (high salinity) water-wet oil relative permeability and capillary pressure calculations will default to the values defined in the appropriate relative permeability tables.

See "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for details of the end-point scaling procedure.

## HWSWU

## Scaled high salinity (water-wet) saturation table maximum water saturations

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The HWSWU keyword specifies the maximum water saturation (that is, the highest water saturation in a water saturation function table) within each grid block for scaling the (high salinity) water-wet oil-water capillary pressure and water relative permeability saturation tables.

The maximum water saturation is used to scale both the oil-water capillary pressure and water relative permeability curves. The tabulated capillary pressure curves are linearly scaled between the connate water saturation defined using the [HWSWL](#) or [HWSWLP](#) keywords and the maximum water saturation defined using the HWSWU keyword. The tabulated water relative permeability curves are scaled between the critical water saturation defined using the [HWSWCR](#) keyword and the maximum water saturation defined using the HWSWU keyword.

The HWSWU keyword should only be used if water is present in the model and if the end-point scaling and surfactant options have been selected via the RUNSPEC keywords [ENDSCALE](#) and [SURFACT](#) (or [SURFACTW](#)) respectively.

The HWSWU keyword should be followed by one real number for each grid block in the current input box specifying the maximum water saturation. The saturation should be in the range 0.0 to 1.0 inclusive. The data must be terminated by a slash (/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If the keyword HWSWU is omitted for some or all of the grid blocks in a model where it could be specified, the maximum water saturations for the (high salinity) water-wet water relative permeability and capillary pressure calculations will default to the values defined in the appropriate relative permeability tables.

See "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for details of the end-point scaling procedure.

## HXFIN

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

## Local grid size ratios in x-direction

The keyword HXFIN can be used to dictate the size ratios of each cell in a local grid refinement. It should be placed after the CARFIN keyword introducing the local grid and before the terminating ENDFIN. HXFIN applies only to Cartesian refinements.

HXFIN should be followed by NX values, where NX is the total number of cells in the refined grid along the X-direction as specified in keyword CARFIN item 8. The values represent the X-direction size ratios for each the refined grid cells.

You may default the size ratios for **all** the refined cells belonging to a particular host cell. If no ratios are given for a host cell, it is divided up in equal proportions. Each host cell must have the size ratios of its constituent refined cells either all set or all defaulted.

Local grid refinement is described in "[Local grid refinement and coarsening](#)" in the *ECLIPSE Technical Description*.

### Example

To divide a host grid of 3 layers into a refined grid of 7 layers, with splitting ratios defined for the middle layer of the host grid:

```
NXFIN
3 2 2 /
HXFIN
3* 1.0 2.0 2* /
```

## HYDRHEAD Sets reference data for output of hydraulic heads

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises reference data that is used if either HYDH or HYDHFW is requested in the [RPTRST](#) keyword, or one of the SUMMARY section keywords writing out head data is requested. The record consists of some or all of the following data items, and is terminated by a slash (/).

1. The reference depth for hydraulic head calculation.  
UNITS: m (METRIC), ft (FIELD), cm (LAB)
2. The density of freshwater. Only needed if HYDHFW requested or another freshwater head.  
UNITS: kg/m<sup>3</sup> (METRIC), lb/ft<sup>3</sup> (FIELD), gm/cc (LAB)
3. Do you want to remove the depth terms from the block head calculation? YES or NO ?  
DEFAULT: NO

Heads are calculated using the formula

$$HEAD = z_{ref} - z + (p_w - p_{atm}) / (\rho g)$$

where

$z_{ref}$  is the reference depth (item 1)

$z$  is the depth of the grid block (or the well)

$p_w$  is the water phase pressure

$p_{atm}$  is the atmospheric pressure

$\rho$  is the density of water and

$g$  is the acceleration due to gravity.

If item 3 is set to YES the two depth terms are removed from the definition. Note that this only applies to the grid block heads output to restart files or the summary section. Well heads can be adjusted by using the [WHEDREFD](#) keyword.

### Example

```

HYDRHEAD
45.0000 999.0 /

```

## Define hydrocarbon type

In a run with  $N_c$  components, this keyword defines the component type. This keyword can be used with the [SOLID](#) option for predicting asphaltene precipitation (see "[Solid phase](#)" in the *ECLIPSE Technical Description*).

The keyword should be followed by  $N_c$  values. Each value should be one of the following:

N Non-hydrocarbon

H Hydrocarbon

P Paraffin

C Cyclic hydrocarbon (naphthene)

A Aromatic

DEFAULT: H

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

This keyword is used by the multiphase flash. For asphaltene precipitation, the heaviest hydrocarbon should be an aromatic.

### Example

For a four-component system with one EoS region:

```

.....
HYDRO
H H P A /
.....

```

## Local grid size ratios in z-direction

The keyword HZFIN can be used to dictate the size ratios of each cell in a local grid refinement. It should be placed after the [CARFIN](#) or [RADFIN](#) keyword introducing the local grid and before the terminating [ENDFIN](#).

HZFIN should be followed by NZ values, where NZ is the total number of cells in the refined grid along the Z-direction as specified in keyword [CARFIN](#) item 10, or [RADFIN](#) item 8. The values represent the Z-direction size ratios for each of the refined grid cells. You may default the size ratios for **all** the refined cells belonging to a particular host cell. If no ratios are given for a host cell, it will be divided up in equal proportions. Each host cell must have the size ratios of its constituent refined cells either all set or all defaulted.

The form of the input is analogous to [HXFIN](#) and [HYFIN](#).

## I

This section contains an alphabetic listing of keywords starting with the letter I.

## IHOST

## Groups LGRs together in the same process

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword is used to assign local grids manually to a process when using domain decomposition in a run containing LGRs. If the LGR is not assigned manually to a process, it will be automatically assigned to the process which has the smallest number of active refined cells already allocated to it. Declaring the largest LGRs first in the GRID section assists this facility.

The IHOST keyword must be placed after all the local grids have been defined in the GRID section (the keyword must appear after the last `ENDFIN` in the GRID section).

The data consists of a record for each local grid, each containing the following items of data and terminated with a slash (/). The set of records must end with a blank record, containing only a slash (/). The LGRs can be specified in any order. If an LGR does not appear in the IHOST keyword it will be assigned automatically to a process.

1. Local grid name
2. Process number

This should be an integer between 0 and NDMAIN ([item 1](#) in the RUNSPEC section keyword `PARALLEL`).

positive Assign the LGR to the specified process.

0 ECLIPSE will automatically assign the LGR to a process.

DEFAULT: 0

If any LGRs have been amalgamated using keyword `AMALGAM`, ECLIPSE will assign the whole amalgamation to the process assigned to the first LGR listed in that amalgamation.

## Example

```
IHOST
-- LGR      process
   'NORTH'   1 /
   'SOUTH'   2 /
   'EAST'    1 /
   'SOUTH'   0 / Any available process
   'CENTRAL' 0 / Any available process
/
```

## Requests IKU three-phase relative permeabilities

This keyword requests the use of the IKU three-phase relative permeability model. This is applied to all three phases. For the water phase, both water-oil and water-gas tables must be entered using the [SWF3](#) keyword (rather than [SWFN](#)). For the gas phase, both gas-oil and gas-water tables must be entered using the [SGF3](#) keyword (rather than [SGFN](#)).

The IKU method can be used with endpoint scaling. In this case the usual critical water and gas saturation values ([SWCR](#), [SGCR](#)) are interpreted as critical water and gas in oil. Critical water in gas values are entered with [SWGCR](#); critical gas in water values are entered with [SGWCR](#).

The IKU method combines the two-phase contributions (for example  $K_{rgo}$  and  $K_{rgw}$  in the case of  $K_{rg}$  using a saturation weighting. The look-up for the two contributions is done using a normalized saturation, scaled to a common critical saturation. The critical saturation is an average of that of the individual curves, using a geometric construction in the saturation ternary diagram.

Note that specifying [SOF3](#), [SWF3](#) and [SGF3](#) with [RPTPROPS](#) will output the three-phase relative permeabilities for the oil, water and gas phases, respectively.

At present the IKU relative permeability technique cannot be used with hysteresis or miscibility. Water and gas saturation tables cannot be plotted with [GRAF](#) with this option. The IKU model is described in "[IKU method](#)" in the *ECLIPSE Technical Description*.

## Imbibition saturation function region numbers

This keyword is used in runs in which the hysteresis option is being used (see the item **HYSTER** in the **SATOPTS** keyword). It specifies which saturation table is to be used for each cell for imbibition processes. The usual saturation table numbers specified using the **SATNUM** keyword are used for drainage processes and equilibration.

The keyword should be followed by one integer for every grid block in the current input box, specifying the saturation function region to which it belongs. The region number should not be less than 1 or greater than **NTSFUN** (item 1 in the **TABDIMS** keyword). The data must be terminated by a slash (/).

The saturation function region number specifies which set of saturation functions (input using either: **SGFN**, **SO2**, **SO3**, **SO32D** and **SWFN**, or: **SGOF**, **SLGOF** and **SWOF** in the **PROPS** section) should be used to calculate relative permeabilities and capillary pressures in each grid block when hysteresis is being used.

If hysteresis is required in only part of the reservoir, the hysteresis model can be switched off in specific grid blocks by setting their **IMBNUM** numbers equal to their **SATNUM** numbers.

Further forms of this keyword allow an imbibition saturation table number to be specified for each face of a grid block, when using directional relative permeabilities. These table numbers specify the saturation table numbers used during imbibition processes to calculate relative permeabilities for flows out of a grid block across the six grid block faces (+X, -X, +Y, -Y, +Z, -Z). These forms are:

**IMBNUMX** Imbibition saturation table numbers for the +X face of a grid block

**IMBNUMX-** Imbibition saturation table numbers for the -X face of a grid block

**IMBNUMY** Imbibition saturation table numbers for the +Y face of a grid block

**IMBNUMY-** Imbibition saturation table numbers for the -Y face of a grid block

**IMBNUMZ** Imbibition saturation table numbers for the +Z face of a grid block

**IMBNUMZ-** Imbibition saturation table numbers for the -Z face of a grid block

The saturation tables used during drainage processes are specified with the equivalent form of the **KRNUM** keyword.

In a radial grid, alternative forms should be used for flows in the radial and azimuthal directions:

**IMBNUMR** Imbibition saturation table numbers for the +R face of a grid block

**IMBNUMR-** Imbibition saturation table numbers for the -R face of a grid block

**IMBNUMT** Imbibition saturation table numbers for the +T face of a grid block

**IMBNUMT-** Imbibition saturation table numbers for the -T face of a grid block

The +T direction is that of increasing azimuthal angle. The **IMBNUMX** and **IMBNUMZ** keywords are the same in both radial and Cartesian grids.

None of the directional imbibition saturation table keywords (**IMBNUM** and related keywords) should be used unless **DIRECT** is selected in **RUNSPEC** keyword **SATOPTS**. **IMBNUMX**, **IMBNUMY-** and **IMBNUMZ-** should only be used if **IRREVERS** is also selected in **SATOPTS**. If **IRREVERS** is not selected,

the saturation tables specified `IMBNUMX` are used for both the +X and -X faces of each grid block. Similarly `IMBNUMY` is used for the +Y and -Y faces, and `IMBNUMZ` for the +Z and -Z faces.

If a table number is defaulted for any grid cell, the table number is filled in using the data entered under the `IMBNUM` keyword.

ECLIPSE 100

The imbibition region numbers can be modified during the simulation by re-specifying the `IMBNUM` keyword in the `SCHEDULE` section. This procedure should only be carried out with care and is **not** recommended in general.

ECLIPSE 300

If the `ODD3P` relative permeability and capillary pressure hysteresis model has been selected, the `IMBNUM` keyword should not be used. Instead, the primary, secondary hysteresis and tertiary hysteresis saturation region numbers should be specified using the `PSTNUM`, `ISTNUM` and `DSTNUM` keywords respectively.

In all cases blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*2).

Note that spaces must not be inserted on either side of the asterisk.

ECLIPSE 100

---

**Note:** If the `IMBNUM` keyword is not specified when the hysteresis option has been selected, the imbibition saturation region numbers will be defaulted to 1.

---

ECLIPSE 300

---

**Note:** If the `IMBNUM` keyword is not specified when the hysteresis option has been selected, an error condition will be reported and program execution will terminate.

---

See also the keywords `IMBNUMMF`, `EHYSTR` and `HYSTCHCK`.

See "[Hysteresis](#)" in the *ECLIPSE Technical Description* for further information.

## Example

With `NTSFUN=2` specified in keyword `TABDIMS`; `NDIVIX=10`, `NDIVIY=6` and `NDIVIZ=2` specified in `RUNSPEC` keyword `DIMENS`; and no input `BOX` set:

```
IMBNUM
50*1 70*2 /
```

## IMBNUMMF Matrix-fracture imbibition region numbers

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is optional, and only concerns dual porosity runs (keyword [DUALPORO](#) in [RUNSPEC](#)) using the hysteresis option (item [HYSTER](#) in keyword [SATOPTS](#)).

The keyword allows the independent specification of the matrix-fracture imbibition saturation tables. ECLIPSE uses the upstream mobilities to calculate the flows, so

- flow from the matrix to the fracture reflects the imbibition table specified for the matrix (top half of the grid), and
- flow from the fracture to the matrix reflects the imbibition table specified for the fracture (bottom half of the grid).

If a table number is defaulted for any grid cell, the table number is filled in using the data entered under the [IMBNUM](#) keyword.

The keyword should be followed by one integer for every grid block in the current input box, specifying its imbibition table region number for matrix- fracture flow. The region number should not be less than 1 or greater than [NTSFUN](#) (keyword [TABDIMS](#)). The data must be terminated by a slash (/).

In all cases blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

See "[Dual porosity](#)" and "[Hysteresis](#)" in the *ECLIPSE Technical Description* for further information.

## IMKRVD

## Imbibition relative permeability end-point versus depth tables

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The different forms of this keyword specify the depth variation of the relative permeability for the imbibition saturation tables. The corresponding drainage relative permeabilities can be set by using the [ENKRVD](#) keyword.

Seven keywords are provided to allow the relative permeability end-points within each grid cell to be scaled independently. These keywords are:

**IMKRVD** Relative permeability end-points for the non-directional saturation function tables

**IMKRVDX** Relative permeability end-points for the +X face of each grid cell

**IMKRVDX-** Relative permeability end-points for the -X face of each grid cell

**IMKRVDY** Relative permeability end-points for the +Y face of each grid cell

**IMKRVDY-** Relative permeability end-points for the -Y face of each grid cell

**IMKRVDZ** Relative permeability end-points for the +Z face of each grid cell

**IMKRVDZ-** Relative permeability end-points for the -Z face of each grid cell

In radial grids the same directional keywords should be used to represent the relative permeability end-points for flows in the +R,-R,+T,-T,+Z,-Z directions respectively.

The keywords can only be used when both the End Point Scaling and Hysteresis options are in use (see keywords [ENDSCALE](#) and [SATOPTS](#) in the [RUNSPEC](#) section).

The data comprises [NTENDP](#) (item 3 of keyword [ENDSCALE](#)) tables of relative permeability end-points versus depth, one for each end-point scaling region. Each table consists of 8 columns of data, and must be terminated by a slash (/).

1. Depth values.

The values should increase monotonically down the column.

UNITS: m ([METRIC](#)), ft ([FIELD](#)), cm ([LAB](#))

2. The corresponding values of the maximum water relative permeabilities.
3. The corresponding values of the maximum gas relative permeabilities.
4. The corresponding values of the maximum oil relative permeabilities.
5. Water relative permeability at the critical oil (or gas) saturation.
6. Gas relative permeability at the critical oil (or water) saturation.
7. Oil relative permeability at the critical gas saturation.
8. Oil relative permeability at the critical water saturation.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than [NSENDP](#) (item 4 of keyword [ENDSCALE](#)). If an end-point is defaulted for all depth values, in a problem where a value could correctly be defined, then the end-point for each cell in the same scaling region is the value in the appropriate saturation function table. However if an end-point is defaulted

at a certain depth but has been defined at other depths, the end-point versus depth table is filled in by linear interpolation within the table and constant extrapolation at the ends of the table. End point values entered for absent phases are ignored.

If both directional and irreversible end-point scaling is requested using switches 'DIRECT' and 'IRREVERS' in `ENDSCALE`, then the relative permeability end-points for flow across the +X and -X faces of a grid cell are set using the keywords `IMKRVDX`, `IMKRVDX-`. Similarly `IMKRVDY`, `IMKRVDY-` are used for the +Y, -Y faces and the keywords `IMKRVDZ`, `IMKRVDZ-` for the +Z, -Z faces. Scaling of the well connection relative permeability tables is performed using the `IMKRVD` keyword.

When the end-point scaling is directional and reversible ('DIRECT' but not 'IRREVERS' is specified in `ENDSCALE`), the keyword `IMKRVDX` defines the relative permeability end-points for the +X and -X faces of each grid cell. Keywords `IMKRVDY`, `IMKRVDZ` are used for both the +Y, -Y faces and the +Z, -Z faces of each grid cell respectively. Scaling of well connection relative permeability tables is performed using the `IMKRVD` keyword.

If `ENDSCALE` is specified without either switch 'DIRECT' or 'IRREVERS', then none of the directional forms of the `IMKRVD` keyword are allowed. The `IMKRVD` keyword then defines the new relative permeability end-points for flow out of each grid cell face, and the well connection relative permeabilities.

See also keyword `ENDNUM` in the `REGIONS` section, and keywords `ENKRVD` and `IMPTVD` in the `PROPS` section.

	SCHEDULE

This keyword allows you to specify the depth variation of the imbibition maximum capillary pressure for different end-point scaling regions within the reservoir. The keyword can only be used when the end-point scaling option is active (keyword [ENDSCALE](#) in the [RUNSPEC](#) section) together with the hysteresis model (switch 'HYSTER' in [RUNSPEC](#) section keyword [SATOPTS](#)). The corresponding drainage table data is specified using keyword [ENPCVD](#).

The data comprises [NTENDP](#) (item 3 of keyword [ENDSCALE](#)) tables of maximum capillary pressure end-points versus depth, one for each end-point scaling region. Each table consists of 3 columns of data, and must be terminated by a slash (/).

1. Depth values.

The values should increase monotonically down the column.

UNITS: m ([METRIC](#)), ft ([FIELD](#)), cm ([LAB](#))

2. The corresponding values of the maximum gas-oil capillary pressure.

UNITS: bars ([METRIC](#)), psi ([FIELD](#)), atm ([LAB](#))

3. The corresponding values of the maximum water-oil capillary pressure.

UNITS: bars ([METRIC](#)), psi ([FIELD](#)), atm ([LAB](#))

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than [NSENDP](#) (item 4 of keyword [ENDSCALE](#)). If a maximum capillary pressure is defaulted for all depth values, in a problem where a value could correctly be defined, then the end-point for each cell in the same scaling region is the value in the appropriate saturation function table. However, if a maximum capillary pressure is defaulted and the end-point has been defined at other depths, the end-point versus depth table is filled in by linear interpolation within the table and constant extrapolation at the ends of the table. End point values entered for absent phases are ignored.

## Selects the IMPES solution option

This keyword selects the IMPES Solution option. Under IMPES (IMplicit Pressures, EXplicit Saturations), only the cell pressures are solved in coupled form at each iteration, the saturation and composition variables being held constant in the interblock flows. These are then updated at the end of the timestep, once the new pressure values are known.

See "[Formulation of the Equations](#)" in the *ECLIPSE Technical Description* for more information.

IMPES contains no items.

- When using ECLIPSE 300, the maximum rate of change of capillary pressure in explicit cells specified by the [DPCDT](#) keyword, which is assumed to be active by default for the IMPES solution method, should be reviewed and checked for compatibility with the magnitudes of the oil-water and gas-oil capillary pressures specified via the saturation functions.
- The IMPES solution option cannot be used in conjunction with the [PARALLEL](#) option in ECLIPSE 100.
- The [DIMPES](#) keyword in the SCHEDULE section can be used to dynamically set the IMPES solution procedure in ECLIPSE 100.

## Import data

This keyword enables values such as porosities and permeabilities to be imported from an INIT file. The keyword contains two records, each terminated by a slash (/).

The first record contains the filename, where the extension of the file specifies the type and format of the file.

There are currently two choices of file name extensions:

- INIT binary input
- FINIT formatted input (ASCII)

The file must be in a format as given by output from an ECLIPSE simulation.

The second record contains the list of arrays to be read.

The keyword can be used for fast initialization of the grid arrays. This is especially useful when running [SECTOR](#) models.

---

**Note:** In order to obtain the correct information from the INIT file, this keyword also requires the grid file. The EGRID file, if present, is used in preference to the GRID file.

---

### Example

```

-- Import from OLDCase.INIT
IMPFIL
  'OLDCase.INIT' /
  PORO PERMX PERMY PERMZ /

```

## IMPLICIT

### Sets the solution procedure to fully implicit

This keyword sets the solution procedure to IMPLICIT for the whole simulation.

Use of the `DIMPLICIT` keyword in the SCHEDULE section is preferred. Please consult this keyword for more information.

#### Example

```
IMPLICIT
```

## Imports grid file data

The `IMPORT` keyword specifies the name of the binary file to be imported from a grid pre-processor at the current position in the data file.

When used in the `GRID` section, this keyword supplies an equivalent input for data generated using a grid pre-processor, which would otherwise be specified by keywords with associated formatted data.

This keyword can also be used to import binary data from other programs in single or double precision.

The keyword should be followed by the following items of data:

1. Name of import file

The file name should not exceed 72 characters in length.

2. Formatted flag

There are two choices:

`FORMATTED`    formatted file

`UNFORMATTED` unformatted file

The word may be shortened to `F` or `U`.

DEFAULT: `UNFORMATTED`

The data should be terminated by a slash (/).

See also the [GDFILE](#) keyword.

### Example

This entry causes ECLIPSE to import grid data from the unformatted file `ROCK.GRDBIN`. At the end of that file, ECLIPSE switches back to the next keyword in the current file.

```
IMPORT
ROCK.GRDBIN /
```

## IMPSAT

### The IMPSAT solution option

This keyword selects the IMPSAT solution option. This treats pressure and phase saturations implicitly, but phase compositions explicitly. This method is ideal for runs involving large capillary pressures, which would cause instability in [IMPES](#) or [AIM](#) methods.

## Imbibition end-point versus depth tables

The different forms of this keyword specify the depth variation of the imbibition table end-points for different end-point scaling regions within the reservoir. The corresponding drainage table end-points are specified using the [ENPTVD](#) keyword.

Seven keywords are provided to allow the saturation end-points within each grid cell to be scaled independently. These keywords are:

IMPTVD Saturation end-points for the non-directional saturation function tables

IMPTVDX Saturation end-points for the +X face of each grid cell

IMPTVDX- Saturation end-points for the -X face of each grid cell

IMPTVDY Saturation end-points for the +Y face of each grid cell

IMPTVDY- Saturation end-points for the -Y face of each grid cell

IMPTVDZ Saturation end-points for the +Z face of each grid cell

IMPTVDZ- Saturation end-points for the -Z face of each grid cell

In radial grids the same directional keywords should be used to represent the saturation end-points for flows in the +R,-R,+T,-T,+Z,-Z directions respectively.

The keywords can only be used when both the end-point scaling and hysteresis options are in use (see keywords [ENDSCALE](#) and [SATOPTS](#) in the [RUNSPEC](#) section).

The data comprises NTENDP ([item 3](#) of keyword [ENDSCALE](#)) tables of saturation end-points versus depth, one for each end point scaling region. Each table consists of 9 columns of data, and must be terminated by a slash (/).

1. Depth values.

The values should increase monotonically down the column.

UNITS: m ([METRIC](#)), ft ([FIELD](#)), cm ([LAB](#))

2. The corresponding values of the connate water saturation.
3. The corresponding values of the critical water saturation.
4. The corresponding values of the maximum water saturation.
5. The corresponding values of the connate gas saturation.
6. The corresponding values of the critical gas saturation.
7. The corresponding values of the maximum gas saturation.
8. The corresponding values of the critical oil-in-water saturation.
9. The corresponding values of the critical oil-in-gas saturation.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSENDP ([item 4](#) of keyword [ENDSCALE](#)). Each saturation entry should be in the range 0.0 to 1.0 inclusive. If a saturation end-point is defaulted for all depth values, in a problem where a value could correctly be defined, then the end-point for each cell in the same scaling region is the value in

the appropriate saturation function table. However if a saturation end-point is defaulted and the end-point has been defined at other depths, the end-point versus depth table is filled in by linear interpolation within the table and constant extrapolation at the ends of the table. End point values entered for absent phases are ignored.

If both directional and irreversible end-point scaling is requested using switches 'DIRECT' and 'IRREVERS' in [ENDSCALE](#), then the saturation end-points for flow across the +X and -X faces of a grid cell are set using the keywords `IMPTVDX`, `IMPTVDX-`. Similarly `IMPTVDY`, `IMPTVDY-` are used for the +Y, -Y faces and the keywords `IMPTVDZ`, `IMPTVDZ-` for the +Z, -Z faces. Scaling of the well connection relative permeability tables and capillary pressure functions for equilibration are performed using the `IMPTVD` keyword.

When the end-point scaling is directional and reversible ('DIRECT' but not 'IRREVERS' is specified in [ENDSCALE](#)), the keyword `IMPTVDX` defines the saturation end-points for the +X and -X faces of each grid cell. Keywords `IMPTVDY`, `IMPTVDZ` are used for both the +Y, -Y faces and the +Z, -Z faces of each grid cell respectively. Scaling of well connection relative permeability tables and capillary pressure tables for equilibration are performed using the `IMPTVD` keyword.

If [ENDSCALE](#) is specified without either switch 'DIRECT' or 'IRREVERS', then none of the directional forms of the `IMPTVD` keyword are allowed. The `IMPTVD` keyword then defines the new saturation end-points for flow out of each grid cell face, for well connection relative permeabilities and for capillary pressure evaluations in the equilibration algorithm.

See also keyword [ENDNUM](#) in the [REGIONS](#) section, and keywords [ENPTVD](#) and [IMKRVD](#) in the [PROPS](#) section.

	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword scales the connate water or gas end-point of the imbibition capillary pressure curves without scaling the corresponding oil relative permeability curves. The connate saturations are entered as functions of depth for different end-point scaling regions within the reservoir. The keyword can only be used when the end-point scaling option is active (keyword `ENDSCALE` in the `RUNSPEC` section) together with the hysteresis model (switch 'HYSTER' in `RUNSPEC` section keyword `SATOPTS`). The corresponding drainage table data is specified using keyword `ENSPCVD`.

The data comprises `NTENDP` (item 3 of keyword `ENDSCALE`) tables of connate saturation end-points versus. depth, one for each end-point scaling region. Each table consists of 3 columns of data, and must be terminated by a slash (/).

1. Depth values.

The values should increase monotonically down the column.

UNITS: m (`METRIC`), ft (`FIELD`), cm (`LAB`)

2. The corresponding values of the connate gas saturation.

3. The corresponding values of the connate water saturation.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than `NSENDP` (item 4 of keyword `ENDSCALE`). If a saturation end-point is defaulted for all depth values, in a problem where a value could correctly be defined, then the end-point for each cell in the same scaling region is the value in the appropriate saturation function table. However if a saturation end-point is defaulted and the end-point has been defined at other depths, the end-point versus depth table is filled in by linear interpolation within the table and constant extrapolation at the ends of the table. End-point values entered for absent phases are ignored.

See also keyword `ENDNUM` in the `REGIONS` section, and the keywords `ENSPCVD`, `SWLPC` and `SGLPC` in the `PROPS` section.

### Example

```

## Include the contents of another named file

The keyword should be followed by the name of a file from which input is to be taken. This file will be opened, and read to the end of the file unless an **ENDINC** keyword is encountered. The file is then closed, and input resumed from the main file, starting from the next keyword after the **INCLUDE** keyword.

The **INCLUDE** file name may have up to 132 characters.

The data should be terminated by a slash (/).

Nested **INCLUDE** files are possible.

**INCLUDE** files have restrictions when used in the **RUNSPEC** section.

### Examples

#### Example 1

This example causes the program to continue input from the file `CASE1.PVI`. At the end of that file, the program switches back to the next keyword in the current file.

```
INCLUDE
CASE1.PVI /
```

#### Example 2

Take input from the `CASE.PVI` file in the `Includes` directory:

```
INCLUDE
'Includes/CASE1.PVI' /
```

## Requests output of an INIT file

The INIT file contains a summary of data entered in the GRID, PROPS and REGIONS sections.

If this keyword is included in the GRID section, the program writes out an Initial Data file, containing grid properties and saturation table data, which can be read into the graphics packages.

The file may be formatted (for transfer between computers with different operating systems, or just for readability), or unformatted (the default). If the [FMTOUT](#) keyword is used in the RUNSPEC section, the INIT file will be formatted.

In ECLIPSE 100, if the INIT keyword is used, the INIT file will **not** contain the VE geometry data, as this can make the INIT file very large.

For ECLIPSE 100, See the [FILLEPS](#), and RUNSPEC section keyword [INSPEC](#).

The INIT keyword has no associated data.

## INRAD

## Inner radius for radial geometry or radial local grid refinements

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The INRAD keyword has two main uses. It can either

- Specify the inner radius of the reservoir if radial geometry is used (the [RADIAL](#) keyword must be specified in the RUNSPEC section) or
- Specify the inner radius of the radial refinement (the INRAD keyword must be placed within the appropriate [RADFIN](#) / [ENDFIN](#) bracket).

In either case, this keyword should be followed by a single positive real number defining the inner radius, and a slash (/).

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: 0.5 ft = 0.1524 m

INRAD is required only if a radial system is specified using block centered geometry.

### Notes

Another way to specify the inner radius of a radial refinement is to use the [RADFIN](#) keyword. item 10 of the [RADFIN](#) keyword can be used to specify this value. If this value is defaulted, or if you wish to overwrite a previously specified value, then the INRAD keyword can be used. The INRAD keyword should be placed within the [RADFIN](#) / [ENDFIN](#) bracket so that the refinement will use this data accordingly.

See also "[Defining radial local grid refinements](#)" in the *ECLIPSE Technical Description*.

### Example

```
INRAD
0.2 /
```

## INSPEC

### Request an initial index file

This keyword requests that an Initial Index file should be written to describe the arrays in the [INIT](#) file. By default, an Initial Index file is always written, but this can be disabled by using the [NOINSPEC](#) keyword.

See "[File handling in ECLIPSE](#)" in the *ECLIPSE Technical Description*.

The keyword has no associated data.

x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used to activate the integrated capillary pressure option in dual porosity runs. The keyword should only be used in dual porosity runs with the gravity drainage option active (keywords [DUALPORO](#) and [GRAVDR](#) or [GRAVDRM](#) in the RUNSPEC section). The integrated  $P_c$  option modifies the input capillary pressure curves to improve the prediction of final oil recovery from a matrix block.

The keyword should be followed by one item of data terminated by a slash (/).

1. Phase flag:

WATER requests that the water-oil capillary pressure curves should be modified.

GAS requests that the gas-oil capillary pressure curves should be modified.

BOTH requests that both the water-oil and gas-oil capillary pressure curves should be modified.

DEFAULT: BOTH

If the INTPC keyword is not present, the curves are not modified.

See "[Dual porosity](#)" in the *ECLIPSE Technical Description* for a description of the integrated capillary pressure option.

---

**Note:** The INTPC option may now be used with the alternative gravity drainage model (GRAVDRM in the RUNSPEC section), as a new pseudoization specific to the GRAVDRM model is now automatically provided if that model is used. In previous versions this use was not advised as the new pseudoization was not available. In the event that unadvised use of INTPC with GRAVDRM was made with pre-2007.1 versions, its behavior can be restored with [item 107](#) in OPTIONS (ECLIPSE 100) or [item 126](#) in OPTIONS3 (ECLIPSE 300).

---

### Example

```
INTPC
  BOTH /

## IONROCK

## Rock ion exchange capacity

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword may only be used when the ECLIPSE 100 multi-component brine model (keyword [BRINE](#) in conjunction with keyword [ECLMC](#) in the RUNSPEC section) is active.

The IONROCK keyword defines the ion exchange capacity of the rock. This will be used in the cation exchange calculation. Refer also to keywords [IONXSURF](#) and [IONXROCK](#).

See "[Brine tracking](#)" in the *ECLIPSE Technical Description* for details of this option.

The keyword should be followed by one non-negative real number for every grid block in the current input box, specifying the rock ion exchange capacities. The data must be terminated by a slash (/).

The ion exchange capacity is entered in moles per unit pore volume.

UNITS: kg-M/rm<sup>3</sup> (METRIC), lb-M/rb (FIELD), gm-M/rcc (LAB)

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0.02). Note that spaces must not be inserted on either side of the asterisk.

## Example

```
IONROCK
200*0.05 /
```

## IONXROCK **Rock ion exchange constant**

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword may only be used when the ECLIPSE 100 multi-component brine model (keyword [BRINE](#) in conjunction with keyword [ECLMC](#) in the RUNSPEC section) is active.

The IONXROCK keyword activates ion exchange on rock surfaces and defines the ion exchange constant,  $\beta^r$ , in the exchange equilibrium expression

$$\frac{(C_{++})(C_+^r)^2}{(C_{++}^r)(C_+)^2} = \beta^r q^r \quad \text{Eq. 3.89}$$

where

$C_{++}$  denotes the divalent cation concentration

$C_+$  denotes the monovalent cation concentration

$C_{++}^r$  denotes the divalent cation concentration associated with the rock

$C_+^r$  denotes the monovalent cation concentration associated with the rock

$q^r$  denotes the rock ion exchange capacity

$\beta^r$  denotes the ion exchange constant

See "[Brine tracking](#)" in the *ECLIPSE Technical Description* for details of this option. IONXROCK must be used together with keyword [IONROCK](#) which defines the rock ion exchange capacity.

The keyword should be followed by NTSFUN records of data (see item 1 in keyword [TABDIMS](#)), each containing a single non-negative real number. Each record must be terminated by a slash (/).

UNITS: (kg-M/rm<sup>3</sup>)<sup>-1</sup> (METRIC), (lb-M/rb)<sup>-1</sup> (FIELD), (gm-M/rcc)<sup>-1</sup> (LAB)

DEFAULT: 0.0 (exchange equilibrium ignored)

### Example

For NTSFUN=2:

```

IONXROCK
-- beta
 0.25 /
 0.35 /

```

## IONXSURF Surfactant ion exchange constant

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword may only be used when the ECLIPSE 100 multi-component brine model (keyword [BRINE](#) in conjunction with keyword [ECLMC](#) in the RUNSPEC section) is active in conjunction with the Surfactant option (keyword [SURFACT](#) in the RUNSPEC section).

The IONXSURF keyword activates ion exchange on surfactant micelles and defines the surfactant equivalent molecular weight and the ion exchange constant,  $\beta^s$ , in the exchange equilibrium expression

$$\frac{(C_{++})(C_+^s)^2}{(C_+^s)(C_+)^2} = \beta^s C^s \quad \text{Eq. 3.90}$$

where

$C_{++}$  denotes the divalent cation concentration

$C_+$  denotes the monovalent cation concentration

$C_{++}^s$  denotes the divalent cation concentration associated with surfactant

$C_+^s$  denotes the monovalent cation concentration associated with surfactant

$C^s$  denotes the surfactant concentration

$\beta^s$  denotes the ion exchange constant

See "[Brine tracking](#)" in the *ECLIPSE Technical Description* for details of this option.

The keyword should be followed by NTSFUN records of data (see item 1 in keyword [TABDIMS](#)), each containing two non-negative real numbers. Each record must be terminated by a slash (/).

1. Equivalent molecular weight of surfactant.

UNITS: kg/kg-M (METRIC), lb/lb-M (FIELD), gm/gm-M (LAB)

DEFAULT: no default

2. Ion exchange constant.

UNITS: (kg-M/rm<sup>3</sup>)<sup>-1</sup> (METRIC), (lb-M/rb)<sup>-1</sup> (FIELD), (gm-M/rcc)<sup>-1</sup> (LAB)

DEFAULT: 0.0 (exchange equilibrium ignored)

**Note:** The equivalent molecular weight refers to the weight of surfactant per mole of “active sites”. A surfactant molecule may have more than one active anionic site. For example, a divalent surfactant with a molecular weight of 500 kg/kg-M has an equivalent weight of 250 kg/kg-M.

### Example

For NTSFUN=2:

```

IONXSURF
-- Mw beta

```

500	0.25	/
435	0.35	/

## ISGAS

## Run is gas condensate

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This optional keyword states that the run is a gas condensate. The keyword has three effects:

- Single phase hydrocarbon blocks are taken as gas. See also [FACTLI](#).
- The flash is simplified. When testing the stability of a single phase fluid, it is usual to do two tests, the first assuming the single phase is liquid, and the second assuming the single phase is vapor. However, when this keyword is used, only one test is performed, assuming the single phase fluid is a vapor. This simplification is justified if the fluid is not near the bubble point.
- Since single phase oil states cannot exist, there is no possibility of direct oil to gas transitions, and the near critical interpolation of  $K_{ro}$  and  $K_{rg}$  is not performed. (This interpolation is described in "[Near critical oil and gas relative permeabilities](#)" in the *ECLIPSE Technical Description*). See also [NOMIX](#).

ISGAS contains no items.

---

**Note:** ISGAS should not be used if the fluid is close to the bubble point. Otherwise there will be a sudden change in the vapor fraction from near zero to one as the pressure increases from just below the bubble point pressure to just above the bubble point pressure. This will cause problems in the simulation (unless the fluid is also near the critical point when the vapor and liquid properties are similar). Furthermore, the simplification in the flash calculation is no longer justified and may lead to some two phase states being incorrectly identified as one phase.

---

## ISTNUM

## Secondary hysteresis saturation function region numbers

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by one integer for every grid block in the current input box specifying the secondary hysteresis saturation function region to which it belongs. This keyword is used together with PSTNUM and DSTNUM if the ODD3P relative permeability and capillary pressure hysteresis model has been selected in the PROPS section. The region number should not be less than 1 or greater than NTSFUN (see keyword TABDIMS). The data must be terminated by a slash (/).

The secondary hysteresis saturation function region number specifies which set of saturation functions (input using SOF3, SGF3, and SWF3 in the PROPS section) should be used to calculate the secondary hysteresis relative permeabilities and capillary pressures in each grid block.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

For grid blocks for which the secondary hysteresis saturation function region numbers are not specified, the values will be assigned from those defined for the primary saturation function region numbers using the PSTNUM keyword. The ODD3P model is implicitly hysteretic. However, hysteresis may be deselected on a per grid block basis by setting the secondary and tertiary hysteresis saturation region numbers equal to the primary saturation region numbers.

See also the saturation function keywords SOF3, SGF3 and SWF3 in the PROPS section and the primary and tertiary hysteresis saturation region numbers PSTNUM and DSTNUM in the REGIONS section.

### Example

With NTSFUN=2 specified in keyword TABDIMS; NDIVIX=8, NDIVIY=6 and NDIVIZ=6 specified in RUNSPEC keyword DIMENS; and no input BOX set:

```
ISTNUM
144*1 96*2 /
```

## ISGL-OWCR Imbibition table end-points

## ISOLNUM

## Identifies extent of each independent reservoir region

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The ISOLNUM keyword defines the regions of the reservoir that are not connected by a flow path within the reservoir and should not be used in any other circumstances. The only coupling is by the well facilities (through group control). Once the isolated regions of the reservoir have been identified, ECLIPSE will solve them more efficiently as separate units, whose linear equations in general require different numbers of iterations to converge. (See "[Independent reservoir regions](#)" in the *ECLIPSE Technical Description*.)

The keyword should only be used if NRFREG has been set to a value greater than 1 in the RUNSPEC section keyword [REGDIMS](#).

The keyword should be followed by one integer for each grid cell in the full field, specifying the independent reservoir region number to which it belongs. The data must be terminated by a slash (/).

There must be at least one active cell allocated to each reservoir region between 1 and NRFREG. Any cells given a reservoir region number of 0 or > NRFREG are treated as inactive.

ECLIPSE can be made to output the ISOLNUM array for an existing model by specifying the [RPTISOL](#) keyword. The ISOLNUM array is output to the Debug file if there is more than one independent reservoir within the model.

### Example

Two layers separated by an inactive layer:

```
ISOLNUM
1200*1
1200*0
1200*2 /
```

## **J**

This section contains an alphabetic listing of keywords starting with the letter J.

# JALS

## Linear solver for thermal problems

	<b>ECLIPSE 100</b>
x	<b>ECLIPSE 300</b>
x	<b>SPECIAL</b>
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword controls the JALS linear solver that can dramatically reduce CPU times of thermal runs. The JALS linear solver is the default for thermal simulations. The use of the JALS linear solver is most likely to have a benefit for 'harder' problems.

The JALS linear solver employs the constrained pressure residual (CPR) technique in which an approximate pressure system is solved for each outer iteration. The solution of the pressure system is referred to as the inner iteration. The GMRES algorithm is used for both the outer and inner iteration. The GMRES algorithm is similar to the ORTHOMIN algorithm and requires storing a set of search directions.

The JALS solver can be enabled in two modes. In mode 2, the solver is generally more accurate and the simulation should require less linear iterations. However, the cost per linear iteration is higher in mode 2 than in mode 1. Since the total CPU time of a simulation is a product of both the number of linear iterations required and the CPU cost per linear iteration there may be circumstances where the model will run faster in mode 1.

With the JALS solver, the memory location for these search directions can either be the heap or the stack. By default, the storage location is the heap since this ensures a stable executable. Placing the search directions on the stack can yield a performance increase since memory allocation and access to the stack is generally faster. However, if the capacity of the stack is exceeded ECLIPSE will abort. On the Windows system, the size of the stack is fixed. On Linux systems, the stack size can often be configured and set unlimited. Please consult your systems administrator. It is recommended that initial runs are performed using the HEAP options.

By default, the JALS solver uses 20 outer iterations, 4 CPR iterations and no residual check (item 4 of JALS set to "OFF"). For some models, 20 iterations may not be enough. Setting item 4 of this keyword to "ON" will set the same number of iterations, but turn the residual check on so that an extra 20 iterations are allowed in any timestep where this check is triggered. Since this switch is checking that the linearized version of the problem has converged residuals, this forces additional non-linear iterations which may slow down a simulation run.

The keyword should be followed by up to four items, and must be terminated by a slash (/).

1. Switch for JALS solver
  - 2 Enabled in mode 2
  - 1 Enabled in mode 1
  - 0 Off

DEFAULT: 2
2. Memory location for inner iteration search directions
 

HEAP On the heap

STACK On the stack

DEFAULT: HEAP
3. Memory location for outer iteration search directions
 

HEAP On the heap

STACK On the stack

DEFAULT: HEAP

4. Use of residual check, or switch to previous version of JALS (either 2009.1 or 2008.3)

ON Residual check turned on

OFF Residual check turned off

DEFAULT: OFF

---

**Note:** It is currently not possible to use the JALS solver in a thermal dual porosity (or dual permeability) run containing local grid refinements.

---

## Example

```
JALS
2 HEAP HEAP OFF /
```

## JFUNC

## Activates the Leverett J-function option

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used to activate the Leverett J-function option, which scales the water-oil and/or gas-oil capillary pressure functions according to the grid block porosity and permeability. (See "[Leverett J-function](#)" in the *ECLIPSE Technical Description* for further details.)

The keyword may only be used if end-point scaling is switched on using the keyword [ENDSCALE](#) in the RUNSPEC section.

The keyword should be followed by some or all of the following items terminated by a slash (/):

1. J-function flag.

WATER Requests the J-function option for the water-oil capillary pressure only.

GAS Requests the J-function option for the gas-oil capillary pressure only.

BOTH Requests the J-function option for both water-oil and gas-oil capillary pressure.

DEFAULT: BOTH

2. Oil-water surface tension.

UNITS: dynes/cm (METRIC), dynes/cm (FIELD), dynes/cm (LAB), dynes/cm (PVT-M)

The oil-water surface tension must be supplied if the first data item is set to either WATER or BOTH.

3. Oil-gas surface tension.

UNITS: dynes/cm (METRIC), dynes/cm (FIELD), dynes/cm (LAB), dynes/cm (PVT-M)

The oil-gas surface tension must be supplied if the first data item is set to either GAS or BOTH.

4. Alternative power for the porosity term ( $\alpha$ )

DEFAULT: 1/2

5. Alternative power for the permeability term ( $\beta$ )

DEFAULT: 1/2

6. Permeability Direction

XY The average of [PERMX](#) and [PERMY](#) values

X [PERMX](#) value

Y [PERMY](#) value

Z [PERMZ](#) value

DEFAULT: XY

The J-function option scales the capillary pressure functions according to the rock porosity and permeability.

The dimensionless J-function is **entered in place of** the capillary pressure function, specified using either the [SWFN](#), [SGFN](#) or the [SWOF](#), [SGOF](#), [SLGOF](#) family of keywords (see information written for the third or fourth column of these keywords).

The capillary pressure is **then** calculated as follows:

$$P_c = J(S) \cdot ST \cdot \left( \frac{\text{Porosity}}{\text{Permeability}} \right)^{1/2} \cdot U_{\text{const}} \quad \text{Eq. 3.91}$$

where

$J(S)$  J-function entered in the capillary pressure column of the saturation function tables [SWFN](#) or [SGFN](#)

ST surface tension - data item 2 or 3

Porosity cell porosity

Permeability cell permeability

$U_{\text{const}}$  constant depending on the unit system employed

= 0.318316 (METRIC pressure: barsa perm: mD)

= 4.61678 (FIELD pressure: psia perm: mD)

= 0.314153 (LAB pressure: atma perm: mD)

= 0.314153 (PVT-M pressure: atma perm: mD).

If data item 6 is defaulted the permeability is taken as  $K = (K_x + K_y)/2$ , unless the model is a cross section, in which case  $K$  is taken as the appropriate horizontal permeability, or unless it is a one-dimensional model, in which the permeability is taken in the direction of the row or column of cells. In addition, irrespective of the permeability direction specified by item 6:

- if the numbers of cells in the x and y directions are both equal to 1, the z-direction permeability values will be used
- if the number of cells in the x direction only is equal to 1, the y-direction permeability values will be used
- if the number of cells in the y direction only is equal to 1 the x-direction permeabilities will be used.

---

**Note:** For the [INIT](#) file output, the above equation will define the output under the heading PCW or PCG. It is important to note that the capillary pressure chosen from the input table (SWFN or SGFN) will, by default, be the maximum value. If [item 74](#) in [OPTIONS](#) is used, then the minimum value will be used instead.

---

In the above equation, the scaling factor term is expressed as follows:

$$\text{Scaling Factor} = ST \cdot \left( \frac{\text{Porosity}}{\text{Permeability}} \right)^{1/2} \cdot U_{\text{const}} \quad \text{Eq. 3.92}$$

---

**Note:** The scaling factor will be output under the heading PCW or PCG in the [RPTPROPS](#) keyword. For ECLIPSE 100 only, the argument ENDPT must also be set in the [RPTPROPS](#) keyword.

---

If data items 4 or 5 are present the capillary pressure will be interpreted as follows:

$$P_c = J(S) \cdot ST \cdot \left( \frac{\text{Porosity}^\alpha}{\text{Permeability}^\beta} \right) \cdot U_{\text{const}}$$

ECLIPSE 100

If the surface tension is required to be a function of pressure then the pressure dependent capillary pressure option (STOW and STOG keywords) can be used to modify the surface tension. In gas-water cases, the JFUNC keyword should apply to the 'WATER' phase, and the oil-water surface tension is taken to be the gas-water surface tension. The gas-oil surface tension and scaling for gas-oil  $P_c$  is ignored. In this case:

$$P_c = J(S) \cdot ST \cdot \frac{ST(P)}{ST_{ref}} \cdot \left(\frac{Porosity}{Perm}\right)^{1/2} \cdot U_{const} \quad \text{Eq. 3.93}$$

where

ST(P) and  $ST_{ref}$  are input using the STOG or STOW keywords.

ECLIPSE 100

---

**Note:** If the SWATINIT keyword is used in conjunction with the JFUNC keyword, then the J-function scaling is ignored in regions of the field where the SWATINIT array has been set, and will use PPCWMAX instead if set. If the PCW keyword is used in conjunction with the JFUNC keyword, the input PCW array will be ignored when the J-function selects the water-oil capillary pressure. Similarly, if the PCG keyword is input, the input PCG array is ignored when the J-function selects the gas-oil capillary pressure. The maximum capillary pressure for each cell is reported to the INIT file. This is shown as PCW or PCG properties in the 3D Viewer.

---

JFUNC
WATER 22.0 /
```

## JFUNCR

## Activates the Leverett J-function option per saturation table

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used to activate the Leverett J-function option on a per saturation table basis, in order to scale either, both or neither the water-oil and the gas-oil capillary pressure functions according to the grid block porosity and permeability. This is an alternative to and extends the functionality of the [JFUNC](#) keyword which applies a single set of parameters to the entire reservoir model. (See "[Leverett J-function](#)" in the *ECLIPSE Technical Description* for further details.)

The JFUNCR keyword can only be used if end-point scaling has been selected using the keyword [ENDSCALE](#) in the RUNSPEC section.

The JFUNCR keyword comprises NTSFUN tables of data, where NTSFUN is defined by item 1 of the keyword [TABDIMS](#) in the RUNSPEC section. Each table consists of one row of data containing some or all of the following items, and terminated by a slash (/):

1. J-function flag.

WATER Requests the J-function option for the water-oil capillary pressure only.

GAS Requests the J-function option for the gas-oil capillary pressure only.

BOTH Requests the J-function option for both water-oil and gas-oil capillary pressure.

NONE Signifies that the water-oil and gas-oil capillary pressure values entered into the saturation function tables should be used directly without application of the Leverett J-Function scaling.

DEFAULT: BOTH

items 2 to 6 inclusive, which are defined below, are ignored and need not be specified if the first data item is set to NONE.

2. Oil-water surface tension.

UNITS: dynes/cm (METRIC), dynes/cm (FIELD), dynes/cm (LAB), dynes/cm (PVT-M)

The oil-water surface tension must be supplied if the first data item is set to either WATER or BOTH.

3. Oil-gas surface tension.

UNITS: dynes/cm (METRIC), dynes/cm (FIELD), dynes/cm (LAB), dynes/cm (PVT-M)

The oil-gas surface tension must be supplied if the first data item is set to either GAS or BOTH.

4. Power for the porosity term ( $\alpha$ )

DEFAULT: 0.5

5. Power for the permeability term ( $\beta$ )

DEFAULT: 0.5

6. Permeability direction

XY The average of [PERMX](#) and [PERMY](#) values

X PERMX value

Y PERMY value

Z PERMZ value

DEFAULT: XY

Table 1 must be specified. The contents of tables 2 onwards may be defaulted entirely whereupon the values will be copied from the corresponding values defined in the previous table.

The J-function calculation scales the capillary pressure functions according to the rock porosity and permeability. The dimensionless J-function values are **entered instead of** the capillary pressure values in the saturation function tables, specified using either the [SWFN](#), [SGFN](#) or the [SWOF](#), [SGOF](#), [SLGOF](#) family of keywords (see the description of capillary pressure defined in the final columns of these keywords).

When the dimensionless J-Function values are specified instead of the capillary pressure values in the saturation function tables, the capillary pressure is calculated according to the expression:

$$P_c = J(S) \cdot S_f \quad \text{Eq. 3.94}$$

where the scaling factor  $S_f$  is defined by the expression:

$$S_f = ST \cdot \left( \frac{\text{Porosity}^\alpha}{\text{Perm}^\beta} \right) \cdot U_{\text{const}} \quad \text{Eq. 3.95}$$

where:

$J(S)$  J-function values from the input saturation tables

ST Surface tension - data item 2 or 3

Porosity Cell porosity

Perm Cell permeability

$\alpha$  Porosity power

$\beta$  Permeability power

$U_{\text{const}}$  is a constant which depends upon the unit system employed

= 0.318316 (METRIC pressure: barsa perm: mD)

= 4.61678 (FIELD pressure: psia perm: mD)

= 0.314153 (LAB pressure: atma perm: mD)

= 0.314153 (PVT-M pressure: atma perm: mD).

If data item 6 is defaulted, for a three-dimensional reservoir model, the permeability is calculated as the average of the x and y cell permeability values, that is,  $K = (K_x + K_y)/2$ . If the reservoir model is a cross section, the permeability value  $K$  is obtained from the appropriate horizontal permeability. For a one-dimensional model, the permeability value  $K$  is obtained from the permeability corresponding to the direction of the row or column of cells. In addition, irrespective of the permeability direction specified by item 6:

- if the numbers of cells in the x and y directions are both equal to 1, the z-direction permeability values will be used
- if the number of cells in the x direction only is equal to 1, the y-direction permeability values will be used
- if the number of cells in the y direction only is equal to 1 the x-direction permeabilities will be used.

For models which incorporate directional relative permeabilities, the J-function scaling factors for all directions will be the same and are calculated from the values defined in the JFUNC tables associated with the SATNUM array. The JFUNC tables associated with the directional drainage arrays KRNUMX, KRNUMX-, KRNUMY, KRNUMY-, KRNUMZ and KRNUMZ- will be ignored. Similarly for models which incorporate both hysteresis and directional relative permeabilities, the J-Function scaling factors for all directions will be the same and are calculated from the values defined in the JFUNC tables associated with the IMBNUM array. The JFUNC tables associated with the directional imbibition arrays IMBNUMX, IMBNUMX-, IMBNUMY, IMBNUMY-, IMBNUMZ and IMBNUMZ- are ignored.

Using the JFUNC keyword it is possible to specify a combination of regions some of which use J-function values and others of which use capillary pressure values in their associated saturation function tables. Care should be exercised, therefore, in order to ensure that the type of data in the capillary pressure column in each of the saturation function tables matches the corresponding specification for that region in the JFUNC keyword.

The input values specified in the JFUNC keyword may be output by including the option JFUNC with the RPTGRID keyword.

The scaled tables may be inspected and verified upon a per grid block basis by means of the diagnostic output specified via the EPSDEBUG keyword.

---

**Note:** For the INIT file output, the above equation will define the output under the heading PCW or PCG. It is important to note that the capillary pressure chosen from the input table (SWFN or SGFN) will, by default, be the maximum value. If item 74 in OPTIONS is used, then the minimum value will be used instead.

---

---

**Note:** The scaling factor will be output under the heading PCW or PCG in the RPTPROPS keyword. For ECLIPSE 100 only, the argument ENDPT must also be set in the RPTPROPS keyword.

---

ECLIPSE 100

If the surface tension is required to be a function of pressure, the pressure dependent capillary pressure option (STOW and STOG keywords) can be used to modify the surface tension. In gas-water cases, the JFUNC keyword should apply to the water phase, and the oil-water surface tension is taken to be the gas-water surface tension. The gas-oil surface tension and scaling for gas-oil Pc is ignored. In this case:

$$P_c = J(S) \cdot ST \cdot \frac{ST(P)}{ST_{ref}} \cdot \left( \frac{\text{Porosity}^\alpha}{\text{Perm}^\beta} \right) \cdot U_{const} \quad \text{Eq. 3.96}$$

where

ST(P) and ST<sub>ref</sub> are input using the STOG or STOW keywords.

---

**Note:**

ECLIPSE 100

If the SWATINIT keyword is used in conjunction with the JFUNC keyword, then the J-Function scaling is ignored in regions of the field where the SWATINIT array has been set, and will use PPCWMAX instead if set. If the PCW keyword is used in conjunction with the JFUNC keyword, the input PCW array will be

ignored when the J-function selects the water-oil capillary pressure. Similarly, if the `PCG` keyword is input, the input `PCG` array is ignored when the J-function selects the gas-oil capillary pressure.

---

## Example

With `NTSFUN=5`:

```
JFUNCR
BOTH  22.0 18.0 0.50 0.50 X /
GAS   1*   17.0 0.52 0.48 Y /
WATER 23.0 1*   0.54 0.46 Z /
/
NONE /
-- Table 4 copied from table 3
-- Capillary pressures taken directly from
-- region No 5 saturation function tables
```

## Gas relative permeability damage initiation

The KRGDI keyword specifies the molar density of individual components at which damage initiates, see the [KRGDM](#) keyword.

The data comprises NTSFUN rows of data (see item 1 of the [TABDIMS](#) keywords) each terminated by a slash (/).

Each row consists of N entries, where N = number of hydrocarbon components + the number of water components.

UNITS: kg-M/rm<sup>3</sup> (METRIC), lb-M/rb (FIELD), gm-M/rcc (LAB), kg-M/rm<sup>3</sup> (PVT-M)

### Example

With NTSFUN=2, 6 hydrocarbon components and 1 water component. Damage occurring due to the presence of the sixth hydrocarbon component at concentrations greater than 0.5.

```
KRGDI
5*0.0 0.5 0.0 /
5*0.0 0.5 0.0 /
```

## Gas relative permeability damage multipliers

The KRGDM keyword enables the gas relative permeability to be modified to account for formation damage. The KRGDM data consists of damage factors for each component tabulated against gas relative permeability. The modified relative permeability values are then computed as

$$K_{rg} = M_d K_{rg}'$$

where

$K_{rg}'$  is the relative permeability prior to the damage calculation and

$M_d$  is the damage multiplier given by

$$M_d = \prod_i \frac{1}{1 + D_i(K_{rg}') \times \max(0, Z_i - I_i)}$$

where the product is taken over all hydrocarbon and water components specified with the [COMPS](#) and [COMPW](#) keywords:

$D_i$  is the damage factor for a given  $K_{rg}'$  and component, found by interpolating the KRGDM data

$Z_i$  is the molar concentration of component  $i$  (moles per reservoir volume).

The component molar concentrations can be output in the SUMMARY section using the BMLSC and BMWAT keywords, and in the SOLUTION and SCHEDULE section using the MLSC and MWAT mnemonics in the [RPTRST](#), [RPTSOL](#), [RPTSCHED](#) keywords.

$I_i$  is the initial concentration at which damage occurs for a given component.

See the [KRGDI](#) keyword

The damage multiplier  $M_d$  can be written to the restart files by including the KRGDM item in the RPTRST keyword.

The data comprises NTSFUN tables (see item 1 of keyword [TABDIMS](#)) each terminated by a slash (/). The tables must have at least 2 but not more than NSSFUN rows of data (see item 3 of keyword [TABDIMS](#)).

Each table consists of N columns of data, where  $N = 1 + \text{number of hydrocarbon components} + \text{number of water components}$ :

Column 1	Gas relative permeability Values should be between 0 and 1 and should increase monotonically down the column.
Columns 2 to COMPS + 1	Damage factors for hydrocarbon components UNITS: (kg-M/rm <sup>3</sup> ) <sup>-1</sup> (METRIC), (lb-M/rb) <sup>-1</sup> (FIELD), (gm-M/rcc) <sup>-1</sup> (LAB)
Columns COMPS + 2 to COMPS + COMPW + 1	Damage factors for water components

UNITS: (kg-M/rm<sup>3</sup>)<sup>-1</sup> (METRIC), (lb-M/rb)<sup>-1</sup> (FIELD), (gm-M/rcc)<sup>-1</sup> (LAB)

---

**Note:** The damage factors must have values of zero or greater.

---

---

**Note:** The KRGD keyword is only allowed in compositional simulations.

---

## Example

## KRG-IKRGR Scaled end-point gas relative permeabilities

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The KRG, KRGR, IKRG and IKRGR keywords allow scaling of the relative permeability of gas within each grid block. KRG scales the  $K_r$  at the maximum gas saturation (typically at connate water), and KRGR scales the relative permeability at residual oil saturation (or critical water in a gas-water run). The keyword can only be used when the end-point scaling option is active (keyword [ENDSCALE](#) in the RUNSPEC section).

If the KRGR keyword has not been used, the KRG keyword has the effect of scaling the relative permeability value calculated from the appropriate saturation table after the scaled saturation end-points have been accounted for. Hence:

$$K_{rg} = K_{rg}(\text{Table}) \frac{\text{KRG}(\text{GridBlock})}{K_{rg\max}(\text{Table})} \quad \text{Eq. 3.97}$$

The relative permeability is taken to be the value at either the maximum saturation of the saturation table, or at SGU if this has been specified. This is usually equal to  $1 - S_{wco}$ .

If the KRGR keyword has been used, then the scaling honors the  $K_r$  at the critical saturation (SR) of the displacing phase. When the alternative scaling using three saturation nodes is invoked by keyword [SCALECRS](#), SR is given by

SR = 1 - SOGCR - SWL in gas/oil or gas/oil/water runs

SR = 1 - SWCR in gas/water runs

where SOGCR, SWL and SWCR are the scaled values. When the alternative scaling method is not employed, only the two nodes SGCR and SGU are used to scale the saturation endpoints, and SR is taken to be the transformed value of

$$\text{SR}(\text{Table}) = 1.0 - S_{ogcr}(\text{Table}) - S_{wco}(\text{Table})$$

or

$$\text{SR}(\text{Table}) = 1.0 - S_{wcr}(\text{Table}).$$

Hence the two cases are:

$$\text{SG} < \text{SR} \quad K_{rg} = K_{rg}(\text{Table}) \frac{\text{KRGR}(\text{GridBlock})}{(K_{rg}(\text{SR}))(\text{Table})} \quad \text{Eq. 3.98}$$

$$\text{SG} > \text{SR} \quad K_{rg} = \text{KRGR} + \frac{\text{KRG} - \text{KRGR}}{K_{rg\max} - K_{rg}(\text{SR})} (K_{rg}(\text{Table}) - K_{rg}(\text{SR})) \quad \text{Eq. 3.99}$$

Fourteen keywords are provided to allow the maximum gas relative permeability to be set for each grid cell independently. These keywords are:

KRG      Max gas  $K_r$  for the non-directional saturation function tables

KRGX     Max gas  $K_r$  for the +X face of each grid cell

KRGX-    Max gas  $K_r$  for the -X face of each grid cell

KRGY     Max gas  $K_r$  for the +Y face of each grid cell

KRGY-    Max gas  $K_r$  for the -Y face of each grid cell

KRGZ	Max gas $K_r$ for the +Z face of each grid cell
KRGZ-	Max gas $K_r$ for the -Z face of each grid cell
KRGR	$K_r$ at residual for the non-directional saturation function tables
KRGRX	$K_r$ at residual for the +X face of each grid cell
KRGRX-	$K_r$ at residual for the -X face of each grid cell
KRGRY	$K_r$ at residual for the +Y face of each grid cell
KRGRY-	$K_r$ at residual for the -Y face of each grid cell
KRGRZ	$K_r$ at residual for the +Z face of each grid cell
KRGRZ-	$K_r$ at residual for the -Z face of each grid cell

In radial grids the same directional keywords should be used to represent the gas  $K_r$  values for flows in the +R,-R,+T,-T,+Z,-Z directions respectively.

---

**Note:** None of the KRG keywords should be used if gas is not present in the model. The keyword [ENDSCALE](#) should be specified in the RUNSPEC section.

---

If both directional and irreversible end-point scaling is requested using switches 'DIRECT' and 'IRREVERS' in [ENDSCALE](#), then the maximum gas  $K_r$  values for flow across the +X and -X faces of a grid cell are set using the keywords KRGX, KRGX-. Similarly KRGY, KRGY- are used for the +Y,-Y faces and the keywords KRGZ, KRGZ- for the +Z,-Z faces.

When the end-point scaling is directional but reversible ('DIRECT' but not 'IRREVERS' is specified in [ENDSCALE](#)), the keyword KRGX defines the maximum gas  $K_r$  values for both the +X and -X faces of each grid cell. Keywords KRGY, KRGZ are used for both the +Y,-Y faces and the +Z,-Z faces of each grid cell respectively.

If [ENDSCALE](#) is specified without either switch 'DIRECT' or 'IRREVERS', then none of the directional forms of the KRG keyword are allowed. The KRG keyword then defines the maximum gas  $K_r$  value for flow across each grid cell face.

Each KRG keyword should be followed by one real number for each grid block in the current input box, specifying the maximum gas relative permeability value. The data must be terminated by a slash (/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If any of the KRG\* keywords are omitted in a model where they could be accepted, then the maximum gas  $K_r$  value defaults to the value used in the appropriate gas saturation function table.

If pure normalized curves are used where (1.0-SOGCR- SWL) is equal to SGU, then depending on the scaling option used (see the [SCALECRS](#) keyword) the two end-points may be equal. If this is the case both KRG and KRGR apply to the same point, and the KRGR keyword is ignored.

If the Hysteresis Model is active (see keyword [SATOPTS](#)), then the KRG, KRGR data scales the drainage curve. The imbibition curve can be scaled by using the equivalent IKRG (IKRGR, IKRGX, IKRGX-, ...) keyword.

See also keywords [SGU](#) and [ENKRVD](#) in the PROPS section.

Refer to "[Saturation Table Scaling](#)" of the *ECLIPSE Technical Description* for more information.

ECLIPSE 300

If the [ODD3P](#) relative permeability and capillary pressure hysteresis model is selected, this keyword will be ignored.

## Directional relative permeability table numbers

The different forms of this keyword allow a saturation table number to be specified for every face of every grid block. These table numbers specify which sets of saturation functions (input using either: [SGFN](#), [SOF2](#), [SOF3](#), [SOF32D](#) and [SWFN](#), or: [SGOF](#), [SLGOF](#) and [SWOF](#) in the PROPS section) should be used to calculate relative permeabilities for flows out of each grid block across the six grid block faces (+X, -X, +Y, -Y, +Z or -Z).

KRUNUMX Saturation table numbers for the +X face of each grid block

KRUNUMX- Saturation table numbers for the -X face of each grid block

KRUNUMY Saturation table numbers for the +Y face of each grid block

KRUNUMY- Saturation table numbers for the -Y face of each grid block

KRUNUMZ Saturation table numbers for the +Z face of each grid block

KRUNUMZ- Saturation table numbers for the -Z face of each grid block.

In a radial grid, alternative forms should be used for flows in the radial and azimuthal directions:

KRUNUMR Saturation table numbers for the +R face of each grid block

KRUNUMR- Saturation table numbers for the -R face of each grid block

KRUNUMT Saturation table numbers for the +T face of each grid block

KRUNUMT- Saturation table numbers for the -T face of each grid block.

The +T direction is that of increasing azimuthal angle. The KRUNUMZ and KRUNUMZ- keywords are the same in both radial and Cartesian grids.

None of these keywords should be used unless directional relative permeabilities have been enabled by the keyword [SATOPTS](#). KRUNUMX-, KRUNUMY- and KRUNUMZ- should be used only if irreversible directional relative permeabilities have been enabled by the keyword [SATOPTS](#). If reversible relative permeability tables are to be employed, the saturation tables specified using KRUNUMX are used for both the X+ and X- faces of each grid block. Similarly KRUNUMY is used for the Y+ and Y- faces, and KRUNUMZ for the Z+ and Z- faces.

The relative permeability is thus looked up in the saturation table for flow across the relevant face, for example KRUNUMX.

If a table number is defaulted for any grid cell, the table number is filled in using the data entered under the [SATNUM](#) keyword.

---

**Note:** The potential difference between two cells uses the capillary pressures in the tables addressed by each of the KRUNUM keywords. If this is not required, then the capillary pressure data in these tables should be set equal to that in the SATNUM tables.

---

ECLIPSE 100 only

**Note:** The saturation function region numbers can be modified during the simulation by re-specifying the KRNUM keyword in the SCHEDULE section. This procedure should only be carried out with care and is **not** recommended in general.

The keyword should be followed by one integer for every grid block in the current input box, specifying the saturation table number for the appropriate face. The table number should not be less than 1 or greater than NTSFUN (see keyword [TABDIMS](#)). The data must be terminated by a slash (/).

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example, 115\*2). Note that spaces must not be inserted on either side of the asterisk.

	SCHEDULE

This keyword is optional and allows the independent specification of the matrix-fracture saturation tables in dual porosity or dual porosity/dual permeability runs. ECLIPSE uses the upstream mobilities to calculate the flows, so

- flow from the matrix to the fracture reflects the saturation table specified for the matrix (top half of the grid) and
- flow from the fracture to the matrix reflects the saturation table specified for the fracture (bottom half of the grid).

If a table number is defaulted for any grid cell, the table number is filled in using the data entered under the [SATNUM](#) keyword.

The keyword should be followed by one integer for every grid block in the current input box, specifying the saturation table region number for matrix-fracture flow. The region number should not be less than 1 or greater than NTSFUN (item 1 in keyword [TABDIMS](#)). The data must be terminated by a slash (/).

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

See "[Dual porosity](#)" in the *ECLIPSE Technical Description* for further information.

## Oil relative permeability damage multipliers

The KRODM keyword enables the oil relative permeability to be modified to account for formation damage. The KRODM data consists of damage factors for each component tabulated against oil relative permeability. The modified relative permeability values are then computed as

$$K_{ro} = M_d K_{ro}'$$

where

$K_{ro}'$  is the relative permeability prior to the damage calculation and

$M_d$  is the damage multiplier given by

$$M_d = \prod_i \frac{1}{1 + D_i(K_{ro}') \times \max(0, Z_i - I_i)}$$

where the product is taken over all hydrocarbon and water components specified with the [COMPS](#) and [COMPW](#) keywords:

$D_i$  is the damage factor for a given  $K_{ro}'$  and component, found by interpolating the KRODM data

$Z_i$  is the molar concentration of component  $i$  (moles per reservoir volume).

The component molar concentrations can be output in the SUMMARY section using the BMLSC and BMWAT keywords, and in the SOLUTION and SCHEDULE section using the MLSC and MWAT mnemonics in the [RPTRST](#), [RPTSOL](#), [RPTSCHED](#) keywords.

$I_i$  is the initial concentration at which damage occurs for a given component

See the [KRODI](#) keyword

The damage multiplier  $M_d$  can be written to the restart files by including the KRODM item in the RPTRST keyword.

The data comprises NTSFUN tables (see item 1 of keyword [TABDIMS](#)) each terminated by a slash (/). The tables must have at least 2 but not more than NSSFUN rows of data (see item 3 of keyword [TABDIMS](#)).

Each table consists of N columns of data, where  $N = 1 + \text{number of hydrocarbon components} + \text{number of water components}$ :

Column 1	Oil relative permeability Values should be between 0 and 1 and should increase monotonically down the column.
Columns 2 to COMPS + 1	Damage factors for hydrocarbon components UNITS: (kg-M/rm <sup>3</sup> ) <sup>-1</sup> (METRIC), (lb-M/rb) <sup>-1</sup> (FIELD), (gm-M/rcc) <sup>-1</sup> (LAB)
Columns COMPS + 2 to COMPS + COMPW + 1	Damage factors for water components

UNITS: (kg-M/rm<sup>3</sup>)<sup>-1</sup> (METRIC), (lb-M/rb)<sup>-1</sup> (FIELD), (gm-M/rcc)<sup>-1</sup> (LAB)

---

**Note:** The damage factors must have values of zero or greater

---

**Note:** The KRODM keyword is only allowed in compositional simulations.

---

## KRO-ORG

## Scaled end point oil relative permeabilities

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The KRO, KRORW, KRORG, IKRO, IKRORW and IKRORG keywords scale the relative permeability of oil within each grid block. KRO scales the  $K_r$  at the maximum oil saturation (typically at connate water), KRORW scales the relative permeability at the critical water saturation, and KRORG scales the relative permeability at the critical gas saturation. The keyword can only be used when the end-point scaling option is active (keyword [ENDSCALE](#) in the RUNSPEC section).

If the KRORW and KRORG keywords have not been used, the KRO keyword has the effect of scaling the relative permeability value calculated from the appropriate saturation table after the scaled saturation end-points have been accounted for. Hence:

$$K_{ro} = K_{ro}(\text{Table}) \frac{KRO(\text{GridBlock})}{K_{romax}(\text{Table})} \quad \text{Eq. 3.100}$$

The relative permeability is taken to be the value at either the maximum saturation of the saturation table or at SWL if this has been specified.

If the KRORW or KRORG keywords have been used, then the scaling honors the  $K_r$  at the critical saturation (SR) of the displacing phase. When the alternative scaling using three saturation nodes is invoked by keyword [SCALECRS](#), SR is given by

SR = 1 - SWCR - SGL for the KRORW keyword

SR = 1 - SGCR - SWL for the KRORG keyword

where SWCR and SGCR etc. are the scaled values. When the alternative scaling method is not employed, only two nodes are used to scale the saturation end-points, and SR is taken as the transformed value of  $SR(\text{Table}) = 1.0 - S_{wcr}(\text{Table}) - S_{gco}(\text{Table})$  for the KRORW keyword, or  $SR(\text{Table}) = 1.0 - S_{gcr}(\text{Table}) - S_{wco}(\text{Table})$  for the KRORG keyword.

Hence the two cases are:

$$SO < SR \quad K_{ro} = K_{ro}(\text{Table}) \frac{KROR(\text{GridBlock})}{(K_{ro}(SR))(\text{Table})} \quad \text{Eq. 3.101}$$

$$SO > SR \quad K_{ro} = KROR + \frac{KRO - KROR}{K_{romax} - K_{ro}(SR)} (K_{ro}(\text{Table}) - K_{ro}(SR)) \quad \text{Eq. 3.102}$$

**Note:** In three-phase cases using the STONE II Model for three-phase relative permeability (see keyword [STONE2](#)), the oil relative permeability is a function of the water and gas relative permeabilities, and hence the oil relative permeability is modified by use of the [KRW](#) and [KRG](#) keywords to scale the water and gas relative permeabilities.

Twenty-one keywords are provided to allow the maximum oil relative permeability to be set for each grid cell independently. These keywords are:

KRO	Max oil $K_r$ for the non-directional saturation function tables
KROX	Max oil $K_r$ for the +X face of each grid cell
KROX-	Max oil $K_r$ for the -X face of each grid cell

KROY	Max oil $K_r$ for the +Y face of each grid cell
KROY-	Max oil $K_r$ for the -Y face of each grid cell
KROZ	Max oil $K_r$ for the +Z face of each grid cell
KROZ-	Max oil $K_r$ for the -Z face of each grid cell
KRORW KRORG	$K_r$ at critical for the non-directional tables
KRORWX KRORGX	$K_r$ at critical for the +X face of each grid cell
KRORWX- KRORGX-	$K_r$ at critical for the -X face of each grid cell
KRORWY KRORGY	$K_r$ at critical for the +Y face of each grid cell
KRORWY- KRORGY-	$K_r$ at critical for the -Y face of each grid cell
KRORWZ KRORGZ	$K_r$ at critical for the +Z face of each grid cell
KRORWZ- KRORGZ-	$K_r$ at critical for the -Z face of each grid cell

In radial grids the same directional keywords should be used to represent the oil  $K_r$  value for flows in the +R,-R,+T,-T,+Z,-Z directions respectively.

None of the KRO keywords should be used if oil is not present in the model. The keyword [ENDSCALE](#) should also be set in the RUNSPEC section.

If both directional and irreversible end-point scaling is requested using switches 'DIRECT' and 'IRREVERS' in [ENDSCALE](#), then the maximum oil  $K_r$  values for flow across the +X and -X faces of a grid cell are set using the keywords KROX, KROX-. Similarly KROY, KROY- are used for the +Y,-Y faces and the keywords KROZ, KROZ- for the +Z,-Z faces.

When the end-point scaling is directional but reversible ('DIRECT' but not 'IRREVERS' is specified in [ENDSCALE](#)), the keyword KROX defines the maximum oil  $K_r$  values for both the +X and -X faces of each grid cell. Keywords KROY, KROZ are used for both the +Y,-Y faces and the +Z,-Z faces of each grid cell respectively.

If [ENDSCALE](#) is specified without either switch 'DIRECT' or 'IRREVERS', then none of the directional forms of the KRO keyword are allowed. The KRO keyword then defines the maximum oil  $K_r$  value for flow across each grid cell face.

Each KRO keyword should be followed by one real number for each grid block in the current input box, specifying the maximum oil relative permeability value. The data must be terminated by a slash(/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If any of the KRO\* keywords are omitted in a model where they could be accepted, then the maximum oil  $K_r$  value defaults to the value used in the appropriate oil saturation function table.

If pure normalized curves are used where [SWCR](#) equals [SWL](#) or [SGCR](#) equals [SGL](#), then depending on the Scaling option used (see the [SCALECRS](#) keyword) the two end-points may be equal. If this is the case, both

KROW and KRORW (or KROG and KRORG) apply to the same point and the KRORW (KRORG) keyword is ignored.

If the Hysteresis model is active (see keyword [SATOPTS](#)), then the KRO, KRORW, KRORG data will scale the drainage curve. The imbibition curve can be scaled by using the equivalent IKRO (IKRORW, IKROGX, IKROX-, ...) keyword.

See also keywords SWL and [ENKRVD](#) in the PROPS section.

Refer to "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for more information.

ECLIPSE 300

If the [ODD3P](#) relative permeability and capillary pressure hysteresis model is selected, this keyword will be ignored.

## Example

```

## Water relative permeability damage initiation

The KRWDI keyword specifies the molar density of individual components at which damage initiates, see the [KRWDM](#).

The data comprises NTSFUN rows of data (see item 1 of the [TABDIMS](#) keyword) each terminated by a slash (/).

Each row consists of N entries, where N = number of hydrocarbon components + the number of water components.

UNITS: kg-M/rm<sup>3</sup> (METRIC), lb-M/rb (FIELD), gm-M/rcc (LAB), kg-M/rm<sup>3</sup> (PVT-M)

### Example

With NTSFUN=2, 6 hydrocarbon components and 1 water component. Damage occurring due to the presence of the sixth hydrocarbon component at concentrations greater than 0.5.

```
KRWDI
5*0.0 0.5 0.0 /
5*0.0 0.5 0.0 /
```

## Water relative permeability damage multipliers

The KRWDM keyword enables the water relative permeability to be modified to account for formation damage. The KRWDM data consists of damage factors for each component tabulated against water relative permeability. The modified relative permeability values are then computed as

$$K_{rw} = M_d K_{rw}'$$

where

$K_{rw}'$  is the relative permeability prior to the damage calculation and

$M_d$  is the damage multiplier given by

$$M_d = \prod_i \frac{1}{1 + D_i(K_{rw}') \times \max(0, Z_i - I_i)}$$

where the product is taken over all hydrocarbon and water components specified with the [COMPS](#) and [COMPW](#) keywords:

$D_i$  is the damage factor for a given  $K_{rw}'$  and component, found by interpolating the KRWDM data

$Z_i$  is the molar concentration of component  $i$  (moles per reservoir volume).

The component molar concentrations can be output in the SUMMARY section using the BMLSC and BMWAT keywords, and in the SOLUTION and SCHEDULE section using the MLSC and MWAT mnemonics in the [RPTRST](#), [RPTSOL](#) and [RPTSCHED](#) keywords.

$I_i$  is the initial concentration at which damage occurs for a given component

See the [KRWDI](#) keyword.

The damage multiplier  $M_d$  can be written to the restart files by including the KRWDM item in the RPTRST keyword

The data comprises NTSFUN tables (see item 1 of keyword [TABDIMS](#)) each terminated by a slash (/). The tables must have at least 2 but not more than NSSFUN rows of data (see item 3 of keyword [TABDIMS](#)).

Each table consists of N columns of data, where  $N = 1 + \text{number of hydrocarbon components} + \text{number of water components}$ :

Column 1	Water relative permeability Values should be between 0 and 1 and should increase monotonically down the column.
Columns 2 to COMPS + 1	Damage factors for hydrocarbon components UNITS: (kg-M/rm <sup>3</sup> ) <sup>-1</sup> (METRIC), (lb-M/rb) <sup>-1</sup> (FIELD), (gm-M/rcc) <sup>-1</sup> (LAB)
Columns COMPS + 2 to COMPS + COMPW + 1	Damage factors for water components UNITS: (kg-M/rm <sup>3</sup> ) <sup>-1</sup> (METRIC), (lb-M/rb) <sup>-1</sup> (FIELD), (gm-M/rcc) <sup>-1</sup> (LAB)

---

**Note:** The damage factors must have values of zero or greater.

---

**Note:** The KRWDM keyword is only allowed in compositional simulations.

---

## Example

With NTSFUN=2 and NSSFUN $\geq$ 4, 6 hydrocarbon components and 1 water component. Damage occurring due to the presence of the sixth hydrocarbon component.

```

## KRW-IKRWR Scaled end-point water relative permeabilities

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The KRW, KRWR, IKRW and IKRWR keywords scale the relative permeability of water within each grid block. KRW scales the  $K_r$  at the maximum water saturation (typically at a water saturation of 1.0), and KRWR scales the relative permeability at residual oil saturation (or residual gas in a gas- water run). The keyword can only be used when the end-point scaling option is active (keyword [ENDSCALE](#) in the RUNSPEC section).

If the KRWR keyword has not been used, the KRW keyword has the effect of scaling the relative permeability value calculated from the appropriate saturation table after the scaled saturation end-points have been accounted for. Hence:

$$K_{rw} = K_{rw}(\text{Table}) \frac{\text{KRW}(\text{GridBlock})}{K_{rw\max}(\text{Table})} \quad \text{Eq. 3.103}$$

The relative permeability is taken to be the value at either the maximum saturation of the saturation table or at SWU if this has been specified.

If the KRWR keyword has been used, then the scaling honors the  $K_r$  at the critical saturation (SR) of the displacing phase. When the alternative scaling method using three saturation nodes is invoked by keyword [SCALECRS](#), SR is given by

SR = 1 - SOWCR - SGL in gas/oil or gas/oil/water runs

SR = 1 - SGCR in gas/water runs

where SOWCR and SGCR are the scaled values. When the alternative scaling method is not employed, only the two nodes SWCR and SWU are used to scale the saturation end-points, and SR is taken to be the transformed value of  $SR(\text{Table}) = 1.0 - S_{owcr}(\text{Table}) - S_{gco}(\text{Table})$  or  $SR(\text{Table}) = 1.0 - S_{gcr}(\text{Table})$ .

Hence the two cases are:

$$SW < SR \quad K_{rw} = K_{rw}(\text{Table}) \frac{\text{KRWR}(\text{GridBlock})}{(K_{rw}(\text{SR}))(\text{Table})} \quad \text{Eq. 3.104}$$

$$SW > SR \quad K_{rw} = \text{KRWR} + \frac{\text{KRW} - \text{KRWR}}{K_{rw\max} - K_{rw}(\text{SR})} (K_{rw}(\text{Table}) - K_{rw}(\text{SR})) \quad \text{Eq. 3.105}$$

Fourteen keywords are provided to allow the maximum water relative permeability to be set for each grid cell independently. These keywords are:

KRW      Max water  $K_r$  for the non-directional saturation function tables

KRWX     Max water  $K_r$  for the +X face of each grid cell

KRWX-    Max water  $K_r$  for the -X face of each grid cell

KRWY     Max water  $K_r$  for the +Y face of each grid cell

KRWY-    Max water  $K_r$  for the -Y face of each grid cell

KRWZ     Max water  $K_r$  for the +Z face of each grid cell

KRWZ-    Max water  $K_r$  for the -Z face of each grid cell

KRWR  $K_r$  at residual for the non-directional saturation function tables

KRWRX  $K_r$  at residual for the +X face of each grid cell

KRWRX-  $K_r$  at residual for the -X face of each grid cell

KRWR Y  $K_r$  at residual for the +Y face of each grid cell

KRWR Y-  $K_r$  at residual for the -Y face of each grid cell

KRWR Z  $K_r$  at residual for the +Z face of each grid cell

KRWR Z-  $K_r$  at residual for the -Z face of each grid cell

In radial grids the same directional keywords should be used to represent the water  $K_r$  value for flows in the +R,-R,+T,-T,+Z,-Z directions respectively.

None of the KRW keywords should be used if water is not present in the model. The keyword [ENDSCALE](#) should also be specified in the RUNSPEC section.

If both directional and irreversible end-point scaling is requested using switches 'DIRECT' and 'IRREVERS' in keyword [ENDSCALE](#), then the maximum water  $K_r$  values for flow across the +X and -X faces of a grid cell are set using the keywords KRWX and KRWX-. Similarly KRWY and KRWY- are used for the +Y,-Y faces and the keywords KRWZ and KRWZ- for the +Z,-Z faces.

When the end-point scaling is directional but reversible ('DIRECT' but not 'IRREVERS' is specified in [ENDSCALE](#)), the keyword KRWX defines the maximum water  $K_r$  values for both the +X and -X faces of each grid cell. Keywords KRWY, KRWZ are used for both the +Y,-Y faces and the +Z,-Z faces of each grid cell respectively.

If [ENDSCALE](#) is specified without either switch 'DIRECT' or 'IRREVERS', then none of the directional forms of the KRW keyword are allowed. The KRW keyword then defines the maximum water  $K_r$  value for flow across each grid cell face.

Each KRW keyword should be followed by one real number for each grid block in the current input box, specifying the maximum water relative permeability value. The data must be terminated by a slash(/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If any of the KRW\* keywords are omitted in a model where they could be accepted, then the maximum water  $K_r$  value defaults to the value used in the appropriate water saturation function table.

If pure normalized curves are used where (1.0-SOWCR-SGL) is equals to SWU, then depending on the Scaling option used (see the [SCALECRS](#) keyword) the two end-points may be equal. If this is the case both KRW and KRWR apply to the same point, and the KRWR keyword is ignored.

If the Hysteresis model is active (see keyword [SATOPTS](#)), then the KRW, KRWR data scales the drainage curve. The imbibition curve can be scaled by using the equivalent IKRW (IKRWR, IKRWX, IKRWX-, ...) keyword.

If in addition to conventional hysteresis, WAG hysteresis has been specified (see the [WAGHYSTR](#) keyword) the additional end-point scaling keywords KRWH, KRWRH, IKRWH and IKRWRH data are available to scale the two-phase and three-phase WAG hysteresis water relative permeability saturations functions. These are

specified via the [WH2NUM](#) and [WH3NUM](#) keywords for saturation regions with WAG hysteresis applied to the water phase. The hysteresis models are described in more detail in "[Hysteresis in WAG floods](#)" in the *ECLIPSE Technical Description*.

See also keywords [SWU](#) and [ENKRVD](#) in the PROPS section.

Refer to "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for more information.

ECLIPSE 300

If the [ODD3P](#) relative permeability and capillary pressure hysteresis model is selected, this keyword will be ignored.

## Example

```

This keyword can only be used with the [THERMAL](#) option.

KVAN specifies up to three constants for each oil component. These constants are used to calculate an oil component K-value as a function of temperature and pressure. For each oil component, the K-value is fitted according to the equation

$$K(P, T) = e^{A-B/(T+C)} / P$$

where

$T$  is the temperature (K (METRIC), °R (FIELD), K (LAB), K (PVT-M)), and

$P$  is the pressure (barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)).

The keyword is followed by up to three rows, each containing  $N_c$  columns of data described below. The set of records is ended by a blank record, containing only a slash.

1. A,  $N_c$  values

UNITS: ln (P)

2. B,  $N_c$  values

UNITS: K (METRIC), °R (FIELD), K (LAB), K (PVT-M)

3. C,  $N_c$  values

UNITS: K (METRIC), °R (FIELD), K (LAB), K (PVT-M)

---

**Note:** This keyword is equivalent to [KVCR](#). Internally ECLIPSE 300 will convert the coefficients of this keyword into KVCR coefficients and any reporting in the print file will be under the KVCR keyword.

---

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of [TABDIMS](#). The use of multiple EoS regions is discussed in "Equations of state regions" in the *ECLIPSE Technical Description*.

## Example

```

KVAN
-- C1      C2      HEAVY
   11.34   14.85   0
   1693   10252   0
   -7.16   -85.4   0
/

```

## KVCOMP

**K-value interpolation component**

KVCOMP specifies the component for which the K-value tables are interpolated. The K-value tables are specified with the [KVABCn](#) keywords and the corresponding interpolation points using the [KVMF](#) keyword.

**Example**

```
KVCOMP
 2 /
```

	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword requests that a K-value table be generated internally. It is followed for each pressure table (from 1 to NTPVT as specified by item 2 of keyword [TABDIMS](#)) by a sample composition and the minimum and maximum pressures. The table will be K-value table 1.

Column 1 to  $N_c$  Composition.

Column  $N_c+1$  Minimum pressure.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: 1 atma

Column  $N_c+2$  Maximum pressure.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: 500 atma

### The KVALUES option

If KVGGEN is used to generate a K-value table, the [KVALUES](#) keyword may be used in the RUNSPEC section to apply it to the simulation, or it may be used in a separator flash ([SEPCOND](#) or [FIELDSEP](#)).

### The THERMAL option

In [THERMAL](#) mode, when an EoS (equation of state) environment is set by including [CGDTYPE](#), [CODTYPE](#), [CGVTYPE](#) or [COVTYPE](#), the K-value tables KVTABT1 ... KVTABT9 ([KVTABTn](#)) are filled using the EoS. Temperatures for the tables need to be set using [KVTEMP](#). Note that only the first EoS region number is used when generating the tables. For pressures below the dew point or above the bubble point, the last two-phase K-value is expanded as  $K_{bub} * P_{bub} / P$  and  $K_{dew} * P_{dew} / P$ .

### Example

Generate K-values for the specified sample from 10 to 2500 psia.

```
KVGGEN
0.0247 0.2516 0.2407 0.0733 0.4097 10 2500 /
```

## K-value mole fractions

KVMF specifies the mole fractions of the nominated component at which K-value tables are available. The interpolation component is specified using the [KVCOMP](#) keyword.

The number of K-value tables and hence the number of values required by this keyword is set with 24<sup>th</sup> item in the [TABDIMS](#) keyword in the RUNSPEC section. Values must lie in the interval [0,1] and be monotonically increasing.

### Example

```
KVMF
0.0 0.5 1.0 /
```

## KVTABCn

## Tables of K-values at composition n (n = 1 to 9)

	ECLIPSE 100

	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword family KVTABCn (where n is an integer between 1 and 9) enables K-values to be entered to control liquid-vapor phase equilibrium at differing compositions. The compositions are specified as a mole fraction of a nominated component using the *KVMF* and *KVCOMP* keywords.

KVTABCn is a pressure table, and it is possible to enter more than one table; these can be assigned to cells using the *PVTNUM* keyword in the REGIONS section.

The table has  $N_c + 1$  columns, where  $N_c$  is the number of components in the run. The first column is of pressure values, the remaining columns are the K-values for each component at these pressures. The K-values should be positive and greater than  $10^{-6}$ .

Column 1            The oil phase pressure.

Values should increase monotonically.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

Columns 2 to  $N_c$     The corresponding K-values for each component.

+1

The K-value for component  $c$  is  $K_c = y_c / x_c$ , where  $y_c$  and  $x_c$  are mole fractions of component  $c$  in the vapor and liquid phases respectively.

## Example

```

KVTABC1
  5  .1197  .0192
 50  .0128  .0020
 95  .0071  .0011
140  .0051  .00081

	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword enables K-values to be entered to control liquid-vapor phase equilibrium. If the [KVALUES](#) keyword was specified in the RUNSPEC section, these are used instead of the equation of state equal fugacity relationships to obtain the composition of the liquid and vapor hydrocarbon phases in a cell, and the split of the total moles in the cell between these phases.

The K-values may also be used to control separators.

KVTABLE is a pressure table. It is possible to enter more than one table, and these can be assigned to cells using the [PVTNUM](#) keyword in the REGIONS section.

The table has  $N_c + 1$  columns, where  $N_c$  is the number of components in the run. The first column is of pressure values, the remainder the K-values for each component at these pressures.

Column 1            The oil phase pressure.

Values should increase monotonically.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

Column 2 to  $N_c$     The corresponding K-values for each component.

+1

The K-value for component  $c$  is  $K_c = y_c / x_c$ , where  $y_c$  and  $x_c$  are mole fractions of component  $c$  in vapor and liquid phases respectively.

## Example

```

## KVTABTn

## Tables of K-values at T=Tn (n = 1 to 9)

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword family KVTABTn (where n is an integer between 1 and 9) enables K-values to be entered to control liquid-vapor phase equilibrium at the temperature Tn, corresponding to the nth value specified in the [KVTEMP](#) keyword.

These keywords can only be used with the [THERMAL](#) option.

KVTABTn is a pressure table, and it is possible to enter more than one table; these can be assigned to cells using the [PVTNUM](#) keyword in the Regions section.

The table has  $N_c + 1$  columns, where  $N_c$  is the number of components in the run. The first column is of pressure values, the remaining columns are the K-values for each component at these pressures. The K-values should be positive and greater than  $10^{-6}$ .

Column 1      The oil phase pressure.

Values should increase monotonically.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

Columns 2 to  $N_c + 1$       The corresponding K-values for each component. All values should be greater than zero.

The K-value for component  $c$  is  $K_c = y_c / x_c$ , where  $y_c$  and  $x_c$  are mole fractions of component  $c$  in vapor and liquid phases respectively.

If temperatures are encountered that are less than T1, then the K-value is linearly extrapolated to 0 at an absolute temperature of 0.

---

**Note:** Thermal simulation stability can be affected by the pressure spacing with this keyword. It is recommended that equal intervals are used between the pressures.

---

---

**Note:** There may be convergence problems in the thermal flash if all the K-values in a row are 1.

---

See also keyword [KVTEMP](#).

### Example

```

KVTABT1
  5  .1197  .0192
 50  .0128  .0020
 95  .0071  .0011

## Oil component K-value fitting function

This keyword can only be used with the [THERMAL](#) option.

For each oil component, the oil component K-value is fitted according to the equation

$$K(P, T) = e^{5.372697 \cdot (1+A_c) \cdot (1-T_{crit}/T)} \cdot P_{crit} / P \quad \text{Eq. 3.106}$$

where

$T$  is the temperature (K (METRIC), °R (FIELD), K (LAB), K (PVT-M))

$P$  is the pressure (barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M))

$A_c$  is the acentric factor for each component as entered with keyword [ACF](#)

$T_{crit}$  is the component critical temperature as entered with keyword [TCRIT](#)

$P_{crit}$  is the component critical pressure as entered with keyword [PCRIT](#).

This keyword requires acentric factors with keyword [ACF](#), critical temperatures and pressures with keywords [TCRIT](#) and [PCRIT](#).

There is no data for this keyword.

### Example

x	ECLIPSE 300
x	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword activates the Lagrangian tracer solver option. For more information on this option see "[Lagrangian tracer solver](#)" in the *ECLIPSE Technical Description*.

The data consists of four items, describing the maximum number of streamlines and streamline segments, along with the target number of streamlines and the minimum number of streamlines for each cell. The data must be terminated by a slash (/).

1. The maximum number of streamlines.  
DEFAULT: (Number of components + number of phases) times number of cells in model times 0.1.
2. The maximum number of streamline segments. Each streamline is made up of a number of segments, with the number of segments being one greater than the number of cells the streamline passes through. This entry is the maximum number of streamline segments which can be traced in total, that is the sum of the number of segments for all streamlines.  
DEFAULT: 100 times maximum number of streamlines.
3. The target number of streamlines as a fraction of the total number of cells in the grid.  
DEFAULT: 0.1
4. The minimum number of streamlines to pass through any cell.  
DEFAULT: 1

**Note:**

- The Lagrangian tracer solver is not compatible with the radial local grid refinement.
- The Lagrangian tracer solver is not compatible with local grid refinements where two refined regions are immediately adjacent, or a refinement is immediately adjacent to a fault. A fault running through a refined area is also not permitted.
- The Lagrangian tracer solver is not compatible with dual porosity.
- The Lagrangian tracer solver is not compatible with explicit NNCs set using [NNC](#) keyword.

**Example**

Up to 4000 streamlines comprising up to 100000 streamline segments. The algorithm will initially trace approximately 0.2 streamlines per cell, and will then add streamlines until every cell contains at least one streamline segment.

```
LAGTRAC
4000 100000 0.2 1 /
```

## LAGTRUPD Specifies the update criteria for the Lagrangian tracer solver option

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The data consists of four items, describing the maximum time between retraces of the streamlines, the maximum time between updates of tracer concentrations of the streamlines, the maximum change in any completion flow rate before retraces of the streamlines, and the tracer solver method. The data must be terminated by a slash (/).

1. The maximum time between retraces of the streamlines.  
UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)  
DEFAULT: 0.0
2. The maximum time between updates of the tracer concentration on the streamlines.  
UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)  
DEFAULT: 0.0
3. The maximum fractional change in completion component flow rate before a streamline retrace is forced.  
DEFAULT: 0.05
4. Tracer solver method:  
ADVEC Tracer concentrations are advected along streamlines and averaged at each cell.  
COMPR as ADVEC with compression taken into account.  
DEFAULT: COMPR

### Example

Streamlines will be retraced every 182.5 days or when any completion changes its flow rate by 10% in any component. Tracer concentrations are stored on streamlines at trace, and then every 60 days thereafter. Cell tracer concentrations are derived by advecting tracer concentrations along streamlines from the last time when they were written to streamlines, and then averaging over streamlines in each cell.

```
LAGTRUPD
182.5 60.0 0.1 'ADVEC' /

## LANGMEXT Extended Langmuir Isotherm

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is specific to the compositional coal bed methane option.

The data determines the Langmuir sorption data for each hydrocarbon component in the run. A coal bed methane model can be divided into one or more regions. The number of regions is NTCREG and this number is input by REGDIMS item 6. Coal regions are input with the keyword COALNUM, while coal densities are input using the keyword ROCKDEN. There is one LANGMEXT record for each coal region up to NTCREG records. For further information see "[Coal bed methane model](#)" in the *ECLIPSE Technical Description*.

Each record contains the Langmuir pressure constants  $P_i$  and the Langmuir volume constants  $V_i$  for all components, totaling  $2 * NCOMPS$  entries:

Record 1  $P_1 V_1 P_2 V_2 \dots P_{ncomps} V_{ncomps}$

- $P_i$  has the units of pressure. Values should be larger than zero. The exception is if the volume constant is zero, then the component is completely ignored when calculating the adsorption capacities.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: 0.0

- $V_i$  is given as surface volume of gas over coal weight. The values should be larger or equal to zero.

UNITS:  $\text{sm}^3/\text{kg}$  (METRIC), Mscf/ton (FIELD), scc/gm (LAB),  $\text{sm}^3/\text{kg}$  (PVT-M)

DEFAULT: 0.0

Record 2  $P_1 V_1 P_2 V_2 \dots P_{ncomps} V_{ncomps}$

Defines the Langmuir constants for coal region number two.

Records 3 to NTCREG: Each record defines the Langmuir constants for coal regions 3 to NTCREG.

A record is terminated by a slash (/) a second slash terminates the keyword.

The number of records should equal the maximum number of coal regions as set with keyword COALNUM.

Each pressure constant  $P_i$  and volume constant  $V_i$  defines a Langmuir curve for component i. The volume constants define the maximum storage capacity and are input as surface volume of gas over coal-weight. The pressure constant defines the pressure at half of the Langmuir volume.

---

**Note:** In FIELD units the storage constant is not given in the natural units of ECLIPSE but instead as Mscf/ton (where 1 ton = 2000 lb; the so-called **short ton**). If [item 112](#) in OPTIONS3 is set to a non-zero value, the ton is taken to be a **long ton** (2240 lb).

---

### Example

Three components and two coal regions:

```
LANGMEXT
-- psia      Mscf/ton      coal region 1
276.0       0.9938           --CO2
3951.0     0.482            -- N2
680.0      0.486 /         --CH4
-- psia      Mscf/ton      coal region 2
276.0       0.961           --CO2
3951.0     0.441            -- N2
680.0      0.442/         --CH4
/
```

## LANGMPL Langmuir pressure scaling

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword may be used with the coal bed methane model (see "[Coal bed methane model](#)" in the *ECLIPSE Technical Description*).

The keyword scales the pressure used when calculating the adsorption capacity on a cell by cell basis.

The keyword should be followed by one real number for every grid block, specifying a multiplier. The data field should be terminated by a slash (/).

Grid blocks are ordered with the X axis index cycling fastest (from 1 to NDIVIX), followed by the Y axis index (from 1 to NDIVIY), and finally the Z axis index (from 1 to NDIVIZ). NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword [DIMENS](#). Repeat counts may be used for repeated values (for example 115\*0.9). Note that spaces must not be inserted on either side of the asterisk (\*).

Only the values given for the coal cells are used. See the [COALNUM](#) keyword. So for a dual porosity run with only the matrix cells being coal cells, it is sufficient to supply NDIVIX \* NDIVIY \* NDIVIZ /2 values. In the case of the ECLIPSE 300 instant sorption model values must be applied for all cells with coal.

The keyword is entirely optional and if not specified, or defaulted, a value of unity will be used.

### Example

With NDIVIX = 10, NDIVIY = 1 and NDIVIZ = 2 specified in RUNSPEC keyword [DIMENS](#):

```
LANGMPL
10*0.8 /
```

The pressures of the first 10 grid cells (i.e. the coal matrix cells) are multiplied with 0.8 when computing the adsorption capacity.

### Example - ECLIPSE 300 instant sorption

With NDIVIX=10, NDIVIY=1 and NDIVIZ=2 specified in RUNSPEC keyword [DIMENS](#):

```
LANGMPL
20*0.8 /
```

The pressures of the first 20 grid cells are multiplied with 0.8 when computing the adsorption capacity.

# LANGMUIR Tables of coal surface gas concentration

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is specific to the coal bed methane option.

The data comprises NTCREG (see keyword [REGDIMS](#), item 6) tables of Langmuir isotherm data, each terminated by a slash (/). For ECLIPSE 100, each table consists of 2 columns of data, while for ECLIPSE 300 each table consists of [NCOMPS](#) + 1 columns of data.

1 The fracture pressure.

In ECLIPSE 300, the partial pressure,  $y_i P$ , is used to look up the adsorption capacity for each component, where  $y_i$  is the gas phase mole fraction of component  $i$  and  $P$  is the connected pore volume/fracture pressure.

The pressure used to look up the adsorption capacity is scaled with the coal grid cell [LANGMPL](#) value if this keyword is present.

Values should increase monotonically down the column.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

2 The corresponding surface gas concentration (the first component in ECLIPSE 300)

Values should be increase monotonically down the column.

UNITS:  $\text{sm}^3/\text{m}^3$  (METRIC), Mscf/ft<sup>3</sup> (FIELD), scc/cc (LAB)

3 to [NCOMPS](#) + 1 (ECLIPSE 300 only) The corresponding surface gas concentration for each of the remaining components. Values should be level or increasing down the column.

UNITS:  $\text{sm}^3/\text{m}^3$  (METRIC), Mscf/ft<sup>3</sup> (FIELD), scc/cc (LAB)

The entire table may be defaulted, provided the table is not the first. Defaulted tables are replaced with a copy of the previous table.

The coal region number [COALNUM](#) is used to look up the table.

There must be the same number of entries in each column of a given table. This number (rows) should not be less than 2 or greater than [NSSFUN](#) (item 3 in keyword [TABDIMS](#)).

ECLIPSE 100

If [OPTIONS](#) keyword [item 180](#) is activated, the number of tables should equal [NTSFUN](#) (see keyword [TABDIMS](#)) and the region keyword [SATNUM](#) is used to look up the table.

See also the [LANGSOLV](#) and [COALADS](#) keywords and "Coal bed methane model" in the *ECLIPSE Technical Description* for further information.

This keyword may be used with the coal bed methane model (see "[Coal bed methane model](#)" in the *ECLIPSE Technical Description*).

The keyword scales the adsorption capacity on a cell by cell basis for each component.

The keyword should be followed by one real number for every grid block, specifying a multiplier for the adsorption capacity. The data field should be terminated by a slash (/).

Grid blocks are ordered with the X axis index cycling fastest (from 1 to NDIVIX), followed by the Y axis index (from 1 to NDIVIY), and then the Z axis index (from 1 to NDIVIZ) for each component. NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword [DIMENS](#). Repeat counts may be used for repeated values (for example 115\*0.9). Note that spaces must not be inserted on either side of the asterisk (\*).

Only the values given for the coal cells are used. See [COALNUM](#).

The keyword is entirely optional and if not specified, or defaulted, the adsorption capacity as specified by [LANGMEXT](#) or [LANGMUIR](#) is used unaltered.

---

**Note:** This keyword cannot be used with [LANGMULT](#), [GASSATC](#) or [GASADDEC](#).

---

### Example

With NDIVIX=10, NDIVIY=1 and NDIVIZ=2 specified in RUNSPEC keyword [DIMENS](#):

```
LANGMULC
5* 5*0.2 10*0.0 -- component 1
5* 5*0.4 10*0.0 -- component 2/
```

The first 5 cells are unaltered, while the 5 next cells are scaled to 20% of the adsorption capacity, for the first component, the second component is scaled with 40% of the adsorption capacity as given by the Langmuir isotherm.

## LANGMULT Langmuir multiplier

This keyword may be used with the coal bed methane model (see "[Coal bed methane model](#)" in the *ECLIPSE Technical Description*).

The keyword scales the adsorption capacity on a cell by cell basis.

The keyword should be followed by one real number for every grid block, specifying a multiplier for the adsorption capacity. The data field should be terminated by a slash (/).

Grid blocks are ordered with the X axis index cycling fastest (from 1 to NDIVIX), followed by the Y axis index (from 1 to NDIVIY), and finally the Z axis index (from 1 to NDIVIZ). NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword [DIMENS](#). Repeat counts may be used for repeated values (for example 115\*0.9). Note that spaces must not be inserted on either side of the asterisk (\*).

Only the values given for the coal cells are used, see [COALNUM](#). So for a dual porosity run with all matrix cells being coal cells, it is sufficient to supply  $NDIVIX * NDIVIY * NDIVIZ / 2$  values.

The keyword is entirely optional and if not specified, or defaulted, the adsorption capacity as specified by [LANGMEXT](#) or [LANGMUIR](#) is used unaltered.

---

**Note:** This keyword cannot be used with [LANGMULC](#), [GASSATC](#) or [GASADDEC](#).

---

### Example

With NDIVIX=10, NDIVIY=1 and NDIVIZ=2 specified in RUNSPEC keyword [DIMENS](#):

```
LANGMULT
5* 5*0.2 /
```

The first 5 cells are defaulted to unity, while the 5 next cells are scaled to 20% of the adsorption capacity as given by the Langmuir isotherm. The remaining cells, not specified, are set to the default value of unity.

## LANGSOLV Tables of coal surface solvent concentration

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS

	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is specific to the coal bed methane option.

The data comprises NTCREG (see keyword [REGDIMS](#), item 6) tables of Langmuir isotherm data for the solvent component, each terminated by a slash (/). Each table consists of 2 columns of data:

1. The fracture pressure.

Values should increase monotonically down the column.

The pressure used to look up the adsorption capacity is scaled with the coal grid cell [LANGMPL](#) values if this keyword is present.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

2. The corresponding surface solvent concentration.

Values should be level or increasing down the column.

UNITS:  $\text{sm}^3/\text{m}^3$  (METRIC),  $\text{Mscf}/\text{ft}^3$  (FIELD),  $\text{scc}/\text{cc}$  (LAB)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (item 1 in keyword [TABDIMS](#)).

The entire table may be defaulted, provided the table is not the first. Defaulted tables are replaced with a copy of the previous table.

The coal region number [COALNUM](#) is used to look up the table.

If [item 180](#) in [OPTIONS](#) is activated, the number of tables should equal NTSFUN (see keyword [TABDIMS](#)) and the region keyword [SATNUM](#) is used to look up the table.

See also the [LANGMUIR](#) and [COALADS](#) keywords and "Coal bed methane model" in the *ECLIPSE Technical Description* for further information.

### Example

With NTCREG=2 and NSSFUN≥7

```

LANGSOLV

## Units for linear combination of phases

This keyword sets the units of the linear combination of oil, water and gas as defined in keyword [LINCOM](#). This keyword is optional and used for reporting purposes only. If it is not entered or defaulted the default string is used.

For example, the volume of a quantity,  $V_S$ , may be equal to

$$V_S = \alpha V_{oil} + \beta V_{wat} + \gamma V_{gas} \quad \text{Eq. 3.107}$$

and the flow rate of this quantity,  $Q_S$ , equal to

$$Q_S = \alpha Q_{oil} + \beta Q_{wat} + \gamma Q_{gas} \quad \text{Eq. 3.108}$$

for coefficients  $\alpha$ ,  $\beta$ ,  $\gamma$ . The units of  $V_S$  are specified with this keyword which determines the units of  $\alpha$ ,  $\beta$ ,  $\gamma$  (see [LINCOM](#)). The units of  $Q_S$  are assumed to be those of  $V_S$  per day (METRIC, FIELD, PVT-M) or per hour (LAB).

The keyword is followed by a single line of data terminated with a slash (/).

- Up to 4 characters to define the units of  $V_S$ .

DEFAULT: UNIT

### Example

```
LCUNIT
SM3 /
```

## LGR

## Set options for LGR and coarsening

	ECLIPSE 300
x	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword sets options and dimensions for local grid refinement and coarsening. (See "Local grid refinement and coarsening" in the *ECLIPSE Technical Description* for further information.)

The data consists of some or all of the following items, describing the dimensions and switches required for the local grid refinement and coarsening options. The data must be terminated by a slash (/).

1. MAXLGR The maximum number of LGRs in the model.  
DEFAULT: 0
2. MAXCLS The maximum number of cells in each LGR  
DEFAULT: 0
3. MCOARS The maximum number of amalgamated coarse cells  
DEFAULT: 0
4. MAMALG The maximum number of LGR amalgamations  
DEFAULT: 0
5. MXLALG The maximum number of LGRs in any amalgamation  
DEFAULT: 0
6. LSTACK The length of the stack of previous search directions used by the linear solver for LGR simulations. For cases where LGRs are defined, if LSTACK is zero or negative, it defaults to [NSTACK](#), the global stack value.  
DEFAULT: NSTACK (10)
7. Specify pressure interpolation for LGR runs
 

INTERP This specifies that pressures are to be bilinearly interpolated spatially in global cells neighboring a Cartesian local grid refinement to enhance the accuracy of flow calculations between local and global cells (sometimes known as the Quandalle correction). This option is ignored in VE runs or for radial local grids. This is performed as an integrated part of the fully implicit pressure solution.

NOINTERP Pressure interpolation is not to be used

DEFAULT: NOINTERP
8. NCHCOR The total number of grid cells contained in grid coarsenings that straddle domain boundaries in Parallel runs.  
DEFAULT: 0

## Example

```
LGR
--MAXLGR  MAXCLS  MCOARS  MAMALG  MXLALG  LSTACK  Pressure      NCHCOR
--                2      400    0        1        2 /      Interpolation
```

## LGRCOPY

## Allow LGRs to automatically inherit rock property data from host cells

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
x	RUNSPEC
x	GRID
x	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword requests an option for processing the local grid refinement data. It allows the LGR rock properties to be automatically inherited from their global host cells when the LGR is defined, instead of at the end of processing for the GRID section. This will in turn allow the user to use an operator keyword on the LGR cells without the need to set LGR cells first.

If the LGRCOPY keyword is present in the RUNSPEC section, this option will apply to every LGR in the model. If individual LGRs request this option, then this keyword can be used inside the relevant [CARFIN](#) / [ENDFIN](#), [RADFIN](#) / [ENDFIN](#), [REFINE](#) / [ENDFIN](#) pair.

This keyword has no associated data.

### Treatment without LGRCOPY

If LGRCOPY is not specified, values of porosity, permeability and so on, are copied to local grid cells from the global host cells at the end of processing the GRID section. In most cases this is adequate, but it is also possible to define properties directly for some, or all, of the cells within a local grid by specifying grid arrays between the [CARFIN](#) / [ENDFIN](#), [RADFIN](#), [RADFIN4](#) / [ENDFIN](#) or [REFINE](#) / [ENDFIN](#) pairs.

When the end of the GRID section is reached, any values that have not been explicitly defined for local cells are then copied from the global host cells.

For example:

```

CARFIN
'LGR1'  5 10   5 10   1 4 18 18   8   5 /
EQUALS
'PORO'  0.3  1 18 1 18 1 4 /
'PERMZ' 50.0 1 18 1 18 1 4 /
'NTG'   0.9  1 18 1 18 1 4 /
/
MULTIPLY
'PORO'  0.5  6 13 6 13 1 2 /
'NTG'   0.2  6 13 6 13 1 2 /
/
ENDFIN

```

This defines the porosities only in the top four layers on the local grid, and these are subsequently modified for the top two layers with the [MULTIPLY](#) keyword. The porosities for cells in the bottom four layers are copied from their host cells in the global grid.

Since properties are not copied from host cells until the end of the GRID section is reached, when LGRCOPY is not present it is not possible to modify any property for cells within the local grid (by using the [ADD](#), [COPY](#) or [MULTIPLY](#) keywords, for instance) without previously defining the property for those cells within the LGR, as shown in the above example.

### Treatment with LGRCOPY

When LGRCOPY is specified, values for any cells within the LGR which have not been explicitly defined will be copied from the global cells 'just in time' to allow property modification. It is important to note that the order of property specification in the dataset becomes relevant here. For instance, if the LGR uses non-default values for DX, these must have been specified before the modification keyword if they are to be taken into account when determining which global cell each local cell lies in.

Consider the previous example without LGRCOPY use. Say, the model contains only one LGR, so the LGRCOPY keyword could either be specified in the RUNSPEC section to apply to that LGR, or placed just after CARFIN definition (as in this example). It is possible to have:

```

PORO
0.3 5 10 5 10 1 2 /
NTG
0.9 5 10 5 10 1 2 /
CARFIN
  'LGR1' 5 10 5 10 1 4 18 18 8 5 /
LGRCOPY
EQUALS
'PERMZ' 50.0 1 18 1 18 1 4 /
/
MULTIPLY
'PORO' 0.5 6 13 6 13 1 2 /
'NTG' 0.2 6 13 6 13 1 2 /
/
ENDFIN

```

This defines PORO and NTG for the global cells which correspond to the top four layers on the local grid, so is the exact analogy of the example above. It would be more useful if, say, these values were also required for a larger range of global cells of which the LGR was a subset. Using LGRCOPY, the range of cells in the global specification just needs to be expanded, whereas without it the dataset needs two specifications for each keyword: one for the global cells and another one for the local cells.

Similarly, LGRCOPY will invoke automatic inheritance of global properties within a REFINE / ENDFIN pair in the EDIT section.

---

**CAUTION:** The CARFIN / RADFIN / REFINE... ENDFIN keywords must be placed after the global properties in the dataset, in order for the local properties to be automatically inherited from the global properties.

---

## Notes

- It is not possible to use the LGRCOPY keyword with keyword DPGRID.
- This keyword cannot be used with the EXTFIN / ENDFIN set for specifying unstructured local grids.
- The LGRCOPY keyword can be used with the keywords EQUALS, ADD, MULTIPLY, COPY, MAXVALUE, MINVALUE and COPYBOX.

### ECLIPSE 300 only

- For integer-valued keywords (MULTNUM, OPERNUM and FLUXNUM) in the GRID section only, if only a subset of the local cells have values set by the user inside an LGR, LGRCOPY is unable to copy global values to unset LGR cells.
- It is not possible to use the LGRCOPY keyword together with the DX, DY, DZ, TOPS, MIDS, MULTX, MULTY, MULTZ, MULTX-, MULTY- and MULTZ- keywords. If local values for these properties are required, they need to be set by the user within the refinement, or the properties will be copied from host cells when the end of the GRID section is reached.

### ECLIPSE 100 only

- Use of the AMALGAM keyword does not affect LGRCOPY. If used in the GRID section, LGRCOPY must still be specified for each individual LGR as required.

- For radial LGRs, only properties which also exist in the Cartesian global grid can be copied using LGRCOPY - for instance, [PERMR](#) cannot be copied since the global grid has [PERMX](#) and [PERMY](#).

## Example

```
LGRCOPY
```

## LGRFREE

## Solves a local grid refinement using local timestepping

x	ECLIPSE 100
	ECLIPSE 300

	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

LGRFREE can be used at any time during the run to designate that a local grid should be solved using local timestepping. If a local grid has previously been designated as an in-place refinement using the LGRLOCK keyword, the LGRFREE keyword returns it to local timestepping (which is the default solution method for local grid refinements).

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/). The set of records must end with a blank record, containing only a slash (/).

1. Name of the local grid refinement - up to 8 characters.

A local grid name root ending in an asterisk (\*) may be used to refer to several local grids on the same record.

If the keyword is entered without any data records (that is followed only by a blank record), all local grids are solved using local timestepping.

If the local grid is part of an amalgamation specified using the keyword [AMALGAM](#), the whole amalgamation is solved using local timestepping.

See also keyword [LGRLOCK](#).

### Example

This returns the 'in-place' refinement SOUTH to local timestepping.

```
LGRFREE
SOUTH /
/
```

## LGRLOCK **Solves a local grid refinement in-place**

	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

## Switches a local grid refinement off

LGROFF can be used at any time during the run to switch a local grid refinement off. Optionally, the local grid refinement can be switched on and off automatically depending on the number of active wells it contains. (A well is active if it is open or stopped, but not shut.)

The keyword is followed by either one or two items of data, terminated with a slash (/).

1. Name of the local grid refinement - up to 8 characters.

A local grid name root ending in an asterisk (\*) may be used to refer to several local grids in the same record.

2. Number of active wells required to keep the refinement open.

If set > 0, the refinement is on whenever it contains the stated number of active wells or more, and off whenever the number of active wells falls below the stated number.

DEFAULT: 0, which switches the refinement off unconditionally.

If the LGR is part of an amalgamation specified using the keyword [AMALGAM](#), then the whole amalgamation is switched off (that is all local grids contained in the amalgamation are switched off). The number of active wells specified by item 2 refers to the amalgamation (that is it applies to all wells within local grids contained in the amalgamation).

In addition, refer to the [OPTIONS](#) keyword, [item 56](#).

See also keyword [LGRON](#).

---

**Note:** In parallel runs, LGRs cannot be switched on (using the [LGRON](#) keyword) after they have been switched off.

---

---

**Note:** In parallel runs, wells cannot be declared inside of LGRs (using the [WELSPECL](#) keyword) after the LGRs have been switched off.

---

## Examples

### Example 1

This switches the refinement SOUTH off unconditionally:

```
LGROFF
SOUTH /
```

### Example 2

The refinement NORTH is on whenever it has 2 or more active wells, and off whenever it has less than 2:

```
LGROFF
-- NAME      NWELLS
   NORTH      2      /
```

## LGRON

## Switches a local grid refinement on

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

LGRON can be used at any time during the run to switch a local grid refinement on. Optionally, the local grid refinement can be switched on and off automatically depending on the number of active wells it contains. (A well is active if it is open or stopped, but not shut.)

The keyword is followed by either one or two items of data, terminated with a slash (/).

1. Name of the local grid refinement - up to 8 characters.

A local grid name root ending in an asterisk (\*) may be used to refer to several local grids on the same record.

2. Number of active wells required to keep the refinement open.

If set > 0, the refinement will be on whenever it contains the stated number of active wells or more, and off whenever the number of active wells falls below the stated number.

DEFAULT: 0, which switches the refinement on unconditionally.

In the timestep immediately following a LGRON keyword, all local grids start off with a one-day timestep.

If the LGR is part of an amalgamation specified using the keyword [AMALGAM](#), then the whole amalgamation is switched on (that is all local grids contained in the amalgamation are switched on). The number of active wells specified by item 2 refers to the amalgamation (that is it applies to all wells within local grids contained in the amalgamation).

See also keyword [LGROFF](#).

---

**Note:** Switching a local grid refinement on part way through a run is not advised, in general, since there is no valid procedure for allocating material to refined cells except at initial conditions when equilibration is used. If a refinement is switched on during a simulation, material is distributed to the refined cells within each host cell according to the pore volumes of the refined cells. In particular, for a run employing the vertical equilibrium model, there is no way to set the contact depths correctly while accounting for oil immobilization effects. Neither can the effects of hysteresis be properly accounted for when a local grid is switched on during a simulation.

---

---

**Note:** This keyword has no effect in parallel runs, when an LGR is switched off (using the [LGROFF](#) keyword), it cannot be switched on again.

---

## Examples

## Example 1

This switches the refinement SOUTH on unconditionally:

```
LGRON
'SOUTH' /
```

## Example 2

The refinement NORTH is on whenever it has 2 or more active wells, and off whenever it has less than 2:

```
LGRON
-- NAME      NWELLS
  'NORTH'    2      /
```

## LICENSES

## Reserve ECLIPSE 100 option licenses

	ECLIPSE 300
x	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword may optionally be used to reserve ECLIPSE 100 option FLEX licenses at the beginning of the run, rather than waiting until a keyword activating the option is encountered. For certain options the activating keyword is not encountered until the SCHEDULE section, perhaps part way through a run, and it is possible that the run could be stopped at that point if an appropriate license is not available.

The data consists of one or more records, each containing the name of an ECLIPSE 100 option terminated by a slash (/). The set of records must be terminated by a blank record containing just a slash.

**Note:** This keyword is used by the Simulation launchers to work out which licenses are used (except for "parallel") in order to implement the license aware job scheduling for ECLIPSE 100 and ECLIPSE 300. In such case, the aliases below should not be used.

Please refer to the appropriate documentation in the ECLIPSE distribution, which details which license names are supported.

The option names (with aliases in *italic*) are:

LICENSES option	ECLIPSE option
'eclipse4d'	The Petro-elastic Model
'friction'	The Wellbore Friction Model
'gasfield'	Gas Field Operations Model
'gaslift'	Gas Lift Optimization
'lgr' or ' <i>lgrs</i> '	Local Grid Refinement and Coarsening
'multiseg' or ' <i>multisegwells</i> '	Multisegment Wells
'network' or ' <i>networks</i> '	The Network Option
'unencodedhmd'	Allow unencoded sensitivities output from the Gradient option.

Table 3.19: LICENSES options

Each option name can be in upper or lower case, and must be spelled out fully. Abbreviations are not recognized.

For the 2014.1 release of ECLIPSE, a number of license options were retired. If the LICENSES keyword is used with the following options, a warning message will be issued advising that the option has been retired.

- CO<sub>2</sub> Storage
- Coal Bed Methane Model
- Environmental Tracers
- Flux Boundary Conditions
- Foam Model
- Gas Calorific Value Control

- Polymer Flood Model
- Gi Pseudo-Compositional Model
- Solvent Model
- Surfactant Model

## Example

```
LICENSES  
  'network' /  
  'lgr' /  
  'friction' /

## LIFTOPT

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

## Turns on gas lift optimization

The LIFTOPT keyword activates the gas lift optimization facility (see "Gas lift optimization" of the *ECLIPSE Technical Description*), and sets parameters governing the lift gas increment size, the minimum economic gradient, and the frequency of optimization calculations. This keyword must be entered before any of the other keywords associated with the facility, namely [GLIFTOPT](#) and [WLIPTOPT](#).

The keyword is followed by a line containing between two and four items, ending with a slash (/).

## 1. Increment size for lift gas injection rate

Lift gas is allocated to individual wells in whole numbers of the increment size.

If gas lift optimization is no longer required, it can be turned off by entering a zero or negative number.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC), Mscf/day (FIELD), scc/hr (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

## 2. Minimum economic gradient of improvement in oil production rate per unit increase in lift gas injection rate

Further lift gas increments will not be allocated to a well if the resulting increase in oil production rate, multiplied by the well's weighting factor, divided by the lift gas increment size, is less than the minimum economic gradient.

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/Mscf (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

## 3. Minimum interval between gas lift optimizations

This item determines the frequency at which subsequent gas lift optimizations are performed. The distribution of lift gas is optimized at each timestep that starts after the specified interval has elapsed since the previous optimization.

ECLIPSE 100

If there is a production network, gas lift can only be optimized when the network is being balanced. The minimum interval between network balances is set in item 1 of keyword [NETBALAN](#).

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

DEFAULT: 0.0 (which will cause an optimization to be performed every timestep)

4. Optimize gas lift during each of the first [NUPCOL](#) iterations of the timestep?

**YES** The lift gas distribution is optimized during each of the first [NUPCOL](#) Newton iterations of the timestep. This enables flow targets and limits to be observed more accurately. (The value of [NUPCOL](#) can be set using keyword [NUPCOL](#) or [GCONTOL](#)). During any remaining iterations, the lift gas allocation will remain constant so as not to hinder their convergence.

**NO** Optimization is only performed in the first Newton iteration of the timestep. This takes less time than the **YES** option, but if reservoir conditions change appreciably over the timestep then rate targets and limits may not be obeyed accurately.

ECLIPSE 100

If there is a production network (see "Network option" in the *ECLIPSE Technical Description*), optimization can only be performed when the network is being balanced. Thus, the **YES** option to optimize in each of the first [NUPCOL](#) Newton iterations can only be used if the network is also being balanced with this frequency. (Setting a negative balancing interval in item 1 of keyword [NETBALAN](#) causes the network to be balanced in each of the first [NUPCOL](#) Newton iterations.) If the network is balanced only in the first iteration, the **NO** option is used regardless of the entry here.

DEFAULT: YES

End the data record with a slash (/).

## Example

```
LIFTOPT
-- increment    minimum    optimization    opt in lst
-- size         gradient   interval       NUPCOL its?
-- SM3/DAY      SM3/SM3    DAYS
4E4            5E-3      0.0            YES          /
```

## Limits for Li-correlation

This keyword takes two items of data, terminated with a slash (/), for each EoS region:

1. Lower limit for hydrocarbon-water interpolation  $f_g$   
DEFAULT: 0.75
2. Upper limit for hydrocarbon water interpolation  $f_o$   
DEFAULT: 1.25

These values are used to calculate a water-hydrocarbon relative permeability for single phase hydrocarbon states. Oil-gas and gas-oil relative permeabilities are only relevant if both oil and gas are present. This water-hydrocarbon  $K_{rh}$  must tend to the user entered  $K_{ro}$  when the composition is oil-like, and to  $K_{rg}$  when it is gas-like.

To set up a variable to interpolate between these two values, we define the pseudo critical temperature  $T^{\text{crit}}$ , given by the Li correlation as:

$$T^{\text{crit}} = \frac{\sum_j T_{cj} \cdot V_{cj} \cdot z_j}{\sum_j V_{cj} z_j} \quad \text{Eq. 3.109}$$

Then define  $f$  as:

$$f = \frac{T^{\text{crit}}}{T^{\text{res}}}$$

$f$  will clearly be 1 if the reservoir temperature is the critical temperature, but become greater than 1 for an oil ( $T^{\text{crit}} > T^{\text{res}}$ ) and less than 1 for a gas. If we choose values at which the system is to be regarded completely as an oil or a gas as  $f_o$  (1.25 by default) and  $f_g$  (0.75 by default), then an interpolating function may be defined as

$$E = \frac{f - f_g}{f_o - f_g} \quad \text{Eq. 3.110}$$

in the region  $f_g < f < f_o$ , and 0 or 1 outside this range. This goes from 0 when the system is gas-like ( $f$  below  $f_g$ ) to 1 when the system is oil-like ( $f$  above  $f_o$ ), with a linear interpolation in between.

See "[Near critical oil and gas relative permeabilities](#)" in the *ECLIPSE Technical Description* for further information.

	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword sets the coefficients for a linear combination of oil, water and gas. This keyword must be specified if you wish to set a linearly combined production rate target or use a linear combination of the phases to specify a guide rate. For example, the volume of a quantity,  $V_s$ , may be equal to

$$V_s = \alpha V_{oil} + \beta V_{wat} + \gamma V_{gas} \quad \text{Eq. 3.111}$$

and the flow rate of this quantity,  $Q_s$ , equal to

$$Q_s = \alpha Q_{oil} + \beta Q_{wat} + \gamma Q_{gas} \quad \text{Eq. 3.112}$$

for coefficients  $\alpha$ ,  $\beta$ ,  $\gamma$ . These coefficients can be specified using this keyword and then production rate targets may be specified for  $Q_s$ . The units of  $V_s$  can be specified with keyword [LCUNIT](#) (a default value UNIT is assumed). The units of  $Q_s$  are assumed to be those of  $V_s$  per day (METRIC, FIELD, PVT-M) or per hour (LAB).

The keyword is followed by a single line of data terminated with a slash (/).

- Oil coefficient,  $\alpha$ . This quantity can be a user defined argument (UDA) and can be set with keywords [UDQ](#) and [UDADIMS](#).  
 UNITS: UNIT/sm<sup>3</sup> (METRIC), UNIT/stb (FIELD), UNIT/scc (LAB), UNIT/sm<sup>3</sup> (PVT-M). Default value UNIT can be changed with [LCUNIT](#).  
 DEFAULT: 0.0
- Water coefficient,  $\beta$ . This quantity can be a user defined argument (UDA) and can be set with keywords [UDQ](#) and [UDADIMS](#).  
 UNITS: UNIT/sm<sup>3</sup> (METRIC), UNIT/stb (FIELD), UNIT/scc (LAB), UNIT/sm<sup>3</sup> (PVT-M). Default value UNIT can be changed with [LCUNIT](#).  
 DEFAULT: 0.0
- Gas coefficient,  $\gamma$ . This quantity can be a user defined argument (UDA) and can be set with keywords [UDQ](#) and [UDADIMS](#).  
 UNITS: UNIT/sm<sup>3</sup> (METRIC), UNIT/Mscf (FIELD), UNIT/scc (LAB), UNIT/sm<sup>3</sup> (PVT-M). Default value UNIT can be changed with [LCUNIT](#).  
 DEFAULT: 0.0

---

**Note:** This keyword must be specified before any linearly combined rate targets or limits are defined.

---

### Example

```
LINCOM
0.5 0.5 0.002 /
```

## LINKPERM

**Applies grid block permeabilities to cell faces**

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword may optionally be used to instruct ECLIPSE to treat the input grid block permeabilities as applying to the cell faces. ECLIPSE will then use the face permeabilities directly as linking permeabilities in the transmissibility calculation, instead of calculating the linking permeabilities as an average of the adjacent grid block permeabilities.

The keyword should be followed by up to three identifiers, to tell ECLIPSE which face (+ or -) to apply the grid block permeability to in each direction (I, J and K). For any directions not specified, the permeabilities will be treated as block center permeabilities in the usual manner.

The identifier 'I+' indicates that [PERMX](#) or [PERMR](#) should be applied to the face between blocks (I, J, K) and (I+1, J, K). Alternatively, the identifier 'I-' applies the permeability to the face between blocks (I, J, K) and (I-1, J, K).

The identifiers 'J+' and 'J-' apply similarly to [PERMY](#) or [PERMTHT](#), while 'K+' and 'K-' imply that permeabilities input by [PERMZ](#) should refer to corresponding block faces in the Z direction.

The data must be terminated by a slash (/).

The options specified by LINKPERM for each direction override those specified by [PERMAVE](#).

The use of linking permeabilities is described in "[Transmissibility calculations](#)" in the *ECLIPSE Technical Description*.

**Examples****Example 1**

Conventional geometry:

Permeabilities are input by [PERMX](#) for I+ block faces, [PERMY](#) for block centers and [PERMZ](#) for K- block faces.

```
LINKPERM
I+ K- /
```

**Example 2**

Radial geometry:

Permeabilities are input using [PERMTHT](#) for THETA+ block faces, while [PERMR](#) and [PERMZ](#) are defaulted to block center values.

```
LINKPERM
J+ /
```

## LIVEOIL

### The live oil option is to be used

This keyword can only be used with the `THERMAL` option. It allows hydrocarbon components to partition in the liquid (oil) and gas phases. This option is the default when the `THERMAL` keyword is specified in the `RUNSPEC` section.

This keyword has no associated data.

	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The LKRO keyword specifies the value of oil relative permeability at the maximum oil saturation within each grid block for scaling the low salinity (oil-wet) oil relative permeability saturation tables.

The LKRO keyword should only be used if oil is present in the model and if both the end-point scaling and low salinity options have been selected via the RUNSPEC keywords [ENDSCALE](#) and [LOWSALT](#) respectively.

The LKRO keyword should be followed by one real number for each grid block in the current input box specifying the maximum oil relative permeability. The data must be terminated by a slash (/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If the keyword LKRO is omitted for some or all of the grid blocks in a model where it could be specified, the oil relative permeabilities at maximum oil saturation will default to the values defined in the appropriate relative permeability tables.

See "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for details of the end-point scaling procedure.

## LOAD

## Load a SAVE file to perform a fast restart

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The LOAD keyword must be used when performing a fast restart run. It tells ECLIPSE to read the SAVE file generated by the original run. The SAVE file contains processed information from the RUNSPEC, GRID, EDIT, PROPS and REGIONS sections of the original data file, and these sections should be omitted from the data file of the restart run. Thus the LOAD keyword should be the **first** keyword in the data file.

See also keywords [SAVE](#) and [RESTART](#).

The LOAD keyword should be followed by one line of data containing the following items:

1. The root name of the SAVE file to be loaded  
(Enclosed in quotes.)
2. The report step that the run should start from.

---

**Note:** If the run which generated the file referred to in item 1 had the [RPTRST](#) mnemonic BASIC=6, then each timestep in that run will have generated save file information. In this case, the report number that needs to be entered here is the timestep number. This information can be obtained from the print file for that run.

---

## ECLIPSE 100

In ECLIPSE 100 this method of specifying the step at which the runs is to start from is entirely optional. If it is used (this data item is not defaulted) then ECLIPSE 100 will expect to find the time dependent restart record on the SAVE file, see the [SAVE](#) keyword or the [SAVE](#) argument in the [RPTRST](#) keyword. To restart from a standard Restart file the [RESTART](#) keyword should be used in the [SOLUTION](#) section and this data item defaulted.

3. The NOSIM switch for the [RESTART](#) run.  
SIM     Perform a normal simulation run  
NOSIM   Perform a data checking run only  
  
DEFAULT: SIM
4. The formatted/unformatted status of the SAVE file to be read in  
(enclosed in quotes)  
FORMATTED or UNFORMATTED  
DEFAULT: UNFORMATTED
5. A switch to request a SAVE file to be output (enclosed in quotes).  
YES or NO  
DEFAULT: NO

## ECLIPSE 100 only

Terminate the record with a slash (/).

The LOAD keyword is used in place of the RUNSPEC, GRID, EDIT, PROPS and REGIONS sections. It passes control to the SOLUTION section (there is no need to use the SOLUTION keyword), where the [RESTART](#) keyword should be supplied to tell ECLIPSE to read the [RESTART](#) file. The remainder of the data file should specify the [SUMMARY](#) and [SCHEDULE](#) section data.

- ECLIPSE 300** Fast restarts are not supported for parallel runs.
- ECLIPSE 300** In ECLIPSE 300, if the SAVE file is unified or formatted (that is UNISAVE or FMTSAVE used in original run), then UNIFIN or FMTIN should be placed before the LOAD keyword. Note that ECLIPSE 100 does not support multiple SAVE files.
- ECLIPSE 100** The SAVE file switch (item 5) needs to be set to YES if the subsequent Restart files are to be written to the SAVE file. (See the SAVE argument in the [RPTRST](#) keyword.)
- ECLIPSE 100** The pre-2000A ECLIPSE 100 format of the LOAD keyword (without the report step data item) is still recognized, effectively defaulting the report step.
- It is not possible to load a SAVE file from a previous version of ECLIPSE; the SAVE file must be created using the same version of ECLIPSE.

## Examples

### Example 1

## LOWSALT

## Enables modeling of low salinity effects in the Brine model

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword enables the modeling of low salt water. It will automatically turn on the [BRINE](#) option if this keyword is not already present.

See "[Brine tracking](#)" in the *ECLIPSE Technical Description* for further information.

The LOWSALT keyword has no associated data.

## LPCW

## Scaled low salinity (oil-wet) maximum oil-water capillary pressure

x	ECLIPSE 100
	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The LPCW keyword specifies the maximum value of oil-water capillary pressure for scaling the low-salinity (oil-wet) water-oil capillary pressure saturation tables.

The LPCW keyword should only be used if water and oil are present in the model and if both the end-point scaling and low salinity options have been selected via the RUNSPEC keywords [ENDSCALE](#) and [LOWSALT](#) respectively.

The LPCW keyword should be followed by one real number for each grid block in the current input box specifying the maximum oil-water capillary pressure. The data must be terminated by a slash (/).

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If the keyword LPCW is omitted for some or all of the grid blocks in a model where it could be specified, the maximum oil-water capillary pressures at connate water saturation will default to the values defined in the appropriate capillary pressure tables.

See "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for details of the end-point scaling procedure.

### Notes

- The LPCW keyword should not be used in combination with the J-function option specified by the keywords [JFUNC](#) or [JFUNCR](#) because the J-function calculation is used to define the water capillary pressure scaling and any values defined by the input LPCW keyword will be ignored. In this case the maximum capillary pressure for each cell is reported in the INIT file.
- The LPCW values used to scale the oil-water capillary pressure must be consistent with the capillary pressure values in the tables. In particular both must possess the same sign.

### Example

```

-- In the RUNSPEC section:
DIMENS
 1 7 3 /
ENDSCALE
/
-- In the PROPS section:
----- IX1-IX2 JY1-JY2 KZ1-KZ2
BOX
      1 1 2 7 1 3
LPCW
6*10.0
6*12.5
6*15.0 /

```

## LSALTFNC Tables of low-salt weighting factors versus salt concentration

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is set to input the weighting factors for the low-salinity saturation functions as a function of the salt concentration. The data comprises NTSFUN (item 1 of keyword [TABDIMS](#)) tables, each terminated by a slash (/). These coefficients are used in calculating the saturation end points, the water and oil relative permeabilities and the water-oil capillary pressure when the [LWSALT](#) option is active.

Each table consists of 3 columns of data:

1. Salt concentration

Note that the effective salinity from the multi-component brine model (keyword [ECLMC](#)) will not be used to provide salinity values for this table; [ECLMC](#) is incompatible with this keyword.

The values should increase monotonically down the column.

UNITS: kg/sm<sup>3</sup> ([METRIC](#)), lb/stb ([FIELD](#)), gm/scc ([LAB](#)), kg/sm<sup>3</sup> ([PVT-M](#))

2. Weighting factor  $F_1$  for the low-salinity saturation endpoints and the relative permeabilities interpolation.

The values should decrease monotonically down the column.

A value of 0.0 implies that only the high-salinity saturation functions will be used (tables defined by [SATNUM](#)) and a value of 1.0 implies that only low-salinity saturation functions will be used (tables defined by [LWSLTNUM](#)).

The value should not be greater than 1.0 or less than 0.0.

3. Weighting factor  $F_2$  for the low-salinity capillary pressure interpolation.

The values should decrease monotonically down the column.

A value of 0.0 implies that only the high-salinity saturation functions will be used (as defined by [SATNUM](#)) and a value of 1.0 implies that only low-salinity saturation functions will be used (as defined by [LWSLTNUM](#)).

The value should not be greater than 1.0 or less than 0.0.

This item may be defaulted and is then taken as the value in the second column.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than [NSSFUN](#) (item 3 of keyword [TABDIMS](#)).

---

**Note:** NTSFUN tables must be supplied; however the [LWSLTNUM](#) table number is used. A defaulted table after the first one is copied from the previous table.

---

---

**Note:** When the [SURFACTW](#) option is active, the weighting factors in a [LWSLTNUM](#) table are used to interpolate between the immiscible oil-wet high-salinity curves ([SATNUM](#) tables) and immiscible oil-wet low-salinity curves ([LWSLTNUM](#) tables). The same factors are used to interpolate between the immiscible water-wet high-salinity curves (tables defined by [SURFWNUM](#)) and the immiscible water-wet low-salinity curves (tables defined by [LSLTWNUM](#)).

---

## Example

With NTSFUN =4 and NSSFUN >2 specified in keyword `TABDIMS`:

```
LSALTFNC
--unused table
0  1.0 1*
20 0.0 1*
/
-- Second table copied from previous table
-- factors used for salinity interpolation in region 1
/
--unused table
/
-- factors used for salinity interpolation in region 2
0  1.0 1*
30 0.0 1*

This is an optional keyword which modifies the convergence criteria used to control the linear iterations of the WARP linear solver. The WARP linear solver is initiated using the [WARP](#) keyword. See "[Nested factorization for LGRs](#)" in the *ECLIPSE Technical Description* for more details.

Specific criteria may be assigned to individual local grids or sub-grids using keyword [LSCRITS](#), which will override the criteria set here.

The keyword should be followed by some or all of the following items, terminated by a slash (/).

1. **MXOR** Maximum number of orthogonal vectors used in the GMRES linear solver for all local grids.  
DEFAULT: 0
2. **NIT** Maximum number of linear iterations for all local grids.  
DEFAULT: 0
3. **TOL** Required improvement in linear solver RMS residual for all local grids.  
DEFAULT: 1.0E-3

## Example

```
LSCRIT
5 5 1.0E-2 /
```

	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This is an optional keyword which modifies the convergence criteria used to control the linear iterations on individual sub-grids within the WARP linear solver (activated with keyword [WARP](#)). The area covered by a sub-grid can best be seen by visualizing the output from the SUBG mnemonic in the [RPTRST](#) keyword.

The keyword should be followed one or more records. Each record is terminated by a slash (/). The set of records must be terminated by an empty record with a single slash.

1. 'NAME' If the name of a local grid is entered, the convergence criteria in the following items are applied to all sub-grids within this local-grid.

If the string 'BASE' is entered, the convergence criteria in the following items are applied to all sub-grids within the base grid.

If the string does not match an LGR name (or 'BASE'), the first 3 letters of the string are used to identify the group of sub-grids to which the convergence criteria are to be applied:

'--C' The rest of the 8-character string is interpreted as a color index. The convergence criteria in the following items are applied to all sub-grids with this color. The color of sub-grids is best visualized using the output from the COLR mnemonic in the [RPTRST](#) keyword.

'--S' The rest of the 8-character string is interpreted as a sub-grid index. The convergence criteria in the following items are applied to the sub-grid with this index. The sub-grids within WARP are best visualized using the output from the SUBG mnemonic in the [RPTRST](#) keyword

2. MXOR Maximum number of the orthogonal vectors used in the GMRES linear solver for this local grid.

DEFAULT: 0

3. NIT Maximum number of linear iterations for this sub-grid.

DEFAULT: 0

4. TOL Required improvement in linear solver RMS residual for this sub-grid.

DEFAULT: 1.0E-3

See "[The ECLIPSE 300 WARP linear solver](#)" in the *ECLIPSE Technical Description*.

---

**Note:** The index to individual sub-grids will change as a function of the number of processors set in the [PARALLEL](#) keyword, or the coloring strategy specified in the [WCOL](#) keyword.

---

### Example

```
LSCRITS
BASE 10 10 1.0E-4 / --set base grid
--C3 1 1 1.0E-3 / --set color 3
--L2 3 3 1.0E-4 / --set level 2 refinement
rad01 40 40 1.0E-7 / --set lgr rad01
rad02 40 40 1.0E-7 / --set lgr rad02
rad01 40 40 1.0E-7 / --set lgr rad01
/

## LSTWNUM Low-salt water-wet saturation function region numbers

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by one integer for every grid block specifying the low-salinity water-wet saturation function region to which it belongs. The region number should not be less than 1 or greater than NTSFUN (see item 1 of keyword [TABDIMS](#)). The data must be terminated by a slash (/).

The low salinity water-wet saturation function region number specifies the saturation table (input using [SWFN](#), [SOF3](#) and related keywords, in the PROPS section) to be used to calculate relative permeabilities and capillary pressures in each grid block.

The water-wet curves are computed as a weighted average between the low salinity water-wet saturation functions (LSTWNUM region number) and the high salinity water-wet saturation functions ([SURFNUM](#) region number). The low-salinity weighting factors are taken from the LWSLNUM table in the [LSALTFNC](#) keyword.

This keyword can be used only if the [SURFACTW](#) and [LOWSALT](#) keywords have been entered in the RUNSPEC section to initialize the modeling of the low salinity effects in the brine model, and the surfactant change to wettability.

Grid blocks are ordered with the X-axis index cycling fastest, followed by the Y- and Z-axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

---

**Note:** The LSTWNUM keyword or its alias [LWSNUM](#) must be specified if the [LOWSALT](#) and [SURFACTW](#) options have been specified.

---

### Example

With NTSFUN=4 specified in keyword [TABDIMS](#) and NDIVIX=8, NDIVIY=6 and NDIVIZ=5 specified in RUNSPEC keyword [DIMENS](#):

```
LSTWNUM
144*3 96*4 /
```

## LSNUM

## Low salinity (oil-wet) saturation function region numbers

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by one integer for every grid block specifying the low-salinity saturation function region to which it belongs. The region number should not be less than 1 or greater than NTSFUN (see item 1 of keyword [TABDIMS](#)). The data must be terminated by a slash (/).

The low salinity oil-wet saturation function region number specifies the saturation table (input using [SWFN](#), [SOF3](#) and related keywords in the PROPS section) to be used to calculate relative permeabilities and capillary pressures in each grid block.

The oil-wet curves are computed as a weighted average between the low salinity oil-wet saturation functions (LSNUM region number) and the high salinity oil-wet saturation functions ([SATNUM](#) region number). The low-salinity weighting factors are taken from the LSNUM region specified tables in the [LSALTFNC](#) keyword.

This keyword can be used only if the [LOWSALT](#) keyword has been entered in the RUNSPEC section.

When the Surfactant option is active, the LSNUM region numbers correspond to the immiscible low salinity curves. For the [SURFACTW](#) option, this corresponds to the immiscible oil-wet low salinity curves. The SATNUM region numbers correspond to the immiscible high salinity curves or to the immiscible oil-wet high salinity curves if the SURFACTW option is active.

Grid blocks are ordered with the X-axis index cycling fastest, followed by the Y- and Z-axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

---

**Note:** The LSNUM keyword is an alias for the [LWSLTNUM](#) keyword. One of these keywords must be specified if the [LOWSALT](#) option has been specified.

---

### Example

With NTSFUN=2 specified in keyword [TABDIMS](#) and NDIVIX=8, NDIVIY=6 and NDIVIZ=5 specified in RUNSPEC keyword [DIMENS](#):

```
LSNUM
 144*1 96*2 /
```

## LSOGCR

## Scaled low salinity (oil-wet) critical oil-in-gas saturations

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The LSOGCR keyword specifies the critical oil in gas saturation (that is, the largest oil saturation for which the oil relative permeability to gas is zero) within each grid block for scaling the low salinity (oil-wet) oil relative permeability to gas saturation tables.

The tabulated oil relative permeability to gas functions are scaled between the critical oil in gas saturation defined by the LSOGCR keyword and the maximum oil saturation defined in terms of the minimum water and gas saturations using the [LSWL](#) and [SGL](#) keywords respectively.

The LSOGCR keyword should only be used if gas is present in the model and if both the end-point scaling and low salinity options have been selected via the RUNSPEC keywords [ENDSCALE](#) and [LOWSALT](#) respectively.

The LSOGCR keyword should be followed by one real number for each grid block in the current input box specifying the critical oil in gas saturation. The saturation should be in the range 0.0 to 1.0 inclusive. The data must be terminated by a slash (/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If the keyword LSOGCR is omitted for some or all of the grid blocks in a model where it could be specified, the critical oil in gas saturations for the low salinity oil relative permeability to gas calculations will default to the values defined in the appropriate relative permeability tables.

See "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for details of the end-point scaling procedure.

## LSWL

## Scaled low salinity (oil-wet) connate water saturations

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The LSWL keyword specifies the connate water saturation (that is, the smallest water saturation in a water saturation function table) within each grid block for scaling the low salinity (oil-wet) oil-water capillary pressure and oil relative permeability to water tables.

The tabulated oil-water capillary pressure functions are scaled linearly between the connate water saturation defined using the LSWL keyword and the maximum water saturation defined using the LSWU keyword.

The LSWL keyword is also used for scaling the oil relative permeability curves.

If the connate water saturation has additionally been specified using the LSWLPC keyword, this saturation end-point will be used instead for scaling the oil-water capillary pressure curves. The connate water saturation entered using LSWL will then only be used to scale the oil relative permeability curves.

The LSWL keyword should only be used if water is present in the model and if both the end-point scaling and low salinity options have been selected via the RUNSPEC keywords ENDSCALE and LOWSALT respectively.

The LSWL keyword should be followed by one real number for each grid block in the current input box specifying the connate water saturation. The saturation should be in the range 0.0 to 1.0 inclusive. The data must be terminated by a slash (/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If the keyword LSWL is omitted for some or all of the grid blocks in a model where it could be specified, the connate water saturations for low salinity (oil-wet) oil relative permeability and capillary pressure calculations will default to the values defined in the appropriate relative permeability tables.

See "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for details of the end-point scaling procedure.

## LTOSIGMA Calculate Sigma from Lx, Ly, Lz

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is optional in dual porosity runs with the viscous displacement option active (keyword VISCD in the RUNSPEC section). It enables ECLIPSE to calculate the sigma factor from the input matrix block dimensions Lx, Ly and Lz.

The keyword should be followed by some or all of the following items, to allow SIGMA to be calculated from Lx, Ly, Lz. Item 4 is used to calculate SIGMAGD from Lz if the gravity drainage option is active.

The data must be terminated by a slash (/).

Items 1 to 3:  $f_x, f_y, f_z$  factors in the Sigma calculation. DEFAULT: 4.0

item 4:  $f_{gd}$  factor in the Sigmagd calculation. DEFAULT: 0.0

item 5: Specify the transmissibility option to use

XONLY Use the X-permeability only (see below)

ALL Use all three directional permeabilities

DEFAULT: XONLY

This sigma factor is calculated from the matrix block size using the expression:

$$\Sigma = \frac{f_x}{l_x^2} + \frac{f_y}{l_y^2} + \frac{f_z}{l_z^2} \quad \text{Eq. 3.113}$$

where

$l_x, l_y$  and  $l_z$  are x, y and z dimensions of the matrix blocks entered using the LX, LY and LZ keywords.

(Any zero (defaulted) values of  $l_x, l_y$  or  $l_z$  do not contribute to this sum.)

The Sigmagd factor is calculated from the matrix block height the using the expression:

$$\Sigma_{gd} = \frac{f_{gd}}{l_z^2} \quad \text{Eq. 3.114}$$

or zero when  $l_z = 0.0$  (defaulted).

If item 5 is defaulted (XONLY), the Sigma factor is used directly in the matrix-to-fracture transmissibility calculations. In this case the transmissibility is given by

$$\text{TR} = \text{CDARCY} \cdot K \cdot V \cdot \sigma \quad \text{Eq. 3.115}$$

where K is taken as the X-permeability in the matrix.

Setting item 5 to ALL modifies the calculation of the transmissibility to utilize the matrix permeability in all three directions:

$$\text{TR} = \text{CDARCY} \cdot V \cdot \left( \frac{f_x \cdot K_x}{l_x^2} + \frac{f_y \cdot K_y}{l_y^2} + \frac{f_z \cdot K_z}{l_z^2} \right) \quad \text{Eq. 3.116}$$

---

**Note:** Any values of SIGMA(V) and SIGMAGD(V) entered in the GRID section are ignored if the keyword is used.

---

See also the [LX](#), [LY](#), [LZ](#), [SIGMA](#) and [SIGMAGD](#) keywords.

## Example

```
LTOSIGMA
4.0 4.0 0.0 /
```

## LTRACE

# Force a streamline trace for the Lagrangian tracer solver option

The LTRACE keyword contains no items. When this keyword is encountered, streamlines will be retraced at the end of the next timestep.

### Example

```
LTRACE
```

	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword sets up a number of tracers for a lumped simulation (keyword [LUMPDIMS](#) in the [RUNSPEC](#) section), associating each of them with a particular lumped component used in the study.

The keyword should be followed by one line for each lumped hydrocarbon component in the simulation. Each line must contain the data items listed below, and is terminated by a slash (/). The set of records must end with a blank record, containing only a slash (/)

Record 1 'Lumped' hydrocarbon component name

Each name must correspond to those given in the [CNAMES](#) keyword.

Record 2 The number of detailed components in this lumped component, NDET

Record 3 Name given to the tracer representing the first detailed component of item 1

...

...

3+NDET-1 Name given to the tracer representing the NDET<sup>th</sup> detailed component of item 1

---

**CAUTION:** The order in which these tracer names are entered is very important, as it is implicitly used by the [DETAILVD](#) keyword when calculating the mole fractions of the initial distribution of the detailed components, and by other keywords defining detailed component properties.

---

---

**Note:** It is not necessary to have a detailed representation of every component in the 'lumped' simulation.

---

### Example

Two lumped components, having two and three detailed components respectively:

```
LUMPING
C1 2 Z1 Z2/
C2 3 Z3 Z4 Z5/
/
```

## LWKRO

## Scaled low salinity water-wet end point oil relative permeabilities

## LWKRORW Scaled low salinity water-wet end point oil relative permeabilities

x	ECLIPSE 100
	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The LWKRORW keyword specifies the value of oil relative permeability at the critical water saturation within each grid block for scaling the low salinity water-wet oil relative permeability saturation tables.

The LWKRORW keyword should only be used if oil and water are present in the model and if the end-point scaling, low salinity and surfactant wettability options have been selected via the RUNSPEC keywords [ENDSCALE](#), [LOWSALT](#) and [SURFACTW](#) respectively.

The LWKRORW keyword should be followed by one real number for each grid block in the current input box specifying the oil relative permeability at the critical water saturation. The data must be terminated by a slash (/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If the keyword LWKRORW is omitted for some or all of the grid blocks in a model where it could be specified, the oil relative permeabilities at critical water saturation will default to the values defined in the appropriate relative permeability tables.

See "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for details of the end-point scaling procedure.

## LWPCW

## Scaled low salinity water-wet maximum oil-water capillary pressure

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The LWPCW keyword specifies the maximum value of oil-water capillary pressure for scaling the low salinity water-wet water-oil capillary pressure saturation tables.

The LWPCW keyword should only be used if water and oil are present in the model and if the end-point scaling, low salinity and surfactant wettability options have been selected via the RUNSPEC keywords [ENDSCALE](#), [LOWSALT](#) and [SURFACTW](#) respectively.

The LWPCW keyword should be followed by one real number for each grid block in the current input box specifying the maximum oil-water capillary pressure. The data must be terminated by a slash (/).

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If the keyword LWPCW is omitted for some or all of the grid blocks in a model where it could be specified, the maximum oil-water capillary pressures at connate water saturation will default to the values defined in the appropriate capillary pressure tables.

See "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for details of the end-point scaling procedure.

### Notes

- The LWPCW keyword should not be used in combination with the J-function option specified by the keywords [JFUNC](#) or [JFUNCR](#) because the J-function calculation is used to define the water capillary pressure scaling and any values defined by the input LPCW keyword will be ignored. In this case the maximum capillary pressure for each cell is reported in the INIT file.
- The LWPCW values used to scale the oil-water capillary pressure must be consistent with the capillary pressure values in the tables. In particular both must possess the same sign.

## LWSLTNUM Low-salt oil-wet saturation function region numbers

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by one integer for every grid block specifying the low-salinity saturation function region to which it belongs. The region number should not be less than 1 or greater than NTSFUN (see item 1 of keyword [TABDIMS](#)). The data must be terminated by a slash (/).

The low salinity oil-wet saturation function region number specifies the saturation table (input using [SWFN](#), [SOF3](#) and related keywords in the PROPS section) to be used to calculate relative permeabilities and capillary pressures in each grid block.

The oil-wet curves are computed as a weighted average between the low salinity oil-wet saturation functions (LWSLTNUM region number) and the high salinity oil-wet saturation functions ([SATNUM](#) region number). The low-salinity weighting factors are taken from the LWSLTNUM table in the [LSALTFNC](#) keyword.

This keyword can be used only if the [LOWSALT](#) keyword has been entered in the RUNSPEC section to initialize the modeling of the low salinity effects in the Brine Model.

When the surfactant option is active, the LWSLTNUM region numbers correspond to the immiscible low salinity curves. For the [SURFACTW](#) option, it corresponds to the immiscible oil-wet low salinity curves. The SATNUM region numbers correspond to the immiscible high salinity curves or to the immiscible oil-wet high salinity curves if the SURFACTW option is active.

Grid blocks are ordered with the X-axis index cycling fastest, followed by the Y- and Z-axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

---

**Note:** The LWSLTNUM keyword or its alias [LSNUM](#) must be specified if the [LOWSALT](#) option has been specified.

---

### Example

With NTSFUN=2 specified in keyword [TABDIMS](#) and NDIVIX=8, NDIVIY=6 and NDIVIZ=5 specified in RUNSPEC keyword [DIMENS](#):

```
LWSLTNUM
144*1 96*2 /
```

## LWSNUM

	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The LWSOGCR keyword specifies the critical oil in gas saturation (that is, the largest oil saturation for which the oil relative permeability to gas is zero) within each grid block for scaling the low salinity water-wet oil relative permeability to gas saturation tables.

The tabulated oil relative permeability to gas functions are scaled between the critical oil in gas saturation defined by the LWSOGCR keyword and the maximum oil saturation defined in terms of the minimum water and gas saturations using the [LSWL](#) and [SGL](#) keywords respectively.

The LWSOGCR keyword should only be used if gas is present in the model and if the end-point scaling, low salinity and surfactant wettability options have been selected via the RUNSPEC keywords [ENDSCALE](#), [LOWSALT](#) and [SURFACTW](#) respectively.

The LWSOGCR keyword should be followed by one real number for each grid block in the current input box specifying the critical oil in gas saturation. The saturation should be in the range 0.0 to 1.0 inclusive. The data must be terminated by a slash (/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If the keyword LWSOGCR is omitted for some or all of the grid blocks in a model where it could be specified, the critical oil in gas saturations for the low salinity water-wet oil relative permeability to gas calculations will default to the values defined in the appropriate relative permeability tables.

See "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for details of the end-point scaling procedure.

## LWSWL

## Scaled low salinity water-wet connate water saturations

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The LWSWL keyword specifies the connate water saturation (that is, the smallest water saturation in a water saturation function table) within each grid block for scaling the low salinity water-wet oil-water capillary pressure and oil relative permeability to water tables.

The tabulated oil-water capillary pressure functions are scaled linearly between the connate water saturation defined using the LWSWL keyword and the maximum water saturation defined using the LWSWU keyword.

The LWSWL keyword is also used for scaling the oil relative permeability curves.

If the connate water saturation has additionally been specified using the LWSWLPC keyword, this saturation end-point will be used instead for scaling the oil-water capillary pressure curves. The connate water saturation entered using LWSWL will then only be used to scale the oil relative permeability curves.

The LWSWL keyword should only be used if water is present in the model and if the end-point scaling, low salinity and surfactant wettability options have been selected via the RUNSPEC keywords ENDSCALE, LOWSALT and SURFACTW respectively.

The LWSWL keyword should be followed by one real number for each grid block in the current input box specifying the connate water saturation. The saturation should be in the range 0.0 to 1.0 inclusive. The data must be terminated by a slash (/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If the keyword LWSWL is omitted for some or all of the grid blocks in a model where it could be specified, the connate water saturations for low salinity water-wet oil relative permeability and capillary pressure calculations will default to the values defined in the appropriate relative permeability tables.

See "Saturation table scaling" in the *ECLIPSE Technical Description* for details of the end-point scaling procedure.

	SUMMARY
	SCHEDULE

This keyword is entirely optional.

The keyword actually specifies **grid axes** and the grid origin relative to the map coordinates. It is normally output by grid pre-processors so that the origin of the maps used to generate the grid can be stored. The origin is then available through the Grid file for post-processing.

In figure 3.9, the map coordinates are a right-handed system with the z-axis pointing **up**. The grid is laid out on the map; its axes form a right-handed system with the z-axis pointing **down**, using the ECLIPSE convention, and therefore appear as a left-handed system in the diagram.

The grid axes are specified by three points: a point on the grid Y-axis, the grid origin, and a point on the X-axis. They are given in this order to conform to the right-handed map coordinate system used.

Following the keyword line, there is a single record containing six items of data, ending with a slash (/):

1. X1 The X coordinate of one point of the grid Y-axis relative to the map  
UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)
2. Y1 The Y coordinate of one point of the grid Y-axis relative to the map  
UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)
3. X2 The X coordinate of the grid origin relative to the map  
UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)
4. Y2 The Y coordinate of the grid origin relative to the map  
UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)
5. X3 The X coordinate of one point of the grid X-axis relative to the map  
UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)
6. Y3 The Y coordinate of one point of the grid X-axis relative to the map  
UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

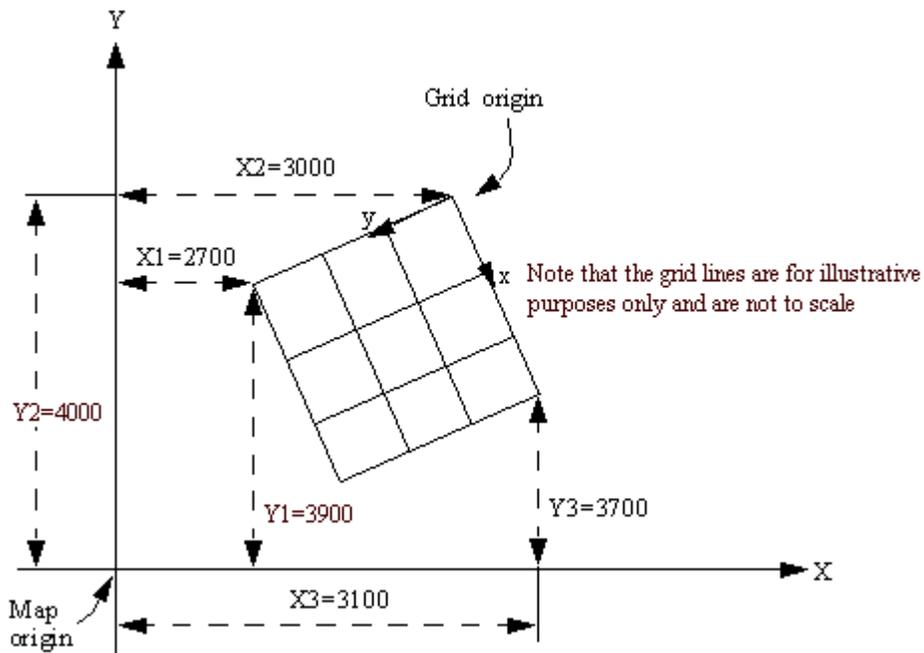

Figure 3.9. Meanings of the MAPAXES keyword entries

See also the [MAPUNITS](#) keyword.

### Example

```
MAPAXES
2700 3900 3000 4000 3100 3700 /
```

## MAPUNITS **Specifies units used for MAPAXES data**

x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is entirely optional. It is normally output by grid pre-processors.

The MAPUNITS keyword defines the units used for the [MAPAXES](#) data, which defines the simulation grid position with respect to maps.

Following the keyword line, there is a single record containing one item of data, ending with a slash (/).

---

**CAUTION:** Use the European spelling METRES: the US spelling METERS is not recognized.

---

### Example

```
MAPUNITS
METRES /
```

The units are then available through the GRID file for post-processing.

See also the [MAPAXES](#) keyword.

## MASSFLOW Tables of river massflow data

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is used to define the upstream massflow boundary condition of a river as a function of the time.

The keyword is followed by NMMAST tables with a maximum of MXMAST entries in each. These numbers are set with the RIVRDIMS keyword. Each table is terminated with a slash (/).

Each table consists of 5 columns of data:

1. Day  
 The name of the month abbreviated to three characters  
 JAN, FEB, MAR, APR, MAY, JUN, JLY, AUG, SEP, OCT, NOV or DEC.  
 JUL is an acceptable alternative to JLY.
2. Year input should be a 4 digit integer.
3. Time of observation in 24 hour clock format, hh:mm  
 Do not use 24:00; use 00:00 of the following day.
4. Massflow at this time  
 UNITS: m<sup>3</sup>/day (METRIC), ft<sup>3</sup>/day (FIELD), cc/hr (LAB)

There is a minimum of two rows of data per table. End the table with a slash (/). After the first tables subsequent tables may be defaulted to the previous table by just entering a slash.

The times, items 1-3 considered as a whole, must be monotonically increasing down the table.

### Example

```
MASSFLOW
1 JAN 1995 00:00 1589.0
8 FEB 1995 2:45 2010.0
15 SEP 1995 12:00 307.0
/
```

## MATCORR **Initiates the material correction option**

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The material correction option can be used to reduce the accumulated material balance error in a simulation. In some cases the facility may allow the simulation to run more quickly. The application of the technique when the non-linear equations are not fully converged should only be tried with great care.

The application of material correction is not available in conjunction with the parallel option.

The keyword is followed by the following items of data, all of which are normally defaulted. The data must be terminated with a slash (/).

1. Newton iteration number after which the correction can be applied, provided the solution has reached the convergence criteria supplied in items 2 and 3.

DEFAULT: 12

2. Non-linear convergence error.

DEFAULT: 0.01

3. Material balance error.

DEFAULT: 1E-6

Following a timestep, the material balance correction subtracts any material balance error from the residual of the subsequent timestep. Hence the material balance error at one timestep is carried over and resolved at the next timestep. This method leads to very small accumulated material balance errors.

The correction is applied either when the timestep has converged, or earlier when the input data items allow.

### Examples

#### Example 1

Apply the material balance correction.

```
MATCORR
/
```

#### Example 2

Apply the material balance correction after Newton iteration 2, provided the solution has converged to a looser than normal tolerance.

```
MATCORR
3 0.1 1E-6 /
```

## MAXTRANZ **Maximum z-transmissibility**

	<b>SPECIAL</b>
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by a single positive real number, the maximum allowed z-transmissibility between two cells. Where calculated values are larger than this value, they are reduced.

UNITS: cP.rm<sup>3</sup>/day/bars (METRIC), cP.rb/day/psi (FIELD), cP.rcc/hr/atm (LAB), cP.rm<sup>3</sup>/day/atm (PVT-M)

DEFAULT: 1.0E20 (all unit sets)

### Example

```
MAXTRANZ
20000 /
```

## MAXVALUE **Apply a maximum limit to an array in the current box**

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
x	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword may be followed by any number of records, each of which is terminated by a slash (/). The data is terminated by a null record (that is a record with no data before the terminating slash). Each record consists of at least two items of data.

1. The name of the array to be modified.
2. The maximum value for the array specified by item 1.

The constant should not be negative, but may be real or integer.

The following data items may be used to redefine the input box for this and subsequent operations within the current keyword. If these items are not defined (a slash is inserted after item 2), they default to the values that were used for the previous operation within the current keyword. For the first operation in the keyword, the box defaults to the values set by the most recent [BOX](#) or [ENDBOX](#) keyword. If there is no preceding [BOX](#) or [ENDBOX](#) in the current section, the box is taken to include the entire reservoir.

3. IX1 First block to be modified on the X axis.
4. IX2 Last block to be modified on the X axis.
5. JY1 First block to be modified on the Y axis.
6. JY2 Last block to be modified on the Y axis.
7. KZ1 First block to be modified on the Z axis.
8. KZ2 Last block to be modified on the Z axis.

The data must satisfy

$$1 \leq IX1 \leq IX2 \leq NDIVIX$$

$$1 \leq JY1 \leq JY2 \leq NDIVIY$$

$$1 \leq KZ \leq KZ2 \leq NDIVIZ \text{ (where NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword DIMENS)}$$

**Note:** If the MAXVALUE keyword is used before an array has been input, it has no effect on that array when it is subsequently input. MAXVALUE can only operate on arrays that are already input.

See also keywords [BOX](#), [ENDBOX](#), [EQUALS](#), [ADD](#), [MULTIPLY](#), [MINVALUE](#) and [COPY](#).

### Example

In the PROPS section:

```

-- ARRAY   MAX   ----- BOX -----
MAXVALUE
  'SWL'    0.35   3 8   1 10   3 3 /
  'SWCR'   0.40           / defaults to last specified box
/

```

## MEMORY

**Allocates the required memory at start of run**

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data consists of 2 integers, the second of which allows the user to change the default memory allocations for character strings that ECLIPSE 100 uses when running. For parallel runs the value is applied to each processor.

ECLIPSE 100 and 300 use dynamic memory. Therefore, this keyword is of little value and should be avoided.

This keyword is ignored by ECLIPSE 300 runs.

The first item is ignored in ECLIPSE 100. The second item allows the imposition of a fixed amount of memory for character strings in ECLIPSE 100. The simulation will stop with an error if this amount is exceeded. By default, ECLIPSE 100 determines a large enough size dynamically.

1. Unused.
2. A fixed amount of character memory in thousands of CHARACTER\*8 strings.

DEFAULT: in ECLIPSE 100 the character storage is allocated to an adequate value at run time.

**Example**

This run allocates a fixed storage for 20 000 (twenty thousand) CHAR\*8 strings.

```
MEMORY
1* 20 /
```

## MEMSAVE Indicates use of Up-Front Memory option

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The up-front memory option can only be used if you already know the active cell information when building a dataset.

There are 2 different ways this option may be used:

1. The [ACTNUM](#) keyword and its data must be supplied at the very top of the GRID section before the grid properties have been specified.
2. Use the [GDFILE](#) keyword to import an extensible grid file. Only .EGRID files can be imported as this grid file contains the necessary active cell information required to use this option. The [GDFILE](#) keyword, together with the imported filename, must be specified at the very top of the GRID section.

Local grid refinement option. If a deck contains local grid refinements, it is important that the LGR data, including any ACTNUM information, be specified very early on in the GRID section, otherwise grid property arrays will not be set up properly.

To compute grid properties, such as pore volume and transmissibility, ECLIPSE will focus on the active cells only. This is especially important for large models that have difficulty processing the GRID section, and reaching the PROPS section.

MEMSAVE contains no items.

---

**Note:** Not all runs will benefit from using this keyword. For instance, simulation runs that could benefit are datasets with a low ratio of active cells to total number of grid cells; decks using [EQUALS](#) / [ADD](#) / [MULTIPLY](#) / [COPY](#) to define grid properties like [PORO](#), [PERMX](#), for example.

---

### Current restrictions

If any of the following keywords are present in a dataset, then the simulator will turn the up-front memory option off: [AQUDIMS](#), [CONDFLTS](#), [COAL](#), [COARSEN](#), [DUALPORO](#), [EXTFIN](#), [FLUXNUM](#), [GEOMECH](#), [HMDIMS](#), [MPFA](#), [NINEPOIN](#), [PARALLEL](#), [PEBI](#), [SOLVDIMS](#), [THERMAL](#), [USEFLUX](#), [VDFLOW](#), [VDKRO](#), [VDKRG](#)

For any of the above options, a warning message will be output, and the run will continue as normal.

## MESSAGE Specify a message

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
x	RUNSPEC
x	GRID
x	EDIT
x	PROPS
x	REGIONS
x	SOLUTION
x	SUMMARY
x	SCHEDULE

This enables a message to be defined to the error handling system. This system produces output normally seen on the screen when running interactively, and is echoed to the print and debug files. Examples of messages produced by the program are:

```

@--Message
@ Processing GRID data
@--Message
@ Neither NTG nor DZNET entered
@ All net to gross ratios taken as unity
@--Message
@ Problem has 36 active cells

```

The MESSAGE keyword allows you to define such a one-line message. This can be useful for establishing landmarks in large Print files.

Like the TITLE keyword, the line immediately after the MESSAGE keyword is taken as the message, and no quotes or slash characters are required.

This should not be confused with the MESSAGES keyword, used to set limits on the error handling system.

### Example

This defines a message to be displayed.

```

MESSAGE
Starting CO2 injection phase of run

```

In ECLIPSE 100 this example produces an output message of the form:

```

@--MESSAGE AT TIME          0.0  DAYS  (1-JAN-2009):
@           Starting CO2 injection phase of run

```

In ECLIPSE 300 the output message format is:

```

@--Message
@ Starting CO2 injection phase of run

```

## MESSAGES Resets message print and stop limits

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
x	GRID
x	EDIT
x	PROPS
x	REGIONS
x	SOLUTION
x	SUMMARY
x	SCHEDULE

This keyword can be used to reset the print and stop limits for messages of any severity type.

There are 6 levels of severity:

1. Message (Not an error, purely informative)
2. Comment (Probably not a data error)
3. Warning (Possibly a data error)
4. Problem (Calculation difficulties)
5. Error (Definitely a data error)
6. Bug (Suspected programming error).

Printing of a particular type of message ceases after its print limit has been reached. The run stops if a particular type of message is generated more times than its stop limit. However, the run is switched into data checking mode if any error message is generated, so that no timestep calculations are performed after the next [TIME](#), [TSTEP](#) or [DATES](#) keyword.

The keyword should be followed by some or all of the following integers, terminated by a slash (/). Repeat counts (for example 3\*1000) and defaults (for example 2\*) can be used if required. Any items defaulted or left unspecified will not be altered. The items are initialized with their default values.

1. Print limit for severity 1 messages  
DEFAULT: 1000000
2. Print limit for severity 2 messages  
DEFAULT: 1000000
3. Print limit for severity 3 messages  
DEFAULT: 10000
4. Print limit for severity 4 messages  
DEFAULT: 100
5. Print limit for severity 5 messages  
DEFAULT: 100
6. Print limit for severity 6 messages  
DEFAULT: 100
7. Stop limit for severity 1 messages  
DEFAULT: 1000000
8. Stop limit for severity 2 messages  
DEFAULT: 1000000
9. Stop limit for severity 3 messages  
DEFAULT: 10000
10. Stop limit for severity 4 messages

DEFAULT: 100

11. Stop limit for severity 5 messages

DEFAULT: 10

12. Stop limit for severity 6 messages

DEFAULT: 1

ECLIPSE 300

This item only applies to severity 6 messages issued in the SCHEDULE section.

---

**Note:** It is not advisable to alter the stop limits for messages of severity 5 and 6.

---

ECLIPSE 100

13. Print limit for groups of frequently output messages. Each group of messages (e.g. PVT table extrapolation warnings, messages about connections between non-neighbor connections between local grid refinements) has a tally (per processor) which is incremented each time a message from the group is output

DEFAULT: 10

**Note:** Messages duplicated across multiple processors in parallel are only output once in the main PRT file but will still contribute to the message tally for each processor.

---

## Example

```
MESSAGES
2* 10 5* 10000 /      alters print and stop limits for warnings
```

## MESSOPTS Controls severity type for messages reporting timesteps forced to be accepted

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to control the severity type for messages reporting timesteps that are forced to be accepted.

The keyword should be followed by the following items, terminated by a slash (/).

1. Mnemonic ACCPTIME.
2. An integer selecting the severity type:
  - 1 Report forced timesteps as message.
  - 2 Report forced timesteps as comment.
  - 3 Report forced timesteps as warning.
  - 4 Report forced timesteps as problem.

In ECLIPSE 100, timesteps that are forced to be accepted are reported by default with problem severity type.

In ECLIPSE 300, timesteps that are forced to be accepted are reported by default with message severity type.

---

**Note:** The total number of timesteps forced to be accepted is printed in the PRT file in the summary at the end of a run independently of the use of this keyword.

---

**Note:** The use of this keyword may increase the number of occurrences of certain severity type messages. If the number of occurrences of a particular type of messages increases up to reaching the print or stop limit for messages of such severity type, then printing that type of message will cease or the run will stop. The [MESSAGES](#) keyword can be used to reset print and stop limits for messages of any severity type.

---

### Example

```
MESSOPTS
  ACCPTIME 3 /      reports forced timesteps as Warning messages
```

## METRIC

### Metric units are to be used

This indicates that metric units are to be used. Note that this is the default unit convention.

See "[Units](#)" in the *ECLIPSE Technical Description* for further details.

The keyword has no associated data.

## Specify cell mid-point depths

The keyword should be followed by one real number for each grid block in the current input box.

This keyword specifies the depth value of the middle of each cell. This is an alternative to **TOPS**, the TOPS value being obtained as:

$$\text{TOPS}_i = \text{MIDS}_i - \frac{\text{DZ}_i}{2} \quad \text{Eq. 3.117}$$

This keyword should not be confused with **DEPTH**, used in the EDIT section to overwrite the calculated cell center depth values.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

## Example

For a reservoir 20 by 4 by 4 with depth of 5025 ft:

```
MIDS
320*5025 /
```

## MINDZNET

**Minimum net thickness for active cell**

	<b>ECLIPSE 100</b>
x	<b>ECLIPSE 300</b>
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by a single non-negative real number, the minimum net thickness (**DZ**) allowed for an active cell. If the value is zero, the check will not be performed and no cells will be set inactive because their thickness is too small.

In **THERMAL** runs, cells with net thickness below the minimum, will be treated as rock-filled cells and may still be active.

The data must be followed by a slash.

Cells with a smaller net DZ value are regarded as inactive.

UNITS: m (**METRIC**), ft (**FIELD**), cm (**LAB**), m (**PVT-M**)

DEFAULT: 0.000001 (all unit sets)

**Example**

```
MINDZNET
0.1 /
```

## MINNNCT

## Sets a cutoff transmissibility below which a non-neighbor connection is deleted

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword is optional and is used to declare threshold transmissibility values below which a non-neighbor connection is deleted.

The keyword should be followed by up to three positive real numbers: the cutoff transmissibility, the cutoff diffusivity, and the cutoff thermal transmissibility. Any or all of these can be defaulted.

UNITS:

Transmissibility      cP.m<sup>3</sup>/day/bars (METRIC), cP.rb/day/psi (FIELD), cP.rcc/hr/atm (LAB),  
cP.m<sup>3</sup>/day/atm (PVT-M)

Diffusivity            m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

Thermal  
transmissibility      kJ/day/K (METRIC), Btu/day/°R (FIELD), J/hr/K (LAB), kJ/day/K (PVT-M)

DEFAULT: no cutoff

The data must be terminated by a slash (/).

**Note:** If non-neighbor connections are input using the **NNC** keyword, the cutoff is only applied if the **MINNNCT** keyword is specified before the **NNC** keyword.

If the **MINNNCT** keyword is specified with one or more of its arguments defaulted, those values default to zero (no cutoff). However, if the keyword is not specified, the default values are 10<sup>-6</sup> for transmissibility and 10<sup>-20</sup> for diffusivity and thermal transmissibility.

If a non-neighbor connection has one or more of transmissibility, diffusivity and/or thermal transmissibility above the threshold value, but also one or more of them is below the threshold value, the values which are below the threshold value will be reset to zero.

If a model does not use the diffusivity and/or thermal transmissibility options, any values specified for them are ignored.

For some models, setting very small values for the cutoffs, or no cutoff, can result in an extremely large number of non-neighbor connections being generated. This has implications both for speed and memory requirements and is best avoided unless non-neighbor connections with very small transmissibility are significant for the model in question.

### Example

```
MINNNCT
0.01 2*1E-20 /
```

## MINPORV

## Set a minimum pore volume a cell must have to be active

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is used to declare a threshold pore volume that a cell must exceed or it will be made inactive.

The keyword should be followed by a single positive real number, the minimum pore volume of an active cell, in the current units.

UNITS:  $\text{rm}^3$  (METRIC), rb (FIELD), rcc (LAB),  $\text{rm}^3$  (PVT-M)

DEFAULT: 0.000001 (all unit sets)

The data must be terminated by a slash (/).

The keyword causes any cell with a pore volume less than the input value to become inactive.

An inactive cell does not contribute to the total volume of the system, and is treated, by default, as a barrier. In order for the non-neighbor connections to be established between adjoining cells across an inactive cell, pinchouts must be enabled using the [PINCH](#) keyword, and non-neighbor connections must be enabled (which is done by default unless keyword [NONNC](#) is encountered in the RUNSPEC section).

In the absence of MINPORV, the default minimum pore volume is 1.0E-6 (in the current units).

See also the related keyword [MINPV](#), and [MINPVV](#) in ECLIPSE 100.

MINPV is an alias for MINPORV.

---

**CAUTION:** Cells modified with this keyword will remain inactive unless the [ACTNUM](#) value for these cells is set to 1.

---

---

**Note:** In a THERMAL simulation a cell will only be set inactive if the rock volume is also less than the minimum rock volume specified with the [MINROCKV](#) keyword.

---

### Example

```
MINPORV
0.001 /
```

## MINPORV9

## Set a minimum pore volume for calculation of nine-point transmissibilities

	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is used to declare a threshold pore volume that a cell must exceed to employ nine-point transmissibilities when the [MPFA](#) keyword is used to select the nine-point MPFA scheme.

See "[Tensor permeability](#)" in the *ECLIPSE Technical Description* for further information.

The keyword should be followed by a single positive real number, the minimum pore volume in the current units in order to calculate nine-point transmissibilities for this cell.

UNITS:  $\text{rm}^3$  (METRIC), rb (FIELD), rcc (LAB),  $\text{rm}^3$  (PVT-M)

DEFAULT: 0.000001 (all unit sets)

The data must be terminated by a slash (/).

The keyword causes any cell with a pore volume less than the input value to use the normal five-point transmissibilities.

In the absence of MINPORV9, the default minimum pore volume is 1.0E-6 (in the current units).

---

**CAUTION:** Cells modified with this keyword will remain inactive unless the ACTNUM value for these cells is set to 1.

---

### Example

```
MINPORV9
0.001 /
```

## MINPV

## Sets a minimum pore volume a cell must have to be active

x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword is used to declare a threshold pore volume that a cell must exceed or it will be made inactive.

The keyword should be followed by a single positive real number, the minimum pore volume of an active cell, in the current units.

UNITS:  $\text{m}^3$  (METRIC), rb (FIELD), rcc (LAB),  $\text{m}^3$  (PVT-M)

DEFAULT 0.000001 (all unit sets)

The data must be terminated by a slash (/).

The keyword causes any cell with a pore volume less than the input value to become inactive.

An inactive cell does not contribute to the total volume of the system, and is treated by default as a barrier. In order for non-neighbor connections to be established between adjoining cells across an inactive cell, pinchouts must be enabled using the keyword [PINCH](#) or [PINCHOUT](#), and non-neighbor connections must be enabled (which is done by default unless keyword [NONNC](#) is encountered in the RUNSPEC section).

Cells that have been set inactive using the [ACTNUM](#) keyword remain so even if their pore volume exceeds the threshold; using MINPV only affects active cells.

In the absence of MINPV, the default minimum pore volume is 1.0E-6 (in the current units).

In ECLIPSE 100, the sum of the total pore volume removed from the grid is output, along with the total number of cells removed. A list of all the cells that are made inactive can be obtained by setting switch 35 of the [RPTGRID](#) keyword > 0 (mnemonic MINPV).

See also keyword [MINPVV](#).

---

**CAUTION:** Cells modified with this keyword will remain inactive unless the ACTNUM value for these cells is set to 1.

---

---

**Note:** In a THERMAL simulation a cell will only be set inactive if the rock volume is also less than the minimum rock volume specified with the [MINROCKV](#) keyword.

---

### Example

```
MINPV
 4500 /
```

This keyword is used to declare a threshold pore volume that a cell must exceed or it will be made inactive.

The keyword should be followed by one positive real number for every cell in the current input box, specifying its threshold pore volume in the current units, terminated with a slash (/).

UNITS:  $\text{rm}^3$  (METRIC), rb (FIELD), rcc (LAB),  $\text{rm}^3$  (PVT-M)

DEFAULT: 0.000001 (all unit sets)

The keyword causes any cell with a pore volume less than the input value associated with that cell to become inactive.

An inactive cell does not contribute to the total pore volume of the system, and is treated by default as a barrier. In order for non-neighbor connections to be established between adjoining cells across an inactive cell, pinchouts must be enabled using the keyword [PINCH](#) or [PINCHOUT](#), and non-neighbor connections must be enabled (they are enabled by default unless keyword [NONNC](#) is encountered in the [RUNSPEC](#) section).

Cells which have been set inactive via the [ACTNUM](#) keyword remain so even if their pore volume exceeds the threshold; using MINPVV only affects active cells.

Any minimum pore volumes that are not specified by the end of the GRID section default to 1.0E-6 (in the current units). In the absence of [MINPV](#) or MINPVV, this is the default for all cells.

A list of all the cells that are made inactive can be obtained by the argument MINPVV in the [RPTGRID](#) keyword.

In ECLIPSE 100, a sum of the total pore volume removed from the grid is output, along with the total number of cells removed (using the MINPVV mnemonic).

See also keyword [MINPV](#).

---

**CAUTION:** Cells modified with this keyword will remain inactive unless the ACTNUM value for these cells is set to 1.

---

**Note:** In a THERMAL simulation a cell will only be set inactive if the rock volume is also less than the minimum rock volume specified with the [MINROCKV](#) keyword.

---

### Example

```

----- IX1-IX2 JY1-JY2 KZ1-KZ2
BOX
      1  8  2  2  2  3
MINPVV
1000.0 1000.0 1000.0 1000.0 1000.0 1000.0 1000.0 1000.0
 500.0 500.0 500.0 500.0 500.0 500.0 500.0 500.0 /

```

## MINROCKV **Minimum rock volume for active cell**

	<b>ECLIPSE 100</b>
x	<b>ECLIPSE 300</b>
x	<b>SPECIAL</b>
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword can only be used with the THERMAL option (keyword [THERMAL](#) in the RUNSPEC section).

MINROCKV should be followed by a single positive real number, the minimum rock volume of an active cell. Cells with a smaller rock volume than this are regarded as having zero rock volume. Cells with zero rock and pore volume are regarded as inactive, in thermal simulations.

UNITS:  $\text{rm}^3$  (METRIC), rb (FIELD), rcc (LAB),  $\text{rm}^3$  (PVT-M)

DEFAULT: 0.000001 (all unit sets)

See "[Thermal option](#)" in the *ECLIPSE Technical Description* for further information on this option.

---

**CAUTION:** Cells modified with this keyword will remain inactive unless the ACTNUM value for these cells is set to 1.

---

### Example

```
MINROCKV
0.001 /
```

## MINRV

# Minimum rock volume for active cell

This keyword can only be used with the THERMAL option (keyword [THERMAL](#) in the RUNSPEC section).

MINRV is an alias for [MINROCKV](#).

	<b>ECLIPSE 100</b>
x	<b>ECLIPSE 300</b>

## MINVALUE

## Apply a minimum limit to an array in the current box

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
x	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword may be followed by any number of records, each of which is terminated by a slash (/). Each record consists of at least two items of data. The data is terminated by a null record, a record with no data before the terminating slash (/).

1. The name of the array to be modified.
2. The minimum value for the array specified by item 1.

The constant should not be negative, but may be real or integer.

The following items may be used to redefine the input box for this and subsequent operations within the current keyword. If these items are not defined (a slash is inserted after item 2), they default to the values that were used for the previous operation within the current keyword. For the first operation in the keyword, the box defaults to the values set by the most recent [BOX](#) or [ENDBOX](#) keyword. If there is no preceding [BOX](#) or [ENDBOX](#) in the current section, the box is taken to include the entire reservoir.

3. IX1 First block to be modified on the X axis.
4. IX2 Last block to be modified on the X axis.
5. JY1 First block to be modified on the Y axis.
6. JY2 Last block to be modified on the Y axis.
7. KZ1 First block to be modified on the Z axis.
8. KZ2 Last block to be modified on the Z axis.

The data must satisfy

$$1 \leq IX1 \leq IX2 \leq NDIVIX$$

$$1 \leq JY1 \leq JY2 \leq NDIVIY$$

$$1 \leq KZ1 \leq KZ2 \leq NDIVIZ \text{ (where NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword DIMENS)}$$

---

**Note:** If the MINVALUE keyword is used before an array has been input, it will have no effect on that array when it is subsequently input. MINVALUE can only operate on arrays that are already input.

---

See also keywords [BOX](#), [ENDBOX](#), [EQUALS](#), [ADD](#), [MULTIPLY](#), [MAXVALUE](#) and [COPY](#).

### Example

In the PROPS section:

```

-- ARRAY   MAX   ----- BOX -----
MINVALUE
'SGU'     0.65   / defaults to whole current input box
'SGU'     0.8    4*   2 2   / layer 2
/

```

## Miscibility function tables

The MISC keyword is required in runs which use the Solvent option in miscible mode (keywords [MISCIBLE](#) and [SOLVENT](#) in the RUNSPEC section). See "[Miscible flood modeling](#)" and "[Solvent model](#)" in the *ECLIPSE Technical Description* for further details of these options.

The data consists of NTMISC (see keyword [MISCIBLE](#)) tables of miscibility functions, which control the transition from miscible to immiscible relative permeability models. Each table must be terminated by a slash.

Each table consists of 2 columns of data:

1. The local solvent fraction ( $S_{\text{solvent}} / (S_{\text{solvent}} + S_{\text{gas}})$ )

The values should increase monotonically down the column and cover the range 0 to 1.

2. The corresponding miscibility on a scale from 0 to 1.

Zero corresponds to immiscible relative permeabilities and one to miscible relative permeabilities.

The values must span the range [0,1] and should be level or increasing down the column. This means that the first value must be 0 and the last value must be 1.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSMISC (see keyword [MISCIBLE](#)).

### Example

With NTMISC=1 and NSMISC≥4

```
MISC
0.0 0.0
0.1 0.5
0.3 1.0
1.0 1.0 /
```

## MISCEXP

### Miscibility exponent

When the [MISCIBLE](#) option is used, this keyword allows the exponent of the surface tension ratio to be changed. This is described in more detail in "[Surface tension effects](#)" in the *ECLIPSE Technical Description*.

The keyword contains a single item of data.

DEFAULT: 0.25

#### Example

```
MISCEXP  
0.34 /
```

	<b>ECLIPSE 100</b>

## MISCIBLE

**Miscible treatment of hydrocarbons**

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword requests a miscible treatment of hydrocarbon relative permeabilities and capillary pressures. The treatment is different between ECLIPSE 100 and ECLIPSE 300.

In ECLIPSE 100, the MISCIBLE keyword enables the miscible flood model based on the Todd-Longstaff treatment. See "[Miscible flood modeling](#)" in the *ECLIPSE Technical Description* for further information.

In ECLIPSE 300, the MISCIBLE keyword activates dependence of relative permeability and capillary pressure on surface tensions according to the [PARACHOR](#) values. See "[Surface tension effects](#)" in the *ECLIPSE Technical Description* for further information. The MISCIBLE keyword should only be used for Compositional runs using ECLIPSE 300, not Black Oil runs.

**Enable the miscible gas flood option (ECLIPSE 100)**

The keyword should be followed by some or all of the following items, describing the dimensions of the miscible residual oil saturation tables and the method for calculating the upstream relative permeabilities. The data must be terminated by a slash (/).

## 1. NTMISC

The number of tables of miscible residual oil saturation versus water saturation, and the maximum number of mixing parameter regions. (See the keywords [TLMIXPAR](#) and [SORWMIS](#) in the [PROPS](#) section).

DEFAULT: 1

## 2. NSMISC

The maximum number of saturation nodes in any table of miscible residual oil saturation versus water saturation (see the keyword [SORWMIS](#) in the [PROPS](#) section).

DEFAULT: 20

## 3. Option for upstreaming hydrocarbon relative permeabilities.

**TWOPOINT** The two-point upstreaming algorithm is to be used to calculate the hydrocarbon component relative permeabilities.

Note that the TWOPOINT upstreaming option is not available in Solvent runs.

**NONE** The standard single point upstreaming method is used involving only the immediate upstream cell

DEFAULT: NONE

The vertical equilibrium option (keyword [VE](#)) should not be used with the miscible gas flood option.

**Example**

Using ECLIPSE 100:

```
MISCIBLE
 2 25 TWOPOINT /
```

## Use dependence on surface tensions in properties (ECLIPSE 300)

The keyword does not require items 1 to 3 above. Any values are skipped. The keyword should be followed by a single slash (/).

If this option is used, parachor values should be entered in the `PROPS` section using the `PARACHOR` keyword, or the `STVP` keyword added to provide the variation of surface tension with pressure.

### Example

Using ECLIPSE 300:

```
MISCIBLE  
/
```

## MISCNUM

## Miscibility region numbers

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by one integer for every grid block in the current input box specifying the miscibility region to which it belongs.

## ECLIPSE 100 miscible flood model

The region number should not be less than 0 or greater than NTMISC (see keyword [MISCIBLE](#)). The data must be terminated by a slash (/).

A positive value of the miscibility region number specifies which value of the mixing parameter (input using the keyword [TLMIXPAR](#)) should be used to calculate the effective PVT properties of the gas and oil components in each cell of the grid. A positive miscibility region number also specifies which table of miscible residual oil saturation versus water saturation should be used in the calculation of the relative permeabilities and effective oil and gas PVT properties.

Grid blocks which are allocated a miscibility region number of 0 are assumed to contain immiscible oil and gas. The mixing parameter is set automatically to 0 in these regions and the gas/oil relative permeabilities are computed from immiscible data. Any cells for which MISCNUM is not explicitly defined are given a MISCNUM value of 1.

The miscibility region numbers can be modified during the simulation by re-specifying the MISCNUM keyword in the SCHEDULE section. This procedure should only be carried out with care and is **not** recommended in general.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

The MISCNUM keyword may only be used in miscible flood simulations (keyword [MISCIBLE](#) in [RUNSPEC](#)). However, the MISCNUM keyword is not obligatory in these cases - a default region number of 1 is assumed for each grid cell. When using the polymer flood model (keyword [POLYMER](#) in [RUNSPEC](#)) the [PLMIXNUM](#) keyword should be used instead.

See also the keywords [SORWMIS](#) and [TLMIXPAR](#) in the [PROPS](#) section.

The ECLIPSE 100 treatment of miscibility is described in "[Miscible flood modeling](#)" in the *ECLIPSE Technical Description*.

## Example

```

-- In the RUNSPEC section:
MISCIBLE
 2 /
DIMENS
 8 6 5 /
-- In the REGIONS section (with no input box set):
MISCNUM
72*0 72*1 96*2 /

```

## ECLIPSE 300 miscible model - surface tension effects

When using the [MISCIBLE](#) option, the default treatment is to allow the relative permeabilities to approach straight lines as the interphase surface tension approaches zero. This is described in "[Saturation functions](#)" in the *ECLIPSE Technical Description*. MISCNUM allows the user to specify a saturation table to be used in this limit. This option allows the user to use a saturation table to control numerical dispersion at low surface

tensions. This option should be used with care in the near critical region, as there may be a discontinuity if the system becomes single phase.

The saturation function region number specifies which set of saturation functions (input using [SGFN](#), [SOF2](#) and related keywords) should be used to calculate relative permeabilities and capillary pressures in each grid block in the miscible limit.

---

**Note:** In ECLIPSE 300 the MISCNUM keyword is not permitted with end point scaling. If this is set with [ENDSCALE](#), MISCNUM will use UNSCALED endpoints.

---

### Example

With 240 cells and two miscible limit regions:

```
MISCNUM
144*1 96*2 /
```

## MISCSTR

## Miscibility surface tension reference

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

When the [MISCIBLE](#) option is used, this keyword allows the reference surface tension to be set. If MISCSTR is not used, the average initial state surface tension is used as the reference. The keyword is followed by some or all of these data items, terminated with a slash:

1. The reference surface tension - flow is immiscible when the surface tension is greater than or equal to this value.

UNITS: dynes/cm (METRIC), dynes/cm (FIELD), dynes/cm (LAB), dynes/cm (PVT-M)

2. The maximum surface tension expected.

UNITS: dynes/cm (METRIC), dynes/cm (FIELD), dynes/cm (LAB), dynes/cm (PVT-M)

If a non-default value is entered, a warning is issued after each report step if a surface tension has been calculated that exceeds this maximum. Note that during the relative permeability interpolation the curves are taken to be the immiscible curves for cells with a surface tensions above the reference value.

Values should not be less than the reference surface tension - if they are they will be increased to equal the reference surface tension.

3. The maximum surface tension used to scale the input capillary pressure curves.

UNITS: dynes/cm (METRIC), dynes/cm (FIELD), dynes/cm (LAB), dynes/cm (PVT-M)

If this data item is not set, the maximum assumed is the reference value. Setting item 3 allows scaling of the capillary pressure beyond the reference value of surface tension.

Values should not be less than the reference surface tension - if they are they will be increased to equal the reference surface tension.

The use of these parameters is discussed in "[Surface tension effects](#)" in the *ECLIPSE Technical Description*.

See also keyword [MISCSTRP](#).

## Example

```
MISCSTR
52 /
```

## MISCSTRP **Miscibility surface tension reference pressure**

	<b>ECLIPSE 100</b>
x	<b>ECLIPSE 300</b>
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

When the [MISCIBLE](#) option is used, this keyword is an alternative to [MISCSTR](#) for specifying the surface tension at which immiscible conditions are deemed to exist.

The problem with MISCSTR is that you will not generally know the surface tension at which the rock curve data was measured. MISCSTRP allows a pressure to be specified at which the reservoir fluid composition will be flashed, to obtain the reference value. This will usually be well below the initial reservoir pressure, far enough away from the critical point for the oil and gas to be thoroughly immiscible.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

## MISCSTRR

## Miscibility reference surface tension by saturation region

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

When the [MISCIBLE](#) option is used, this keyword allows the reference surface tension to be set by saturation region number. If no reference surface tension is set or implied via any of the keywords [MISCSTR](#), [MISCSTRR](#), [MISCSTRP](#) or [STVP](#) then the average initial surface tension, calculated using the Macleod Sugden correlation, is used as the reference for the whole reservoir.

For each saturation table present, the keyword is followed by some or all of these data items, terminated with a slash:

1. The user reference surface tension - flow is immiscible when the surface tension is greater than or equal to this value.

UNITS: dynes/cm (METRIC), dynes/cm (FIELD), dynes/cm (LAB), dynes/cm (PVT-M)

If this value is defaulted, then the average value of the initial surface tension over this saturation region is used.

2. The maximum surface tension expected.

UNITS: dynes/cm (METRIC), dynes/cm (FIELD), dynes/cm (LAB), dynes/cm (PVT-M)

If a non-default value is entered, a warning is issued after each report step if a surface tension has been calculated that exceeds this maximum, for this saturation region.

Values should not be less than the reference surface tension - if they are they will be increased to equal the reference surface tension.

3. The maximum surface tension used to scale the input capillary pressure curves.

UNITS: dynes/cm (METRIC), dynes/cm (FIELD), dynes/cm (LAB), dynes/cm (PVT-M)

If this data item is not set, the maximum assumed is the reference value. Setting item 3 allows scaling of the capillary pressure beyond the reference value of surface tension, for this saturation region.

Values should not be less than the reference surface tension - if they are they will be increased to equal the reference surface tension.

4. The pressure at which the reservoir fluid composition is flashed, to obtain the reference value. This item overrides any value placed in item 1.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

The problem with using item 1 is that the you do not generally know the surface tension at which the rock curve data was measured. This pressure is usually well below the initial reservoir pressure, far enough away from the critical point for the oil and gas to be thoroughly immiscible.

The use of these parameters is described in "[Surface tension effects](#)" in the *ECLIPSE Technical Description*.

The MISCSTRR keyword overrides any data present in the MISCSTR and MISCSTRP keywords. However, the STVP keyword overrides data in the MISCSTRR keyword.

### Example

```
MISCSTRR
1* 1* 1* 10 /
```

```
3 3.2 3.9 1* /  
1* 3.6 1* 1* /
```

## MIXACTG

## Specify gas activity functions for aqueous components

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword must be used to specify the gas activity function, for each aqueous component, when the [MIXWPERM](#) option is activated. The data for each soluble component consists of two records. The first record is the component index. This is followed by a table consisting of four columns of data. Each record is terminated by a slash. A null record, that is, a record with no data before the terminating slash, must end this keyword.

This keyword is only compatible with the [CO2SOL](#), [H2SSOL](#) and [GASSOL](#) options and must be entered together with [MIXWPERM](#) and [MIXACTO](#). Note that, when used in conjunction with [GASSOL](#), keyword [MIXACTG](#) must be entered after the [SOLUAQA](#) keyword.

This keyword must only be used in [FULLIMP](#) mode.

For further details concerning the associated mixed water permeability model, see "[Mixed water relative permeability modeling](#)" in the *ECLIPSE Technical Description*.

## Record 1

One item of data:

1. The component index defined by the [CNAMES](#) keyword. Note that this index should correspond to CO<sub>2</sub> if the [CO2SOL](#) option is being used and H<sub>2</sub>S if the [H2SSOL](#) option is being used. When the [GASSOL](#) option is used, the set of indices entered should match those listed, in a similar fashion, under the [SOLUAQA](#) keyword.

## Record 2

A table consisting of four columns of data.

1. Pressure.  
Values should increase monotonically down the column.  
UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)
2. Activity coefficient of  $T^0$  in the gas activity function, at the specified pressure.  
UNITS: Dimensionless
3. Activity coefficient of  $T$  in the gas activity function, at the specified pressure.  
UNITS: 1/K (METRIC), 1/°R (FIELD), 1/K (LAB), 1/K (PVT-M)
4. Activity coefficient of  $T^2$  in the gas activity function, at the specified pressure.  
UNITS: 1/K<sup>2</sup> (METRIC), 1/°R<sup>2</sup> (FIELD), 1/K<sup>2</sup> (LAB), 1/K<sup>2</sup> (PVT-M)

## Example

```
MIXACTG
 2/
--Pressure   bi1      bi2      bi3
 1.0000     0.0001   0.0001   0.0001
100.0000    0.0001   0.0001   0.0001
200.0000    0.0001   0.0001   0.0001
```

```
/
 4/
--Pressure  bi1      bi2      bi3
 1.0000    0.0001  0.0001  0.0001
100.0000   0.0001  0.0001  0.0001
200.0000   0.0001  0.0001  0.0001
/
/ null record terminates table
```

If the gas activity coefficients listed above are repeated for the oil activity coefficients (see keyword [MIXACTO](#)) then, for each pressure specified in the example above, the activity parameters are valid for all temperatures up to 70 degrees Celsius.

## MIXACTO

	SUMMARY
	SCHEDULE

This keyword is optional, and is used to scale the [LANGMUIR](#) Isotherm data on a cell-by-cell basis. See "[Coal bed methane model](#)" in the *ECLIPSE Technical Description* for further information.

The keyword should be followed by one real number for each cell in the current input box. The values denote the maximum surface gas concentration in the scaled [LANGMUIR](#) table. Data need only be supplied for the matrix cells, that is the upper half of the grid. The data must be terminated by a slash(/).

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0.22). Note that spaces must not be inserted on either side of the asterisk (\*).

UNITS:  $\text{sm}^3/\text{m}^3$  (METRIC),  $\text{Mscf}/\text{ft}^3$  (FIELD),  $\text{scc}/\text{cc}$  (LAB)

The keyword can be used in conjunction with the [EQUALS](#), [ADD](#) and [MULTIPLY](#) keywords.

See also keywords [LANGMUIR](#), [MLANGSLV](#) and [GASSATC](#).

## Example

```

## MPFA

## Specify options for tensor permeabilities

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies that multipoint transmissibilities are to be used in the discretized flow equations. If tensor permeabilities are entered then the discretization accounts for the tensor permeabilities in a consistent manner.

The keyword should be followed by two items followed by a slash (/).

1. Specify the basis in which the permeability tensor is defined.

The permeability tensor  $K$  is assumed to be symmetric and is specified by its physical components  $K_{11} = \text{PERMX}$ ,  $K_{22} = \text{PERMY}$ ,  $K_{33} = \text{PERMZ}$ ,  $K_{12} = \text{PERMXY}$ ,  $K_{23} = \text{PERMYZ}$  and  $K_{31} = \text{PERMZX}$ .

The tensor may be supplied in the following bases:

- 1  $K$  is defined in the Cartesian x, y and z axes.
- 2  $K$  is defined in each corner point cell relative to the coordinate system formed by joining the midpoints of opposite faces in a corner point cell.
- 3  $K$  is defined in the bedding plane by the vectors obtained by joining the midpoints of opposite faces in the corner point cell in the logical  $i$  and  $j$  directions. The third basis vector is chosen normal to the bedding plane.

DEFAULT: 2

2. Type of transmissibility calculation used in the multipoint flux approximation.
  - 0 Ignore all the cross terms and calculate standard two-point corner point transmissibilities. This diagonalizes the permeability tensor in a form suitable for the standard [NEWTRAN](#) calculation. In the absence of faults, it is equivalent to the standard [HALFTRAN](#) calculation when the vector  $K \underline{d}$  is parallel to the common cell face normal in the half of each connecting cell adjacent to the common face, where  $\underline{d}$  is the vector joining either cell center to the center of the common face.
    - 1 The 'O' method is used to give a 27 point stencil in 3D or a 9 point stencil in 2D.
    - 2 The 'U' method is used to give a 19 point stencil in 3D or a 9 point stencil in 2D.

DEFAULT: 0

---

**Note:** The multipoint flux approximation deals with both non-orthogonality and the tensor permeability. For an orthogonal grid with the principal axes of the tensor aligned with the coordinate directions, the standard 5 or 7 point schemes are recovered.

---

See "[Tensor permeability](#)" in the *ECLIPSE Technical Description* for further information.

---

**Note:** The use of the MPFA option is not allowed with the [WARP](#) solver. Please use the pre-2002A solver (ECLSOL) instead by setting [item 66](#) in `OPTIONS3` to a non-zero value.

---

## MPFANUM

## Identifies regions where the multipoint flux discretization is used

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The MPFANUM keyword indicates regions in which to apply the multipoint flux discretization (see keywords [MPFA](#) and [MPFNNC](#) and also "[Tensor permeability](#)" in the *ECLIPSE Technical Description*).

The MPFANUM keyword should be followed by one integer for every grid block in the current input box, specifying the discretization flag for each grid block. The flag should be set either to 1 to indicate that the multipoint flux discretization is to be employed, or to zero in regions where the standard finite-difference discretization is required (five points in 2D, seven points in 3D).

Any grid blocks not explicitly assigned a MPFANUM value are defaulted to a value of 1. You must set the MPFANUM value explicitly to zero for any regions where the nine-point scheme is not required.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

When using the ECLIPSE 100 Local Grid Refinement option, the MPFANUM array should **not** be defined between the [CARFIN](#) and [ENDFIN](#) keywords. Within local grids, the MPFANUM array is inherited from the host cells in the global grid.

### Example

To apply the MPFA scheme only in a 2\*2\*2 region in a 4\*4\*3 field:

```

MPFANUM
 1 1 0 0
 1 1 0 0
 0 0 0 0
 0 0 0 0
 1 1 0 0
 1 1 0 0
 0 0 0 0
 0 0 0 0
 0 0 0 0
 16*0 /

```

## MPFNNC

## Explicit entry of multi-point flux non-neighbor connections

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies transmissibilities for multipoint flows.

The form of the keyword to define a single multipoint NNC is as follows:

```

MPFNNC
  IX IY IZ JX JY JZ TRANP /
                KX KY KZ TRANS /
                ..... /
/
/

```

Each line defining the primary non-neighbor connection (NNC) is terminated with a slash (/). This is followed by any number of lines defining the associated secondary NNCs. End the list of secondary NNCs with a single slash (/). After the last non-neighbor connection definition, a single slash terminates the list. It is possible to specify this keyword more than once in the grid data.

The items for each multipoint NNC are:

IX, IY, IZ The coordinates of the first cell joined to the primary non-neighbor connection.

JX, JY, JZ The coordinates of the second cell joined to the primary non-neighbor connection.

TRANP The transmissibility of the primary non-neighbor connection

UNITS: cP.rm<sup>3</sup>/day/bars (METRIC), cP.rb/day/psi (FIELD), cP.rcc/hr/atm (LAB), cP.rm<sup>3</sup>/day/atm (PVT-M)

KX, KY, KZ The coordinates of the second cell joined to IX, IY, IZ by the secondary non-neighbor connection

TRANS The transmissibility of the secondary non-neighbor connection

UNITS: cP.rm<sup>3</sup>/day/bars (METRIC), cP.rb/day/psi (FIELD), cP.rcc/hr/atm (LAB), cP.rm<sup>3</sup>/day/atm (PVT-M)

---

**Note:** A non-neighbor connection is allowed between two cells that are actually neighbors (or between two cells where ECLIPSE would form a non-neighbor connection in the absence of the MPFNNC keyword; this simply adds to the existing transmissibility. Any multipoint NNC input with transmissibility less than 0.000001 results in a warning and is ignored. Connections to inactive cells result in a warning, and are ignored.

---

---

**Note:** All the transmissibilities need to be generated externally and the MPFNNC keyword should be used to apply the multipoint flux capability within ECLIPSE 100. This facility is intended primarily for use with unstructured grids, and the multi-point NNC coefficients could be provided by FloGrid. On structured grids, tensor permeabilities may be used in ECLIPSE 300 and the MPFA keyword activates the multipoint flux scheme. The MPFNNC keyword should not be used in the same data set as the MPFA keyword.

---

**Note:** The multipoint flux facility is a rigorous treatment to avoid discretization errors arising from grid non-orthogonality. However, the large number of connections and extra calculations required in the simulator mean that the run time will increase considerably.

---

## Example

```
MPFNNC
11 11 11 10 10 10 1.0 /
      22 22 22 2.0 /
      33 33 33 3.0 /
      44 44 44 4.0 /
/
23 24 25 11 12 13 7.0 /
      32 32 32 1.0 /
      33 33 33 2.0 /
      34 34 34 3.0 /
/
/
```

## MSFN

## Miscible saturation functions

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is entirely optional and should only be used in miscible runs (keyword **MISCIBLE** in the RUNSPEC section) and in runs using the Solvent Model. It allows the use of a relative permeability curve for the miscible displacement. See "**Miscible flood modeling**" and "**Solvent model**" in the *ECLIPSE Technical Description* for further details of these options.

The keyword data comprises NTSFUN (see keyword **TABDIMS**) tables of solvent/oil miscible saturation functions, each terminated by a slash (/).

Each table consists of 3 columns of data. The first column is the normalized total gas fraction (that is solvent and gas saturation if Solvent and only gas saturation if no Solvent). The next two columns are the relative permeability multipliers for the (gas+solvent) and the oil respectively ( $M_{krsg}$  and  $M_{kro}$ ).

1. The normalized total gas phase fraction (gas+solvent)  
Values should span the range 0 to 1 and increase monotonically down the column.
2. The corresponding (gas+solvent) relative permeability multiplier.  
Values should be between 0 and 1 and should be level or increasing down the column.
3. The corresponding oil relative permeability multiplier.  
Values should be between 0 and 1 and should be level or decreasing down the column.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (see keyword **TABDIMS**).

Note that the relative permeabilities supplied in this keyword are normalized and honor the end-point supplied in the **SORWMIS** and **SGCWMIS** keywords. **SORWMIS** supplies the critical oil saturation as a function of water saturation, and **SGCWMIS** the critical gas saturation. Hence when the flood is totally miscible (see the **MISC** and **PMISC** keywords) the (gas+solvent) and the oil relative permeabilities are taken as:

$$k_{rsg} = M_{krsg} \left( \frac{S_g + S_s - S_{gc}}{S_n - S_{gc} - S_{or}} \right) k_m(S_n) \quad \text{Eq. 3.118}$$

$$k_{ro} = M_{kro} \left( \frac{S_o - S_{or}}{S_n - S_{gc} - S_{or}} \right) k_m(S_n) \quad \text{Eq. 3.119}$$

If no solvent is present then  $S_s = 0$ .

Where

- $S_g$  is the gas saturation
- $S_s$  is the solvent saturation (which is zero if the solvent model is not used)
- $S_n$  is the total hydrocarbon saturation  $S_n = S_o + S_g + S_s$
- $S_{gc}$  is the critical gas saturation, **SGCWMIS**
- $S_{or}$  is the critical oil saturation, **SORWMIS**

$k_m(S_n)$  is the relative permeability of hydrocarbon to water.

If the MSFN keyword is not supplied, the relative permeabilities are taken as straight line functions, that is

$$k_{rsg} = \frac{S_g + S_s - S_{gc}}{S_n - S_{gc} - S_{or}} k_m(S_n) \quad \text{Eq. 3.120}$$

$$k_{ro} = \frac{S_o - S_{or}}{S_n - S_{gc} - S_{or}} k_m(S_n) \quad \text{Eq. 3.121}$$

See also the [MISC](#), [PMISC](#), [SSFN](#), [SORWMIS](#) and [SGCWMIS](#) keywords.

## Example

With NTSFUN=2 and NSSFUN≥6

```

MSFN
-- Default table
-- Sfrac  MKrsg  MKro
0.0      0.0    1.0
1.0      1.0    0.0  /
-- Modified table
0.0      0.0    1.0
0.4      0.2    0.5
0.6      0.4    0.4
1.0      1.0    0.0  /

```

## MSGFILE

## MULSGGD **Dual porosity matrix-fracture coupling multiplier for oil-gas gravity drainage**

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

If the dual porosity option is being used (keyword `DUALPORO` in the RUNSPEC section), and the alternative matrix-fracture coupling transmissibilities for oil-gas gravity drainage have been specified in the grid section through the `SIGMAGD` or `SIGMAGDV` keywords, then this keyword can be used to specify a multiplier in the SCHEDULE section which will modify further these matrix-fracture coupling transmissibilities.

If this keyword is used, a single multiplier is applied to the entire current grid. To specify values for individual cells, use the `MULSGGDV` keyword.

The keyword should be followed by one single positive real number, which will be applied to every cell in the current grid.

UNITS: dimensionless

### Example

```
MULSGGD
0.5 /
```

## MULSGGDV Dual porosity matrix-fracture coupling multiplier for oil-gas gravity drainage

## MULTFLT

**Modifies the transmissibility across a named fault**

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
x	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The MULTFLT keyword can be used to modify the transmissibility (and diffusivity) across a fault previously defined using the [FAULTS](#) keyword.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/):

1. Fault name (up to 8 characters)  
(as specified in the [FAULTS](#) keyword)  
A fault root name, ending with an asterisk (\*) can also be used to refer to several faults in one record.
2. Transmissibility multiplier  
DEFAULT: 1.0
3. Diffusivity multiplier  
(used only if the Diffusion option is enabled with the [DIFFUSE](#) keyword in the RUNSPEC section)  
DEFAULT: 1.0

The set of records must end with a blank record containing only a slash (/).

**Notes**

- If a fault is referred to twice in one or more MULTFLT keywords, the transmissibility multiplier is taken from the last entry.
- If the fault has been specified with a face X, Y or Z in the [FAULTS](#) keyword, then using the MULTFLT keyword in the GRID section modifies the [MULTX](#), [MULTY](#) and [MULTZ](#) arrays along the fault trajectory. If the MULTX, MULTY or MULTZ keyword is used for some cells, in addition to the MULTFLT keyword, then the resultant transmissibility multiplier is the product of the two input multipliers.

Similarly, if negative direction transmissibility multipliers are enabled (using the [GRIDOPTS](#) keyword in the RUNSPEC section), and if the fault has been specified with a face X-, Y- or Z- in the [FAULTS](#) keyword, then using the MULTFLT keyword in the GRID section modifies the [MULTX-](#), [MULTY-](#) and [MULTZ-](#) arrays along the fault trajectory. If the MULTX-, MULTY- or MULTZ- keyword is used for some cells, in addition to the MULTFLT keyword, then the resultant transmissibility multiplier is the product of the two input multipliers.

- Use of the MULTFLT keyword in the EDIT section multiplies the transmissibilities along fault trajectories specified by the [FAULTS](#) keyword in the GRID section. The transmissibilities for any non-neighbor connections across such a fault are also modified to reflect the multiplier analogously to the use of MULTX, MULTY or MULTZ.

Similarly, with the [MULTX-](#), [MULTY-](#), [MULTZ-](#) keywords.

- If two faults with different names run along the same face of a cell, then both transmissibility multipliers are applied.
- Refer also to the keywords, [FAULTS](#) and [RPTGRID](#).
- The MULTFLT keyword can be used in the SCHEDULE section to modify the transmissibilities along the fault trajectory during the run. The effect of this keyword in the SCHEDULE section is cumulative,

so every time the MULTFLT keyword is encountered, it multiplies the current transmissibility across a specific face.

- The modified transmissibilities can be output to the Print file by using the mnemonic MULT in the [RPTSCHED](#) keyword.
- If the transmissibilities have been imported from a GSG file rather than calculated (by using the TRANPORV mnemonic in the [PETOPTS](#) keyword) MULTFLT will be ignored in the GRID section and must be specified in the EDIT section instead if required.
- If a fault is specified twice, the transmissibility multiplier will be applied twice. In ECLIPSE 300, this behavior can be turned off by setting [item 248](#) of the OPTIONS3 keyword to 1.
- If [TRANX](#), [TRANY](#) or [TRANZ](#) keywords are used then MULTFLT should appear after these keywords in the EDIT section. Otherwise, as TRANX, TRANY and TRANZ set transmissibility explicitly, they will selectively override MULTFLT for neighboring connections.

## Example

Refer to the [FAULTS](#) keyword example:

```
MULTFLT
-- Multiplier (no diffusion)
zigzag 0.2 /
block 1.4 /
/
```

## MULTIN

### Indicates that input files are multiple

This indicates that input files, which may be either multiple or unified, are to be multiple. This is the default; unified files may be requested with the [UNIFIN](#) keyword.

Multiple files enable the progress of the run to be monitored, and are generally preferred; but they do produce a larger number of files, which may be inconvenient on machines without a directory structure.

This keyword has no associated data.

## MULTIPLY **Multiply array by a constant in current box**

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
x	EDIT
x	PROPS
x	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

The keyword may be followed by any number of records, each of which is terminated by a slash (/). The data is terminated by a null record, with no data before the terminating slash(/).

Each record consists of at least two items of data:

1. The name of the array to be modified
2. The constant by which the array, specified by item 1, is to be multiplied

The constant should not be negative, but may be real or integer. This item should not be defaulted.

---

**Note:** Negative multipliers and more complex arithmetic operations are available using the [OPERATE](#) keyword.

---

The following items of data define the limits of a box within the grid over which the value is to be set.

These items may be used to redefine the input box for this and subsequent operations within the current keyword. The values are used until reset or until the end of the keyword.

If they are not defined (a slash is inserted after item 2), they default to the values which were used for the previous operation within the current keyword.

For the first operation in the keyword, the box defaults to the values set by the most recent [BOX](#) or [ENDBOX](#) keyword. If there is no preceding [BOX](#) or [ENDBOX](#) in the current section, the box is taken to include the entire reservoir.

3. First block to be modified on the X axis (IX1)
4. Last block to be modified on the X axis (IX2)
5. First block to be modified on the Y axis (JY1)
6. Last block to be modified on the Y axis (JY2)
7. First block to be modified on the Z axis (KZ1)
8. Last block to be modified on the Z axis (KZ2)

The data must satisfy:

$$1 \leq IX1 \leq IX2 \leq NDX$$

$$1 \leq JY1 \leq JY2 \leq NDY$$

$$1 \leq KZ1 \leq KZ2 \leq NDZ,$$

where NDX, NDY, NDZ are the limits in the current BOX.

ECLIPSE 100

If the MULTIPLY keyword is used in the PROPS section to modify the end-point scaling arrays, the modification is only made to the end points that have been previously defined. If a cell has **not** been assigned a value, the end point defaults to the table value.

MULTIPLY is now available in the REGIONS and SOLUTION sections.

[TNUM](#) arrays can also be used with the MULTIPLY keyword.

ECLIPSE 100

In the REGIONS section only integer values should be used.

See also keywords BOX, ENDBOX, [EQUALS](#), [ADD](#) and [COPY](#).

- The list above is not exhaustive, but includes the most common examples.
- Keywords in brackets are for radial geometry runs.
- The multiplied quantity may be less than unity, in order to divide.
- The use of the MULTIPLY keyword assumes that a value has already been assigned to the array, either explicitly or using the EQUALS keyword (except in the EDIT section, where the array has already been calculated after processing the GRID section).
- The ADD, COPY, EQUALS and MULTIPLY keywords are processed as they are read, so that repeated operations are possible.
- **Item 2 should not be defaulted.** However, this facility is retained for back-compatibility. If this item is defaulted, this will be treated differently by ECLIPSE 100 and ECLIPSE 300. For ECLIPSE 100, the defaulted value is assumed to be undefined, whereas for ECLIPSE 300, the defaulted value is assumed to be zero. The subsequent processing will depend, therefore, both upon the specific keyword to which the operation is being applied and which simulator is being used.

**Examples****Example 1**

In the EDIT section:

```

----- ARRAY      CONSTANT ----- BOX -----
MULTIPLY
      TRANX      500          3 8 1 10 3 3 /
      TRANZ       0          / defaults to last specified box
      PORV      100.0        / defaults to last specified box
/

```

**Example 2**

In the GRID section:

```

----- ARRAY      CONSTANT ----- BOX -----
MULTIPLY

```

```
PERMX 0.1      3 8 1 10 3 3 /  
PERMZ 0        / defaults to last specified box  
PORO  0.2      / defaults to last specified box  
/
```

## MULTIREG **Multiplies an array by a constant in a given region**

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
x	EDIT
x	PROPS
x	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

MULTIREG is similar to the [MULTIPLY](#) keyword, but uses either [FLUXNUM](#) flux regions, [MULTNUM](#) regions or [OPERNUM](#) regions, rather than boxes of cells.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated by a slash (/).

The records can be terminated early using the slash character (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

Each record consists of the following items of data:

1. The name of the array to be modified
2. The constant by which the array, specified by item 1, is to be multiplied  
The constant should not be negative, and, for the REGIONS section, should be an integer.  
DEFAULT: 0.0
3. The flux region number, MULTNUM region number or OPERNUM region number (with choice of region determined using item 4) The flux region number refers to the region defined using the FLUXNUM keyword in the GRID section. It is not necessary to use the Flux Boundary option.

The MULTNUM region number refers to the region defined using the MULTNUM keyword in the GRID section.

The OPERNUM region number refers to the region defined using the OPERNUM keyword in the GRID or REGIONS section.

4. Choice of region: MULTNUM (M), FLUXNUM (F) or OPERNUM (O).

DEFAULT: M

The set of records is ended by a blank record, containing only a slash (/).

---

**Note:** The FLUXNUM keyword, MULTNUM keyword or OPERNUM keyword must be entered before the MULTIREG keyword. If item 4 is defaulted, then the MULTNUM keyword is used.

---

In ECLIPSE 100, this keyword may not be used to modify the [PBUB](#) or [PDEW](#) arrays.

In ECLIPSE 300, this keyword may be used in SCHEDULE section. However, this is a specialist facility.

---

**Note:** In the SCHEDULE section, regions (predefined by the FIPxxxx keyword in the REGIONS section) can be used in item 4.

---

**Notes**

- The list above is not exhaustive, but includes the most common examples.
- Keywords in brackets are for radial geometry runs.
- The multiplied quantity may be less than unity, in order to divide.
- The use of the MULTIREG keyword assumes that a value has already been assigned to the array.
- Each record must refer to the same region. It is not possible to choose a different region for each data record.
- The MULTIREG keyword is not available for use with local grid systems (ECLIPSE 100 only).

See also keywords [EQUALREG](#), [FLUXNUM](#), [MULTNUM](#), [OPERNUM](#), [ADDREG](#), and [COPYREG](#).

**Additional notes**

ECLIPSE 300 only

Additional notes for the use of this keyword in the SCHEDULE section. Again, this is a specialist facility. In the SCHEDULE section, the effect of this keyword will be as follows:

Keyword	Description
<a href="#">DIFFMMF</a>	Modifies the matrix-fracture diffusivity in dual-porosity runs. If output is required for flexible restart in the model, these multiplier values will be output as DIFFMMFS.
<a href="#">MULSGGD</a> <a href="#">MULSGGDV</a>	Modifies the matrix-fracture coupling transmissibility for oil-gas gravity drainage in dual-porosity runs. If output is required for flexible restart in the model, these multiplier values will be output as MULSGGDS.
<a href="#">MULTSIG</a> <a href="#">MULTSIGV</a>	Modifies the matrix-fracture coupling transmissibility in dual-porosity runs. If output is required for flexible restart in the model, these multiplier values will be output as MULTSIGS.
<a href="#">MULTX</a> <a href="#">MULTY</a> <a href="#">MULTZ</a>	Modifies transmissibility in the X/Y/Z-direction. If output is required for flexible restart in the model, the multiplier values will be output as MULTXS/MULTYS/MULTZS.

Keyword	Description
PERMX PERMY PERMZ	Modifies permeability in the X/Y/Z-direction. Also approximates the corresponding transmissibility multiplier MULTX/MULTY/MULTZ determined from the ratio of the new permeability value to the old one. If output is required for flexible restart in the model, the permeability values will be output as MODPERMX/MODPERMY/MODPERMZ.
PORO	Modifies porosity. Modifies the corresponding pore volume by a multiplier MULTPV determined from the ratio of the new porosity value to the old one. If output is required for flexible restart in the model, the porosity values will be output as MODPORO, and the pore volume multipliers will be output as MULTPVS.
SIGMA SIGMAV	Modifies the matrix-fracture coupling transmissibility in dual-porosity runs. If output is required for flexible restart in the model, these multiplier values will be output as SIGMA.
WORK ( 1 / 2 )	These are work arrays to be stored for subsequent use. If output is required for flexible restart in the model, these values will be output as WORK ( 1 / 2 ).

/

```

## MULTMF

## Transmissibility multipliers for matrix-fracture coupling

This keyword specifies a transmissibility multiplier for flow between fractures and matrix in a dual porosity run (keyword [DUALPORO](#) in the RUNSPEC section).

The MULTMF keyword is followed by a value for each matrix cell, in normal grid order with the X-index changing fastest.

	ECLIPSE 100

## MULTNUM

## Defines regions for applying inter-region transmissibility multipliers

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword provides an alternative region definition for applying inter-region multipliers, instead of applying them to flux regions defined by [FLUXNUM](#). The MULTNUM keyword can be used to work with transmissibility multipliers using the keyword [MULTREGT](#), or with the [MULTREGP](#) keyword (which sets a pore volume multiplier for a specific region).

To use this keyword, the maximum number of MULTNUM regions must first be defined. To do this, the 2<sup>nd</sup> item in the [GRIDOPTS](#) keyword in the RUNSPEC section must be set greater than zero.

The MULTNUM keyword should be followed by one integer for each grid cell, specifying the region number to which it belongs. The data must be terminated by a slash (/).

Any cells not explicitly assigned a value of MULTNUM will be taken to be in region 1.

---

**Note:** In ECLIPSE 100, 0 is a valid value for MULTNUM similarly to [FLUXNUM](#). In ECLIPSE 300, 0 is an invalid value for MULTNUM.

---

In ECLIPSE 100, the MULTNUM array can be copied into the REGIONS section arrays ([FIPNUM](#) and [PVTNUM](#) for example) using the [COPY](#) keyword.

The MULTNUM array can be used with keywords [MULTIREG](#), [ADDREG](#) and [EQUALREG](#) in the GRID section.

In ECLIPSE 100 *only*, the MULTNUM keyword cannot be used inside a CARFIN/RADFIN...ENDFIN bracket.

For use with the Dual Porosity option, only the matrix cells or the fracture cells need to be input in ECLIPSE 100. The cell values in the other porosity will be copied automatically. If the user wants to specify matrix cells and fracture cells separately, then [item 117](#) in [OPTIONS](#) should be set greater than 0.

For use with Dual Porosity option, both matrix and fracture cells should be provided for ECLIPSE 300. MULTNUM use with [MULTREGT](#) or [MULTREGP](#), will automatically copy all matrix cells to the corresponding fracture cells, so dummy fracture values could be input. For other MULTNUM uses, there is no copying of data from the matrix to fracture cells.

The regions for inter-region transmissibility multipliers can be output to the Print file by using the mnemonic MULTNUM in the [RPTGRID](#) keyword.

### Example

To define 9 separate regions in a 4\*4\*3 field (with the maximum number of MULTNUM regions set equal to 9):

```
MULTNUM
1 1 2 2
1 1 2 2
3 3 3 3
4 4 4 4
5 5 5 5
6 7 8 8
6 7 8 8
6 7 8 8
16*9 /
```

## MULTOUT

### Indicates that output files are multiple

This indicates that output files which may be either multiple or unified are to be multiple. This is the default; unified files may be requested with the [UNIFOUT](#) keyword.

This keyword has no associated data.

	SCHEDULE

This indicates that summary output files which may be either multiple or unified are to be multiple. This is the default.

This keyword overwrites the behavior of the [UNIFOUT](#) keyword.

This keyword has no associated data.

## MULTPV

## Pore volume multipliers

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
x	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword should be followed by one non-negative real number for every grid block in the current input **BOX**. The values specified act as multipliers on the pore volumes. When used in the **GRID** section, these are the pore volumes calculated by ECLIPSE for each grid block. When used in the **EDIT** section, with ECLIPSE 300 they must act on values specified by **PORV** in the edit section; with ECLIPSE 100 it is recommended that they do so. When used in the **SCHEDULE** section, they act on the latest values produced by either **GRID** or **EDIT**. The data must be terminated by a slash (/).

Any **MULTPV** values that are not specified when the end of the **GRID** section is reached, default to 1.0.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0). Note that spaces must not be inserted on either side of the asterisk.

### Use in the EDIT section

If **MULTPV** is entered in the **EDIT** section, it acts as an additional multiplier on the pore volumes after any edited pore volumes have been read from the **EDIT** section. Use of **MULTPV** in the **EDIT** section in ECLIPSE 300 is only to provide modifiers to values of **PORV** entered explicitly in the **EDIT** section, and this is also the recommended practice in ECLIPSE 100. **MULTPV** should otherwise normally be specified in the **GRID** section rather than in the **EDIT** section. In ECLIPSE 300, ensure that the boxes for input of **PORV** and **MULTPV** match.

### Use in the SCHEDULE section

**MULTPV** can be used in the **SCHEDULE** section to modify the pore volumes during the run. Material is still conserved, so modifying the pore volume causes a step change in the pressure. Large sudden changes in the pore volume should be avoided.

This is a specialist facility, and is not recommended for general use. Note that the effect of **MULTPV** in the **SCHEDULE** section is cumulative: each time **MULTPV** is encountered in the **SCHEDULE** section, it multiplies the current pore volumes. So for a given cell, the base pore volume is multiplied by the product of all multipliers specified for that cell in the **SCHEDULE** section up to the current simulation time.

In ECLIPSE 100, the modified pore volume can be output to the Print file by using the mnemonic **MULT** in the **RPTSCHEd** keyword.

### Example

```

----- IX1-IX2 JY1-JY2 KZ1-KZ2
BOX
      5   6   3   8   4   6   /
MULTPV
36*1.25 /

```

## MULTR

## Transmissibility multipliers in the radial direction

The keyword is used in radial geometry and is analogous to [MULTX](#) in Cartesian geometry.

The keyword should be followed by one non-negative real number for every grid block in the current input box. The data must be terminated by a slash (/).

The values specified act as multipliers on the transmissibilities calculated by the program for the +R faces of each grid block.

Thus, a value of MULTR specified for block (I, J, K) multiplies the transmissibility between blocks (I, J, K) and (I+1, J, K).

Any MULTR values which are not specified when the end of the GRID section is reached, default to 1.0.

Grid blocks are ordered with the R axis index cycling fastest, followed by the Theta and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0). Note that spaces must not be inserted on either side of the asterisk.

In ECLIPSE 100 MULTR can also be used in the EDIT section.

---

**Note:** For ECLIPSE 100 compatibility when using ECLIPSE 300, the SCHEDULE section keyword MULTR has been aliased to MULTR. However, MULTR can still be used in the SCHEDULE section.

---

See also keyword [MULTR-](#).

### Example

```

----- IR1-IR2 JT1-JT2 KZ1-KZ2
BOX
      5   5   3   8   4   6   /
MULTR
18*0 /

```

## MULTR-

## Transmissibility multipliers in the negative radial direction

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
x	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword is used in radial geometry and is analogous to [MULTX-](#) in Cartesian geometry.

In order to use [MULTR-](#), the negative direction transmissibility multipliers must be enabled using the keyword [GRIDOPTS](#) in the [RUNSPEC](#) section.

The keyword should be followed by one non-negative real number for every grid block in the current input box. The data must be terminated by a slash (/).

The values specified act as multipliers on the transmissibilities calculated by the program for the -R face of each grid block.

Thus, a value of [MULTR-](#) specified for block (I, J, K) multiplies the transmissibility between blocks (I, J, K) and (I-1, J, K).

Any [MULTR-](#) values which are not specified when the end of the [GRID](#) section is reached default to 1.0.

In [ECLIPSE 100](#), [MULTR-](#) can also be used in the [EDIT](#) section.

Grid blocks are ordered with the R axis index cycling fastest, followed by the theta and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0). Note that spaces must not be inserted on either side of the asterisk.

See also the [MULTR](#) keyword.

If both [MULTR](#) and [MULTR-](#) are specified, then the product is used. For example, if [MULTR](#) is specified for cell (I, J, K) and [MULTR-](#) is specified for cell (I+1, J, K), then the product of the nominated [MULTR](#) and [MULTR-](#) values is used to multiply the transmissibility between blocks (I, J, K) and (I+1, J, K).

### Example

```
----- IR1-IR2 JT1-JT2 KZ1-KZ2
BOX
      5  5  3  8  4  6  /
MULTR-
 18*0 /
ENDBOX
```

## MULTREAL **Activates multi-realization licensing**

x	<b>ECLIPSE 100</b>
x	<b>ECLIPSE 300</b>
x	<b>SPECIAL</b>
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is used to activate the multiple-realization (MR) licensing. It is generated by a trusted program which creates an associated key file. The keyword cannot be added or modified by the user as this will cause the failure of validation against the key file. In such a case, the simulator will either stop or revert to the ordinary licensing depending on the value of the second item. Further information about the MR licensing can be found in "[Multiple realization](#)" in the *ECLIPSE Technical Description*.

The MULTREAL keyword is optional and should be followed by up to 2 data items, terminated by a slash (/).

1. A session identifier shared by all datasets generated simultaneously from the same case. The length of this string must not exceed 64 characters.
2. Specify if the simulator should revert to the standard licensing if the a multiple realization license is not available or this case cannot be validated successfully. The value is either YES or NO.

DEFAULT: YES

### Example

```
-- Example of keyword generated by a trusted program
MULTREAL
  'C38CCB5D-5D9A-4544-BCA4-42B13866A8B5' NO /
```

## MULTREGD **Multiplies the diffusivity between flux or MULTNUM regions**

x	ECLIPSE 100
	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
x	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The MULTREGD keyword can be used to set a diffusivity multiplier between regions. The regions must previously have been defined using keyword [FLUXNUM](#), [MULTNUM](#) or [OPERNUM](#) in the GRID section.

If MULTNUM is to be used, then storage for the MULTNUM array must be requested by setting the second item greater than zero in the RUNSPEC section keyword [GRIDOPTS](#). MULTREGD will apply to diffusivities between MULTNUM regions.

If FLUXNUM is to be used, then storage for the flux region data should be reserved by setting the fourth item in the RUNSPEC section keyword [REGDIMS](#). MULTREGD will then apply to diffusivities between flux regions defined using FLUXNUM.

If OPERNUM is to be used, then storage for the OPERNUM array should be reserved by setting the seventh item in the RUNSPEC section keyword [REGDIMS](#). MULTREGD will then apply to diffusivities between regions defined using OPERNUM.

The keyword can only be used when the Molecular Diffusion option is active (keyword [DIFFUSE](#) in the RUNSPEC section).

The MULTREGD keyword is followed by any number of data records. Each record contains the following six items of data, and is terminated with a slash (/).

- From region number (I)
 

A non-positive or defaulted value acts as a wildcard on all regions.

DEFAULT: Negative
- To region number (J)
 

A non-positive or defaulted value acts as a wildcard on all regions.

DEFAULT: Negative
- Diffusivity multiplier for all diffusivities connecting regions I and J
- Direction(s) in which to apply the multiplier:
 

Either X, Y, Z, XY, YZ, XZ or XYZ.

DEFAULT: XYZ
- Flag governing application of multiplier to non-neighbor connections:
 

NNC            Apply the diffusivity multiplier only to non-neighbor connections between regions I and J

NONNC        Do not apply the diffusivity multiplier to any non-neighbor connections between regions I and J

ALL            Apply the diffusivity multiplier to all connections between regions I and J

NOAQUNNC    Do not apply the diffusivity multiplier to numerical aquifer connections.

DEFAULT: ALL

6. Choice of region: MULTNUM (M), FLUXNUM (F) or OPERNUM (O)

DEFAULT: M

The set of records must end with a blank record containing only a slash (/).

## Notes

The multipliers specified in the MULTREGH keyword are applied **after** accounting for any data entered in either the GRID or EDIT sections.

- If either region number I or J is set non-positive or defaulted, then that region identifier is taken as a wildcard and the multiplier is applied between all regions I and J, with  $I \neq J$ , matching the template.
- If the region numbers I and J are equal and positive, then the rock thermal conductivities **within** that region in the specified direction(s) are multiplied by the given value, as well as any thermal conductivities connecting **any** other regions.
- The keyword does **not** affect the non-neighbor connections between matrix and fracture blocks in a dual porosity simulation.
- Non-neighbor connections arising from numerical aquifer connections to the grid are modified by MULTREGH unless the NOAQUNNC flag is set in item 5.
- If a combination of region numbers I and J is specified twice, then the latest multiplier is applied for the rock thermal conductivities between the two regions; the multipliers are not cumulative. This is true even if different region sets are specified - it is not possible to specify a multiplier between regions I and J using MULTNUM and a different multiplier between regions I and J using FLUXNUM. However, an individual rock thermal conductivity may be modified by more than one multiplier, if it is between different region number combinations for different region sets.
- This facility can be used to modify connections between PVT regions by assigning FLUXNUM or MULTNUM in the GRID section equal to the PVT regions, and then **COPY** ing FLUXNUM or MULTNUM to PVTNUM in the REGIONS section.
- This keyword cannot be used in conjunction with nested LGRs.

**CAUTION:** For backward compatibility reasons, while the default region set is MULTNUM, if some lines of data have a different region set specified, the first region specified is used as the default for all lines which have no region set specified. Defaulting some region sets while specifying others is not recommended.

## Example

```
MULTREGD
-- 'From' region      'To' region      Diffusivity      Directions      NNCs
                    multiplier
      1                2                0.5 /
      1                3                0.0 /
      4                4                0.4              'XY' /
      5                1*              0.75 / Between region 5 and any region.
/
```

## MULTREGH **Multiplies the rock thermal conductivity between flux or MULTNUM regions**

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
x	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The MULTREGH keyword can be used to set a rock thermal conductivity multiplier between regions, for the Temperature option (see "Temperature option" in the *ECLIPSE Technical Description*). The regions must previously have been defined using keyword [FLUXNUM](#), [MULTNUM](#) or [OPERNUM](#) in the GRID section.

If MULTNUM is to be used, then storage for the MULTNUM array must be requested by setting the second item greater than zero in the RUNSPEC section keyword [GRIDOPTS](#). MULTREGH applies to rock thermal conductivities between MULTNUM regions.

If FLUXNUM is to be used, then storage for the flux region data should be reserved by setting the fourth item in the RUNSPEC section keyword [REGDIMS](#). The MULTREGH will then apply to rock thermal conductivities between flux regions defined using FLUXNUM.

If OPERNUM is to be used, then storage for the OPERNUM array should be reserved by setting the seventh item in the RUNSPEC section keyword [REGDIMS](#). MULTREGH will then apply to rock thermal conductivities between regions defined using OPERNUM.

This keyword can only be used when the Temperature option is active (keyword [TEMP](#) in the RUNSPEC section), and the rock thermal conductivities must have been defined using keyword [THCONR](#) in the GRID section.

The MULTREGH keyword is followed by any number of data records. Each record contains the following six items of data, and is terminated with a slash (/).

- From region number (I)
  - A non-positive or defaulted value acts as a wildcard on all regions.
  - DEFAULT: Negative
- To region number (J)
  - A non-positive or defaulted value acts as a wildcard on all regions.
  - DEFAULT: Negative
- Rock thermal conductivity multiplier for all thermal conductivities connecting regions I and J
- Direction(s) in which to apply the multiplier:
  - Either X, Y, Z, XY, YZ, XZ or XYZ.
  - DEFAULT: XYZ
- Flag governing application of multiplier to non-neighbor connections:
  - NNC        Apply the rock thermal conductivity multiplier only to non-neighbor connections between regions I and J
  - NONNC     Do not apply the rock thermal conductivity multiplier to any non-neighbor connections between regions I and J
  - ALL        Apply the thermal conductivity multiplier to all connections between regions I and J
  - NOAQUNNC Do not apply the rock thermal conductivity multiplier to numerical aquifer connections.

DEFAULT: ALL

6. Choice of region: MULTNUM (M), FLUXNUM (F) or OPERNUM (O)

DEFAULT: M

The set of records must end with a blank record containing only a slash (/).

## Notes

The multipliers specified in the MULTREGH keyword are applied **after** accounting for any data entered in either the GRID or EDIT sections.

- If either region number I or J is set non-positive or defaulted, then that region identifier is taken as a wildcard and the multiplier is applied between all regions I and J, with  $I \neq J$ , matching the template.
- If the region numbers I and J are equal and positive, then the rock thermal conductivities **within** that region in the specified direction(s) are multiplied by the given value, as well as any thermal conductivities connecting **any** other regions.
- The keyword does **not** affect the non-neighbor connections between matrix and fracture blocks in a dual porosity simulation.
- Non-neighbor connections arising from numerical aquifer connections to the grid are modified by MULTREGH unless the NOAQUNNC flag is set in item 5.
- If a combination of region numbers I and J is specified twice, then the latest multiplier is applied for the rock thermal conductivities between the two regions; the multipliers are not cumulative. This is true even if different region sets are specified - it is not possible to specify a multiplier between regions I and J using MULTNUM and a different multiplier between regions I and J using FLUXNUM. However, an individual rock thermal conductivity may be modified by more than one multiplier, if it is between different region number combinations for different region sets.
- This facility can be used to modify connections between PVT regions by assigning FLUXNUM or MULTNUM in the GRID section equal to the PVT regions, and then **COPY** ing FLUXNUM or MULTNUM to PVTNUM in the REGIONS section.
- This keyword cannot be used in conjunction with nested LGRs.

---

**CAUTION:** For backward compatibility reasons, while the default region set is MULTNUM, if some lines of data have a different region set specified, the first region specified is used as the default for all lines which have no region set specified. Defaulting some region sets while specifying others is not recommended.

---

## Example

```
MULTREGH
-- 'From' region      'To' region      Conductivity
                    multiplier
      1                2                0.5 /
      1                3                0.0 /
      4                4                0.4
      5                1*              0.75 / Between region 5 and any region.
/
```

## MULTREGP **Multiplies the pore volumes for specific flux or MULTNUM region**

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
x	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The MULTREGP keyword can be used to set a pore volume multiplier for a specific region. The regions must previously have been defined using keyword [FLUXNUM](#), [MULTNUM](#) or [OPERNUM](#) in the GRID section.

If MULTNUM is to be used, then storage for the MULTNUM array must be requested by setting the 2nd item greater than zero in the RUNSPEC section keyword [GRIDOPTS](#). MULTREGP applies to pore volumes to the MULTNUM regions.

If FLUXNUM is to be used, then storage for the flux region data should be reserved by setting the fourth item in the RUNSPEC section keyword [REGDIMS](#). MULTREGP will then apply to pore volumes between flux regions defined using FLUXNUM.

If OPERNUM is to be used, then storage for the OPERNUM array should be reserved by setting item 7 in the RUNSPEC section keyword [REGDIMS](#). MULTREGP will then apply to pore volumes between flux regions defined using OPERNUM.

The MULTREGP keyword is followed by any number of data records. Each record contains the following three items of data, and is terminated with a slash (/).

1. Region number (I)  
DEFAULT: Negative
2. Pore volume multiplier for region I
3. Choice of region: MULTNUM (M), FLUXNUM (F) or OPERNUM (O)  
DEFAULT: M

The set of records must end with a blank record containing only a slash (/).

### Notes

- The multipliers specified in the MULTREGP keyword are applied **after** accounting for any [MULTPV](#) values specified in the GRID or EDIT sections.
- If a region number is specified twice, then the latest multiplier is applied for that region; the multipliers are not cumulative. This is true even if different region sets are specified - it is not possible to specify a multiplier for region 1 using MULTNUM and a different multiplier for region 1 using [FLUXNUM](#). However, an individual grid block's pore volume may be modified by more than one multiplier, if it is in different region numbers for different region sets.
- The multipliers for specific regions can be output to the Print file using the mnemonic MULTREGP in the [RPTGRID](#) keyword.
- For MULTREGP to be used in the EDIT section, [PORV](#) values should also be specified in the EDIT section.
- If the pore volume values are not specified, a warning message will be produced.
- Only positive region numbers will be able to modify the pore volume given the pore volume multiplier assigned to that region. A pore volume multiplier assigned to a zero or negative region number will have no effect on the pore volumes.

- This keyword cannot be used in conjunction with nested LGRs.

---

**CAUTION:** For backward compatibility reasons, while the default region set is MULTNUM, if some lines of data have a different region set specified, the first region specified is used as the default for all lines which have no region set specified. Defaulting some region sets while specifying others is not recommended.

---

## Example

```
MULTREGP
-- Region Pore Volume Multiplier Region Set
   1      0.5
   2      0.0
   4      0.4
   5      0.75
   O/
/
```

## MULTREGT **Multiplies the transmissibility between flux or MULTNUM regions**

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
x	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The MULTREGT keyword can be used to set a transmissibility multiplier between regions. The regions must previously have been defined using keyword [FLUXNUM](#), [MULTNUM](#) or [OPERNUM](#) in the GRID section.

If MULTNUM is to be used, then storage for the MULTNUM array must be requested by setting the second item greater than zero in the RUNSPEC section keyword [GRIDOPTS](#). MULTREGT applies to transmissibilities between MULTNUM regions.

If FLUXNUM is to be used, then storage for the flux region data should be reserved by setting the fourth item in the RUNSPEC section keyword [REGDIMS](#). MULTREGT will then apply to transmissibilities between flux regions defined using FLUXNUM.

If OPERNUM is to be used, then storage for the OPERNUM array should be reserved by setting the item 7 in the RUNSPEC section keyword [REGDIMS](#). MULTREGT will then apply to transmissibilities between regions defined using OPERNUM.

The MULTREGT keyword is followed by any number of data records. Each record contains the following six items of data, and is terminated with a slash (/).

1. From region number (I)
  - A non-positive or defaulted value acts as a wildcard on all regions.
  - DEFAULT: Negative
2. To region number (J)
  - A non-positive or defaulted value acts as a wildcard on all regions.
  - DEFAULT: Negative
3. Transmissibility multiplier for all transmissibilities connecting regions I and J
4. Direction(s) in which to apply the multiplier:
  - Either X, Y, Z, XY, YZ, XZ or XYZ.
  - DEFAULT: XYZ
5. Flag governing application of multiplier to non-neighbor connections:
  - NNC            Apply the transmissibility multiplier only to non-neighbor connections between regions I and J
  - NONNC        Do not apply the transmissibility multiplier to any non-neighbor connections between regions I and J
  - ALL            Apply the transmissibility multiplier to all connections between regions I and J
  - NOAQUNNC    Do not apply the transmissibility multiplier to numerical aquifer connections.
  - DEFAULT: ALL
6. Choice of region: MULTNUM (M), FLUXNUM (F) or OPERNUM (O)
  - DEFAULT: M

The set of records must end with a blank record containing only a slash (/).

When using MULTREGT in the SCHEDULE section with ECLIPSE 100, only the first three items (and item 6 if required) should be specified; the remaining items assume that values are specified in the GRID section or are defaulted. The effect of using MULTREGT in the SCHEDULE section is cumulative. Hence if MULTREGT is specified twice for the same connection between regions, the product of the transmissibility multipliers is used.

The effect of MULTREGT in the GRID section is not cumulative.

## Notes

- The multipliers specified in the MULTREGT keyword are applied **after** accounting for any values of [MULTX](#), [MULTY](#), [MULTZ](#), or [MULTFLT](#) entered in either the GRID or EDIT sections.
- Similarly, the multipliers specified in this keyword are applied after accounting for any values of [MULTX-](#), [MULTY-](#) or [MULTZ-](#).
- If either region number I or J is set non-positive or defaulted, then that region identifier is taken as a wildcard and the multiplier is applied between all regions I and J, with  $I \neq J$ , matching the template.
- If the region numbers I and J are equal and positive, then the transmissibilities **within** that region in the specified direction(s) are multiplied by the given value, as well as any transmissibilities connecting **any** other regions.
- The keyword does **not** affect the non-neighbor connections between matrix and fracture blocks in a dual porosity simulation.
- Non-neighbor connections arising from numerical aquifer connections to the grid are modified by MULTREGT unless the NOAQUNNC flag is set in item 5.
- In ECLIPSE 100, if a combination of region numbers I and J is specified twice, then the latest multiplier is applied for the transmissibilities between the two regions; the multipliers are not cumulative. This is true even if different region sets are specified - it is not possible to specify a multiplier between regions I and J using MULTNUM and a different multiplier between regions I and J using FLUXNUM. However, an individual transmissibility may be modified by more than one multiplier, if it is between different region number combinations for different region sets.
- In ECLIPSE 100, this facility can be used to modify connections between PVT regions by assigning FLUXNUM or MULTNUM in the GRID section equal to the PVT regions, and then [COPY](#) ing FLUXNUM or MULTNUM to [PVTNUM](#) in the REGIONS section.
- In order to use MULTREGT in the EDIT section, [TRANX](#), [TRANY](#), [TRANZ](#) values should also be specified in the EDIT section. If the transmissibility values are not specified, a warning message will be produced.
- The multipliers between regions can be output to the print file using the mnemonic MULTREGT in the [RPTGRID](#) keyword.
- This keyword cannot be used in conjunction with nested LGRs.
- In ECLIPSE 300, when specifying region numbers for individual LGR cells for use with MULTREGT, global host cell values which are greater than 1 will overwrite local cell region numbers which are equal to 1, even if these have been explicitly set rather than defaulted. Region numbers greater than 1 should be used for LGR cells which have host cells not in region 1.

**CAUTION:** For backward compatibility reasons, while the default region set is MULTNUM, if some lines of data have a different region set specified, the first region specified is used as the default for all lines which have no region set specified. Defaulting some region sets while specifying others is not recommended.

## Example

```
MULTREGT
-- 'From' region  'To' region  Transmissibility  Directions  NNCs
multiplier
      1           2           0.5 /
      1           3           0.0 /
      4           4           0.4           'XY' /
      5           1*         0.75 /  Between region 5 and any region.
/
```

## MULTSAVE Indicates that save files are multiple

	<b>ECLIPSE 100</b>
x	<b>ECLIPSE 300</b>
	<b>SPECIAL</b>
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This indicates that ECLIPSE 300 SAVE files, which may be either multiple or unified, are to be multiple. This is the default; unified SAVE files may be requested with the [UNIFSAVE](#) keyword.

This keyword also allows the writing of SAVE files to be controlled. The keyword contains an integer data item.

1. Select how multiple SAVE files are used:
  - 1 Suppress SAVE files.
  - 0 Overwrite the first SAVE file at each step.
  - 1 Produce SAVE files at each [SAVE](#) keyword.

DEFAULT: 0

The setting of MULTSAVE affects the operation of the [AUTOSAVE](#) keyword.

This keyword is not available in ECLIPSE 100, and will be ignored.

ECLIPSE 300 does not allow a SAVE file to be written during a parallel run. Fast restarts are not supported for parallel runs in ECLIPSE 300.

## MULTSIG

**Dual porosity matrix-fracture coupling multiplier**

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

If the dual porosity option is being used (keyword [DUALPORO](#) in the RUNSPEC section), and the matrix-fracture coupling transmissibilities have been specified in the grid section through the [SIGMA](#) or [SIGMAV](#) keywords, then this keyword can be used to specify a multiplier in the SCHEDULE section which will modify further these matrix-fracture coupling transmissibilities.

If this keyword is used, a single multiplier is applied to the entire current grid. To specify values for individual cells, use the [MULTSIGV](#) keyword.

If this keyword is used multiple times or it is used in combination with [MULTSIGV](#) then the effect of the multipliers will be cumulative.

The keyword should be followed by one single positive real number, which will be applied to every cell in the current grid.

UNITS: dimensionless

**Example**

```
MULTSIG
0.5 /
```

## MULTSIGV

**Dual porosity matrix-fracture coupling multiplier**

## MULTTHT

## Transmissibility multipliers in the theta direction

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword is used in radial geometry and is analogous to [MULTY](#) in Cartesian geometry.

The keyword should be followed by one non-negative real number for every grid block in the current input box. The data must be terminated by a slash (/).

The values specified act as multipliers on the transmissibilities calculated by the program for the +Theta faces of each grid block.

Thus, a value of MULTTHT specified for block (I, J, K) multiplies the transmissibility between blocks (I, J, K) and (I, J+1, K).

Any MULTTHT values that are not specified when the end of the GRID section is reached, default to 1.0.

Grid blocks are ordered with the R axis index cycling fastest, followed by the theta and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0). Note that spaces must not be inserted on either side of the asterisk.

In ECLIPSE 100, MULTTHT can also be used in the EDIT section.

---

**Note:** For ECLIPSE 100 compatibility when using ECLIPSE 300, the SCHEDULE section keyword MULTTTHT has been aliased to MULTTHT. However, MULTTTHT can still be used in the SCHEDULE section as documented in previous releases.

---

See also keyword [MULTTHT-](#).

## Example

```

----- IR1-IR2 JT1-JT2 KZ1-KZ2
BOX
      4   6   3   3   4   6   /
MULTTHT
 9*0.01 /
ENDBOX

```

## MULTTHT- Transmissibility multipliers in the negative theta direction

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
x	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword is used in radial geometry and is analogous to [MULTY-](#) in Cartesian geometry.

In order to use [MULTTHT-](#), the negative direction transmissibility multipliers must be enabled using the keyword [GRIDOPTS](#) in the RUNSPEC section.

The keyword should be followed by one non-negative real number for every grid block in the current input box. The data must be terminated by a slash (/).

The values specified act as multipliers on the transmissibilities calculated by the program for the -theta faces of each grid block.

Thus, a value of [MULTTHT-](#) specified for block (I, J, K) multiplies the transmissibility between blocks (I, J, K) and (I, J-1, K).

Any [MULTTHT-](#) values that are not specified when the end of the GRID section is reached default to 1.0.

In ECLIPSE 100, [MULTTHT-](#) can also be used in the EDIT section.

Grid blocks are ordered with the R axis index cycling fastest, followed by the theta and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0). Note that spaces must not be inserted on either side of the asterisk.

See also the [MULTTHT](#) keyword.

If both [MULTTHT](#) and [MULTTHT-](#) are specified, then the product is used. For example, if [MULTTHT](#) is specified for cell (I, J, K) and [MULTTHT-](#) is specified for cell (I, J+1, K), then the product of the nominated [MULTTHT](#) and [MULTTHT-](#) values is used to multiply the transmissibility between blocks (I, J, K) and (I, J+1, K).

### Example

```
----- IR1-IR2 JT1-JT2 KZ1-KZ2
BOX
      4   6   3   3   4   6   /
MULTTHT
  9*0.01 /
ENDBOX
```

## MULTX

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
x	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

## Transmissibility multipliers in X-direction

The keyword should be followed by one non-negative real number for every grid block in the current input box. The data must be terminated by a slash (/).

The values specified act as multipliers on the transmissibilities calculated by the program for the +X face of each grid block or specified directly using [TRANX](#) in the EDIT section.

Thus, a value of MULTX specified for block (I, J, K) multiplies the transmissibility between blocks (I, J, K) and (I+1, J, K).

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0). Note that spaces must not be inserted on either side of the asterisk.

See also keyword [MULTX-](#).

### Non-neighbor connections

Any non-neighbor connections generated due to faults have transmissibilities that reflect the MULTX values. Non-neighbor connections entered explicitly using the [NNC](#) keyword are not affected.

### Use in the GRID section

If MULTX is entered in the GRID section, then it applies only to the transmissibilities calculated by the program using the information in the GRID section, and **not** to any transmissibilities entered directly in the EDIT section using the [TRANX](#) keyword. Any MULTX values that are not specified when the end of the GRID section is reached, default to 1.0.

### Use in the EDIT section (ECLIPSE 100 only)

If MULTX is entered in the EDIT section, then it acts as an additional multiplier on the transmissibilities after the reading of any modified transmissibilities from the EDIT section. Any non-neighbor connections are modified to reflect the edited values of MULTX.

Use of the MULTX multiplier in the EDIT section is **not** recommended in general, except as a modifier to values of [TRANX](#) entered explicitly in the EDIT section. The keyword MULTX should normally be specified in the GRID section rather than in the EDIT section.

### Use in the SCHEDULE section

MULTX can be used in the SCHEDULE section to modify the transmissibilities during the run. Well connection transmissibility factors are **not** affected by this keyword (instead, use [WPIMULT](#) for example, for this purpose).

Note that the effect of MULTX in the SCHEDULE section is cumulative. In other words, each time MULTX is encountered in the SCHEDULE section, it multiplies the current X-direction transmissibility. So for a given cell, the base X-direction transmissibility is multiplied by the product of all multipliers specified for that cell in the SCHEDULE section up to the current simulation time.

The modified transmissibilities can be output to the Print file by using the mnemonic MULT in the [RPTSCHED](#) keyword.

In ECLIPSE 300, if values are defaulted or set negative, the transmissibilities for the corresponding cells are not modified.

**Note:** For ECLIPSE 100 compatibility when using ECLIPSE 300, the SCHEDULE section keyword MULTTX has been aliased to MULTX. However, MULTTX can still be used in the SCHEDULE section.

---

## Example

This example multiplies the transmissibility values in a box by 0.2

```
----- IX1-IX2 JY1-JY2 KZ1-KZ2
BOX
      5   5   3   8   4   6   /
MULTX
 18*0.2 /
ENDBOX
```

## MULTX-

## Transmissibility multipliers in the negative X-direction

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
x	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword should be followed by one non-negative real number for every grid block in the current input box. The data must be terminated by a slash (/).

The values specified act as multipliers on the transmissibilities calculated by the program for the -X face of each grid block or specified directly using [TRANX](#) in the EDIT section.

Thus, a value of MULTX- specified for block (I, J, K) multiplies the transmissibility between blocks (I, J, K) and (I-1, J, K).

In order to use MULTX-, the negative direction transmissibility multipliers must be enabled using the keyword [GRIDOPTS](#) in the RUNSPEC section.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0). Note that spaces must not be inserted on either side of the asterisk.

See also the [MULTX](#) keyword.

If both the MULTX keyword and MULTX- are specified, then the product is used. For example, if MULTX is specified for the block (I, J, K) and MULTX- is specified for the block (I+1, J, K), then the program uses the product of the nominated MULTX and MULTX- values to multiply the calculated transmissibility between the two adjacent blocks.

### Non-neighbor connections

Any non-neighbor connections generated due to faults have transmissibilities that reflect the MULTX and MULTX- values. A fault non-neighbor connection between a cell (I, J, K1) and a cell (I+1, J, K2) in an adjacent column has a transmissibility factor of MULTX for block (I, J, K1) or MULTX- for block (I+1, J, K2) or the product of the two. Non-neighbor connections entered explicitly using the [NNC](#) keyword are not affected.

### Use in the GRID section

If MULTX- is entered in the GRID section, then it applies only to the transmissibilities calculated by the program using the information in the GRID section, and **not** to any transmissibilities entered directly in the EDIT section using the [TRANX](#) keyword. Any MULTX- values that are not specified when the end of the GRID section is reached, default to 1.0.

### Use in the EDIT section (ECLIPSE 100 only)

If MULTX- is entered in the EDIT section, then it acts as an additional multiplier on the transmissibilities after reading any modified transmissibilities from the EDIT section. Any non-neighbor connections are modified to reflect the edited values of MULTX-.

Use of the MULTX- multiplier in the EDIT section is **not** recommended in general, except as modifiers to values of [TRANX](#) entered explicitly in the EDIT section. The keyword MULTX- should normally be specified in the GRID section rather than in the EDIT section.

## Use in the SCHEDULE section

MULTX- can be used in the SCHEDULE section to modify the transmissibilities during the run. Well connection transmissibility factors are **not** affected by this keyword (instead, use [WPIMULT](#) for example, for this purpose).

The modified transmissibilities can be output to the print file by using the mnemonic MULT in the [RPTSCHED](#) keyword.

In ECLIPSE 300, if values are defaulted or set negative, the transmissibilities for the corresponding cells are not modified.

## Example

```
----- IX1-IX2 JY1-JY2 KZ1-KZ2
BOX
      5  5  3  8  4  6  /
MULTX-
 18*0 /
ENDBOX
```

## Transmissibility multipliers in Y-direction

The keyword should be followed by one non-negative real number for every grid block in the current input box. The data must be terminated by a slash (/).

The values specified act as multipliers on the transmissibilities calculated by the program for the +Y face of each grid block or specified directly using [TRANXY](#) in the EDIT section.

Thus, a value of `MULTY` specified for block (I, J, K) multiplies the transmissibility between blocks (I, J, K) and (I, J+1, K).

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0). Note that spaces must not be inserted on either side of the asterisk.

See also keyword [MULTY-](#).

### Non-neighbor connections

Non-neighbor connections entered explicitly using the [NNC](#) keyword are not affected.

### Use in the GRID section

If `MULTY` is entered in the `GRID` section, then it applies only to the transmissibilities calculated by the program using the information in the `GRID` section, and **not** to any transmissibilities entered directly in the `EDIT` section using the [TRANXY](#) keyword. Any `MULTY` values which are not specified when the end of the `GRID` section is reached, default to 1.0.

### Use in the EDIT section (ECLIPSE 100 only)

If `MULTY` is entered in the `EDIT` section, then it acts as an additional multiplier on the transmissibilities after the reading of any modified transmissibilities from the `EDIT` section. Any non-neighbor connections will be modified to reflect the edited values of `MULTY`.

Use of the `MULTY` multiplier in the `EDIT` section is **not** recommended in general, except as a modifier to values of [TRANZ](#) entered explicitly in the `EDIT` section. The keyword `MULTY` should normally be specified in the `GRID` section rather than in the `EDIT` section.

### Use in the SCHEDULE section

`MULTY` can be used in the `SCHEDULE` section to modify the transmissibilities during the run. Well connection transmissibility factors are **not** affected by this keyword (instead, use [WPIMULT](#) for example, for this purpose).

Note that the effect of `MULTY` in the `SCHEDULE` section is cumulative. In other words, each time `MULTY` is encountered in the `SCHEDULE` section, it multiplies the current Y-direction transmissibility. So for a given cell, the base Y-direction transmissibility is multiplied by the product of all multipliers specified for that cell in the `SCHEDULE` section up to the current simulation time.

The modified transmissibilities can be output to the Print file by using the mnemonic `MULT` in the [RPTSCHED](#) keyword.

In `ECLIPSE 300`, if values are defaulted or set negative, the transmissibilities for the corresponding cells are not modified.

**Note:** For ECLIPSE 100 compatibility when running ECLIPSE 300, the SCHEDULE section keyword MULTTX has been aliased to MULTY. However, MULTTY can still be used in the SCHEDULE section.

---

## Example

This example multiplies the transmissibility values in a box by zero.

```
----- IX1-IX2 JY1-JY2 KZ1-KZ2
BOX
      5  5  3  8  4  6 /
MULTY
  18*0.0 /

## MULTY-

## Transmissibility multipliers in the negative Y-direction

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
x	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword should be followed by one non-negative real number for every grid block in the current input box. The data must be terminated by a slash (/).

The values specified act as multipliers on the transmissibilities calculated by the program for the -Y face of each grid block or specified directly using [TRANXY](#) in the EDIT section.

Thus, a value of MULTY- specified for block (I, J, K) multiplies the transmissibility between blocks (I, J, K) and (I, J-1, K).

In order to use MULTY-, the negative direction transmissibility multipliers must be enabled using the keyword [GRIDOPTS](#) in the RUNSPEC section.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0). Note that spaces must not be inserted on either side of the asterisk.

See also the [MULTY](#) keyword.

If both the MULTY keyword and MULTY- are specified, then the product is used. For example, if MULTY is specified for the block (I, J, K) and MULTY- is specified for the block (I, J-1, K), then the program uses the product of the nominated MULTY and MULTY- values to multiply the calculated transmissibility between the two adjacent blocks.

### Non-neighbor connections

Any non-neighbor connections generated due to faults have transmissibilities that reflect the MULTY and MULTY- values. A fault non-neighbor connection between a cell (I, J, K1) and a cell (I, J+1, K2) in an adjacent column has a transmissibility factor of MULTY for block (I, J, K1) or MULTY- for block (I, J+1, K2) or the product of the two. Non-neighbor connections entered explicitly using the [NNC](#) keyword are not affected.

### Use in the GRID section

If MULTY- is entered in the GRID section, then it applies only to the transmissibilities calculated by the program using the information in the GRID section, and **not** to any transmissibilities entered directly in the EDIT section using the [TRANXY](#) keyword. Any MULTY- values that are not specified when the end of the GRID section is reached, default to 1.0.

### Use in the EDIT section (ECLIPSE 100 only)

If MULTY- is entered in the EDIT section, then it acts as an additional multiplier on the transmissibilities after reading any modified transmissibilities from the EDIT section. Any non-neighbor connections are modified to reflect the edited values of MULTY-.

Use of the MULTY- multiplier in the EDIT section is **not** recommended in general, except as modifiers to values of [TRANXY](#) entered explicitly in the EDIT section. The keyword MULTY- should normally be specified in the GRID section rather than in the EDIT section.

## Use in the SCHEDULE section

MULTY- can be used in the SCHEDULE section to modify the transmissibilities during the run. Well connection transmissibility factors are **not** affected by this keyword (instead, use [WPIMULT](#) for example, for this purpose).

The modified transmissibilities can be output to the print file by using the mnemonic MULT in the [RPTSCHED](#) keyword.

In ECLIPSE 300, if values are defaulted or set negative, the transmissibilities for the corresponding cells are not modified.

## Example

```
----- IX1-IX2 JY1-JY2 KZ1-KZ2
BOX
      5  5  3  8  4  6  /
MULTY-
  18*0  /
ENDBOX
```

## Transmissibility multipliers in Z-direction

The keyword should be followed by one non-negative real number for every grid block in the current input box. The data must be terminated by a slash (/).

The values specified act as multipliers on the transmissibilities calculated by the program for the +Z face of each grid block or specified directly using [TRANZ](#) in the EDIT section.

Thus, a value of MULTZ specified for block (I, J, K) multiplies the transmissibility between blocks (I, J, K) and (I, J, K+1).

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0). Note that spaces must not be inserted on either side of the asterisk.

See also keyword [MULTZ-](#).

### Non-neighbor connections

Non-neighbor connections entered explicitly using the [NNC](#) keyword are not affected.

### Use in the GRID section

If MULTZ is entered in the GRID section, then it applies only to the transmissibilities calculated by the program using the information in the GRID section, and **not** to any transmissibilities entered directly in the EDIT section using the [TRANZ](#) keyword. Any MULTZ values which are not specified when the end of the GRID section is reached, default to 1.0.

### Use in the EDIT section (ECLIPSE 100 only)

If MULTZ is entered in the EDIT section, then it acts as an additional multiplier on the transmissibilities after the reading of any modified transmissibilities from the EDIT section. Any non-neighbor connections will be modified to reflect the edited values of MULTZ.

Use of the MULTZ multiplier in the EDIT section is **not** recommended in general, except as a modifier to values of [TRANZ](#) entered explicitly in the EDIT section. The keyword MULTZ should normally be specified in the GRID section rather than in the EDIT section.

### Use in the SCHEDULE section

MULTZ can be used in the SCHEDULE section to modify the transmissibilities during the run. Well connection transmissibility factors are **not** affected by this keyword (instead, use [WPIMULT](#) for example, for this purpose).

Note that the effect of MULTZ in the SCHEDULE section is cumulative. In other words, each time MULTZ is encountered in the SCHEDULE section, it multiplies the current Z-direction transmissibility. So for a given cell, the base Z-direction transmissibility is multiplied by the product of all multipliers specified for that cell in the SCHEDULE section up to the current simulation time.

The modified transmissibilities can be output to the Print file by using the mnemonic MULT in the [RPTSCHED](#) keyword.

In ECLIPSE 300, if values are defaulted or set negative, the transmissibilities for the corresponding cells are not modified.

**Note:** For ECLIPSE 100 compatibility when running ECLIPSE 300, the SCHEDULE section keyword MULTTX has been aliased to MULTZ. However, MULTTZ can still be used in the SCHEDULE section as documented in previous releases.

---

## Example

This example multiplies the transmissibility values in a box by 1000.

```
----- IX1-IX2 JY1-JY2 KZ1-KZ2
BOX
      1  11   1  19   2   2 /
MULTZ
 209*1000.0 /
ENDBOX
```

	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword should be followed by one non-negative real number for every grid block in the current input box. The data must be terminated by a slash (/).

The values specified act as multipliers on the transmissibilities calculated by the program for the -Z face of each grid block or specified directly using [TRANZ](#) in the EDIT section.

Thus, a value of MULTZ- specified for block (I, J, K) multiplies the transmissibility between blocks (I, J, K) and (I, J, K-1).

In order to use MULTZ-, the negative direction transmissibility multipliers must be enabled using the keyword [GRIDOPTS](#) in the RUNSPEC section.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0). Note that spaces must not be inserted on either side of the asterisk.

See also the [MULTZ](#) keyword.

If both the MULTZ keyword and MULTZ- are specified, then the product is used. For example, if MULTZ is specified for the block (I, J, K) and MULTZ- is specified for the block (I, J, K+1), then the program uses the product of the nominated MULTZ and MULTZ- values to multiply the calculated transmissibility between the two adjacent blocks.

### Non-neighbor connections

Any non-neighbor connections generated due to pinchouts have transmissibilities that reflect the MULTZ values for the upper of the two cells connected across a pinchout, and the MULTZ- values for the lower of the two cells. A pinchout non-neighbor connection in column (I, J) between layers K1 and K2, with K2 > K1, has its calculated transmissibility multiplied by the value of MULTZ for cell (I, J, K1) and MULTZ- for cell (I, J, K2). Non-neighbor connections entered explicitly using the [NNC](#) keyword are not affected.

### Use in the GRID section

If MULTZ- is entered in the GRID section, then it applies only to the transmissibilities calculated by the program using the information in the GRID section, and **not** to any transmissibilities entered directly in the [EDIT](#) section using the [TRANZ](#) keyword. Any MULTZ- values that are not specified when the end of the GRID section is reached, default to 1.0.

### Use in the EDIT section (ECLIPSE 100 only)

If MULTZ- is entered in the EDIT section, then it acts as an additional multiplier on the transmissibilities after reading any modified transmissibilities from the EDIT section. Any non-neighbor connections are modified to reflect the edited values of MULTZ-.

Use of the MULTZ- multiplier in the EDIT section is **not** recommended in general, except as modifiers to values of [TRANZ](#) entered explicitly in the EDIT section. The keyword MULTZ- should normally be specified in the GRID section rather than in the EDIT section.

## Use in the SCHEDULE section

MULTZ- can be used in the SCHEDULE section to modify the transmissibilities during the run. Well connection transmissibility factors are **not** affected by this keyword (instead, use [WPIMULT](#) for example, for this purpose).

The modified transmissibilities can be output to the Print file by using the mnemonic MULT in the [RPTSCHED](#) keyword.

In ECLIPSE 300, if values are defaulted or set negative, the transmissibilities for the corresponding cells are not modified.

In a run with  $N_c$  components, this keyword associates a mean molecular weight with each component.

The keyword should be followed by  $N_c$  values.

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

UNITS: kg/kg-M (METRIC), lb/lb-M (FIELD), gm/gm-M (LAB), kg/kg-M (PVT-M)

DEFAULT: There are no component-wise default values. The users are recommended not to default these to the internal default value.

### Example

Molecular weights for a four-component study:

```
MW
18 32 45.6 78.0 /
```

## MWDETAIL Molecular weights for detailed components

In a run with  $N_d$  detailed components, this keyword associates a mean molecular weight with each of the detailed components. Lumped simulations are enabled with the [LUMPDIMS](#) keyword in the RUNSPEC section; further details can be found in "[Delumping and lumping](#)" in the *ECLIPSE Technical Description*.

The keyword should be followed by a record of  $N_d$  values, terminated with a slash, for each reservoir equation of state region. The values represent the molecular weight of each detailed component, in the order in which the detailed components are defined in the [LUMPING](#) keyword.

If multiple equations of state are being used, a record of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

UNITS: kg/kg-M (METRIC), lb/lb-M (FIELD), gm/gm-M (LAB), kg/kg-M (PVT-M)

### Example

Molecular weights for a study with 8 detailed components and one EoS region:

```
MWDETAIL
18 32 45.6 78.0 56.2 37.6 67.8 81.0 /

## Confirm number of components

This keyword may be read in the PROPS section to confirm the number of components in a compositional run. NCOMPS contains an item of data which specifies the number of components to be used.

This keyword is not usually required, as the number of components will have been specified by keyword `COMPS` in the RUNSPEC section. If present it is read, and an error message is produced if the item's value does not match that specified with `COMPS`. The purpose of NCOMPS is to ensure that included files produced by PVT *i* have the correct number of components, and PVO files automatically contain this keyword.

### Example

Confirm that twelve components are present:

```

NCOMPS
12 /

```

## NCONSUMP Gas consumption for extended network nodes

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used to specify a constant gas consumption rate at a particular node in the extended network (see "The extended network model" in the *ECLIPSE Technical Description*), and optionally to assign the consumption also to a group in the [GRUPTREE](#) hierarchy. It may be used as an alternative to the [GCONSUMP](#) keyword when the extended network model is employed (keyword [NETWORK](#) present in the [RUNSPEC](#) section).

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Node name
2. Gas consumption rate at the node  
 UNITS: sm<sup>3</sup>/day (METRIC), Mscf/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)  
 DEFAULT: Zero
3. Name of the group from which the node's consumption should also be removed  
 DEFAULT: Not removed from any group

---

### Note:

- If item 3 is defaulted, the node's gas consumption is **not** removed from a group, even if the node is a source node and thus corresponds to a group. The default action is therefore different from that in [GCONSUMP](#).
- The group defined in item 3 replaces any group previously defined for the same purpose by this keyword or item 8 in keyword [NETCOMPA](#).

---

**CAUTION:** Do not use both [NCONSUMP](#) and [GCONSUMP](#) to declare consumption at corresponding nodes and groups; this could double the consumption.

---

See also keyword [GCONSUMP](#).

### Example

```
NCONSUMP
  PLAT-A    20    PLAT-A  /
  PLAT-B    15    PLAT-B  /
/
```

## NEFAC

# Efficiency factors for extended network nodes

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword may be used to specify an efficiency factor at a node in the extended network (see "[The extended network model](#)" in the *ECLIPSE Technical Description*). This may be useful if a group efficiency factor has been applied with keyword [GEFAC](#) to a group which does not correspond to a network node; NEFAC may then be used to apply the efficiency factor to an appropriate node in the network, if desired. Alternatively it may be used to set a node's efficiency factor (which governs its contribution to downstream nodes in the network) to a value different from the efficiency factor that has been set for its corresponding group with keyword [GEFAC](#). See "[Well and group efficiency factors](#)" in the *ECLIPSE Technical Description* for further discussion on the handling of efficiency factors.

---

**CAUTION:** Care should be taken if you are also using the [GEFAC](#) keyword with item 3 set to [YES](#), if the node name and the group name are the same. If [GEFAC](#) is entered after [NEFAC](#) then the nodal efficiency factors gets reset by [GEFAC](#). On the other hand, using [NEFAC](#) does **not** change a group's efficiency factor, even if it has the same name as the node. The efficiency values assigned to the groups/nodes can be checked by using the [WELSPEC](#)s mnemonic in the [RPTSCHE](#)D keyword.

---

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Node name
2. Efficiency factor for the node

This is the fractional time for which the node is operational. For example, if the node is 'down' for 10 percent of the time, its efficiency factor will be 0.9.

The efficiency factor must be greater than zero.

DEFAULT: 1.0

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

The efficiency factors for nodes not specified with this keyword are defaulted to 1.0.

### Example

```

NEFAC
  NODE4  0.9 /
/
    
```

## NEI

## Specify composition for non-equilibrium initialization

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword may be used to generate non-equilibrium initialization composition tables internally. It is followed by a sample hydrocarbon composition for each equilibration region number. This is used to generate consistent oil and gas compositions for each cell, by flashing to the cell pressure - effectively a constant composition expansion.

For the [THERMAL](#) option, the simulator tries to match the oil, water and gas saturations in each equilibration region. If the specified compositions cannot match the phase saturations, then the components that have the highest gas phase mole fraction have their compositions adjusted. See "[Initialization with NEI](#)" in the *ECLIPSE Technical Description*.

ECLIPSE Thermal. For the Mixed Hydrostatic Equilibration option, initial saturations should be specified together with items 1 and 2 of the [EQUIL](#) keyword and the NEI keyword. For more information, refer to "[Initializing the study](#)" in the *ECLIPSE Technical Description*.

### Example

```
NEI
0.0247 0.2516 0.2407 0.0733 0.4097 /
```

## NETBALAN Network balancing calculation instructions

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

In ECLIPSE 100 this keyword forces a network balancing calculation to be performed at the next timestep, and controls the frequency of subsequent balancing calculations in the network option (see "[Network option](#)" in the *ECLIPSE Technical Description*). The keyword can also reset the convergence tolerance and iteration limit for the network balancing calculations, and the calculation of the THP for subsea completion manifold groups under production rate control. In addition, the user may enter instructions to control the end of timestep balancing error by limiting the timestep size.

In ECLIPSE 300 this keyword just controls the convergence tolerance and iteration limit. The network will automatically be rebalanced during the first NUPCOL Newton iterations of each timestep (equivalent to a negative entry in item 1), and there is no facility to control the timestep size according to the end of timestep balancing error.

The keyword should be followed by a line containing the following data items, ending with a slash (/). If the record is terminated early, the remaining items assume their default values. Default values can be specified before the slash by null value indicators (n\* , where n is the number of consecutive items to be defaulted). Defaulted items retain their previous values; initial default values are shown below.

### 1. Network balancing interval (ECLIPSE 100 only)

> 0.0 The network is balanced at the beginning of each timestep that starts after the specified interval has elapsed since the previous balancing calculation. Balancing errors build up if the reservoir conditions change significantly over this balancing interval.

= 0.0 The network is balanced at the beginning (that is the zeroth Newton iteration) of every timestep. Balancing errors are only significant if the reservoir conditions change appreciably over the timestep.

< 0.0 The network will be balanced in each of the first NUPCOL Newton iterations of every timestep. (The value of NUPCOL may be set using keyword [NUPCOL](#) or keyword [GCONTOL](#).) The magnitude of the negative value is not significant. This option may cause the timestep to require more Newton iterations to converge, as the wells' THP limits are changed at each balancing calculation. However, the balancing errors at the end of the timestep will generally be small, and are less than the value set in item 2 if the timestep converges within NUPCOL Newton iterations.

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

DEFAULT: 0.0

### 2. Convergence tolerance for network nodal pressures

In ECLIPSE 300 the convergence tolerance for the network is a factor of 10 smaller than the tolerance set here for the network to reservoir coupling. In ECLIPSE 100 these iterations are performed simultaneously and have the same convergence tolerance.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

ECLIPSE 100 DEFAULT: 0.1 bars (METRIC), 1.45 psi (FIELD), 0.09869 atm (LAB, PVT-M).

ECLIPSE 300 DEFAULT: 1E-5 bars (METRIC), 1.45E-4 psi (FIELD), 9.869 E-6 atm (LAB, PVT-M).

### 3. Maximum number of iterations allowed in the network balancing calculation

In ECLIPSE 300 this item governs both the iterations for the network solution and the iterations for coupling the network to the reservoir.

DEFAULT: 10

4. Convergence tolerance for calculating the THP for subsea completion manifold groups under rate control, and for calculating the pressure drop across automatic chokes controlling a group's production rate (ECLIPSE 100 only).

The quantity required is the **fraction** of each group's rate target that is an acceptable error.

The group's production rate may differ from the target by more than this tolerance if the timestep takes more than NUPCOL Newton iterations to converge - see keyword [NUPCOL](#) or [GCONTROL](#).

If the value entered here is greater than the tolerance fraction entered in item 1 of keyword [GCONTROL](#), the value entered in [GCONTROL](#) is used.

DEFAULT: 0.01 Which converges the iterations when the group's rate target is met within one percent.

5. Maximum number of iterations allowed in the calculation of the THP for manifold groups under rate control (ECLIPSE 100 only).

DEFAULT: 10

---

**Note:** The maximum number of iterations for automatic chokes is governed by item 3, since their pressure drops are calculated during the network balancing iterations.

---

6. Target value for the largest branch balancing error at the end of each timestep (ECLIPSE 100 only).

The balancing error is defined as the difference between the pressure drop along the branch when the network was last balanced, and the pressure drop calculated using the current flow rates at the end of the timestep. The largest error in any branch is printed at the end of each timestep. If a value is entered for the target error, ECLIPSE attempts to adjust the timestep length so as to keep the balancing error at approximately its target value, subject of course to any other constraints on the timestep. timesteps limited by the target balancing error can be identified by the mnemonic [NETW](#) printed in the timestep information line.

The target error should be large enough to allow for the convergence tolerances in items 2 and 4.

UNITS: bars ([METRIC](#)), psi ([FIELD](#)), atm ([LAB](#)), atm ([PVT-M](#))

DEFAULT: Infinity (1.0E20) which leaves the timestep sizes unaffected.

7. Maximum permitted value for the largest branch balancing error at the end of the timestep (ECLIPSE 100 only).

If the maximum permitted balancing error is exceeded, ECLIPSE chops the timestep and rebalance the network. Since timestep chops can severely increase the running time of a simulation, a maximum permitted balancing error should only be used with caution, and its value should be several times larger than the target error in item 6.

UNITS: bars ([METRIC](#)), psi ([FIELD](#)), atm ([LAB](#)), atm ([PVT-M](#))

DEFAULT: Infinity (1.0E20)

8. Minimum size for timesteps limited by network balancing error (ECLIPSE 100 only)

A large balancing error is sometimes unavoidable during the timestep in which a well dies. If a target or maximum balancing error has been set in items 6 and 7, it is advisable to set a suitable minimum timestep size to prevent a large reduction in step size when wells die. (The minimum step size does not affect timesteps limited by other reasons, for example time truncation error or convergence difficulty.)

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

DEFAULT: TSMINZ in keyword [TUNING](#).

If the keyword is omitted, all items take their default values.

The keyword may be used any number of times in the SCHEDULE section. Defaulted items retain their previous values.

## Examples - ECLIPSE 100

### Example 1

Sets the target and maximum balancing error, with a minimum step size override of 10 days. The network is balanced at the beginning of every timestep, by default.

```
NETBALAN  
5* 10.0 50.0 10.0 /
```

### Example 2

Cause the network to be balanced in each of the first NUPCOL Newton iterations of every timestep:

```
NETBALAN  
-1.0 /
```

	SUMMARY
x	SCHEDULE

The keyword defines automatic compressors or pumps in the production network when the extended network model is employed (keyword [NETWORK](#) entered in the `RUNSPEC` section). Each compressor/pump occupies a branch of the network, and its operation is modeled by changing the VFP table number or ALQ value of the branch.

See "[Automatic compressors](#)" in the *ECLIPSE Technical Description* for further details.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Inlet node name of the branch where the compressor is located.
2. Outlet node name of the branch where the compressor is located.
3. Name of group whose production rate this compressor will respond to.

The compressor will be activated whenever this group fails to meet its target production rate set for the phase in item 4. If the group does not have a target set, but has a guide rate defined in [GCONPROD](#) and is under `FLD` control from a higher level group, then the compressor is activated when the group cannot make its share of the higher level group's production target.

If other actions to increase the group's production rate may also be performed (for example opening a new well from the drilling queue), the order in which the possible actions are performed can be defined with the [PRORDER](#) keyword.

DEFAULT: ' ' implies the compressor is permanently off

4. Phase whose production rate this compressor responds to.

OIL or GAS

DEFAULT: GAS

5. VFP table number for the branch when the compressor is on.

When the compressor is switched on this replaces the table number previously specified in keyword [BRANPROP](#), which is applied whenever the compressor is off.

Zero will leave the original VFP table number unchanged.

DEFAULT: 0

6. Artificial Lift Quantity to be applied when the compressor is fully on.

When the compressor is fully on this replaces the ALQ value previously specified in keyword [BRANPROP](#), which is applied whenever the compressor is off. Multilevel compressors operating at an intermediate level has an intermediate value of the ALQ (see items 9, 10 and 11).

The artificial lift quantity may be regarded as the compressor or pump power, according to the definition used when the table was calculated (for example with VFP *i*).

UNITS: These depend on what the ALQ was meant to represent when the table was created. Refer to section "[Record 6:ALQ values](#)" in the description of keyword `VFP`PROD.

DEFAULT: 0.0

7. Rate of gas consumption by the compressor when fully on.

When the compressor is fully on this is extracted from the inlet node (item 1) to account for the gas required to power the compressor. Multilevel compressors operating at an intermediate level have an intermediate value of gas consumption (see items 9, 10 and 11). The consumption rate is applied in addition to any consumption specified for the node with keyword `NCONSUMP` or `GCONSUMP`.

UNITS: sm<sup>3</sup>/day (METRIC), Mscf/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: 0.0

---

**Note:** If you wish the consumed gas to be removed from the outlet node of the branch, reverse the order of the inlet and outlet nodes in items 1 and 2.

---

8. Name of the group from which the compressor's gas consumption (item 7) should also be extracted.

Gas consumption from the group hierarchy is taken into account for group reinjection control and sales gas control, and also by the Gas Field Operations Model. (See keyword `GCONSUMP`.)

DEFAULT: ' ' the gas is only extracted from the network, and not the group hierarchy

---

**Note:** The group defined here replaces any group previously defined for the same purpose using this keyword or item 3 of keyword `NCONSUMP`.

---

9. Compressor type.

PERM Will remain on permanently after being turned on.

Keyword `COMPOFF` has no effect.

TEMP Can be turned off manually at any time with the `COMPOFF` keyword (for example whenever the target production rate is reduced). It is turned on automatically again as soon as it is needed.

If the gas field operations model is in use, the compressor is turned off automatically whenever the contract group's target rate decreases. It is turned on automatically again as soon as it is needed.

MULT As TEMP, but with multiple compression levels.

Compression is increased one level at a time until the group's target rate is met.

10. The number of compression levels in a multilevel compressor

(an integer > 0)

This item must be set only if item 9 is set to MULT. Otherwise it must be defaulted.

Any number of levels may be requested, but having a large number of levels slows the run down as each level must be tried in turn.

If there are  $N$  levels, the ALQ and consumption rate at level  $i$  are:

$$ALQ_i = ALQ_1 + (ALQ_N - ALQ_1) \left( \frac{i-1}{N-1} \right) \quad \text{Eq. 3.122}$$

$$CONS_i = CONS_N \cdot \frac{i}{N} \quad \text{Eq. 3.123}$$

where  $ALQ_N$  is defined in item 6,  $CONS_N$  is defined in item 7 and  $ALQ_1$  is defined in item 11.

The VFP table number will be the value set in item 5 when the compressor is operating at its first level and above.

11. Artificial lift quantity at level 1 of multi-level compressor,  $ALQ_1$ .

This item must be set only if item 9 is set to 'MULT'. Otherwise it must be defaulted.

UNITS: These depend on what the ALQ was meant to represent when the table was created. Refer to section "[Record 6:ALQ values](#)" in the description of keyword `VFP`PROD.

12. Compressor switching sequence number.

This prescribes the order in which compressors are turned on if there are two or more compressors responding to the same group (item 3). When a group fails to meet its rate target, the compressor with the lowest sequence number that responds to the group is activated. If the group still cannot meet its target when this is fully on, but has other compressors that respond to it, these other compressors are turned on in increasing order of their sequence number.

If two compressors anywhere in the network share the same sequence number, they are both turned on at the same time, even if they respond to different groups. In this way it is possible to turn on all compressors simultaneously whenever compression is needed anywhere in the field. All multi-level compressors with the same sequence number have their levels incremented simultaneously.

DEFAULT: a value 1 larger than the previous maximum sequence number.

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

See also keywords [PRORDER](#) and [COMPOFF](#).

---

**Note:** An automatic compressor cannot be present if the branch's ALQ is made equivalent to the oil or gas surface density in item 5 of keyword [BRANPROP](#).

---

## Example

The following example defines two compressors responding to the gas production rate of groups 'PL-A' and 'PL-B' respectively. The second one has three compression levels, and consumes gas from the network and from group 'G-B3' in the [GRUPTREE](#) hierarchy.

```

NETCOMPA
-- Inlet  Outlet  Target  Phase  VFP  ALQ  Cons  Cons  Type  Num  ALQ  Seq
-- node   node   group   tab    rate  rate  group  lev  lev 1  num
   N4     N3     PL-A    GAS    1*   50.0  1*   1*   TEMP  1    40.0  /
   N6     N5     PL-B    GAS    1*  100.0 1000  G-B3  MULT  3    40.0  /
/
    
```

This keyword is required if the extended network model is used (keywords [NODEPROP](#) and [BRANPROP](#); see "[The extended network model](#)" in the *ECLIPSE Technical Description*). It turns on the extended network model facilities and reserves storage space for the network description.

The data must be terminated by a slash (/).

1. **NODMAX** The maximum number of nodes in the network model.
2. **NBRMAX** The maximum number of branches in the network model.
3. **NBCMAX** (ECLIPSE 300 only) The maximum number of branches connected to any one node in the network model.

DEFAULT: 20

In ECLIPSE 100, the **NETWORK** keyword should **not** be entered if the standard network model is to be used for the production network (keyword [GRUPNET](#)).

In ECLIPSE 300, the **NETWORK** keyword should **not** be entered if the standard network model is to be used (keywords [GRUPNET](#) and [GNETINJE](#)). The standard and extended network models cannot both be used in the same run.

## NEWTRAN Specifies block corner transmissibilities

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The use of NEWTRAN implies that transmissibilities are calculated from cell corner positions. This permits the automatic calculation of fault transmissibilities, but it may not be back-compatible with existing simulators using block-center calculations.

NEWTRAN has no associated data.

This is the default method for grids specified using the corner point method ([COORD](#) and [ZCORN](#) keywords). If the grid is specified using [DX](#) (or [DR](#)), [DY](#) (or [DTHETA](#)) and [DZ](#) then by default the transmissibilities are calculated using the block-center quantities unless NEWTRAN is specified. (See also keywords [OLDTRAN](#) and [OLDTRANR](#).)

See "[Transmissibility calculations](#)" in the *ECLIPSE Technical Description*.

---

**Note:** When NEWTRAN is specified in a block centered grid, the grid is first converted to a 'fake' corner point representation composed of cuboidal cells with the dimensions specified by [DX](#) (or [DR](#)), [DY](#) (or [DTHETA](#)) and [DZ](#) before calculating transmissibilities. For a dipping block-centered grid, this creates unrealistic fault non-neighbor connections that cannot exist in the true block-centered grid. Thus NEWTRAN should not normally be specified in a block-centered grid.

The keyword is used to declare a maximum possible value for the next timestep. This provides a simpler alternative to using the [TUNING](#) keyword to set this value.

The keyword should be followed by the required items of data, terminated by a slash(/):

1. The maximum length of the next timestep.  
UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)
2. Apply this value at every subsequent report step? YES or NO.  
DEFAULT: NO

The keyword does not restrict the length of the subsequent timesteps following the next timestep if this item is set to NO.

Typically, this keyword may be used to force a short timestep immediately following a large well rate change, to reduce the danger of a timestep chop (see also TMAXWC in Record 1 of the [TUNING](#) keyword).

### Example

This example

```
NEXTSTEP

## NGASREM Removes gas from a node in the extended network

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used in the ECLIPSE 300 extended network (constructed with keywords [BRANPROP](#) and [NODEPROP](#), with keyword [NETWORK](#) present in the RUNSPEC section) to remove gas from the network at a specified node. The amount of gas to be removed can be expressed as either a constant rate or a fraction of the rate flowing through that node. The removal of gas affects the pressure loss in the downstream network branches as their VFP tables are looked up with a smaller gas fraction. However, this is the **only** effect that it does have. It does **not** affect the reported group production rates or the operation of any group gas rate targets/limits, reinjection or group economic limits. A possible use for NGASREM is to remove gas from a network node to account for its removal from the production stream by the [GRUPFUEL](#) keyword.

This keyword is not available in ECLIPSE 100, where [GCONSUMP](#) or [NCONSUMP](#) should be used instead.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Node name
2. Maximum rate of gas removal from the node

The specified rate of gas will be removed, subject to a maximum fraction of the node's gas flow entered in item 3.

UNITS: sm<sup>3</sup>/day (METRIC), Mscf/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: Infinity

3. Maximum fraction of the node's gas flow to be removed

The specified fraction of the node's gas flow is removed, subject to a maximum rate entered in item 2.

DEFAULT: 1.0

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

---

**Note:** The defaults in items 2 and 3 only apply to nodes that have been named in item 1 of this keyword. All other nodes retain their initial values of 0.0 for both quantities, so that no gas is removed from them.

---

---

**CAUTION:** Since gas removal **only** affects the pressure losses in the downstream branches, an error is reported if the node in item 1 has no outflow branch.

---

### Examples

#### Example 1

Remove 20000 units/day of gas from the node. Item 3 defaults to 1.0 to ensure that the gas removal rate does not exceed the flow rate of gas through the node.

```
NGASREM
NODE-5    20000  /
/
```

### Example 2

Remove one tenth of the gas that flows through the node. Item 2 defaults to infinity so that there is no other limit on the removal rate.

```
NGASREM
NODE-5    1*    0.1  /
/
```

## NINENUM

## Identifies the extent of the nine-point region

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The NINENUM keyword indicates regions in which to apply the nine-point discretization scheme for the [NINEPOIN](#) option (activated in the GRID section). This keyword is entirely optional when using the nine-point scheme; if it is not specified then the nine-point discretization is applied everywhere.

The NINENUM keyword should be followed by one integer for every grid block in the current input box specifying the discretization flag for each grid block. The flag should be set either to 1 to indicate that the nine-point discretization is to be employed, or to zero in regions where the standard finite-difference discretization is required (five points in 2D, seven points in 3D).

Any grid blocks not explicitly assigned a NINENUM value is defaulted to a value of 1. You must set the NINENUM value explicitly to zero for any regions where the nine-point scheme is not required.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

---

**Note:** This keyword is not compatible with the local grid refinement option.

---

## Example

To apply the nine-point scheme only in a 2\*2\*2 region in a 4\*4\*3 field:

```
NINENUM
1 1 0 0
1 1 0 0
0 0 0 0
0 0 0 0
1 1 0 0
1 1 0 0
0 0 0 0
0 0 0 0
16*0 /
```

## NINEPOIN

## NMATOPTS Options for the discretized matrix (E100) or multi porosity (E300) models

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

For ECLIPSE 100 the keyword is used to control options associated with the discretized matrix dual porosity model. The model must be activated by including the `NMATRIX` keyword in the `RUNSPEC` section.

For ECLIPSE 300 the keyword means that the model (see "Multi porosity" in the *ECLIPSE Technical Description*), activated with `NMATRIX`, is assigned grid data automatically (similar to the discretized matrix Dual Porosity Model of ECLIPSE 100). This means that grid data only needs to be supplied as for a standard dual porosity case.

The `NMATOPTS` keyword is optional and should be followed by some or all of the following data items, terminated by a slash (/).

1. The assumed geometry of the matrix sub-cells.

Either `LINEAR`, `RADIAL` or `SPHERICAL`

In ECLIPSE 300 there is an additional possibility - `UNIFORM`. This produces a uniform grid within the matrix cells.

A further alternative possibility is `VERTICAL`, which is used to model gravity drainage, whereas the previous options model transient effects in the flow from matrix to fracture. `VERTICAL` uses the matrix cells as a vertical discretization of an individual block of matrix and connects them all to the fracture. See "Vertical discrete matrix gravity drainage model" in the *ECLIPSE Technical Description*. If this option is used then the keyword `GRAVDRE` must have been specified in the `RUNSPEC` section.

In ECLIPSE 100, for any discretized matrix option, the minimum number of global cells in the X direction (keyword `DIMENS`) is 2.

In all cases except `VERTICAL`, the matrix sub-cells only communicate with the fracture system through the outer sub-cell. However, the pressure (and saturation) response from the matrix depends on the assumed geometry of the system. In the case of `VERTICAL` geometry, all matrix sub-cells also connect directly with the fracture, and the physical response from the matrix depends on all connections. In this case, the geometry is uniform as described in the Technical Description.

DEFAULT: `LINEAR`

2. The fraction of the fracture pore volume (or matrix block volume with ECLIPSE 300 - see item 3) is to be used for the size of the outermost matrix sub-cell. It is not used if `UNIFORM` or `VERTICAL` is selected. `VERTICAL` assumes uniform distribution of the matrix volume in the same way as `UNIFORM`.

Once the size of the outermost sub-cell and the number of sub-cells in each matrix cell have been defined, ECLIPSE automatically generates a logarithmic grid within the matrix cells. The maximum and minimum growth factors over the entire model are reported as a message.

To model accurately the initial pressure transient response of the matrix cells, the outermost matrix sub-cell needs to be reasonably small compared to the fracture system.

DEFAULT: 0.1

3. Method for controlling the partitioning (ECLIPSE 300 only).

Either `FPORV` or `MBLKV`

FPORV the fractional value in item 2 is used to construct the size of the first partitioned block from the fracture pore volume.

MBLKV the fractional value in item 2 is used to construct the size of the first partitioned block from the matrix block volume.

Using the time-dependent sorption model in ECLIPSE 300 with the [COAL](#) option, the first pore volume of the matrix sub-grid might be different from the given fractional value since only some of the sub-grid cells might have a pore volume. When there is no pore volume in the matrix (only coal volume) the MBLKV method will be used instead.

DEFAULT: FPORV

For further information see "[Discretized matrix model \(ECLIPSE 100\)](#)" in the *ECLIPSE Technical Description*.

## Example

```
NMATOPTS  
RADIAL 0.05 /
```

## NMATRIX

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

## Use the discretized matrix or multi-porosity model

Defines the number of matrix pore systems.

In ECLIPSE 100 this keyword activates the discretized matrix dual porosity model, in which the matrix is subdivided into smaller cells to allow the modeling of transient effects within the matrix cells (without NMATOPTS, or with the first 3 (ECLIPSE 100) or 4 (ECLIPSE 300) NMATOPTS options), or to create a more detailed representation of gravity drainage (NMATOPTS keyword, VERTICAL option). See the [NMATOPTS](#) keyword in the [GRID](#) section and "Dual porosity" in the *ECLIPSE Technical Description* for more details.

In ECLIPSE 300 this keyword activates the multi-porosity option. See "Multi porosity" in the *ECLIPSE Technical Description*.

---

**Note:** In ECLIPSE 100, explicit initialization of the internal sub-matrix cells is not possible, and the [EQUIL](#) keyword must be used with NMATRIX so that the sub-matrix cells are properly initialized.

---

With this keyword in ECLIPSE 100, the minimum number of global cells in the X direction (keyword [DIMENS](#)) is 2.

With this keyword in ECLIPSE 100, the additional Z-planes for the matrix sub-cells are stored internally and are not part of the deck as described in the [DIMENS](#) or [CARFIN](#) keywords. For this simulator, these keywords should only describe the dual porosity model size.

By contrast, with this keyword in ECLIPSE 300, the additional Z-planes for the matrix sub-cells are explicitly represented in the [DIMENS](#) or [CARFIN](#) keywords. For this simulator, the NZ values in these keywords should be multiples of the number of porosities, that is (NMATRIX+1).

This model is not compatible with the use of block to block connections ([BTOBALFA](#) or [BTOBALFV](#)) or with the use of [DPNUM](#) to create a single porosity region in a dual porosity run.

This keyword should not be used for triple-porosity modeling. The [TRPLPORO](#) keyword should be used instead.

The keyword should be followed by one data item, defining the number of sub-cells required within each original matrix cell. The data item should be followed by a slash (/).

### Example

```
NMATRIX
6 /
```

## NNC

## Set non-neighbor connection values explicitly

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

Non-neighbor connections are usually generated from within the program by faults when corner point geometry is used; from the dual porosity or dual permeability options; or from numerical aquifer options.

This keyword enables a specified transmissibility to be set up between any two cells in the grid.

The keyword consists of a line of data for each required non-neighbor connection, specifying the cells to be linked and the required transmissibility value. The cell coordinates are specified in natural order.

Each line of data must be terminated by a slash (/). After the last non-neighbor connection is defined, an additional slash on a new line terminates the list. It is possible to specify this keyword more than once in the grid data.

The values in each data record are:

1. I-index of first cell joined to the non-neighbor connection (IX)
2. J-index of first cell joined to the non-neighbor connection (IY)
3. K-index of first cell joined to the non-neighbor connection (IZ)
4. I-index of second cell joined to the non-neighbor connection (JX)
5. J-index of second cell joined to the non-neighbor connection (JY)
6. K-index of second cell joined to the non-neighbor connection (JZ)
7. Transmissibility value of the non-neighbor connection (TRAN)

UNITS: cP.rm<sup>3</sup>/day/bars (METRIC), cP.rb/day/psi (FIELD), cP.rcc/hr/atm (LAB), cP.rm<sup>3</sup>/day/atm (PVT-M)

DEFAULT: 0.0

8. This item depends on which simulator is being used:

*ECLIPSE 100* Saturation table number to be associated with flow from the first to the second cell (IST1)

*ECLIPSE 300* Diffusivity value of the non-neighbor connection

DEFAULT: 0.0

9. This item depends on which simulator is being used:

*ECLIPSE 100* Saturation table number to be associated with flow from the second to the first cell (IST2)

*ECLIPSE 300* Usage deprecated. Enter thermal conduction transmissibility value using item 15 of this keyword.

*ECLIPSE 100 only* 10. Pressure table number to be associated with flow from the first to the second cell (IPT1)

*ECLIPSE 100 only* 11. Pressure table number to be associated with flow from the second to the first cell (IPT2)

*ECLIPSE 100 only* 12. The face associated with flow from the first to the second cell (ZF1)

Choose one of: X+, X-, Y+, Y-, Z+, Z-

This information is used only by the VE option (keyword [VE](#) in the RUNSPEC section).

*ECLIPSE 100 only*

13. The face associated with flow from the second to the first cell (ZF2)

Choose one of: X+, X-, Y+, Y-, Z+, Z-

This information is used only by the VE option (keyword [VE](#) in the RUNSPEC section).

14. Diffusivity value of the non-neighbor connection (DIFF)

This information is used by the molecular diffusion option (keyword [DIFFUSE](#) in the RUNSPEC section) and the tracer diffusion option (keyword [TRDIF](#) in the PROPS section).

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: 0.0

If a non-default value is input for the diffusivity in ECLIPSE 300 then this value will overwrite any value input in data item 8.

15. This item depends on which simulator is being used:

*ECLIPSE 300 only* Thermal conduction transmissibility value of the non-neighbor connection

Used by the [THERMAL](#) option.

UNITS: kJ/day/K (METRIC), Btu/day/°R (FIELD), J/hr/K (LAB), kJ/day/K (PVT-M)

DEFAULT: 0.0

*ECLIPSE 100 only* 1/(area\*porosity) (Only used in calculations involving the velocity, see [DISPERSE](#) for example).

UNITS: m<sup>-2</sup> (METRIC), ft<sup>-2</sup> (FIELD), cm<sup>-2</sup> (LAB), m<sup>-2</sup> (PVT-M)

DEFAULT: 0.0

16. The area associated with the NNC

Used by the non-Darcy flow option (keyword [VDFLOW](#) in the PROPS section).

UNITS: m<sup>2</sup> (METRIC), ft<sup>2</sup> (FIELD), cm<sup>2</sup> (LAB), m<sup>2</sup> (PVT-M)

DEFAULT: No non-Darcy effect.

17. The linking permeability associated with the NNC.

Used by the non-Darcy flow option (keyword [VDFLOW](#) in the PROPS section).

UNITS: mD (METRIC), mD (FIELD), mD (LAB), mD (PVT-M)

## Notes

*ECLIPSE 100*

The flow between two cells is solved using Newtonian iteration based on the permeability and geometry of the cells. For user input NNCs, we estimate the geometry, that is DX<sub>i</sub> and DX<sub>j</sub> using item 7, 16 and 17 as follows:

$$DX_j = DX_i$$

$$DX_i = \frac{C_{Darcy} AK_{link}}{2T}$$

where

$C_{Darcy}$  is a unit conversion factor

$A$  is the surface area given in item 16

$K_{link}$  is the linking permeability given in item 17

$T$  is the transmissibility given in item 7.

ECLIPSE 100

The last seven items are optional only when `VDFLOW` is not active. Therefore, if the slash is placed after item 7, the table numbers are defaulted to those for the cells joined. If directional relative permeabilities are employed, the positive X-direction table number is used.

ECLIPSE 300

Data items 8 and 9 can still be used to maintain back compatibility; it is, however, recommended to use the equivalent data items 14 and 15.

ECLIPSE 100

A non-neighbor connection between two cells which are actually neighbors (or between which ECLIPSE 100 would form a non-neighbor connection in the absence of the NNC keyword) is allowed: this simply adds to the existing transmissibility. In addition, any NNC input with transmissibility less than 0.000001 is ignored. Furthermore, if a transmissibility value of 1.0D-20 or less is entered, then a warning message is issued, and the NNC is ignored. Connections to inactive cells result in a warning, and are ignored.

## Examples

### Example 1

Two non-neighbor connections are defined, one between cells (1, 1, 1) and (3, 1, 1), and one between cells (1, 2, 1) and (4, 2, 1), each of transmissibility 0.1972.

```

NNC
1 1 1 3 1 1 0.1972 /
1 2 1 4 2 1 0.1972 /
/

```

### Example 2

General format for ECLIPSE 100

```

```

## NNCGEN

## Set non-neighbor connection values between cells in any two grids explicitly

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

Non-neighbor connections are usually generated from within the program by faults when corner point geometry is used; from the dual porosity or dual permeability options; or from numerical aquifer options.

This keyword enables a specified transmissibility to be set up between any two cells in any two grids.

The keyword consists of a line of data for each required non-neighbor connection, specifying the cells to be linked and the required transmissibility value. The cell coordinates are specified in natural order.

The values in each data record are:

- Grid of first cell  
DEFAULT: GLOBAL
- I-index of first cell joined to the non-neighbor connection (IX)
- J-index of first cell joined to the non-neighbor connection (IY)
- K-index of first cell joined to the non-neighbor connection (IZ)
- Grid of second cell  
DEFAULT: GLOBAL
- I-index of second cell joined to the non-neighbor connection (JX)
- J-index of second cell joined to the non-neighbor connection (JY)
- K-index of second cell joined to the non-neighbor connection (JZ)
- Transmissibility value of the non-neighbor connection (TRAN)

UNITS: cP.rm<sup>3</sup>/day/bars (METRIC), cP.rb/day/psi (FIELD), cP.rcc/hr/atm (LAB), cP.rm<sup>3</sup>/day/atm (PVT-M)

DEFAULT: 0.0

- Diffusivity value of the non-neighbor connection  
UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: 0.0

- Thermal conduction transmissibility value of the non-neighbor connection, used by the Thermal option (keyword [THERMAL](#) in the RUNSPEC section)

UNITS: kJ/day/K (METRIC), Btu/day/°R (FIELD), J/hr/K (LAB), kJ/day/K (PVT-M)

DEFAULT: 0.0

Each line of data must be terminated by a slash (/). After the last non-neighbor connection is defined, an additional slash on a new line terminates the list.

It is possible to specify this keyword more than once in the GRID section.

## Example

Two non-neighbor connections are defined, one between cells (1, 1, 1) in the global grid and (3, 1, 1) in an LGR called LGR1, and one between cells (1, 2, 1) in LGR1 and (4, 2, 1) in an LGR called LGR2. Each has transmissibility 0.1972.

```
NNCGEN  
'GLOBAL' 1 1 1 'LGR1' 3 1 1 0.1972 /  
'LGR1' 1 2 1 'LGR2' 4 2 1 0.1972 /  
/
```

## Activate the non-Newtonian fluid option

This keyword is used to activate the non-Newtonian fluid option when the polymer option is activated (see [POLYMER](#) keyword). It is followed by two integers, specifying the number of tables (NTHRBL), and the maximum number of rows in a table (NLNHBL). The integers are used in setting the [FHERCHBL](#) keyword. It must be terminated with a slash (/).

For more details please refer to the "[Non-Newtonian fluid flows](#)" option in the *ECLIPSE Technical Description*.

items:

1. NTHRBL: number of tables  
 DEFAULT: NTPVT (number of PVT tables - see item 2 of keyword [TABDIMS](#))
2. NLNHBL: maximum number of rows in a table  
 DEFAULT: 2

### Example

For NTHRBL=2 tables of NLNHBL=4 rows:

```
NNEWTF
2 4 /
```

## NOAIMLGR **Suppress making all refinement cells implicit in AIM runs**

## NOCIRCLE Turn off completion of circle option for local radial refinements

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

By default, radial refinements have the circle completed automatically in their set of grid blocks. Therefore, this keyword should only be used if you do **not** wish the circle to be completed for a particular radial refinement in the theta- or Y-direction.

This keyword only has an effect if placed within a specific radial refinement. If the circle completion option is required to be turned off within a particular radial LGR, the NOCIRCLE keyword should be placed within the LGR's `RADFIN` / `ENDFIN` bracket. Any other radial LGRs present will still have their circles completed.

The NOCIRCLE keyword is followed by one data record containing a single character string, ending with a slash (/).

The character string should be one of the following:

YES Turn off the circle completion within this radial refinement

NO Keep the circle completed within this radial refinement

DEFAULT: YES

---

**Note:** This keyword should not be confused with the GRID section keyword `CIRCLE`. The `CIRCLE` keyword is used to request completion of circle in a radial geometry (global) grid, not within radial refinements

---

Local grid refinement is described in "[Local grid refinement and coarsening](#)" in the *ECLIPSE Technical Description*.

### Example

```

RADFIN
LGR1 1 1 2 3 6 1 4 1* 0.2 /
NOCIRCLE
  YES /
ENDFIN

```

## NODEPROP Defines the extended network node properties

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword must be used to define the properties of the network nodes when the extended network model is employed (keyword [NETWORK](#) in the [RUNSPEC](#) section). Keyword [BRANPROP](#) must have previously been entered. The top node of each network gathering tree (the terminal node) must be a fixed pressure node. Only the fixed pressure node, and other nodes with non-default properties need to be specified here. Nodes with default properties may be omitted from the [NODEPROP](#) keyword data.

The [NODEPROP](#) keyword is followed by any number of records, each containing the following items of data and terminated with a slash (/). The set of records must end with a blank record, containing only a slash.

1. In [ECLIPSE 300](#), the node name

Node names should be unique both within a network and across multiple production and injection networks.

2. Fixed pressure for the terminal node

Default this item, or set it negative, if the node is not a terminal node in the network.

UNITS: barsa ([METRIC](#)), psia ([FIELD](#)), atma ([LAB](#)), atma ([PVT-M](#))

3. Flag indicating whether the uptree branch from this node should act as an automatic choke to impose a flow rate limit.

(The uptree branch is the one towards the terminal node; the outlet branch for a production network or the inlet branch for an injection network.)

An automatic choke acts to control the flow of a target group nominated in item 5 by adjusting the pressure drop across the choke (see "[Automatic chokes](#)" in the *ECLIPSE Technical Description*). The branch must be given a VFP table number of 9999 in keyword [BRANPROP](#) so that its only pressure drop is that of the choke. Note that a terminal node cannot be selected for this purpose, as it has no uptree branch and its pressure is fixed.

### ECLIPSE 100

If the node in item 1 corresponds to a **well group**, this flag indicates whether the corresponding group is a sub-sea completion manifold, so that a group production target will be met by adjusting its wells' THP limits instead of by the standard method of flowing the wells in proportion to their guide rates (see "[Group production control in the network option](#)" in the *ECLIPSE Technical Description*). The uptree branch **can** be given a VFP table number other than 9999 in this case, in [ECLIPSE 100](#) only. Effectively, the choke's pressure drop is added to the pressure drop along the branch.

**YES** The node's uptree branch acts as an automatic choke. A production rate target applied to the group named in item 5 will be met by adjusting the pressure loss across the choke.

**NO** A production target applied to the corresponding group is met by the standard methods of group control.

Manifold groups, and target groups for automatic chokes (item 5), may either have their rate targets set directly with [GCONPROD](#) or indirectly as a share of a higher level group's rate target. In the latter case, that is, if they are subordinate to a higher level group having a production rate target (or a limit that becomes a rate target if violated), they should be given guide rates in keyword [GCONPROD](#). Groups subordinate to an automatic choke's target group should **not** have guide rates. Production wells subordinate to an automatic choke's target group are not subject to guide rate group control.

The convergence tolerance and iteration limit for the calculation of the manifold group's THP, or the choke's pressure loss, are set in keyword **NETBALAN**. It may be necessary to increase the network balancing iteration limit (item 3) substantially if there are any automatic chokes.

ECLIPSE 100

The THP value input in item 10 of keyword **WCONPROD** for the first well in the group will be used as the initial guess for a manifold group's THP in the first timestep. A suitable value entered for this quantity speeds the convergence of the first calculation.

DEFAULT: NO

4. Flag indicating whether gas-lift gas from the corresponding group's subordinate wells should be added to the produced gas entering the network at this source node.

NO Do not include any lift gas flow; only produced gas enters the network at this node.

YES Add the lift gas flows of the subordinate producers to the gas flow entering the network at this node. The lift gas flow is assumed to be equal to the sum of the ALQ values of the subordinate producers, multiplied by their efficiency factors unless instructed otherwise in **WEFAC** item 3. The ALQ variable for the wells must therefore be defined as the rate of lift gas injection. This definition must be selected in the VFP *i* program if it is used to construct the VFP tables.

This item is only relevant to source nodes in a production network, which pass fluid into the network (well groups, satellite groups or Reservoir Coupling master groups). In ECLIPSE 100 they must have the same name as their corresponding groups; in ECLIPSE 300 the correspondence is defined in item 6.

Default this item if the node is not a source node in a production network.

DEFAULT: NO

5. Name of the group whose rate target the automatic choke attempts to match by adjusting the pressure drop across it.

For a production network node, the choke attempts to match this group's production rate target (**GCONPROD** 1). For a water/gas injection network node in ECLIPSE 300, the choke will attempt to match the group's water/gas injection target (**GCONINJE**).

This item is relevant only if item 3 is set to YES.

ECLIPSE 100

If the node in item 1 corresponds to a **well group**, default this item in ECLIPSE 100 since manifold groups must always respond to their **own** rate targets.

DEFAULT: The group of the same name as item 1, if one exists.

ECLIPSE 300 only

6. For a source/sink node, the name of the corresponding group.

This item is relevant only to source nodes in a production network (where fluid produced from the formation enters the network) and sink nodes in an injection network (where fluid leaves the network to be injected into the formation). The node should correspond to a well group or a satellite group. The item names the group that corresponds to the node named in item 1. The source/sink node's inflow/outflow will be equated with the production/injection of the nominated group. (The setting of item 3 of keyword **WEFAC** dictates whether or not the well flows are multiplied by their efficiency factors for this purpose.)

This item is ignored if the node is not a source/sink node. It is also ignored in ECLIPSE 100 because here the source/sink nodes must have the same names as their corresponding groups.

DEFAULT: The group of the same name as item 1, if one exists.

*ECLIPSE 300 only* 7. The type of network to which the node belongs

PROD Production network

WINJ Water injection network

GINJ Gas injection network

All the nodes within a given network (subordinate to the same terminal node) must have the network same type.

This item is ignored in ECLIPSE 100 because the extended network structure supports only production networks.

DEFAULT: PROD

End the data record with a slash (/).

End the set of records with a blank record containing just a slash.

See also keyword [WNETDP](#).

## Example

```

NODEPROP
-- Node      Fixed      Automatic choke      Add      Choke control
-- name      pressure  un uptree branch  lift gas?      group

	SCHEDULE

In a dual porosity (rather than dual permeability) run, it is possible to eliminate the matrix cells prior to entering the linear solver. This yields a significant gain in solver speed, but there are some restrictions: for example, wells may not be completed in the matrix cells.

NODPCO suppresses this elimination, and may be used to avoid these restrictions.

This keyword has no associated data.

This keyword is ignored in ECLIPSE 100.

## NODPPM

# No dual porosity permeability multiplier

## Switch off calculation of derivatives

The keyword switches off calculation of the derivatives for the gradient option. Once a model has been set up and history matched, this allows a prediction run to be advanced without the extra cost of calculating the derivatives.

Once switched off, the calculation may not be switched on again because information from previous times is required to compute the derivatives.

The keyword should be followed by a list of names of gradient parameters to be switched off. These may be either:

- Region keywords [HMxxxxxx](#)
- [HMFAULTS](#)
- [HMMULRGT](#)
- [HMAQUCT](#) and [HMAQUFET](#)
- [HMROCK](#) and [HMROCKT](#)

If the list is defaulted, then calculation of all the derivatives is switched off.

In ECLIPSE 300 it is not possible to selectively switch off derivative calculations. If the NOHMD keyword is found all derivative calculations will be switched off.

The keyword should be followed by a slash (/).

### Example

Switch off parameter HMPORVM and all derivatives for Carter-Tracy aquifers

```
NOHMD
'HMPORVM' 'HMAQUCT' /
```

## Disallow non-neighbor connections

This indicates that non-neighbor connections are **not** allowed. The default is to allow non-neighbor connections. When ECLIPSE can be run without non-neighbor connections, performance may be improved. However, many ECLIPSE features require non-neighbor connections, so this keyword should only be used when it is known that a performance improvement may be made with it.

Non-neighbor connections can be generated by several facilities. These include:

- numerical aquifers,
- faulted corner point geometry,
- dual porosity,
- the NNC-based nine-point scheme, and
- completing the circle in radial studies.
- the WARP solver, in most cases, including parallel runs (ECLIPSE 300 only).
- connections added explicitly by the user, using the [NNC](#) keyword in the GRID section.

When any of these features are present, this keyword must not be used; an error or warning will result if it is included.

The keyword has no associated data.

## NORSSPEC Disables the restart index file output

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL

The keyword requests that a restart index file should **not** be written at the end of the run. By default, the restart index file will always be written. The file contains a list of the arrays written to the Restart file(s) at each restart time.

See "[File handling in ECLIPSE](#)" in the *ECLIPSE Technical Description* for further information.

The keyword has no associated data.

## NOSIM

## Turn off simulation

This keyword turns off timestep simulation in the SCHEDULE section, but the simulator will continue reading and checking the data. This is intended primarily to verify the validity of the keyword syntax prior to submitting a large simulation run.

The keyword has no associated data.

This keyword need only be used if ECLIPSE has given an error message requesting it.

The keyword should be followed by one item, terminated by a slash (/).

1. The maximum number of quantities that can be output at a restart file at each report step.

DEFAULT: 3600

---

**Note:** The above number will not be the same as the number of quantities asked for in the [RPTRST](#) keyword, for example. ECLIPSE adds headers and some other data for its own use that increases the size of the restart file above the number of user-defined quantities.

---

The data should be terminated by a slash (/).

### Example

```
NRSOUT
5000/
```

## NSTACK

## Linear solver stack size

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The data represents the size of the stack of previous search directions held by the linear solver (see "Solution of the linear equations" in the *ECLIPSE Technical Description*). This may be increased if the linear solver shows convergence problems. A good value for many ECLIPSE 100 problems is 10, while many compositional ECLIPSE 300 problems often require 40. Difficult problems may require a larger value. ECLIPSE prints a message advising increased NSTACK if this will increase computing efficiency. Increasing the value of NSTACK increases the memory required for a run.

The keyword should be followed by these data items, terminated by a slash (/).

1. The stack size for the ORTHOMIN or CPR linear solver.

DEFAULT:

10 ECLIPSE 100

40 ECLIPSE 300

20 ECLIPSE 300 using the [JALS](#) solver or [CPR](#) solver

2. Not used at present.

The data should be terminated by a slash (/).

### Examples

*ECLIPSE 100 only*

There is no point in setting NSTACK larger than the maximum number of linear iterations (see LITMAX in keyword [TUNING](#)). The maximum possible NSTACK is printed by ECLIPSE as soon as it has computed the amount of memory required for the run.

*ECLIPSE 100 only*

NSTACK can only be specified in the RUNSPEC section.

#### Example in ECLIPSE 100 only

```
NSTACK
25 /
```

*ECLIPSE 300 only*

The maximum number of linear iterations, specified using the [CVCRIT](#) keyword, should usually be at least the size of the stack.

*ECLIPSE 300 only*

NSTACK can be specified in either the RUNSPEC or the SCHEDULE section.

#### Example in ECLIPSE 300 only

```
NSTACK
50 /
```

## Net to gross thickness ratios

The keyword should be followed by one non-negative real number for every grid block in the current input box. The values specified are used to convert from gross to net thicknesses, and act as multipliers of grid block pore volumes and transmissibilities in the X and Y (or R and Theta) directions, and also on DZ for the calculation of well connection transmissibility factors. The data must be terminated by a slash (/).

Any NTG values which are not specified when the end of the GRID section is reached default to 1.0.

---

**Note:** The use of both NTG and DZNET keywords in the same run is not allowed.

---

Grid blocks whose pore volume is zero are treated by ECLIPSE as inactive. Since the computing time and storage space requirements of a run depend primarily on the number of active grid blocks, it is important that inactive blocks should be unambiguously identified. This is best done by setting either PORO or NTG to zero in inactive blocks. It is also possible to set pore volumes directly (array PORV in the EDIT section), or to use the ACTNUM keyword.

---

**Note:** NTG values only apply to the pore volumes by default. Pre-2007.1 releases of ECLIPSE also scaled the rock volumes by the NTG values. Using [item 117](#) in keyword OPTIONS3 set to a nonzero value will enable the old behavior. For thermal runs both the rock volume and the pore volume should be zero for a cell to become inactive.

---

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0). Note that spaces must not be inserted on either side of the asterisk.

### Example

```

----- IX1-IX2 JY1-JY2 KZ1-KZ2
BOX
      6  11   4   9   2   3   /
NTG
6*0.4 6*0.4 6*0.48 6*0.51 6*0.7 6*0.72
6*0.4 6*0.4 6*0.48 6*0.51 6*0.7 6*0.72
/

## NUPCOL

## Number of iterations to update well targets

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword sets the number of non-linear iterations for which a full hierarchical production/injection system solution is carried out. During any subsequent non-linear iterations of the timestep, the well rate targets will remain unchanged to allow convergence.

When any form of group control option is being used (for example, keyword [GCONPROD](#)), the flow targets of certain wells are directly influenced by the behavior of other wells in the field. For example, the target rates of producers under group control must allow for the production from wells that are under other modes of control within the group. Also injection wells performing reinjection or voidage replacement have flow targets that depend on the behavior of the production wells.

For the group targets to be met exactly, the flow targets of the wells under group control must be recalculated at every Newton iteration. But when the well flow targets change at each iteration, the convergence rate of the iterations is reduced. This is because the Jacobian matrix calculation does not include the terms representing the mutual dependency of the well rates.

As a compromise, the well flow targets are updated in the first NUPCOL Newton iterations of each timestep, and are kept constant for any subsequent iterations. Thus the group/field flow targets are met exactly if the timestep converges within NUPCOL iterations. Any changes in the solution after the first NUPCOL iterations may cause the group/field flow rates to drift slightly away from their targets. In general, larger values of NUPCOL result in the group/field flow targets being met more accurately, but perhaps at the expense of requiring more Newton iterations to achieve convergence.

The value of NUPCOL is initialized to 3 in ECLIPSE 100 and 2 in ECLIPSE 300. This keyword may be used to change the value of this quantity at any time in the simulation.

The keyword should be followed by an integer denoting the last non-linear iteration for which well rate targets are recalculated. The integer should be followed by a slash.

See also keyword [GCONTOL](#).

## Notes

- If the NUPCOL keyword is used in a restart run it must be specified after the restart time, or it will be ignored and the value from the base run will be used instead.
- NUPCOL is also used in other situations where the control mode, or some other quantity, in the well needs to be 'frozen' during the Newton iterations. Some examples are [WELDRAW](#), during gas lift optimization ([LIFTOPT](#)), solving networks ([NETBALAN](#)) and during prioritization (see keywords [PRIORITY](#) and [PRORDER](#) for example).

## Example

```
NUPCOL
4 /
```

## NWATREM

# Removes water from a node in the extended network

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used in the extended network (constructed with keywords [BRANPROP](#) and [NODEPROP](#), with keyword [NETWORK](#) present in the RUNSPEC section) to remove water from the network at a specified node. The amount of water to be removed can be expressed as either a constant rate or a fraction of the rate flowing through that node. The removal of water affects the pressure loss in the downstream network branches as their VFP tables are looked up with a smaller water fraction. However, this is the **only** effect that it has. It does **not** affect the reported group production rates or the operation of any group water rate targets/limits, reinjection or group economic limits; the **group** water rate still represents the rate of water produced from the formation.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Node name
2. Maximum rate of water removal from the node

The specified rate of water is removed, subject to a maximum fraction of the node's water flow entered in item 3.

UNITS: sm<sup>3</sup>/day (METRIC), stb/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: Infinity

3. Maximum fraction of the node's water flow to be removed

The specified fraction of the node's water flow is removed, subject to a maximum rate entered in item 2.

DEFAULT: 1.0

---

**Note:** The defaults in items 2 and 3 only apply to nodes that have been named in item 1 of this keyword. All other nodes retain their initial values of 0.0 for both quantities, so that no water is removed from them.

---

**CAUTION:** Since water removal **only** affects the pressure losses in the downstream branches, an error is reported if the node in item 1 has no outflow branch.

---

## Examples

### Example 1

Remove 20,000 units/day of water from the node. Item 3 defaults to 1.0 to ensure that the water removal rate does not exceed the flow rate of water through the node.

```
NWATREM
NODE-5    20000    /
/
```

## Example 2

Remove half of the water that flows through the node. Item 2 defaults to infinity so that there is no other limit on the removal rate.

```
NWATREM  
NODE-5 1* 0.5 /
```

## NXFIN

## Number of local cells in each global cell of an LGR in X direction

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

If a local grid refinement covers more than one global cell in the x-direction, NXFIN can be used to dictate how many local cells each of the global cells is divided into. The keyword should be placed after the keyword [CARFIN](#) introducing the local grid, and before the local grid data is terminated with [ENDFIN](#). NXFIN does not apply to radial refinements introduced with [RADFIN](#).

NXFIN should be followed by I2-I1+1 values terminated with a slash (/), where I1 and I2 are the I-coordinates defining the box of global grid cells to be refined (items 2 and 3 in keyword [CARFIN](#)). The number of values is thus the number of global cells of the refinement counted along the X-direction. The values represent the number of local cell divisions, counted along the X-direction, in each of the global cells. The sum of the values must, of course, be equal to NX set in item 8 of [CARFIN](#).

In the absence of this keyword, the global cells are refined to contain equal numbers of local cells in the x-direction.

Local grid refinement is described in "[Local grid refinement and coarsening](#)" in the *ECLIPSE Technical Description*.

### Example

```

CARFIN
-- NAME      I1 I2  J1 J2 K1 K2 NX NY NZ
   LGR2      3 4   1 2  5 6  4 2 4 /
--Two global cells in x-direction to become 4 local cells
--with three local cells in first global, 1 in second
NXFIN
3 1 /

```

## NYFIN

## Number of local cells in each global cell of an LGR in Y direction

x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

If a local grid refinement covers more than one global cell in the y-direction, NYFIN can be used to dictate how many local cells each of the global cells is divided into. The keyword should be placed after the keyword [CARFIN](#) introducing the local grid, and before the local grid data is terminated with [ENDFIN](#). NYFIN does not apply to radial local grids introduced with [RADFIN](#).

NYFIN should be followed by J2-J1+1 values terminated with a slash (/), where J1 and J2 are the J-coordinates defining the box of global grid cells to be refined (items 4 and 5 in keyword [CARFIN](#)). The number of values is thus the number of global cells of the refinement counted along the Y-direction. The values represent the number of local cell divisions, counted along the Y-direction, in each of the global cells. The sum of the values must, of course, be equal to NY set in item 9 of [CARFIN](#).

In the absence of this keyword, the global cells will be refined to contain equal numbers of local cells in the y-direction.

The form of the input is analogous to that of [NXFIN](#).

## NZFIN

## Number of local cells in each global cell of an LGR in Z direction

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

If a local grid refinement covers more than one global cell in the z-direction, NZFIN can be used to dictate how many local cells each of the global cells is divided into. The keyword should be placed after the keyword [CARFIN](#) or [RADFIN](#) introducing the local grid, and before the local grid data is terminated with [ENDFIN](#).

NZFIN should be followed by K2-K1+1 values terminated with a slash (/), where K1 and K2 are the K-coordinates defining the box of global grid cells to be refined (items 4 and 5 in either keyword [CARFIN](#) or [RADFIN](#)). The number of values is thus the number of global cells of the refinement counted along the Z-direction. The values represent the number of local cell divisions, counted along the Z-direction, in each of the global cells. The sum of the values must, of course, be equal to NZ set in item 10 of [CARFIN](#), or in item 8 of [RADFIN](#).

In the absence of this keyword, the global cells will be refined to contain equal numbers of local cells in the z-direction.

The form of the input is analogous to that of [NXFIN](#).

## O

This section contains an alphabetic listing of keywords starting with the letter O.

## ODD3P

## Request ODD3P three-phase relative permeability and capillary pressure model

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword, which has no associated data, is used to specify that the three-phase relative permeability and capillary pressure values are to be calculated using the ODD3P method. This is a fully coupled model which incorporates hysteresis and miscibility effects for both relative permeability and capillary pressure. The ODD3P keyword should only be used in three-phase runs.

For the oil phase, the oil-water and oil-gas tables are specified using the [SOF3](#) keyword. For the water phase, the water-oil and water-gas tables must be entered using the [SWF3](#) keyword (rather than [SWFN](#)). For the gas phase, the gas-oil and gas-water tables must be entered using the [SGF3](#) keyword (rather than [SGFN](#)).

The ODD3P method can be used with endpoint scaling. In this case the primary end-point scaling is specified using the [PSORG](#), [PSGRO](#), [PSORW](#), [PSWRO](#), [PSGRW](#) and [PSWRG](#) keywords and the hysteresis end-point scaling is specified using the [HSORG](#), [HSGRO](#), [HSORW](#), [HSWRO](#), [HSGRW](#) and [HSWRG](#) keywords

ECLIPSE uses the default three-phase oil relative permeability model if the keywords [STONE](#), [STONE1](#), [STONE2](#), or ODD3P are omitted from the PROPS section of the input data file.

See "[Saturation functions](#)" in the *ECLIPSE Technical Description* for a description of three-phase oil relative permeability models available in ECLIPSE.

### Example

```
ODD3P
```

## OFM

## Requests output of SUMMARY data in OFM format

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
x	SUMMARY
	SCHEDULE

This keyword requests post-processing of the SUMMARY output into a form that can conveniently be input into the OFM program. The process is analogous to the generation of run summaries (RUNSUM keyword), in that the SUMMARY files are post-processed at the end of the run to convert the SUMMARY output into a new format.

If the OFM keyword is present then either 3 or 4 new files will be generated:

ROOT\_OFM.DEF Defines the tables in the OFM data model

ROOT\_OFM.XY defines the areal (XY) location of either the well or completion

ROOT\_OFM\_WELL.PRD Well data

ROOT\_OFM\_COMP.PRD Completion data

The output is generated for a set of unique identifiers based on connection data if available, and on well data if not. In the case of connections the COFR mnemonic is the controlling mnemonic (if no COFR is present then CGFR and CWFR are alternatives). The unique identifiers take the form WELL:AA\_BB\_CC where AA, BB, CC are the X,Y,Z location of the connection.

It is assumed that if completion data is available, then the well aggregates, etc., will be calculated in OFM. This prevents the possibility of multiple data items carrying the same information once input into the OFM database.

If the controlling connection mnemonic is not present for a given well then the controlling mnemonic for well level data is the WOPR (and if this keyword is not present, then WGPR and WWPR are alternatives). In the case of well data the unique identifier is simply the well name.

For all completions with COFR data the output consists of the superset of all completion mnemonics (C\* keywords) present in the SUMMARY section. If no COFR keyword is present and WOPR is present for a given well, the data consists of the superset of all well mnemonics (W\* keywords). Note that it is possible to produce very large files in cases where the superset of mnemonics used is large combined with large numbers of connections and timesteps.

The following conversions of mnemonic names are carried over automatically to the standard OFM name:

COFR \*OIL

CWFR \*WATER

CGFR \*GAS

CPR \*PRESSURE

WOPR \*OIL

WWPR \*WATER

WGPR \*GAS

WBHP \*PRESSURE

All other mnemonics retain their keyword names.

Once the ECLIPSE run has completed and the OFM-ready files have been produced, these files can easily be imported into OFM by creating a new project and then loading data from ASCII flat files. In the load panel visible after a new project has been created, select then load the four OFM files from a run. The project will then be populated.

The X,Y location of the well will normally be referenced relative to the grid. However, if the [MAPAXES](#) keyword is present in the dataset, then an effective transform to the new MAPAXES origin is performed.

The OFM keyword has no associated data.

See also the keyword [RUNSUM](#).

## Example

OFM

# OIL

## Indicates that the run contains oil

This keyword indicates that a run contains an oil phase. The OIL keyword should be specified whenever an oil phase exists or could exist.

For ECLIPSE 300, the OIL keyword is automatically supplied for any compositional mode run.

The keyword OIL contains no items.

This keyword is optional and can only be used with the ECLIPSE 300 Thermal option.

The keyword defines functions  $f_i(x)$  for each component that are used as indices in calculating the oil phase viscosity.

The data comprises NTPVT tables (item 2 of keyword [TABDIMS](#)) of values  $f_i(x)$  versus  $x$  for each pressure table. Each table consists of  $N_c + 1$  columns of data (described below) and is terminated by a slash (/).

Column 1 Mole fraction values  $x$

The values should be between 0 and 1, and increase monotonically down the column.

Columns 2 to  $N_c + 1$  The corresponding values of oil component viscosity index  $f_i(x)$

The values should be between 0 and 1, and increase monotonically down the column.  
In addition:

$$f_i(0) = 0 \text{ and } f_i(1) = 1$$

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NPPVT see keyword [TABDIMS](#)).

The oil phase viscosity is calculated from the component viscosities:

$$\mu_o = \mu_T(T) = \prod_{i=1}^{N_c} \mu_{oi}^{f_i(x_i)} \quad \text{Eq. 3.124}$$

where

$\mu_{oi}$  are the component viscosities defined by keyword [OILVISCT](#), [OILVISCC](#) or [OILVISCF](#),

$x_i$  are the component mole fractions in the oil phase, and

$f_i(x_i)$  are the viscosity indices defined by this keyword.

If this keyword is not used then linear functions are used:

$$f_i(x_i) = x_i$$

If both the [PVCO](#) and [VISCREF](#) keywords are specified, a pressure dependence modifies the above temperature-dependent viscosities. The oil viscosity at the prevailing pressure is then calculated as follows:

$$\mu_o = \mu_T(T) \frac{\mu_p(P)}{\mu_p(P_{ref})} \quad \text{Eq. 3.125}$$

where

$\mu_T$  is the viscosity defined in equation [3.124](#).

$\mu_p$  is the viscosity from the [PVCO](#) keyword.

$P_{ref}$  is the reference pressure defined by the `VISCREF` keyword.

See "Thermal option" in the *ECLIPSE Technical Description*.

## OILVISCC

## Oil viscosity-temperature correlation

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can only be used with the [THERMAL](#) option. It can be used with the default [LIVEOIL](#) option, but not with the [DEADOIL](#) option.

OILVISCC can be used to specify the temperature dependence of the oil component viscosities using one of four standard correlations:

$$\text{ASTM: } \log_{10}(\mu_{oi} + A) = B \cdot T^{-C} \quad \text{Eq. 3.126}$$

$$\text{Andrade: } \log_{10}(\mu_{oi}) = A + B / T \quad \text{Eq. 3.127}$$

$$\text{Vogel: } \log_{10}(\mu_{oi}) = A + B / (T + C) \quad \text{Eq. 3.128}$$

$$\text{logarithmic: } \log_{10}(\mu_{oi}) = A + B \cdot \log_{10}(T) \quad \text{Eq. 3.129}$$

where  $\mu_{oi}$  is the viscosity of oil component  $i$  (cP) and  $T$  is the temperature.

UNITS: K (METRIC), °R (FIELD), K (LAB), K (PVT-M)

The keyword can be used in two different ways:

- as a correlation, in which case values of  $T$  and  $\mu_{oi}(T)$  are entered and the simulator calculates the coefficients  $A$ ,  $B$  and (where applicable)  $C$
- as a formula, in which case the coefficients  $A$ ,  $B$  and (where applicable)  $C$  should be entered.

The keyword is followed by sets of records. Each set contains one record specifying the correlation name and type, followed by either two or three records that define the coefficients. The set of records is terminated with a slash.

To use the ASTM correlation four records are required:

1. ASTM CORRELATION
2.  $N_c + 1$  values are entered: a temperature  $T_1$  and  $N_c$  viscosities  $\mu_{oi}(T_1)$ , one for each hydrocarbon component.
3.  $N_c + 1$  values are entered: a temperature  $T_2$  and  $N_c$  viscosities  $\mu_{oi}(T_2)$ , one for each hydrocarbon component.
4.  $N_c$  viscosities  $\mu_{oi}(\infty)$  are entered, giving the limiting viscosity for each hydrocarbon component as the temperature tends to infinity.

---

**Note:**

$$\mu_{oi}(T_1) + 1 > \mu_{oi}(\infty) \text{ and } \mu_{oi}(T_2) + 1 > \mu_{oi}(\infty)$$

---

Alternatively, the coefficients can be specified:

1. ASTM FORMULA
2.  $N_c$  values are entered for the coefficient  $A$ , one for each hydrocarbon component.

3.  $N_c$  values are entered for the coefficient  $B$ , one for each hydrocarbon component.
4.  $N_c$  values are entered for the coefficient  $C$ , one for each hydrocarbon component.

---

**Note:**  $A < 1$ ,  $B > 0$  and  $C > 0$

---

To use the Andrade correlation three records are required:

1. ANDRADE CORRELATION
2.  $N_c + 1$  values are entered: a temperature  $T_1$  and  $N_c$  viscosities  $\mu_{oi}(T_1)$ , one for each hydrocarbon component.
3.  $N_c$  viscosities  $\mu_{oi}(\infty)$  are entered, giving the limiting viscosity for each hydrocarbon component as the temperature tends to infinity.

Alternatively, the coefficients can be specified:

1. ANDRADE FORMULA
2.  $N_c$  values are entered for the coefficient  $A$ , one for each hydrocarbon component.
3.  $N_c$  values are entered for the coefficient  $B$ , one for each hydrocarbon component.

To use the Vogel correlation four records are required:

1. VOGEL CORRELATION
2.  $N_c + 1$  values are entered: a temperature  $T_1$  and  $N_c$  viscosities  $\mu_{oi}(T_1)$ , one for each hydrocarbon component.
3.  $N_c + 1$  values are entered: a temperature  $T_2$  and  $N_c$  viscosities  $\mu_{oi}(T_2)$ , one for each hydrocarbon component.
4.  $N_c$  viscosities  $\mu_{oi}(\infty)$  are entered, giving the limiting viscosity for each hydrocarbon component as the temperature tends to infinity.

Alternatively, the coefficients can be specified:

1. VOGEL FORMULA
2.  $N_c$  values are entered for the coefficient  $A$ , one for each hydrocarbon component.
3.  $N_c$  values are entered for the coefficient  $B$ , one for each hydrocarbon component.
4.  $N_c$  values are entered for the coefficient  $C$ , one for each hydrocarbon component.

To use the logarithmic correlation the following records are required:

1. LOG CORRELATION
2.  $N_c + 1$  values are entered: a temperature  $T_1$  and  $N_c$  viscosities  $\mu_{oi}(T_1)$ , one for each hydrocarbon component.
3.  $N_c + 1$  values are entered: a temperature  $T_2$  and  $N_c$  viscosities  $\mu_{oi}(T_2)$ , one for each hydrocarbon component.

Alternatively, the coefficients can be specified:

1. LOG FORMULA
2.  $N_c$  values are entered for the coefficient  $A$ , one for each hydrocarbon component.
3.  $N_c$  values are entered for the coefficient  $B$ , one for each hydrocarbon component.

If different formulae are required for different components, then the set of records can be repeated. If a formula does not apply to a component, the data should be defaulted for that component (by entering 1\*, for example). If no data is entered for a component, the simulator will use viscosities from the [OILVISCF](#) or [OILVISCT](#) keyword.

The set of records is ended by a blank record, containing only a slash.

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as the 9<sup>th</sup> parameter of [TABDIMS](#).

The oil phase viscosity  $\mu_o$  is calculated from:

$$\mu_o = \mu_T(T) = \prod_{i=1}^{N_c} \mu_{oi}^{f_i(x_i)} \quad \text{Eq. 3.130}$$

where

$\mu_{oi}$  are the component viscosities,

$x_i$  are the component mole fractions in the oil phase, and

$f_i(x_i)$  are the viscosity indices defined by the [OILVINDX](#) keyword.

If both the [PVCO](#) and [VISCREF](#) keywords are specified, a pressure dependence modifies the above temperature dependent viscosities. The oil viscosity at the prevailing pressure is then calculated as follows:

$$\mu_o = \mu_T(T) \frac{\mu_p(P)}{\mu_p(P_{vref})} \quad \text{Eq. 3.131}$$

where

$\mu_T$  is the viscosity from this keyword.

$\mu_p$  is the viscosity from the [PVCO](#) keyword.

$P_{vref}$  is the reference pressure defined by the [VISCREF](#) keyword.

## Examples

### Example 1

In this example there is one reservoir EoS region.

```

## OILVISCF

## Oil viscosity function

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can only be used with the [THERMAL](#) option. It can be used with the thermal default [LIVEOIL](#) option, but not the [DEADOIL](#) option.

The data comprises two constants for each oil component that determine a function to calculate oil component viscosity versus temperature. For each oil component, the oil viscosity is fitted according to the equation  $\mu_o = A \cdot T^B$  where T is the temperature

(K (METRIC), °R (FIELD), K (LAB), K (PVT-M)).

The keyword is followed by two records, each containing  $N_c$  columns of data described below. The set of records is ended by a blank record, containing only a slash.

1.  $A$  coefficients, a set of  $N_c$  values is entered, one for each hydrocarbon component

UNITS: cP (METRIC), cP (FIELD), cP (LAB), cP (PVT-M)

2.  $B$  coefficients, a set of  $N_c$  values is entered, one for each hydrocarbon component

UNITS: dimensionless

The oil phase viscosity is calculated from the component viscosities:

$$\mu_o = \mu_T(T) = \prod_{i=1}^{N_c} \mu_{oi}^{f_i(x_i)} \quad \text{Eq. 3.132}$$

where

$\mu_{oi}$  are the component viscosities,

$x_i$  are the component mole fractions in the oil phase, and

$f_i(x_i)$  are the viscosity indices defined by the [OILVINDX](#) keyword.

If both the [PVCO](#) and [VISCREF](#) keywords are specified, a pressure dependence modifies the above temperature dependent viscosities. The oil viscosity at the prevailing pressure is then calculated as follows:

$$\mu_o = \mu_T(T) \frac{\mu_p(P)}{\mu_p(P_{\text{ref}})} \quad \text{Eq. 3.133}$$

where

$\mu_T$  Viscosity from this keyword.

$\mu_p$  Viscosity from the [PVCO](#) keyword

$P_{\text{ref}}$  Reference pressure defined by the [VISCREF](#) keyword.

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of [TABDIMS](#).

## Example

```
OILVISCF  
-- LIGHT COMP LIGHTER COMP  
4.49E9 20.0E9  
-3.4 -3.4  
/
```

## OILVISCT

## Oil viscosity versus temperature data

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used with either the blackoil Temperature option or the compositional Thermal option to specify the temperature dependence of the oil phase viscosity. The way the keyword is used is discussed separately for each option in the next two sections, since there are some slight differences.

The interpolation method for the OILVISCT data can be specified with the [OILVTIM](#) keyword.

## Temperature option

The Temperature option can be used in either ECLIPSE 100 or ECLIPSE 300; see keyword [TEMP](#). When the OILVISCT keyword is used with the temperature option the [VISCREF](#) keyword should be specified to supply the reference conditions for the oil viscosity.

The data comprises NTPVT tables (item 2 of keyword [TABDIMS](#)) of oil component viscosities versus temperature for each pressure table. Each table consists of two columns of data (described below), and is terminated by a slash (/).

## Column

1. Temperature values.

The values should increase monotonically down the column.

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

2. The corresponding values of oil viscosity.

The values should decrease or stay level down the column.

UNITS: cP (METRIC), cP (FIELD), cP (LAB), cP (PVT-M)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NPPVT (see keyword [TABDIMS](#)).

The values of oil viscosity in the OILVISCT keyword are assumed to be at the reference pressure and  $R_s$  value given in the [VISCREF](#) keyword. The oil viscosity at the prevailing pressure and  $R_s$  is calculated as follows:

$$\mu_o = \mu_T(T) \frac{\mu_p(P, R_s)}{\mu_p(P_{\text{ref}}, R_{s \text{ ref}})} \quad \text{Eq. 3.134}$$

where

$\mu_T$  Viscosity from the OILVISCT keyword.

$\mu_p$  Viscosity from the [PVTO](#) (or [PVDO](#)) keyword.

$P_{\text{ref}}$  Reference pressure from the [VISCREF](#) keyword.

$R_{s \text{ ref}}$  Reference  $R_s$  from the [VISCREF](#) keyword.

See "[Temperature option](#)" in the *ECLIPSE Technical Description*.

## ECLIPSE 100

**Note:** ECLIPSE 100 linearly interpolates the reciprocal of the oil viscosities between data points, rather than the values themselves.

## ECLIPSE 300

**Note:** The interpolation method used to obtain oil viscosities between data points can be set with the `OILVTIM` keyword. By default oil viscosities are linearly interpolated between data points.

## Example

With `NTPVT = 1` and `NPPVT ≥ 5`

```
OILVISCT
 10 60
 100 10
 150 2
 200 0.8
 250 0.5
/
```

## ECLIPSE 300 Thermal option

The Thermal option can only be used in ECLIPSE 300; see keyword `THERMAL`. Either this keyword or `OILVISCC` or `OILVISCF` or `THANALV` should be specified to determine the oil viscosity. Keyword `VISCREF` is optional and is only needed if a pressure dependence is required, as discussed below.

The data comprises `NTPVT` tables (item 2 of keyword `TABDIMS`) of oil component viscosities versus temperature for each pressure table. Each table consists of  $N_c + 1$  columns of data (described below), and is terminated by a slash (/).

Column 1	Temperature values.  The values should increase monotonically down the column. UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)
Columns 2 to $N_c + 1$	The corresponding values of oil component viscosity.  The values should decrease or stay unchanged down the column. UNITS: cP (METRIC), cP (FIELD), cP (LAB), cP (PVT-M)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than `NPPVT` (see keyword `TABDIMS`).

The oil phase viscosity is calculated from the component viscosities:

$$\mu_o = \mu_T(T) = \prod_{i=1}^{N_c} \mu_{oi}^{f_i(x_i)} \quad \text{Eq. 3.135}$$

where

$\mu_{oi}$  are the component viscosities

$x_i$  are the component mole fractions in the oil phase

$f_i(x_i)$  are the viscosity indices defined by the `OILVINDX` keyword.

For temperature values outside the interval specified, constant value extrapolation is performed.

If both the `PVCO` and `VISCREF` keywords are specified, a pressure dependence modifies the temperature dependent viscosities described above. The oil viscosity at the prevailing pressure is then calculated as follows:

$$\mu_o = \mu_T(T) \frac{\mu_p(P)}{\mu_p(P_{ref})} \quad \text{Eq. 3.136}$$

where

$\mu_T$  Viscosity from this keyword.

$\mu_p$  Viscosity from the `PVCO` keyword.

$P_{ref}$  The reference pressure defined by the `VISCREF` keyword.

See "Thermal option" in the *ECLIPSE Technical Description*.

**Note:** Oil viscosity in the `DEADOIL` option cannot be lower than 0.1 cP. It will be reset to 0.1 cP.

## Example

```
OILVISCT
 75 1* 5780
100 1* 1380
150 1* 187
200 1* 47
250 1* 17.4
300 1* 8.5
350 1* 5.2
500 1* 2.5
15000 1* 2.4999
/
```

## Oil viscosity temperature interpolation method

This keyword specifies the interpolation method used for the [OILVISCT](#) table which by default is interpolated linearly for a given temperature. However, for heavy oil the viscosity may depend exponentially on the temperature and an interpolation on the logarithm of the viscosity may be more appropriate.

The keyword contains an item of data and should be terminated with a slash (/)

### 1. Interpolation method

**LIN**      Linearly interpolate the viscosity with respect to the temperature.

**LINLOG**    Linearly interpolate the logarithm of the viscosity with respect to the temperature and then take the exponential.

DEFAULT: LIN

## Example

```
OILVTIM
LINLOG /
```

## OLDEQUIL Perform equilibration using the pre-2001A method

	<b>ECLIPSE 100</b>
x	<b>ECLIPSE 300</b>
	<b>SPECIAL</b>
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

Two changes were made to the ECLIPSE 300 equilibration for the 2001A release. The behavior was changed to be the same as that of ECLIPSE 100. The use of the OLDEQUIL keyword implies the pre-2001A behavior:

1. The Equilibration is performed using N horizontal blocks where N is item 9 of the EQUIL keyword.
2. The sign of the capillary pressure (4<sup>th</sup> item of the EQUIL keyword) at the water-oil contact is reversed. A positive value now implies  $P_{oil} > P_{water}$  at the contact.

## OLDTRAN **Specifies block center transmissibilities**

x	<b>ECLIPSE 100</b>
	<b>ECLIPSE 300</b>
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY

In compositional runs, the program supplies a default value of the equation of state  $\Omega_b$  coefficient.

However, as in the case of  $\Omega_a$ , this keyword enables you to modify the value of this coefficient. As for  $\Omega_a$ , only a small variation is advisable and the default value will only be modified if the user defined value is larger than 0. A separate value may be specified for each component.

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

DEFAULT: Peng-Robinson: 0.077796074, RK, SRK and ZJ: 0.08664035

In compositional runs, the program supplies a default value of the equation of state  $\Omega_b$  coefficient.

However, as in the case of  $\Omega_a$ , this keyword enables you to modify the value of this coefficient. As for  $\Omega_a$ , only a small variation is advisable and the default value will only be modified if the user defined value is larger than 0. A separate value may be specified for each detailed component in a lumped simulation.

Lumped simulations are enabled with the [LUMPDIMS](#) keyword in the `RUNSPEC` section; further details can be found in "[Delumping and lumping](#)" in the *ECLIPSE Technical Description*.

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

DEFAULT: Peng-Robinson: 0.077796074, RK, SRK and ZJ: 0.08664035

### Example

```
OMEGABDE
0.0777 2*0.078 0.07677 /
```

## OMEGABS **Overrides default surface $\Omega_b$ values**

# OPERATE **Performs operations on arrays**

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
x	EDIT
x	PROPS
x	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is used to perform arithmetic operations on property arrays.

The keyword may be followed by any number of records, each of which is terminated by a slash (/). The data is terminated by a blank record, containing only a slash.

Each record consists of:

1. The result array.

Items 2-7 may be used to redefine the input box for this and subsequent operations within the current keyword. If items 2-7 are not defined, they default to the values which were used for the previous operation within the current keyword. For the first operation in the keyword, the box defaults to the values set by the most recent **BOX** or **ENDBOX** keyword. If there is no preceding **BOX** or **ENDBOX** in the current section, the box is taken to include the entire reservoir.

2. First block to be modified on the X axis (IX1)
3. Last block to be modified on the X axis (IX2)
4. First block to be modified on the Y axis (JY1)
5. Last block to be modified on the Y axis (JY2)
6. First block to be modified on the Z axis (KZ)
7. Last block to be modified on the Z axis (KZ2)

The data must satisfy:

$$1 \leq IX1 \leq IX2 \leq NDX$$

$$1 \leq JY1 \leq JY2 \leq NDY$$

$$1 \leq KZ1 \leq KZ2 \leq NDZ,$$

where  $NDX$ ,  $NDY$ ,  $NDZ$  are the limits in the current **BOX**.

8. The type of operation. The table below describes valid operations. Let  $X_i$  denote the  $i$ th element of the argument array and  $R_i$  the  $i$ th element of the result array. The Greek letters  $\alpha$  and  $\beta$  are scalar parameters. Examples for valid arrays are given later. All operations are performed with floating point arithmetic. If the result is an integer array, the real value is rounded to the nearest integer.

Result	item 8	item 9	item 10	item 11
$R_i = \alpha X_i + \beta$	'MULTA'	X	$\alpha$	$\beta$
$R_i = R_i + \alpha X_i^\beta$	'POLY'	X	$\alpha$	$\beta$
$R_i = 10^{(\alpha + \beta X_i)}$	'SLOG'	X	$\alpha$	$\beta$
$R_i = \log_{10}(X_i)$	'LOG10'	X	n/a	n/a
$R_i = \ln(X_i)$	'LOGE'	X	n/a	n/a
$R_i = \frac{1}{X_i}$	'INV'	X	n/a	n/a

Result	item 8	item 9	item 10	item 11
$R_i = \alpha X_i$	'MULTX'	X	$\alpha$	n/a
$R_i = \alpha + X_i$	'ADDX'	X	$\alpha$	n/a
$R_i = X_i$	'COPY'	X	n/a	n/a
$R_i = \min(\alpha, X_i)$	'MAXLIM'	X	$\alpha$	n/a
$R_i = \max(\alpha, X_i)$	'MINLIM'	X	$\alpha$	n/a
$R_i = \alpha X_i^\beta$	'MULTP'	X	$\alpha$	$\beta$
$R_i = \text{abs}(X_i)$	'ABS'	X	n/a	n/a
$R_i = X_i R_i$	'MULTIPLY'	X	n/a	n/a

### Notes

- Keywords in brackets are for radial geometry runs
- Operations on integer arrays can lead to unwanted results, since the operations are performed with floating (double) point precision and thereafter translated to an integer representation.
- Extreme caution should be exercised for operations on [TRANX](#), [TRANY](#) and related keywords: X- and Y-transmissibilities reflect cell positions, and have zero values at the edges of the grid.
- See also keywords [BOX](#), [ENDBOX](#), [EQUALS](#), [ADD](#) and [MULTIPLY](#).
- If a [MAXLIM](#) operation is chosen, this will apply a maximum limit to an array in the current box. Refer also to keyword [MAXVALUE](#).
- If a [MINLIM](#) operation is chosen, this will apply a minimum limit to an array in the current box. Refer also to keyword [MINVALUE](#).

- It is possible to use this keyword on arrays between different sections of the dataset. This will enable the use of an operation such as  $SWL = F_n(PORO)$ . For use of the OPERATE keyword in either the PROPS or SOLUTION section of ECLIPSE 100, as well as being able to use existing properties from these data sections, only certain grid properties can be “operated on”. For instance, PORO, PORV, DEPTH, PERMX, PERMY and PERMZ. Similar operations apply to SOLUTION section use inside ECLIPSE 300. In a one- or two-dimensional case, directional information for the collapsed dimensions is not available for use in the SOLUTION section (so, for instance, you cannot use PERMX in the SOLUTION section of a dataset which has only one cell in the x-direction).
- For REGIONS section use in both simulators, it is possible to “operate” on MULTNUM, FLUXNUM and OPERNUM regions (in order of preference).
- It is possible to specify a work array (see “Example 3”) in place of the result array (item 1) and/or the argument array (item 9). Work arrays of double-precision or integer type may be specified, as required by the desired operation. Double precision work array names must begin with the characters ‘WORK’ followed by an integer specifying the index of the array that is the first work array should be named WORK1, the second WORK2, and so on. Integer work array names must begin with the characters ‘IWORK’ followed by an integer specifying the index of the array that is the first integer work array should be named IWORK1, the second IWORK2, and so on. The total number of double precision work arrays used must not exceed item 8 of the REGDIMS keyword, and the total number of integer work arrays used must not exceed item 9 of the REGDIMS keyword. Note that work array elements will be automatically initialized to zero (in ECLIPSE 100, work arrays are reset to zero at the start of each section of the datafile, or when changing between grids, for instance between two local grids or the global grid and a local grid).
- In the SOLUTION section, this keyword is processed at the very end after initialization has been done. It’s therefore important to be careful when combining its use with keywords such as EQUALS, ADD and MULTIPLY. These keywords will always be applied first, even if OPERATE appears before them in the dataset. OPERATE is processed before OPERATER, if both are present.
- Because this keyword is processed after initialization, array names for use in the SOLUTION section are output mnemonics rather than input keywords. For instance, to manipulate grid block temperatures you specify TEMP rather than TEMPI.

## Examples

### Example 1

Set DY equal to DX:

```
OPERATE
--result box  operate  param
  DY    6*  'COPY'    DX  /
/
```

### Example 2

Implement correlations over parts of grid:

```
----in box 1-11 1-19 1-4
OPERATE
PERMX 1 11 1 19 1 4 'MULTA' PORO .444 .5555 /
PERMX 1 11 1 19 1 4 'POLY' PERMX .234 2 /
PERMX 1 11 1 19 1 4 'POLY' PERMX .034 3 /
PERMX 1 11 1 19 1 4 'POLY' PERMX .004 4 /
PERMX 1 11 1 19 1 4 'SLOG' PERMX .000 1.0 /
PERMX 1 11 1 19 1 4 'MULTX' PERMX 2.44 /
```

```
PERMZ 6* 'COPY' PERMX / defaults to last specified box
/
```

In the REGIONS section:

```
OPERATE
SATNUM 6* COPY FIPNUM /
/
```

### Example 3

Use of work arrays (item 8/9 of [REGDIMS](#) must be appropriately specified). For this example, since two double precision work arrays (WORK1, WORK2) are used, item 8 of REGDIMS should be set to 2; and since only 1 integer work array (IWORK1) is needed, then item 9 of REGDIMS should be set to 1:

```
--result box operate argument param
OPERATE
WORK1 6* 'MULTX' PORO .45 /
WORK2 6* 'LOG10' PERMX /
WORK2 6* 'MULTIPLY' WORK1 /
PERMY 6* 'ABS' WORK2 /
/
--result box operate argument param
OPERATE
IWORK1 6* 'MULTX' SATNUM 2 /
FIPNUM 6* 'ADDX' IWORK1 1 /
/
```

## OPERATER **Performs operations on arrays for a specific region**

	SUMMARY
	SCHEDULE

This keyword is used to perform arithmetic operations on property arrays for a specific region.

The keyword may be followed by any number of records, each of which is terminated by a slash (/). The data is terminated by a blank record, containing only a slash.

Each record consists of:

1. The result array,  $R_i$
2. The region number on which to perform the operation (by default this is from `OPERNUM` data, but item 7 below allows the use of other sets of region numbers).

DEFAULT: 0

3. The type of operation. The table below describes valid operations. Let  $X_i$  denote the  $i^{\text{th}}$  element of the argument array, and  $R_i$  the  $i^{\text{th}}$  element of the result array. The Greek letters  $\alpha$  and  $\beta$  are scalar parameters. Examples for valid arrays are given later. All operations are performed with floating point arithmetic. If the result is an integer array, the real value is rounded to the nearest integer.

Result	item 3	item4	item 5	item 6
$R_i = \alpha X_i + \beta$	'MULTA'	X	$\alpha$	$\beta$
$R_i = R_i + \alpha X_i^\beta$	'POLY'	X	$\alpha$	$\beta$
$R_i = 10^{(\alpha + \beta X_i)}$	'SLOG'	X	$\alpha$	$\beta$
$R_i = \log_{10}(X_i)$	'LOG10'	X	n/a	n/a
$R_i = \ln(X_i)$	'LOGE'	X	n/a	n/a
$R_i = \frac{1}{X_i}$	'INV'	X	n/a	n/a
$R_i = \alpha X_i$	'MULTX'	X	$\alpha$	n/a
$R_i = \alpha + X_i$	'ADDX'	X	$\alpha$	n/a
$R_i = X_i$	'COPY'	X	n/a	n/a
$R_i = \min(\alpha, X_i)$	'MAXLIM'	X	$\alpha$	n/a
$R_i = \max(\alpha, X_i)$	'MINLIM'	X	$\alpha$	n/a
$R_i = \alpha X_i^\beta$	'MULTP'	X	$\alpha$	$\beta$
$R_i = \text{abs}(X_i)$	'ABS'	X	n/a	n/a
$R_i = X_i R_i$	'MULTIPLY'	X	n/a	n/a

Table 3.22: Valid operation types

4. Array parameter depending on item 3. Must be supplied, no default.
5. Scalar parameter depending on item 3. Must be supplied if required, no default.

6. Scalar parameter depending on item 3. Must be supplied if required, no default.
7. The name of a fluid-in-place region set to be used instead of the `OPERNUM` region. This can be either an ordinary region defined in the `REGIONS` section, or a dynamic region defined in the `SOLUTION` section. This parameter can be used no earlier than the `SOLUTION` section, and, for dynamic regions, only after the region in question has been defined. The default is to use the `OPERNUM` region.

ECLIPSE 300

This keyword may be used in the `SCHEDULE` section. However, this is a specialist facility.

---

**Note:** In the `SCHEDULE` section, regions (pre-defined by the `FIPxxxx` keyword in the `REGIONS` section) can be used in the new item 7. This region will be used in place of the `OPERNUM` region.

---

### Notes

- The [OPERNUM](#) array must be specified before the OPERATER keyword and its associated data.
- Keywords in brackets are for radial geometry runs
- Operations on integer arrays can lead to unwanted results, since the operations are performed with floating (double) point precision and thereafter translated to an integer representation.
- Extreme caution should be exercised for operations on [TRANX](#), [TRANY](#) and related keywords: X- and Y-transmissibilities reflect cell positions, and have zero values at the edges of the grid.
- See also keywords [EQUALS](#), [ADD](#), [COPY](#) and [MULTIPLY](#).
- If a MAXLIM operation is chosen, this will apply a maximum limit to an array in the current box. Refer also to keyword [MAXVALUE](#).

- If a MINLIM operation is chosen, this will apply a minimum limit to an array in the current box. Refer also to keyword [MINVALUE](#).
- It is possible to use this keyword on arrays between different sections of the dataset. This will enable the use of an operation such as  $SWL = F_n(PORO)$ . For use of the OPERATER keyword in either the PROPS or SOLUTION section of ECLIPSE 100, as well as being able to use existing properties from these data sections, only certain grid properties can be “operated on”. For instance, [PORO](#), [PORV](#), [DEPTH](#), [PERMX](#), [PERMY](#) and [PERMZ](#). Similar operations apply to SOLUTION section use inside ECLIPSE 300. In a one- or two-dimensional case, directional information for the collapsed dimensions is not available for use in the SOLUTION section (so, for instance, you cannot use PERMX in the SOLUTION section of a dataset which has only one cell in the x-direction).
- For REGIONS section use in both simulators, it is possible to “operate” on [MULTNUM](#), [FLUXNUM](#) and [OPERNUM](#) regions (in order of preference).
- It is possible to specify a work array (see “[Example 4](#)”) in place of the result array (item 1) and/or the argument array (item 4). Work arrays of double-precision or integer type may be specified, as required by the desired operation. Double precision work array names must begin with the characters ‘WORK’ followed by an integer specifying the index of the array that is the first work array should be named WORK1, the second WORK2, and so on. Integer work array names must begin with the characters ‘IWORK’ followed by an integer specifying the index of the array that is the first integer work array should be named IWORK1, the second IWORK2, and so on. The total number of double precision work arrays used must not exceed item 8 of the [REGDIMS](#) keyword, and the total number of integer work arrays used must not exceed item 9 of the [REGDIMS](#) keyword. Note that work array elements will be automatically initialized to zero (in ECLIPSE 100, work arrays are reset to zero at the start of each section of the datafile, or when changing between grids, for instance between two local grids or the global grid and a local grid).
- To use this keyword with local grid array values, it must be specified inside an appropriate [CARFIN](#) or [REFINE](#) keyword. Note that this is only sensible for ECLIPSE 300, since for ECLIPSE 100 it is not possible to specify [MULTNUM](#), [FLUXNUM](#) or [OPERNUM](#) data for a local grid.
- In the SOLUTION section, this keyword is processed at the very end stage, after initialization has been completed. It is therefore important to be careful when combining its use with keywords such as [EQUALS](#), [ADD](#) and [MULTIPLY](#). These keywords will always be applied first, even if OPERATER appears before them in the dataset. OPERATE is processed before OPERATER, if both are present.
- Because this keyword is processed after initialization, array names for use in the SOLUTION section are output mnemonics rather than input keywords. For instance, to manipulate grid block temperatures you specify TEMP rather than [TEMP I](#).

## Additional notes

*ECLIPSE 300 only*

Additional notes for the use of this keyword in the SCHEDULE section. Again, this is a specialist facility. In the SCHEDULE section, the effect of this keyword will be as follows:

Keyword	Description
<a href="#">DIFFMMF</a>	Modifies the matrix-fracture diffusivity in dual-porosity runs. If output is required for flexible restart in the model, these multiplier values will be output as <a href="#">DIFFMMFS</a> .
<a href="#">MULSGGD</a> <a href="#">MULSGGDV</a>	Modifies the matrix-fracture coupling transmissibility for oil-gas gravity drainage in dual-porosity runs. If output is required for flexible restart in the model, these multiplier values will be output as <a href="#">MULSGGDS</a> .

Keyword	Description
MULTSIG MULTSIGV	Modifies the matrix-fracture coupling transmissibility in dual-porosity runs. If output is required for flexible restart in the model, these multiplier values will be output as MULTSIGS .
MULTXZ MULTY MULTZ	Modifies transmissibility in the X/Y/Z-direction. If output is required for flexible restart in the model, the multiplier values will be output as MULTXS/MULTYS/MULTZS.
PERMX PERMY PERMZ	Modifies permeability in the X/Y/Z-direction. Also approximates the corresponding transmissibility multiplier MULTX/Y/Z determined from the ratio of the new permeability value to the old one. If output is required for flexible restart in the model, the permeability values will be output as MODPERMX/Y/Z .
PORO	Modifies porosity. Modifies the corresponding pore volume by a multiplier MULTPV determined from the ratio of the new porosity value to the old one. If output is required for flexible restart in the model, the porosity values will be output as MODPORO, and the pore volume multipliers will be output as MULTPVs.
SIGMA SIGMAV	Modifies the matrix-fracture coupling transmissibility in dual-porosity runs. If output is required for flexible restart in the model, these multiplier values will be output as SIGMA.
WORK (1 / 2)	These are work arrays to be stored for subsequent use. If output is required for flexible restart in the model, these values will be output as WORK (1 / 2).

Table 3.23: Additional notes for OPERATER in the SCHEDULE section

ECLIPSE 300 only

Output to the flexible restart file, of the quantities DIFFMMFS, MULSGGDS, MULTSIGS, SIGMA and WORK (1 / 2), is not currently supported for LGRs.

## Examples

### Example 1

Set DY equal to DX:

```
OPERATER
--result region operate param
  DY      2      'COPY'   DX   /
/
```

### Example 2

Implement correlations over different regions of the grid:

```
OPERATER
PERMX 1 'MULTA' PORO .444 .5555 /
PERMX 2 'POLY' PERMX .234 2 /
PERMX 2 'POLY' PERMX .034 3 /
PERMX 2 'POLY' PERMX .004 4 /
PERMX 1 'SLOG' PERMX .000 1.0 /
PERMX 1 'MULTX' PERMX 2.44 /
PERMZ 3 'COPY' PERMX /
/
```

### Example 3

In the REGIONS section:

```

OPERATER
  SATNUM 2 COPY FIPNUM /
/

```

### Example 4

Use of work arrays (item 8 of [REGDIMS](#) must be appropriately specified).

```

--result reg  operate  arg  param
OPERATER
WORK1  1  'MULTX'  PORO  .45 /
WORK2  1  'LOG10'  PERMX /
WORK2  1  'MULTIPLY'  WORK1 /
PERMY  1  'ABS'  WORK2 /
/

--result box  operate  argument  param
OPERATER
IWORK1  1  'MULTX'  SATNUM  2 /
FIPNUM  1  'ADDX'  IWORK1  1 /
/

```

For the example above, since two double precision work arrays (WORK1, WORK2) are used, item 8 of REGDIMS should be set to 2; and since only 1 integer work array (IWORK1) is needed, then item 9 of REGDIMS should be set to 1.

## OPERNUM Defines regions for performing operations on arrays

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

ECLIPSE 100

The OPERNUM keyword provides a region definition for performing arithmetic operations on property arrays using the OPERATER keyword.

The OPERNUM array must be specified before the OPERATER keyword and its associated data.

To use the OPERNUM keyword, the maximum number of OPERNUM regions must first be defined. To do this, item 7 in the REGDIMS keyword in the RUNSPEC section must be set to a value greater than zero.

The OPERNUM keyword should be followed by one integer for each grid cell, specifying the region number to which it belongs. The data must be terminated by a slash (/).

Any cells not explicitly assigned a value of OPERNUM will be taken to be in region 0, which implies that no operation is allowed for this particular cell.

The OPERNUM array can be copied into the REGIONS section arrays (FIPNUM and PVTNUM) using the COPY keyword. However, it cannot be set in this way - it can only be used as the “from” array.

The OPERNUM keyword and its data should be present in the GRID section in order to use the OPERATER keyword in the GRID, EDIT or PROPS section. The OPERNUM keyword can be re-specified in the REGIONS section for use in the REGIONS and SOLUTION sections.

The OPERNUM array can be used with keywords MULTIREG, ADDRREG, EQUALREG and COPYREG.

ECLIPSE 100

**Note:** The OPERNUM keyword cannot be used inside a CARFIN/RADFIN...ENDFIN bracket, so it is currently not possible to use OPERNUM, together with OPERATER, to work on specific LGRs. To do this use the OPERATE keyword instead.

ECLIPSE 100

For use with the Dual Porosity option, only the matrix cells or the fracture cells need to be input. The cell values in the other porosity will be copied automatically. If both matrix and fracture cells are given, a warning message will be output complaining about too much data. If the user wants to specify matrix cells and fracture cells separately, then item 117 in OPTIONS should be set greater than 1. This will also affect use of the MULTNUM, PINCHNUM or FLUXNUM keywords.

ECLIPSE 300

When OPERNUM is defined, both matrix and fracture cells should be provided for use with the dual porosity option if operations are required on fracture cells. There is no copying of OPERNUM data from the matrix to fracture cells.

### Example

To define 9 separate regions in a 4\*4\*3 field (with the maximum number of OPERNUM regions set equal to 9):

```
OPERNUM
1 1 2 2
1 1 2 2
3 3 3 3
4 4 4 4
5 5 5 5
6 7 8 8
6 7 8 8
6 7 8 8
16*9 /
```

## OPTCONS

**Specify optimization constraints**

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE
x	OPTIMIZE

This keyword is used to specify the constraints to be observed during an optimization run.

The keyword must be followed by a set of records each specifying a constraint to be observed in the optimization. If the keyword is not present then the optimization is unconstrained.

This keyword should only appear once in the data file.

Each record should be terminated with a slash (/) and the set of records must end with a slash.

1. Mnemonic specifying quantity to be constrained. These mnemonics are drawn from the summary vector mnemonics. Available mnemonics are.

FOPR Field oil production rate

FWPR Field water production rate

FWIR Field water injection rate

FGPR Field gas production rate

FGIR Field gas injection rate

FLPR Field liquid production rate

FGOR Field gas oil ratio

FWCT Field water cut

GOPR Group oil production rate

GWPR Group water production rate

GWIR Group water injection rate

GGPR Group gas production rate

GGIR Group gas injection rate

GLPR Group liquid production rate

GGOR Group gas oil ratio

GWCT Group water cut

WOPR Well oil production rate

WWPR Well water production rate

WWIR Well water injection rate

WGPR Well gas production rate

WGIR Well gas injection rate

WLPR Well liquid production rate

WGOR Well gas oil ratio

WWCT Well water cut

2. Unique identifier for the domain to which the constraint specified in the first item applies. This should be either just 'FIELD', or the name of a well or group which has already been defined in the SCHEDULE section. The wildcard character '\*' may not be used to specify more than one well or group at the same time. Well lists, specified using the [WLIST](#) keyword, cannot be used as the domain identifier.  
DEFAULT: '<' or 'LE'
3. The type of inequality constraint. This may be set to either '<' or '>' (or 'LE' or 'GE'), depending on whether the constraining value is an upper or a lower bound to the quantity.  
DEFAULT: '<' or 'LE'
4. The value of the constraint, which is the limiting value of the mnemonic specified using items 1 and 2 of the keyword.
5. Index of first report time for this constraint.  
DEFAULT: 0 (or the first report index in a RESTART case)
6. Index of last report time for this constraint.  
DEFAULT: The last report index requested in the SCHEDULE section.

## Example

```
OPTCONS
-- Constrain gas production from well P1,
-- and water injection to well INJE2
'WGPR' P1 '<' 2000.0 /
'WWIR' INJE1 '>' 500.0 /
/
```

## OPTDIMS

## Specify optimization dimensions

	ECLIPSE 100
x	ECLIPSE 300

x	OPTIMIZE

This keyword is used to specify user-defined limits on the size of the optimization problem being considered.

The keyword is followed by a single record consisting of two integers. The record is terminated with a slash (/):

1. The maximum number of outer optimization iterations permitted during the optimization. (Each of these iterations includes calculation of gradients by the adjoint method.)

DEFAULT: 0

2. The maximum number of simulations that may be performed in total during the optimization.

DEFAULT: 1

---

**Note:** Due to these defaults, if the OPTDIMS keyword does not appear in a dataset, then the optimization gradients are calculated, and the run terminated normally.

---

## Example

```

OPTDIMS
-- MOPITS MOPSIM
   10    20  /

```

## OPTFUNC

**Specify objective function for optimization**

	<b>ECLIPSE 100</b>
x	<b>ECLIPSE 300</b>
x	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE
x	OPTIMIZE

This keyword is used to specify the objective function to be optimized in an optimization run of the simulator. This objective function may be composed of several separate component functions, giving flexibility to the engineer.

The keyword must be followed by a set of records each specifying a separate linear component of the objective function. Each record should be terminated with a slash (/) and the set of records must end with a slash. At least one record is required.

This keyword should only appear once in the data file.

1. Mnemonic specifying quantity to be included in the objective function. Implemented mnemonics are:

FOPT Field oil production total

FWPT Field water production total

FWIT Field water injection total

FGPT Field gas production total

FGIT Field gas injection total

FLPT Field liquid production total

GOPT Group oil production total

GWPT Group water production total

GWIT Group water injection total

GGPT Group gas production total

GGIT Group gas injection total

GLPT Group liquid production total

WOPT Well oil production total

WWPT Well water production total

WWIT Well water injection total

WGPT Well gas production total

WGIT Well gas injection total

WLPT Well liquid production total

2. Unique identifier for the domain to which the mnemonic specified in the first item applies.

- For group and well quantities, this should be the name of a group or well. These names should already have been defined in the SCHEDULE section.
- For field type objective function components, this entry assumes the value of 'FIELD'.

It is **not** possible to use the wildcard character '\*' to specify more than one well or group. Well lists, specified using the [WLIST](#) keyword, cannot be used as the domain identifier.

3. Coefficient specifying the weight of this component function in the objective function. Negative values are allowed.  
DEFAULT: 1.0
4. Daily discount rate (as a percentage) to be used in calculating the discount factor for this component.  
DEFAULT: 0.0
5. Index of first report time at which this component is part of the objective function.  
DEFAULT: 0 (or the first report index in a RESTART case)
6. Index of last report time at which this component is part of the objective function.  
DEFAULT: The last report index requested in the SCHEDULE section.

## Example

Objective function is to optimize field oil production while penalizing water production from well 'PROD' between report time indices 2 and 7:

```
OPTFUNC  
  'FOPT' FIELD /  
  'WWPT' PROD -1.0 0.0 2 7/  
/
```

## Activates special program options

The `OPTIONS` keyword can be used to activate special options within particular facilities in ECLIPSE 100. These options are mainly of a temporary or experimental nature, or act to restore back-compatibility with earlier versions of the code.

The keyword should be followed by a number of integers, each of which activates a special option within particular ECLIPSE 100 facilities. A value equal to zero switches off the special option. A value other than zero activates a special option. The data field should be terminated by a slash (/). If fewer than the maximum number integers are read, the remainder are left unchanged. Once an option is activated, it remains activated and retains its value in all subsequent uses of `OPTIONS` keyword unless it is explicitly changed or turned off. Note that repeat counts (for example 3\*0) can be used if required (there must be no spaces before or after the asterisk).

### Control

1. If >0 prevents RS being reset to RSSAT of grid block during the equilibration calculation when the grid cell contains free gas.
2. Well predictor switch  
(<0 off, =0 use as needed, =n use for  $NEWTIT \leq n$ ).

3. Not used at present.

The default setting of principal directions for the linear solver can be overridden using the `SOLVDIRS` keyword.

4. If =1 the critical rather than the connate water saturation is used in the simulation part of a `VE` run to calculate the contact depths. This prevents very small saturations being mobile through the base of the cell, but the `VE` Equilibration option is no longer static.

If =2 the critical rather than the connate saturation is used, as above, however it is only applied to the calculation of the water contact depths. This prevents unrealistic residual oil saturations in the gas zone of three-phase runs.

5. If =1 the critical rather than the connate gas saturation is used in the simulation part of a `VE` run to calculate the contact depths. This prevents very small gas saturations being mobile through the top of the cell, but the `VE` equilibration option is no longer static. This may prevent convergence difficulties when bubble point crossing occurs in a `VE` run.

If =2 the critical rather than the connate saturation is used, as above, however it is only applied to the calculation of the gas contact depths. This prevents unrealistic residual oil saturations in the water zone of three-phase runs.

6. Not used at present.

It is possible to turn off capillary pressure hysteresis using the 4<sup>th</sup> data item in the `EHYSTR` keyword.

7. If <0 Saturation chops are suppressed.  
If >0 Oil saturation chops for `VAPPARS` are also suppressed.
8. Chop on pressure change in well solution iterations to limit drawdown reversal (<0 off, ≥ 0 on for segmented head option).
9. Implicit/explicit water and gas fraction in THP calculations  
≤0 implicit, >0 explicit. See keyword `WVFPEXP`.

If <0 Causes immediate shut-in if flow is negative in any well iteration.

10. If >0 chops on P, R<sub>s</sub> and R<sub>v</sub> are suppressed.
11. If >0 produces quiescent initial conditions for gravity drainage/imbibition calculation in dual porosity runs.
12. Not used at present.

The transition zone end-point scaling is now controlled by the [TZONE](#) keyword in the PROPS section.

13. Not used at present.

The alternative relative permeability scaling option, which preserves the value of  $K_{rw}(S_w = 1 - S_{or})$  etc. can be initiated by using the [SCALECRS](#) keyword on the PROPS section.

14. Flag for controlling formatted data compression output to Restart files. The formatted output keyword [FMTOUT](#) in the RUNSPEC section must be set to true for this option to work.

If = 0 sets compression off for formatted output.

If = 1 sets normal compression on for formatted output, that is only puts a repeat count in front of repeated numbers, but unwanted zeros are not scanned and taken out before the numbers are written out to file.

If = 2 sets full compression on for formatted output, that is the same as flag = 1, but scans for unwanted zeros and take them out before the numbers are written out to file.

Setting the flag to 2 increases the CPU time. Therefore only set to full compression if saving disk space is more important than an increase in CPU time.

15. Number of iterations within a timestep in which a well can be revived after being closed because it cannot operate at the reservoir conditions of the previous iteration (for example under THP control). If = 0 defaults to the usual number of 3 iterations. If < 0 prevents the well being revived.
16. Not used at present.
17. Not used at present.

Pinchout transmissibility calculations are now controlled by the [PINCH](#) keyword.

18. Not used at present.

The use of the VE pseudo-capillary pressures can now be controlled with the [VEFRACP](#) or [VEFRACPV](#) keyword.

19. If set =1, with the vertical equilibrium option switched on, then the original method of calculating interblock flows taking no account of vertical displacements (for example at faults) will be used (see "[Vertical equilibrium](#)" in the *ECLIPSE Technical Description*). Note that this option can have large effects in non-faulted cases specified using block centered input.

If set =2, with a block centered grid and the Vertical Equilibrium option switched on, then the flows are calculated assuming a corner point approximation to the original grid. This option is used in local refinement cases in which the global grid is specified as a block centered grid. (See "[Vertical equilibrium](#)" in the *ECLIPSE Technical Description*)

DEFAULT:

0 In corner point geometry cases,

- 1 In block centered geometry cases.
20. If set >0, the well and group water phase guide rates are increased if necessary to ensure that  $GR_w / GR_o > X$ , where X is the reciprocal of the number entered for this control. This increases production from the wells with lower WORs if a group or the field changes from oil rate control to water rate control.

---

**CAUTION:** If the production distribution is changed too much (by making the minimum water-oil guide rate ratio too large), the group or field may not be able to obey both its oil and water production limits.

---

21. If set >0, Liquid rate controls refers to Oil + Gas instead of Oil + Water. The redefinition of liquid rate to mean total hydrocarbon surface rate applies to:
  - 1 Well liquid rate limits set in [WCONPROD](#) and [WELTARG](#).
  - 2 Group liquid rate limits set in [GCONPROD](#) and [GCONPRI](#) unless the action on violation is well closure or workover
  - 3 Liquid phase guide rates set in [WGRUPCON](#) and [GCONPROD](#)
  - 4 The control phase LIQ selected in item 7 of [WCUTBACK](#).

This option cannot be used with FIELD units, because the oil and gas rates are measured in different quantities.

22. Maximum number of times a hunting warning is printed for a given well. If it hunts any more it is shut or stopped, according to item 9 of keyword [WELSPECS](#). A value of 0 or negative implies no limit.
23. Sets the maximum number of times certain messages are printed. This option controls some warnings about the grid. A value of 0 sets the maximum to the default value of 15. A negative value implies no limit.
24. Not used at present

The pore volume and transmissibility multipliers for the rock compaction option can be tabulated against the effective overburden pressure by using the item 1 in the [ROCKOPTS](#) keyword.

25. If set >0, drainage regions are written to the DEBUG file at each report time.

These are useful for the ECLIPSE 200 Flux Boundary option. Flows are minimal between different drainage regions. Thus if the drainage regions are reasonably stable over a period of time, they can be used with the flux boundary option to save computing time in sensitivity or history matching runs.

If set >1, the location of the sinks (typically wells) within each drainage region is identified by a negative region number.

The computer time used by this option is reported if the argument DRND in [RPTSCHED](#) has been set.

26. If set >0, a more relaxed criterion for switching solution variables is used in cases when a water cell has some hydrocarbon influx. This can be helpful in a few rare cases when negative gas saturations can develop near a water/HC boundary.
27. If set >0, the run is stopped if a timestep fails to converge and the timestep is too small to be chopped (see [TUNING](#) keyword).

If set >9 then the run is stopped following any timestep convergence failure.

28. If set >0 with capillary pressure hysteresis option, then saturation chops will be used for cell that change hysteresis state in the gas phase.

If set >1 then chops are applied to the water phase as well.

29. Not used at present.

30. If set >0, a binary chop is implemented in the well iterations, restricting the solution increments if the residuals get worse. This could help the convergence of the well iterations in certain difficult cases. However, for multisegment well convergence problems you are recommended to try the [WSEGITER](#) keyword before changing this switch.

If set < 0                      binary chops are not applied.

If set = 0 (the default) binary chops are applied in multisegment wells but not in standard wells.

If set >0                      binary chops are applied in all types of well.

If set >1                      an additional pressure chop are applied in multisegment wells, at the value which would cause a drawdown reversal. This is only applied when the connection depth is the same as the depth of the segment's node.

31. If set >0, the average field and region pressure output is the pore-volume weighted-average, instead of the hydrocarbon pore-volume weighted-average. The pore volumes used are those at reference conditions (that is uncompactd pore volumes).

The default average field pressure is

$$FPR = \frac{\Sigma HCPV \cdot p}{\Sigma HCPV}$$

where  $HCPV = PV(1-S_w)$  is the hydrocarbon pore volume and  $p$  is the oil phase pressure. Setting `OPTIONS (31)>0` implies

$$FPR = \frac{\Sigma PV \cdot p}{\Sigma PV}$$

Note that the definition of summary keywords `FPRH`, `RPRH`, `FPRP`, `RPRP` is independent of this switch.

This switch has no effect on the reported average  $R_s$  and  $R_v$  that are defined, for example, by

$$FRS = \frac{\Sigma PV \cdot R_s \cdot S_o}{\Sigma PV \cdot S_o}$$

In addition, if the absolute value of the switch is divisible by 2 and > 0, then the field and average potentials output are the pore-volume weighted-averages, rather than phase pore-volume weighted-averages (which is the default).

As detailed in "[Potential calculations](#)" in the *ECLIPSE Technical Description*, the default potentials reported are (for oil)

$$FPPO = \frac{\Sigma \Phi_o \cdot S_o \cdot PV}{\Sigma S_o \cdot PV}$$

where  $\Phi_o$  is the oil potential and  $S_o$  is the oil saturation.

If  $|OPTIONS(31)|$  is divisible by 2 and  $OPTIONS(31) > 0$ , then the field oil potential is given by

$$FPPO = \frac{\Sigma\Phi_o \cdot PV}{\Sigma PV}$$

32. Number of times a single timestep can be consecutively chopped because a well has switched from rate control to pressure control and died in the same timestep.
- If = 0 defaults to 1.
- If = negative prevents timestep being chopped for this reason. In LGR runs, the global timestep is not chopped for wells in local grids - only the local timesteps are chopped. Setting the control value to between 11 and 20 allows chops of the global timestep, the maximum number of times being equal to the control value minus 10.
33. Number of network balancing iterations in which a well can be revived after being closed because it cannot operate against its current THP.
- If set = 0, this defaults to max (4, NETBAL/2) where NETBAL is the maximum number of network balancing iterations allowed (see the [NETBALAN](#) keyword in the Network option).
34. If set >0 when running the Gas Field Operations Model, prevents wells being opened automatically from the drilling queue during the second pass of the contract period, in the same month that they were opened in the 1<sup>st</sup> pass, if they are not actually needed to meet the DCQ x profile target.
35. If set > 0 ECLIPSE will revert to the pre-98A method of calculating the explicit wellbore head (SEG in [WELSPECS](#) Item 12) when API tracking is used, that is, the head is calculated from the average oil surface density in the well instead of an upstream flow weighted average at each connection.
36. If set >0 with the nine-point scheme active, matrix preconditioning is suppressed (for development testing).
37. If set >0 ECLIPSE replaces the solution state of each local grid cell with that of the global host cell when updating the global solution. This can be useful in cases where a change of state in small local cells takes a longer timescale to be mirrored in the global host cell.
- One example is a gas condensate case where a radial refinement is used around the well. The small cells nearest the well connections may change from gas only to gas and liquid at the start of the simulation, whereas the larger cells do not make this change until later in the simulation.
- Using this option allows ECLIPSE to weight these changes of state by the volume of the cells, essentially smoothing over these transient features.
38. If set >0 the oil gravity terms are calculated using the region average oil reservoir density, rather than the local reservoir density. This can prevent numerically induced flows that may cause convergence problems in some cases.

---

**Note:** The use of this switch is not recommended in general.

---

39. If set >0 ECLIPSE allows regions of different constant  $R_s$  or  $R_v$  to be in contact. This overrides the default behavior that only permits contact between regions of equal constant  $R_s$  or  $R_v$ . Any such connections are now reported as warnings instead of errors.
40. If set >0 the well potential rates are calculated ignoring any THP limits. This option may be useful if the potentials are not used for anything important and the potential flows would extrapolate the VFP tables.

41. If set >0 the well inflow calculation is modified in Vertical Equilibrium runs. The connection depth will be moved to the center of the perforated range within the grid block, and the grid block pressure is corrected to this depth using the hydrostatic gradient of the phases.
42. Time average weighting factor (NWT) for  $B_o$  and  $R_s$  in flash transformation facility (see keyword [COMPFLSH](#)):

$$B_o \text{ (used)} = \frac{(B_o \text{ cell} + [ | \text{NWT} | - 1 ] B_o \text{ (previous)})}{| \text{NWT} |}$$

Set to 2 or greater to damp out any oscillations. A negative value (for example -1) restores the pre-96A treatment of undersaturated oil. Note that a value < -1 also activates time-averaging of the transformation terms.

43. Not used at present.
- The rock data ([ROCK](#) keyword) corresponds to the saturation table ([SATNUM](#)) region numbers rather than the PVT region numbers ([PVTNUM](#)) if item 3 of the [ROCKOPTS](#) keyword is set to the string `SATNUM`.
44. Controls the treatment of the oil density at the water oil contact. If the control is set < 0 then the oil density for flow from a cell containing oil to a 100% water cell is set equal to the average oil density in the two cells. In the water cell the oil is assumed to be saturated. The default case (control = 0) uses the oil density in the oil cell only. The control only has effect on runs containing oil with dissolved gas. Versions of ECLIPSE prior to release 95A used the former method.
45. If set >0, the Kh or denominator term is not calculated from the connection factor if a positive value for this is entered in item 8 of keyword [COMPDAT](#). This option can be used to achieve back-compatibility with pre-95A datasets, if required.
46. Controls the interpolation of [MINPV](#) or [MINPVV](#) to LGRs when either [MINPV](#) or [MINPVV](#) is specified in the global grid but not in local grids. If set to 1, the threshold pore volumes are not copied from global host cells, which is the default for 95A. This reproduces the behavior of pre-95A datasets where the threshold pore volume is defaulted to  $10^{-6}$  in local grids for which it is not explicitly defined.
47. If set > 0, prevents well connection pressures from falling below atmospheric pressure. This may be useful for low pressure pumped wells in which there is an oil-gas interface within the perforated section.
48. If set > 0 in a dual porosity single permeability run, then if any fracture cells are made inactive because the fracture cell pore volumes fall below the threshold set by [MINPV](#) or [MINPVV](#), the corresponding matrix cells are also inactivated.
- If set >1, then any active matrix cells with a corresponding inactive fracture cell are made inactive, for whatever reason the fracture cell is inactive (whether or not this is due to [MINPV](#) or [MINPVV](#)).
49. If set > 0, then well efficiency factors are not taken into account when summing the well ALQs to compare the group lift gas rates with their maximum lift capacities set in keyword [GLIFTLIM](#). This restores back compatibility with pre-96A versions of ECLIPSE, in which efficiency factors are not taken into account.
50. If set > 0, then the nine-point scheme is only applied in the areal dimensions. The option is not used at present.
51. If set = 1, temporal interpolation is used for the first local solution following a global timestep, and the state variable is reset in the global halo cells surrounding the LGR during temporal interpolation. This may improve convergence if the LGR takes several mini-steps to synchronize with the global timestep.

If set = 2, the initial local solution is reset to the values at the end of the previous local timestep when solving the local grids. This was the method used in versions previous to 95A. If set = 3, in addition the flows are recomputed for the first iteration on the local grid.

52. If set = 1, then the input corner point depths for a **VE** run will always be honored as for versions previous to 95A.

If set = 2, the bottom corner point depths for each cell are modified to be consistent with the top depths of the next active cell below in the same column. The number of warning messages issued where this occurs may be limited using **OPTIONS** switch 23.

If set = 0 (the default), the depths are modified to ensure there is no vertical gap between adjacent local and global grid cells on the top and bottom faces of local grids. This is required to calculate the correct solution in local grid cases, for example when a pinched-out layer of non-zero thickness lies adjacent to the top or bottom faces of a local grid.

53. If set > 0, the closure of additional well connections “below” the offending connection in +CON workovers for standard wells is governed purely by their true depth values. This restores the pre-2002A treatment of these workovers.

If set = 0 (the default), the additional connections to be closed are selected according to the connection ordering as discussed in keyword **COMPORD**.

Note that friction wells and multisegment wells always close their connections by their position order along the wellbore, regardless of the setting of this switch.

54. Not used at present.

The control of whether or not well efficiency factors are taken into account in the network branch flows in the extended network model is now governed by item 3 of the **WEFAC** keyword.

55. In the wellbore friction option this can be used to damp the Newton iteration of the well solution if well convergence problems arise. In certain cases, incrementing the well solution by only part of the Newton step, possibly in addition to increasing **MXWSIT** in the **TUNING** keyword, may overcome convergence problems.

If set = n then the increment predicted by the Newton method is damped by a factor of  $1/(1+n)$ . This factor is only applied to the friction wells and values other than  $n=1$  should only be needed in extreme circumstances.

Since this option is primarily intended to overcome convergence problems that sometimes arise when friction wells are initially opened, it is **very** inefficient to leave this option set once the well in question has been successfully opened as, after this time it does not aid, but hinder, the convergence of the well equations.

56. If set > 0, the action of any or **LGRON** keywords in Local Grid Refinement runs is performed before the global grid is solved. By default, the action is applied after the global grid is solved but before the local grids are solved.

If set > 1, the solver weighting factors are set equal to those of the unrefined grid whenever **LGROFF** is encountered.

This switch is ignored for in-place local grids, in which the action is always applied before solving the coupled system.

57. This switch invokes an alternative procedure for handling automatic chokes in the Extended Network option when a low flow target has been set, which may be tried if there are difficulties with the default method. It is quite possible for the choke’s pressure drop iterations to change the pressure at the wellheads sufficiently that all the wells die together. To avoid this happening ECLIPSE ‘chops’ the

iteration in the range of pressures it calculates the wells stop flowing at. By default the well's 'zero flow' THP is calculated by assuming all well variables are fixed, including the BHP, and then calculating the THP at which a zero flow is obtained.

If set = 1 then ECLIPSE calculates the actual THP at which the well would die, now only assuming that the water-cut, gas fraction etc. of the well remain constant.

58. If set > 0, the API tracking option is modified in gas condensate runs to conserve the surface density tracer in the oil phase only. By default the surface density tracer is transported in the oil component present in both the oil and gas phases. This option needs to be used with care, as clearly if a cell's oil is entirely vaporized the 'surface density tracer' becomes infinite, giving a large negative API value.
59. Activates an alternative solver for the Extended Network option. Do **not** use this switch, as the solver is at present currently for experimental purposes only.
60. If set > 0, the dual permeability solver for pre-97A versions is restored. The new dual permeability solver in the 97A release is more efficient, but the old solver is still available for back-compatibility. This option switch should not be used with the CPR linear solver.
61. Not used at present.
62. Ensures back-compatibility with previous versions of ECLIPSE post-processors. Additional information on the ECLIPSE output files may not be treated correctly by pre-98A versions of GRAF and RTView, in which case setting this switch to **negative** produces output which can be loaded into these old versions.
63. Controls the calculation of the hydrostatic head between each connection of a multisegment well and its corresponding grid block. This depends on the difference in depth between the wellbore at the connection and the center of the grid block. The hydrostatic head is calculated using an average density of the fluid mixture in the grid block, weighted according to relative permeability so that only mobile phases contribute. The head is calculated at the start of each timestep and remains constant over the timestep.

If set > 0, the head is also averaged with its value of the previous timestep, to damp out any oscillations that may be caused by the use of explicit quantities. The averaging depends on the value n of this switch:

$$H(\text{used}) = (H(\text{current}) + nH(\text{previous})) / (n + 1)$$

64. Activates options for tracer modeling. Do **not** use this switch as it is currently intended for development purposes only.
65. If set >0, in runs using flux boundary conditions certain error conditions will be reduced to warnings to allow the run to proceed.

If set >0, in a full field DUMPFLUX run, any error messages about wells connecting to multiple flux regions or local grids being situated adjacent to flux boundaries are replaced by warnings. These remain strict errors in the reduced flux USEFLUX run when wells connect both inside and outside the USEFLUX region or if any local grids are adjacent to the USEFLUX region. This switch is useful in cases with many flux regions where it is known *a priori* which flux region numbers constitute the USEFLUX region (using FLUXREG in the reduced run) and that there is no problem with the placing of local grids or wells in the reduced run.

If set >1, in a reduced flux USEFLUX run, any error conditions relating to local grids on the boundary of the reduced flux region are suppressed. Use this option with extreme care as the solutions are probably meaningless since the flux flows are ignored in such cases. This is only added for back-compatibility with versions prior to 98A where the boundary of the reduced region only connected to

the rest of the grid using non-neighbor connections and the error check was missing. Please do **not** use this.

66. If set > 0, it restores pre-98A functionality to Item 1 of record 2 in the [PRORDER](#) keyword and to the QDRILL option in the [WDRILTIM](#) keyword.
67. With effect from the 2014.1 release, this item is no longer available.
68. If set >0, it restores the pre-98A treatment of well connection terms in the preconditioner used to solve the linear equations at each Newton iteration of the timestep. The [OPTIONS](#) keyword should be entered at the top of the dataset. This has no effect when using the Parallel or multisegment well options.
69. Not used at present.
70. If set >0, it restores pre-99A definition of the [SIGMAGD](#) keyword. Pre-99A, the gravity drainage transmissibility was calculated using the X-permeability in the matrix, whereas post-99A the Z-permeability is used. The same effect can be achieved by setting the Z-permeabilities equal to the X-permeabilities in the matrix cells, as these data are not used elsewhere.
71. If set > 0, it restores pre-99A initialization of wells. In pre-99A versions of the code, every time certain well control keywords were called ([WCONPROD](#) for example), the well flows were re-initialized to zero. Now, unless the well has changed type, the well flows are not re-initialized. This has an effect on the guide rate calculation which can lead to small differences of behavior under group control; immediately after one of these keywords the well guide rate phase ratios can now be calculated from the latest flow rate ratios instead of resorting to the potential ratios.
72. Not used at present.
73. Not used at present.

Use item 4 of keyword [WVFPEXP](#) to prevent wells switching to THP control while they are constrained to operate on the unstable side of their VFP curve.

74. When modeling oil-wet systems with the end point scaling option activated, it is advantageous to be able to scale the water-oil capillary pressure at the maximum water saturation (using keyword [PCW](#)) rather than at the entry (connate) water saturation (where the water saturation equals [SWLPC](#)). This switch caters for this situation. Of rather less interest, but for completeness, it is possible to scale the gas-oil capillary pressure (keyword [PCG](#)) at connate rather than maximum gas saturation using this option switch.

If this option is non-zero and divisible by 2 then the water-oil capillary pressure is scaled at the maximum water saturation; and if it is non-zero and divisible by 3 then the gas-oil capillary pressure is scaled at the connate gas saturation.

If set to 1, then any water capillary pressure curves for which  $P_{cow}$  is entirely positive are chosen as water-wet and scaled at the entry saturation [SWLPC](#) while any for which  $P_{cow}$  is entirely negative are scaled at the maximum saturation [SWU](#). For mixed wettability curves, it would be a bit of an illusion to arbitrarily choose which end point to scale at, so setting this option switch to 1 does nothing for such curves

When the [SWATINIT](#) keyword is used to match an initial water distribution then the scaling on  $P_{cow}$  is more sensible if this option is set to 1 when the rocks are either water wet or oil wet (but no mixed wettability rocks). When the [SWATINIT](#) keyword is used to match an initial water distribution for mixed wettability rocks and positive capillary pressure dominated then the scaling on  $P_{cow}$  is more sensible if this option is set to 5 (minimum capillary pressure is fixed). When the [SWATINIT](#) keyword is used to match an initial water distribution for mixed wettability rocks and negative capillary

pressure dominated then the scaling on  $P_{cow}$  is more sensible if this option is set to 7 (maximum capillary pressure is fixed). Note that setting this option to either 5 or 7 does not scale the capillary pressure above GOC, therefore, `SWATINIT` cannot be honored above GOC.

75. This switch is reserved for developer use - do not use.
76. If set to be non-zero, it turns off the monotonicity checks for the saturated concentration of surfactant adsorbed by the rock formation entered in the `SURFADS` keyword.
77. Restores back compatibility with the pre-2000A treatment of drift flux in multisegment wells.
  - If set > 0 the pre-2000A oil-water slip model is used instead of the formula proposed by Hasan and Kabir.
  - If set > 1 then in addition, in a segment inclined at an angle  $\theta$  from the vertical, the drift velocity is the value calculated for vertical flow multiplied by  $\cos \theta$ , instead of being multiplied by  $(\cos \theta)^{0.5}(1 + \sin \theta)^2$ .
78. Restores the use of scratch files for pre-processing geometry data for non-neighbor connections. This may be required on systems with insufficient virtual memory to process the NNCs in memory.
79. If set > 0, the pre-2000A capillary pressure hysteresis behavior is restored; cells with an initial saturation below the wetting phase critical value uses the bounding imbibition curve. The present default behavior is to follow a scanning curve.
  - If set = -1, the pre-2001A `STONE1` three phase relative permeability behavior is restored in end-point scaling cases.

---

**Note:** This is only applicable when switched on in the `RUNSPEC` section.

---

80. Superseded by the `HYMOBGDR` keyword.
81. Restores the pre-2000A ‘capping’ of the polymer concentration. If set > 0, the concentration is capped at a value of  $(\text{OPTIONS}(81) + 1)$  times the maximum injected concentration. A value of 1 restores the pre-2000A behavior of capping at twice the maximum injected polymer concentration.
82. Removes restriction on updating grid block sizes in a local grid refinement. This is only possible for use with block centered geometry.
83. Calculated values of saturations can be slightly less than 0, or slightly greater than 1 - the discrepancy depending on the accuracy of the simulation run. Although this can be useful for gauging the accuracy of the simulation it can be awkward for reporting purposes. If this flag is set > 0, values in the output files are rounded up to 0 or rounded down to 1.
84. When using the `TRACTVD` option the code takes mini timesteps to solve the tracer equations. ECLIPSE should calculate the correct number to take itself. If, for some reason, it is suspected that an instability in the calculation has arisen because ECLIPSE has chosen timesteps too large, the number of mini timesteps can be increased by a factor of  $\text{OPTIONS}(84)+1$ .
  - If negative then the number of mini timesteps will be limited to  $-\text{OPTIONS}(84)$ . This should only be used with great care!
85. Restores the pre-2005A calculation of connection voidage rates at the reference pressure for the well (see item 13 of `WEL SPECS`). The default behavior in 2005A is that a connection’s voidage rate is calculated at the reference pressure for the fluid-in-place region of the connected grid block.
86. Write internal to natural index array to restart file.

87. Restores pre-2005A behavior of the multisegment well model with tracers.
88. The default behavior is for the emulsion viscosity model to be activated in keyword [WSEGSICD](#) and deactivated in keyword [WSEGAICD](#). If this switch is set equal to 1 the emulsion viscosity model is deactivated in keyword [WSEGSICD](#). If set equal to 2 the emulsion viscosity model is activated in keyword [WSEGAICD](#). If set equal to 3 the emulsion viscosity model is both deactivated in keyword [WSEGSICD](#) and activated in keyword [WSEGAICD](#).
89. Relax the monotonic restriction of the [ROCKTAB](#) keyword, allowing non-monotonic pore volume multipliers for Coal Bed Methane runs.
90. If a multiple of 2 then the closure of history matched wells with zero production rates and banned crossflow will not automatically occur.  
  
If a multiple of 3 then the closure of injection wells with zero injection rates and banned crossflow will not automatically occur.  
  
If a multiple of 5 then the derivative limiting in the solvent option (introduced in 2005A) will be turned off.
91. Restores pre-2006.1 behavior in the accumulation of the solution and residual in the linear solver. The default behavior in 2006.1 uses an improved numerical formulation (which is more stable for cells with small pore volume).
92. If set greater than zero, the default behavior of the VFP table specification in the [WCONINJE](#) keyword is changed so that a zero or default value indicates that the previously specified VFP table for this well should continue to be used. (The standard default here is that if a zero or default value is specified, then no THP calculations are performed.)
93. Restores pre-2006.1 well name and well list template matching behavior.
94. If set to a non-zero value, this option restores the pre-2006.1 RS extrapolation, that is a straight linear extrapolation.
95. If set greater than 0 modifies the parallel linear solver to remove connections generated to cells which are in fact completely isolated from the rest of the reservoir.
96. Using ECLIPSE releases from 2008.2 until 2013.1, the derivative of the pore volume with respect to pressure in the Palmer-Mansoori rock model (see the [ROCKPAMA](#) keyword) can be modified for stability. This can help if you encounter convergence problems running the Palmer-Mansoori model.
  - In 2009.1, the default behavior is that the volumetric strain effect is ignored only if it dominates the pressure effect. If a value of 1 is used, then the pre-2009.1 default behavior is restored. If a value of 2 is used, then the volumetric strain effect on this derivative is always ignored.
  - In 2008.2, the default behavior is the same as pre-2008.2. If a value of 1 is used, then the volumetric strain effect on this derivative is always ignored. If a value of 2 is used, then the volumetric strain effect is ignored only if it dominates the pressure effect.
  - From 2013.1 this switch has no effect unless `OPTIONS` item 200 is also set.
97. If set to a non-zero value, then this option restores the pre-2007.1 behavior of some sensitive constants within the program. At 2007.1, the precision of these program constants was increased to reduce cross-platform (and cross-version) differences in behavior.
98. For developer use
99. Generates warning messages from the [AQUANCON](#) keyword when cells cannot be connected to the aquifer because there is an active cell on the aquifer side of the current cell.

100. If set to a value greater than 0, this value is used to specify the minimum percentage separation between two consecutive Rs values for the interpolation of the [PVTO](#) tables when API Tracking is used. An improved interpolation which avoids crossing lines in the interpolated tables is also selected. The fractional separation is specified using the formula  $RsSep = 0.01 * OPTIONS(100)$ . The minimum separation criterion is then calculated as  $((Rs2-Rs1)/Rs1) \geq RsSep$ , where Rs1 and Rs2 are the two Rs nodes being compared. Note that this separation should not be too large. The minimum separation is constrained to be no smaller than 0.01. If this item is defaulted or set to a negative or zero value, the minimum separation criterion between successive Rs nodes defaults to  $10^{-7}$ .
101. If  $> 0$ , this restores pre-2007.1 (and also some pre-2009.1) behavior related to well potential calculations.
- If a multiple of 2, this reverses a 2007.1 fix in the allocation of work-space for well potential calculations. This fix only affects models which use an old-style [RUNSPEC](#) section, and it may result in a change in the reported well quantities in such models. The new behavior can also be produced with pre-2007.1 code by converting the model to use a new-style [RUNSPEC](#) section (for example, using [ECLIPSE Office](#)).
  - If a multiple of 3, this restores the pre-2007.1 logic for only calculating potentials on wells for which they are required. This is equivalent to setting the first item of the [WPOTCALC](#) keyword to 'NO'.
  - If a multiple of 5, this reverses a 2007.1 fix in the preservation of the actual well control mode when well potentials are calculated for the prioritization option (see the [PRIORITY](#) keyword) or for prioritized drilling queues (see the [WDRILPRI](#) keyword).
  - If a multiple of 7, this reverses a 2009.1 fix in the calculation of generalized pseudo-pressure blocking factor during well potential calculations.
102. If set to a non-zero value, the pre-2007.1 implementation of the [BRINE](#) model is restored. This affects the PVT calculations in the reservoir and wells.
103. This controls aspects of the [GCONSALE](#) keyword.
- If set to a value greater than zero value, this restores pre-2007.1 behavior.  
  
In cases where a net sales, import and consumption target of zero has been specified, this sets the [MAXR](#) procedure re-injection fraction limit to a value of 1, instead of the new default value of 100.  
  
It also restores the handling of the lower limit in which a non-positive lower limit was taken to mean that no lower limit was to be applied.
  - If set to a value less than zero, this sets the [MAXR](#) procedure re-injection fraction limit to  $-OPTIONS(103)$  in cases where a net sales, import and consumption target of zero has been specified.
104. If set to a non-zero value, the pre-2007.1 implementations of the scale and gas calorific value models are restored. Prior to 2007.1 the tracer concentrations used in the scale and gas calorific value calculations were lagged by two timesteps. From 2007.1 the lag has been reduced to a single timestep.
105. If set to a non-zero value, the pre-2007.1 use of group efficiency factors (specified with the [GEFAC](#) keyword) in reservoir coupling runs is restored. At 2007.1, various fixes were made to this part of the code.
106. If set to a non-zero value, the pre-2007.1 gravity drainage behavior is restored. At 2007.1, a bug was fixed which would may a change in results for models that contain the [GRAVDR](#) keyword.

107. If set to a non-zero value, the pre-2007.1 behavior when the [INTPC](#) option for integrated capillary pressure is used with the alternative gravity drainage model specified by [GRAVDRM](#) is restored. Although [INTPC](#) was previously allowed with [GRAVDRM](#), the pre-2007.1 behavior did not lead to the correct final recovery in this case, whereas the 2007.1 behavior should do so.
108. If set to a non-zero value, the pre-2008.1 behavior for scale deposition is restored. Scale deposition will only be applied to producing completions (which could belong to producers or crossflowing injectors).
109. If set to a non-zero value, the pre-2007.1 behavior of the [RPTONLY](#) and [RPTONLYO](#) keywords in the [SUMMARY](#) section of restarted runs is restored. At 2007.1 this behavior was changed so that these keywords were ignored if they were present in the [SUMMARY](#) section in restarted runs, and they had to be re-specified at or after the restart time in the [SCHEDULE](#) section.
110. If set to a non-zero value, the pre-2007.3 behavior of the [AQUCHWAT](#) keyword is restored. The density calculation for the water in the aquifer, which is then used in the aquifer inflow equation, has been altered to incorporate the aquifer reference pressure.
111. If set to a non-zero value the pre-2008.1 behavior of the [WTEST](#) keyword is restored. This causes the [WTEST](#) keyword to reset for wells closed as part of a group of producers closed by a single event
112. If set to 1 the pre-2008.1 behavior of the [RADFIN4](#) keyword is restored. The 2008.1 behavior should lead to the porosities always being assigned correctly to the LGR cells, whereas the pre-2008.1 behavior can be incorrect for the case where  $\text{THETA}=4$ .
113. If set to 1 the pre-2008.1 behavior of API tracking in local grid refinements is restored. The 2008.1 behavior correctly calculates oil density in global grid cells using an oil-in-place weighting of local grid cell values.
114. If set to a non-zero value, an improved water and solvent saturation bound-checking is performed.
115. If set to a non-zero value the pre-2008.1 behavior of analytic aquifer inflow equations is used. The 2008.1 behavior correctly calculates the flow from the reservoir to the aquifer in the case of connate water/gas. This change affects all analytical aquifers.
116. This option affects the [POLYMER](#) or [FOAM](#) models with the shear thinning option for releases between 2008.2 and pre-2011.1. If set to non-zero value in these releases, it reverts to pre-2008.1 behavior, which is now the default behavior (upstreamed polymer/foam concentration in the injecting well).
117. Affects dual porosity and dual permeability values using the [MULTNUM](#), [FLUXNUM](#), [PINCHNUM](#) or [OPERNUM](#) keywords. If this option is 1, then [MULTNUM](#) regions must be specified separately for matrix and fracture. If this option is 2 or greater, then regions specified by all of these keywords must be specified separately for matrix and fracture.
118. If set to a non-zero value the pre-2008.2 behavior for the treatment of the [DRSDT](#) or [DRVDT](#) keywords in the presence of vaporized oil and dissolved gas respectively is restored; that is, the limits specified by these keywords are ignored in the presence of vaporized oil and dissolved gas.
119. If set to a non-zero value the pre-2009.1 capillary pressure calculations for the surfactant model are restored. See "[Surfactant model](#)" in the *ECLIPSE Technical Description*.
120. If set to 1 the pre-2008.2 convergence criterion for the standard solver used for tracer tracking is restored.
121. If set to a non-zero value the pre-2008.2 behavior for the calculation of relative permeabilities using Stone's Second Method ([STONE2](#)) with end-point scaling is restored.
122. If set to 1, the pre-2008.2 polymer dead pore volume model is restored.

123. This option affects the behavior of Carter-Tracy aquifer influence function tables. In 2009.1, the interpolation of influence function tables has been improved. The handling of extrapolated data was modified in 2009.2. In 2010.1, the default Carter-Tracy influence table has been extended to cover larger dimensionless time values. If set to 1, the pre-2009.1 behavior is restored. If set to 2, the 2009.1 behavior is restored. If set to 3, the 2009.2 behavior is restored.
124. If set to a non-zero value the pre-2009.1 calculation of the summary quantities FTPC, GTPC, WTPC, CTPC, FTIC, GTIC, WTIC and CTIC for concentrations of partitioned tracers will be restored.
125. If set to a positive value  $N$ , this changes the tolerance used when checking whether the current simulation time is a report time to a new tolerance of  $10^{-N}$ . The default tolerance is  $10^{-3}$  which is equivalent to setting this 3.
126. If set to 1, all active tracers will be solved in each Newton iteration instead of at the end of a timestep. This option can be used to reduce time lag in tracer dependent properties. If set to 2, all active tracers will be solved at the end of a timestep. The default behavior is to solve all tracers at the end of a timestep, unless `ECLMC` is specified in the `RUNSPEC` section, in which case the default behavior is to solve Brine, Surfactant and Alkaline tracers in each Newton iteration, but all other tracers at the end of a timestep.
127. If set to a positive value, the pre-2009.1 behavior for tracer adsorption, using a non-cascade tracer solver, is restored. Prior to 2009.1 the adsorbed tracer amount was not properly reset following a convergence failure.
128. If set to a non-zero value, the pre-2009.1 behavior for the calculation of residual oil saturation for the Stone I relative permeability model with end-point scaling is restored. Prior 2009.1, in some circumstances, the critical saturations used in the calculation of the residual oil were not subject to end-point scaling.
129. For developer use.
130. If set to a non-zero value, the pre-2009.1 behavior for the specific heat unit conversion used in the temperature option is restored.
131. Except for the `MISCNUM` keyword, the documentation states that all `REGIONS` section keywords should be assigned a minimum value of 1. However, it is possible that pre-processor or manual edits to a keyword definition, can set a value of 0, even for inactive cells. To be compatible with the treatment of `REGIONS` section keywords using `EQUALS` / `ADD` / `MULTIPLY` keywords, if `REGIONS` data is specified using a `REGIONS` keyword directly, then error messages can be output for both active and inactive cells. To do this, set this switch to a non-zero value.
132. If set to a non-zero value the pre-2009.1 behavior for `WLIFT` is obtained. Prior to 2009.1 a well would only be revived once when it died on THP control by increasing its Artificial Lift Quantity even if the maximum ALQ value had not been reached.
133. If set to a non-zero value the guide rate calculation method of ECLIPSE 300 is used. Well and group guide rates are allowed to change for the first `NUPCOL` Newton iterations instead of remaining fixed throughout the timestep.
134. If set to 1, a wider range of global cells is used as reference when calculating the geometry of LGR cells. This can provide better output to the EGRID file for visualization purposes.
135. If set to a positive value, the pre-2009.1 interpolation for the `SOF32D` saturation functions family is restored.
136. If set to a non-zero value, the pre-2009.1 behavior for the decay of an adsorbed tracer using a non-cascade tracer solver is restored.

137. If set to a non-zero value, the pre-2009.1 behavior for inter-block velocity calculations is restored.
138. If set to a non-zero value, the pre-2009.1 behavior for the modification of relative permeabilities using [DPKRMOD](#) in dual porosity models is restored.
139. If set to a multiple of 2, the switch activates an alternative method for calculating the mixture density in stagnant connections at the bottom of the well. Instead of using average well phase fractions to estimate the density, it is set equal to the density at the lowest open connection. If set to a multiple of 3, the switch forces crossflowing connections to use the segmented density calculation method instead of the average calculation. This option is only applicable to non-friction wells using the SEG density calculation method (see item 12 of [WELSPECS](#)). This option can be useful in wells with large density variations between the uppermost and lowermost connections where the AVG density calculation method can be inappropriate. However, it should only be used during problem periods and then be switched off otherwise as it can cause convergence problems.
140. If set to a non-zero value, the pre-2009.2 behavior for the interpolation of [PVTO](#) tables for API tracking is restored. For the 2009.2 version onwards the interpolation procedure has been modified to avoid duplicate Rs nodes which could occur for some combinations of table data and minimum Rs node spacing.
141. If set to 1, the pre-2009.2 behavior for the modification of non-neighbor connections in cells which have been coarsened is restored. For the 2009.2 version onwards, the handling of NNCs across x- and y-faults is much improved, and the transmissibility of all NNCs within coarsenings may be slightly altered.  
  
If set to 2, the pre-2011.1 behavior for the transmissibility calculations for coarse cells in which some fine cells are active and others inactive is restored. For the 2011.1 version onwards, a single inactive fine cell in a coarse cell will not zero the transmissibility for the entire coarse cell.  
  
This option should only be used to confirm that a particular change in behavior is due to the improved modeling in 2009.2 and later.
142. Reserved for future use.
143. If set to a non-zero value, this restores the pre-2010.1 behavior for the reporting of partitioned tracer flowrates in river reaches.
144. If set to a non-zero value, the pre-2009.2 behavior for calculating flow rate limits for the [WELDRAW](#) keyword is used.
145. As explained in item 12 of [WELSPECS](#), the hydrostatic heads calculated using segmented densities in the wellbore are damped to reduce the likelihood of stability problems. This is done by combining values from the previous timestep with those of the current timestep in a weighted average. An error has been identified in the implementation of this damping which meant that more damping was being applied than intended. This error has been fixed in the 2010.1 version of the simulator but has not been made the default behavior as it may result in changes in simulation results. The correct damping can be applied by setting this item to a non-zero value.
146. If set to a non-zero value, fluid in place reports and pressure averages include contributions from excavated blocks.
147. If set to a non-zero value, the pre-2010.1 behavior is restored for relative permeability interpolation based on capillary number in the Surfactant Model. For the 2010.1 version onwards the interpolation between immiscible and miscible relative permeability curves is only performed for blocks with a non-zero surfactant concentration. The immiscible curves are used for blocks with a zero surfactant concentration.

148. If set to a non-zero value, the pre-2010.1 behavior of river infiltration equations in the unsaturated regime is restored.
149. If set to a non-zero value, the pre-2010.1 behavior is restored for solving tracers in combination with multisegment wells (MSWs). For the 2010.1 version onwards, an error has been fixed in the coupled iterative solution of the tracers which previously led to wrong tracer rates and concentrations in the MSW segments. The change affects single phase, two phase and partitioned tracers.
150. If set to a non-zero value, the pre-2010.1 behavior is restored for [GECON](#) item 8. For the 2010.1 version onwards, the simulation will not be stopped if a group includes a follow-on well due to be opened in the next timestep.
151. If set to a non-zero value, the pre-2010.1 behavior is restored for calculating pinchout transmissibility values when item 4 of the [PINCH](#) keyword is set to ALL. This had an effect only in the 2010.1 and 2010.2 releases. From 2011.1 onwards the pre-2010.1 behavior has been restored unconditionally.
152. If set to a non-zero value, the pre-2010.1 behavior for the [RPTRST](#) argument `RFIP` is restored. The pre-2010.1 behavior calculated reservoir fluid-in-place to be surface fluid-in-place multiplied by formation volume factor. From 2010.1 this is calculated as pore volume multiplied by saturation.
153. Reserved.
154. If set to 1, the pre-2011.1 behavior of the tracer-tracking option ([TRACERS](#)) is activated. This affects how the injected concentration for crossflowing wells is calculated.
155. This item relates to protection against bad cross-processor NNC set-up
  - If set to 1, a `BUG` message protecting against bad set-ups of cross-processor NNCs is downgraded to a `WARNING` message. This may be used to allow some cases to run which would otherwise terminate with a `BUG` message. However, this is not recommended as the `BUG` message does indicate a serious problem.
  - If set to 2, all the effects of setting to 1 are introduced. Furthermore, the pre-2010.2 behavior regarding NNCs spanning multiple processors in parallel is restored. This behavior is known to be problematic in certain cases.
156. If set to a non-zero value, the pre-2010.2 method for end-point scaling is used with the minimum oil saturation tables ([SOMGAS](#) or [SOMWAT](#)).
157. If set to 1, the pre-2011.1 handling of `SUMMARY` keywords `AAQR`, `AAQT`, `ALQR` and `ALQT` is restored. Before 2011.1, the list associated with these keywords could contain an element referring to a gas analytic aquifer. If the list was empty, all analytic aquifers including gas one were listed. From the 2011.1 version on, using these keywords with a gas analytic aquifer is not allowed. Additionally, the `ALL` summary keyword implies the keywords `AAQRG` and `AAQTG`.
158. If set to 1, the phase saturations and oil-gas ratios are limited to explicitly bounded values. It is possible for a non-linear iteration to produce saturation values that are outside the physical range between 0.0 and 1.0. Usually the amount by which they are outside this range is small, but to prevent any problems with physical correlations, setting this option to 1 forces all saturations (for water, gas, oil and solvent) to be zero if less than zero, and to be one if greater than one, at the end of each non-linear iteration. Similarly, oil-gas ratios will be forced to zero if they are negative.
159. Reserved.
160. This item relates to changes to looped MSWs and ICDs. Pre-2011.1 behavior may be obtained by setting this item to 42 (that is the first, second and fourth bullet points below). The item has the following behavior:

- If set to a multiple of 2, the pre-2011.1 looped MSW behavior is restored. This principally alters the MSW solution predictor.
  - If set to a multiple of 3, the pre-2011.1 behavior of item 6 of [WSEGSOLV](#) is restored. This affects the range of linearization for ICDs, AICDs, labyrinth devices and valves in looped MSWs.
  - If set to a multiple of 5, an alternative MSW linearization is applied for looped wells for high segment flow rates.
  - If set to a multiple of 7, the pre-2011.1 ICD solver implementation is restored.
161. If set to 1, the pre-2011.1 miscible viscosity and density calculations are restored.  
If set to 2, the 2011.1 miscible viscosity and density calculations are restored.  
The default miscible viscosity and density calculations are similar to the original pre-2011.1 calculations.
162. If set to 1, the pre-2011.1 behavior is restored for the reporting of the scaled table end-points in the debug file when [EPSDBGS](#) or [EPSDEBUG](#) is specified. For the 2011.1 version the scaled values are reported when no scaling is applied.
163. If set to 1, duplicated records in the [FAULTS](#) keyword are ignored. If a fault is specified twice, any multipliers associated with it are applied twice.
164. If set to 1, the pre-2011.1 behavior is restored when reading the [SURFVISC](#) keyword. From 2011.1 onwards the water viscosity in [SURFVISC](#) at zero surfactant concentration and reference pressure must be equal to the value entered in the [PVTW](#) keyword.
165. If set to 1, the pre-2011.1 behavior for initial tracer concentrations in cells containing no host phase is restored. This switch also activates equivalent behavior for the initial concentrations of surfactant, foam and polymer.
166. If set to a 1, the pre-2011.1 behavior is restored for the modeling of the two-phase relative permeability of oil to gas when using the [EHYSTR](#) or [EHYSTRR](#) keywords with item 2 set to 4 (Killough hysteresis applied to both wetting and non-wetting phases). In some cases it has been found that the two-phase relative permeability of oil to gas can exceed the maximum value specified in the drainage and imbibition oil saturation function tables, or the maximum value specified via the end-point scaling keywords [KRO](#) and [IKRO](#) (and their directional and irreversible variants) if [ENDSCALE](#) has been specified. Depending upon the choice of three-phase relative permeability model, this can result in the three-phase oil relative permeability also exceeding the maximum value from the tables or end-points. This has been addressed for the 2011.1 version by constraining the maximum value of the two-phase relative permeability of oil to gas to the maximum of the values specified in the drainage or imbibition tables, or end-points. The two-phase oil relative permeability of oil to gas is combined with the two-phase oil relative permeability of oil to water to form the three-phase oil relative permeability. The constraint described here, therefore, will apply to all three-phase oil relative permeability models available in ECLIPSE 100.
167. Reserved.
168. If set to 1, the pre-2011.1 behavior of [WDFACCOR](#) is recovered. This changes D-factor calculations for flow-dependent skin factor if fewer than 3 phases are present in reservoir.
169. If set to 1, the pre-2011.1 behavior is restored for the treatment of the [NOHYST](#) keyword. Prior to 2011.1, hysteresis was not deselected by this keyword if specified after the [SATOPTS](#) keyword or if WAG hysteresis was specified via the [WAGHYSTR](#) keyword.

170. If set to 1, this deactivates the processing of the `ACTNUM` data specified in an EGRID file identified by the `GDFILE` keyword. Note that in previous versions, the default was not to process `ACTNUM`; from 2011.1, processing `ACTNUM` is the default.
171. If set to a negative value, the threshold tolerance for the adsorption calculation when using the cascade tracer solver is changed. The threshold tolerance affects the adsorption by skipping the calculation in cells where the amount of tracer and the rock mass is less than the threshold value. Item 171 can be used to control the threshold value. If set to a negative value, the threshold value is taken as  $10^N$  where  $N$  is the value specified in item 171. The default value is  $10^{-12}$ . The pre-2011.1 value can be restored by setting  $N$  to -6. This option affects active tracers, such as surfactant, alkaline and foam, as well as environmental tracers solved by the cascade method.
172. If set to 1, the pre-2011.1 behavior of `GSSCPTST` is recovered. This affects simulations with local grid refinements.
173. If set to 1, the pressure is chopped if it falls below 1 atmosphere.
174. If set to 1, the pre-2011.1 behavior is restored for the treatment of the `SWATINIT` keyword when read via the `IMPORT` keyword. Prior to 2011.1, this method of reading the `SWATINIT` keyword resulted in some of the saturation table data consistency checks being omitted.
175. Reserved.
176. If set to 1 this reverts to pre-2012.1 behavior for polymer and brine in standard wells.
177. This option allows the use of the gradient option in parallel runs. This combination of features is unsupported and so should be used with caution as it may lead to unexpected results or errors.
178. If set to 1, the pre-2011.2 behavior for the processing of `JFUNCR` with hysteresis is restored. Prior to 2011.2 the per region processing of J-functions was only applied to the imbibition saturation tables for hysteretic models.
179. If set to 1, the pre-2011.2 behavior for calculating radial velocities is restored.
180. If set to 1, this restores the pre-2012.1 behavior for table look up for the coal bed methane option, using `SATNUM` and `PVTNUM` instead of `COALNUM`. This affect the keywords `LANGMUIR`, `LANGSOLV`, `COALADS`, `COALPP` and `DIFFCOAL`.
181. Not used.
182. This switch reverts part or all of the looped multisegment well (MSW) solver to the pre-2012.1 behavior.
- If positive and divisible by 2, the looped MSW solver will not resolve unconverged linear solutions using a direct solver. This may speed up the simulation, but may lead to failed well solutions.
  - If positive and divisible by 3, the predictor will not set every segment to a non-zero flow. This can lead to a singular well Jacobian and therefore problems with the well solution.
  - If positive and divisible by 5, the pre-2012.1 behavior of the tracer solver with looped multisegment wells is recovered. This behavior change can only be made in the `RUNSPEC` section.
183. When set to 1, this switch reverts the network balancing option to pre-2012.1 behavior. An additional check was added to the network balancing option to ensure that all well THP targets reflected their parent group's node pressure. This check improves the accuracy of network balancing in certain circumstances such as when the reservoir coupling option is in use.

184. This switch reverts the behavior of hysteresis to pre-2012.1 behavior. It may affect two separate behaviors:
- When set to a positive value divisible by 2, this switch reverts the enumeration of reservoirs with hysteresis to pre-2012.1 behavior. This alters the initial  $R_v$  value in the reservoir to take account of capillary pressure.
  - When set to a positive value divisible by 3, this switch reverts the calculation of critical gas saturation used to determine saturation chops to the pre-2012.1 behavior. Prior to 2012.1 the saturation curves were sometimes taken from the wrong region for this calculation.
185. This switch allows restarting from versions before 2012.1 if the combination of tracers with polymer or solvent or GI-condensate has been used. In this case, older versions of the code may have corrupted the data. Use of this switch is not recommended.
186. If set to 1, this switch reverts the [WCONPROD](#) and [WCONINJE](#) keywords to their pre-2012.1 behavior with respect to initialization for multisegment wells. Prior to 2012.1, any change of control mode by [WCONPROD](#) or [WCONINJE](#) caused the first guess of the well solution to be re-initialized. From 2012.1, this is not the case unless this option is set. This affects multisegment well convergence characteristics.
187. When set to 1, this switch reverts partitioned tracers to pre-2012.1 behavior. Prior to 2012.1, injecting connection flows of tracer were incorrectly calculated during the solving of the tracer equations.
188. Reserved.
189. When set to 1, this switch reverts the behavior of GSG non-neighbor connection and transmissibility allocation to pre-2012.1 behavior. This behavior in parallel can cause, in some situations, the non-neighbor connections and transmissibilities to be incorrectly communicated between processors.
190. If set to 1 (in the [SOLUTION](#) or earlier sections), the pre-2013.1 method of checking input enumerated saturation data is selected. For the 2013.1 version, the checking of input enumerated saturation data has been extended to check the data values against their expected end-points for end-point data derived both from saturation tables and end-point scaling arrays and tables.
191. This item has been deprecated. To control the number of messages output for dead block connections use item 13 of the [MESSAGES](#) keyword or [OPTIONS](#) [item 220](#).
192. This switch controls the number of warnings output regarding linear convergence problems. It can restore pre-2013.1 levels or suppress message output further.
- If set to 1, this switch restores the pre-2013.1 verbosity of messages regarding linear equation solver convergence problems
  - If set to -1, it reduces messages regarding linear equation solver convergence problems further.
193. If set to 1, the pre-2013.1 behavior of approaching report steps will be active when using the [ZIPPY2](#) keyword.
194. If set to 1, the pre-2012.2 behavior for assigning saturation end-points from end-point scaling arrays for two-phase models will be restored.
195. If set to 1, the pre-2012.2 behavior for a zero determinant detected in the linear solver is restored (stopping with an error). The new behavior is to chop the timestep and try to recover.
196. This option should not be needed in 2013.1 and later releases.
- If set to 1, the pre-2012.1 treatment of network choke branches will be used.

197. If set to 1, a modified WAG hysteresis gas relative permeability model will be used in situations where the transformed gas saturation at the start of the secondary or subsequent drainage cycle falls below the gas saturation at the start of the previous drainage cycle. This modification prevents excessive falls in gas relative permeability which can occur in such circumstances when the primary drainage curve is used to construct the secondary drainage cycle. More details are provided under "[Hysteresis in WAG floods](#)" in the *ECLIPSE Technical Description*.
198. If a well is set not to allow crossflow ([WELSPECS](#) item 10) then, if there are convergence problems, this option will close any open connections that are trying to back flow and retry the well Newton iteration. This option should be set to the number of re-tries the simulator can perform before moving onto the next reservoir Newton iteration. The option is not enabled for multisegment wells.
199. If set to 1, the pre-2013.1 treatment of directional rock compression transmissibility multipliers will be used. This uses the x-direction multiplier for all NNCs.
200. If set to 1, the pre-2013.1 calculations for [ROCKPAMA](#) will be used. The derivative changes as specified in [OPTIONS](#) item 96 are ignored by default from 2013.1.
201. If set to 1, the additional WAG hysteresis regions specified via the [WH2NUM](#) and [WH3NUM](#) keywords and the associated additional processing (which applies whether these have been specified or defaulted) will be ignored. This should be specified in the [RUNSPEC](#) section. This option is only relevant when the [WAGHYSTR](#) keyword has been specified.
202. If set to 1, the pre-2013.1 version of the debug output for the scaled saturation tables specified via either the [EPSDEBUG](#) and [EPSDBGS](#) keywords will be selected.
203. If set to 1, this enables LGRs in [USEFLUX](#) runs where one or more parent cells are inactive because they lie outside the [USEFLUX](#) regions. Note that, by default, such LGRs are disabled.
204. If set to 1, the pre-2013.1 behavior is restored for the model initialization process for the case where item 2 of the [EHYSTR](#) keyword is set to -1.
205. If set to 1, connate gas will be included in the two-point scaling of the oil relative permeability to gas and water; that is, the maximum attainable oil saturation will be assumed to be constrained both by connate water and gas. By default, the connate gas is omitted from these calculations.
206. If set to 1, the pre-2013.1 behavior is restored for well connection ordering. This affects some cases with [COMPORD](#) and [WRFT](#) or [WRFTPLT](#).
207. If set to 1, the pre-2013.1 behavior is restored for tracer calculations in cases with [PARALLEL](#), [VAPOIL](#), [DISGAS](#) and non-neighbor connections. Note that we advise against the use of this option as it recovers incorrect behavior in some cases.
208. If set to 1, the pre-2013.1 behavior is restored for error-checking of the second argument in keywords [PLYVISCS](#), [PLYVISCT](#) and [PLYVSCST](#). In particular, a lower bound of unity is now applied by default; activating this switch will allow any positive value.
209. If set to 1, the pre-2013.2 behavior is restored. The new, default behavior is to use the maximum adsorbed polymer concentration itself in a cell as the reference point for allowing (increasing adsorbate) or disallowing (decreasing adsorbate) changes in the adsorbed concentration. The previous behavior used the maximum solution polymer concentration as a proxy for this and did not take into account salinity changes.
210. If set to 1, the pre-2014.1 behavior is restored for the calculation of relative permeabilities when using the [SURFACT](#) or [LOWSALT](#) models with [ENDSCALE](#).
211. If set to 1, the pre-2014.1 behavior is restored for the calculation of the capillary number when using the [SURFACT](#) and [DUALPORO](#) models.

212. If set to 1, connate gas will be included in the end-point scaling calculation of the saturation at which [KRWR](#) occurs in the end-point scaled saturation space.
- By default connate gas is omitted from these calculations.
213. If set to 1, the pre-2014.1 behavior is restored for the calculation of water relative permeability used as a component in the calculation of the three-phase oil relative permeability for Stone's Second Model [STONE2](#).
- For the 2014.1 version, corrections have been made to the calculation of water relative permeability when subject to hysteresis and end-point scaling.
214. If set to 1, the pre-2014.1 behavior is restored for the calculation of the component cell heights for the [GRAVDR](#) model when used with either the [SURFACT](#) or [LOWSALT](#) models.
215. If set to 1, unset values for enumerated initial pressures in coarsened grids will be replaced with the value from an adjacent cell.
- If set to 2, unset values for all enumerated initial conditions in coarsened grids will be replaced with the value from an adjacent cell.
- This can be used to avoid issues where a pre-processor is unable to assign an enumerated value to an inactive cell which is used as the representative cell for its coarsened cell.
216. If set to 1, the error emitted in parallel when a well is defined using [WELSPECL](#) on an LGR that is switched off is downgraded to a warning.
217. If set to 1, the pre-2014.1 behavior for [VDFLOW](#) is restored such that the value of the inertial coefficient for non-Darcy flow is only applied to the first saturation region when more than one saturation regions have been defined. For the 2014.1 version, the inertial coefficient is applied to all saturation regions.
218. If set to 1, the pre-2014.1 behavior is restored for the non-Darcy flow component specified via the [VDFLOW](#) or [VDFLOWR](#) keyword. Prior to 2014.1 this was **only** applied to the phase mobility calculations for the well connections if the [FHERCHBL](#) keyword had also been specified.
- For the 2014.1 version, by default, the non-Darcy flow component due to the [VDFLOW](#) or [VDFLOWR](#) keyword is not applied to the well connections in any circumstance. If the [VDFLOW](#) or [VDFLOWR](#) flow component is required to be applied to the well connections, this may be enabled by setting this [OPTIONS](#) item to 2. Wells or well completions for which D-Factor calculations have been specified via the [WDFAC](#) keyword the [WDFACCOR](#) keyword or item 12 of the [COMPDAT](#) keyword (or item 13 of the [COMPDATL](#) keyword) will supersede those due to the [VDFLOW](#) or [VDFLOWR](#) keyword.
219. If set to 1, the pre-2014.1 message output format for parallel runs is used; messages from slave processors will not appear in the output files for the master process.
220. If set to 1, the message output limit from [MESSAGES](#) item 13 is ignored.
221. If set to 1, the pre-2014.1 behavior for determining when a non-neighbor connection should be deleted based on its transmissibility is restored. Additionally, values which are below the cutoff value for all of transmissibility, diffusivity and thermal transmissibility will be preserved provided that the NNC itself is preserved. Note that, if this option is used, the diffusivity and thermal transmissibility settings from the [MINNNCT](#) keyword will have no effect.
222. If set to 1, the pre-2014.1 behavior for Killough hysteresis model for water wet systems will be selected. For the 2014.1 version, corrections have been made to the calculation of the wetting phase relative permeability when subject to hysteresis and end-point scaling.
223. If set to 1, more than one occurrence of the [GRIDOPTS](#) keyword is permitted.

224. If set to 1, the pre-2014.1 behavior for **CECON** is restored. UDAs used in **CECON** are applied to all connections in the wells specified with the particular UDA.
225. If set to 1, the pre-2014.1 versions of the **LOWSALT** and **SURFACTW** options are restored. The primary differences between the 2014.1 and pre-2014.1 versions relate to the modeling of end-point scaling when the **ENDSCALE** option has been specified. Prior to the 2014.1 version, end-point scaling was only applied to the high salinity end-points using **SWL** and associated keywords. For the 2014.1 version, end-point scaling has been added for:
- the low salinity (oil-wet) saturation tables by introducing a new set of end-points including **LWSWL**
  - for the high salinity (water-wet) saturation tables by introducing a new set of end-points including **HWSWL**
  - for the low-salinity (water-wet) saturation tables by introducing a new set of end-points including **LWSWL**

**If set to 1, the new end-point scaling arrays may be specified but they will not be used in the simulation.**

226. If set to 1, the effective well bore radius, used in the calculation of the well productivity index, can be greater than the drainage radius. Otherwise, the effective radius will be taken as the minimum of the effective radius and the drainage radius when calculating a well's productivity index. For the ECLIPSE 300 equivalent please refer to [item 317](#) of the **OPTIONS3** keyword.
227. If set to 1, the preferred phase of an injection well is not enforced to match the actual injection phase. For the ECLIPSE 300 equivalent please refer to [item 318](#) of the **OPTIONS3** keyword.
228. By default, prior to polymer shear calculations, ECLIPSE 100 now includes the mobile water saturation in the conversion from flow rate to velocity and, for runs including keyword **SHRATE**, applies a modified conversion factor from velocity to shear rate. If this item is set to 1, this activates the pre-2014.1 conversion from flow rate to velocity in which the mobile water saturation is excluded and may be applied to models that use either **PLYSHEAR** or **PLYSHLOG**.
- If set to 2, this activates the pre-2014.1 conversion from velocity to shear rate and may only be applied to models that use keyword **SHRATE**.
- If set to 3, this activates the pre-2014.1 conversions from flow rate to velocity and from velocity to shear rate and may only be applied to models that use keyword **SHRATE** (see "[Polymer flood model](#)" in the *ECLIPSE Technical Description* for details of the forms of these conversions).
229. If set to 1, the pre-2014.1 behavior for Killough hysteresis model for oil-wet systems will be selected. For the 2014.1 version, corrections have been made in the two phase oil to water relative permeability and connate water saturation was included in the calculation of oil to gas relative permeability.
230. If set to 1, the pre-2014.1 behavior of the 'TRNC' timestepping control for POLYMER/BRINE and SOLVENT runs will be restored.
231. If set to 1, the pre-2014.1 behavior of inverse lookup with three-point end-point scaling will be selected. For the 2014.1 version, corrections have been made in cases where **SCALECRS** is activated.
232. If set to 1, **DUMPFLUX** and **USEFLUX** may be used with various CEOR and tracer options which are normally banned in this combination, but it is the user's responsibility to ensure that no CEOR or tracer effects occur outside the flux boundary.
233. If set to 1, the pre-2014.1 behavior for the input processing of the two-dimensional capillary pressure data specified via the **PCG32D** and **PCW32D** keywords will be restored. Prior to 2014.1, only the first table was used for all saturation regions. If more than table was specified, the second and subsequent

- tables were ignored. For the 2014.1 version, successive tables are read and allocated to their associated saturation regions.
234. If set to 1, the pre-2014.1 behavior for the scaling of gas relative permeability at residual saturation of the displacing phase (**KRGR**) for gas-water models with end-point scaling will be restored. Prior to the 2014.1 version, the residual saturation used to determine the gas relative permeability was calculated using the critical oil in water saturation. For the 2014.1 version, this is calculated using the critical water saturation.
  235. If set to 1, the printed grid property tables in the PRT file will be scaled so that the maximum value in the table is always between 1 and 10. The units are appropriately rescaled to give the correct value overall. The default value of 0 gives the pre-2014.1 scaling, which only allowed certain rescaling magnitudes.
  236. If set to 1, the pre-2014.1 geometry calculations are used to calculate neighbor transmissibilities for corner point geometry. Prior to the 2014.1 version, in some extreme cases (principally with a perfectly vertical fault which has cells on both sides sloping towards the fault) a small transmissibility value can be calculated between cells which are neighbors in i,j,k space even though the cells do not physically touch. When this switch is used, these cell indices and transmissibility values are also output to the debug file.
  237. If set to 1, brine injection with the **WSALT** keyword may be used in dual porosity models with local grid refinements. This combination is banned otherwise. It is the user's responsibility to ensure that the local grid properties do not differ from global cells.
  238. If set to 1, the the pre-2014.1 behavior of the default interphase threshold pressure calculation will be activated. For the 2014.1 version, the interphase threshold pressure when defaulting item 3 of the **THPRES** keyword, will be calculated from the initial conditions considering any phase present in the upstream cell.

	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The `OPTIONS3` keyword can be used to activate special options within particular facilities in ECLIPSE 300. These options are mainly of a temporary or experimental nature, or act to restore back-compatibility with earlier versions of the code.

The keyword should be followed by integers, each of which activates a special option within particular ECLIPSE 300 facilities. A value equal to zero switches off the special option. A value other than zero activates a special option. The data field should be terminated by a slash (/). If fewer than the maximum number of integers are read, the remainder are left unchanged. Once an option is activated, it remains activated and retains its value in all subsequent uses of `OPTIONS3` keyword unless it is explicitly changed or turned off. Note that repeat counts (for example `3*0`) can be used if required (there must be no spaces before or after the asterisk).

1. Set to 1 to obtain the explicit hydrostatic head values in the well model when the head calculation is based on an averaged wellbore density.

Set to -1 to obtain the implicit hydrostatic head values in the well model when the head calculation is based on an averaged wellbore density.

By default, ECLIPSE 300 uses a head calculation that is based on segmented wellbore densities (see item 12 in `WELSPECS` keyword). This head is always treated explicitly and so this switch will have no effect.

2. Set to 1 to obtain the `FREEZEPC` option. This will be overridden if the `FREEZEPC`, `NOFREEZE` or `DPCDT` keywords are used.
3. Set to 1 for saturation clipping
4. New Material Balance Control on Convergence

In thermal runs (2006.1 onward) this option is automatically turned on. It can be turned off in thermal runs by setting a negative value.

5. Set to 1 to use a saturation pressure test to determine the phase in separator calculations.
6. With effect from the 2014.1 release, this item is no longer available.
7. Set to 1 to interpolate initial compositions from the constructed internal tables rather than directly from the user data.

This is to obtain back-compatibility with the 95 versions.

8. Set to 1 to add the water-gas capillary pressure to the water phase rather than to the gas phase for the Gas-Water model.
9. Set to non-zero value to assign a zero THP for zero rate wells. Set to -1 to obtain the pre-2009.1 behavior for this option switch.
10. Controls output of VFP extrapolation messages
  - 0 Report VFP extrapolation at end of run
  - 1 Report VFP extrapolation at end of each report step
  - 2 Report VFP extrapolation at end of each report step and stop run if extrapolation has occurred.
11. If  $> 0$  potential reversal chops are switched on.

If =2 then the potential reversal chops only apply if a significant mobility contrast exists in the two cells.

12. If > 0 the pre-98A equilibration method is used.

13. If > 0 the pre-98A average specific volume derivative is used to normalize the solution change reported in the non-linear iterations.

If < 0 the post-98A average specific volume derivative is used to normalize the solution change reported in the non-linear iterations.

By default, ECLIPSE 300 uses the post-98A method except when running the Thermal option, which uses the pre-98A method by default.

14. If > 0 the actual specific volume normalization is used instead of the average specific volume derivative in the non-linear iterations.

15. If > 0 the reference surface tension, if defaulted, is taken as the initial cell-by-cell values rather than the field average. This was the pre-98A behavior.

16. If > 0 use pre-98A constant slope extrapolation of K-values.

17. If = 1 switch off well BHP solution damping.

18. If = 1 disable the saturation-based Appleyard Chop for the Thermal option.

If = -1 use pre-2004A saturation-based Appleyard Chop for the Thermal option.

19. Turn off non-linear speed-up due to Gain.

If =1, turn off Gain when there has not been a change of state in any cell.

If =2, turn off Gain.

Note that this is also affected by the setting of Item 68. Both items must be set to 'on' for the non-linear speed-up due to Gain to be used (so, by default, Gain is generally off).

20. If > 0 use the COLSUM constraint in the Nested Factorization preconditioner.

If < 0 use the ROWSUM constraint in the Nested Factorization preconditioner.

(By default, COLSUM is used in fully implicit and ROWSUM in IMPES and AIM cases. Prior to 99A COLSUM was used in all cases.)

21. If > 0 attempts to stop Newton iterations oscillating between alternate states.

If < 0 the damping of oscillations in Newton iterations is not activated.

By default, ECLIPSE 300 does not attempt to damp any oscillations in the Newton iterations, except when running the Thermal option, which damps these oscillations by default.

22. If > 0 causes the program to use an alternative set of tables from Haywood instead of the tables from Perry and Green (Thermal option only).

23. If > 0 normalize residuals by total moles rather than hydrocarbon or water moles.

24. If < 0 read the 6 column PVCO keyword but ignore the viscosibility (the pre-2002A behavior)

If > 0 use pre-99A version of PVCO with only 5 columns.

25. If > 0 disable the Appleyard Chop for compositional mode.

26. Activates the new Rachford-Rice solver in the flash (compositional mode).

- 1 Vector flash
- 2 Vector and scalar flash
- 27. If = 1 disable temperature-based Appleyard Chop for the Thermal option.
- 28. If > 0 use constant hydrostatic head for well calculations.
- 29. If > 0 use scalar flash to converge those reservoir cells which are making the transition from a single-phase state to two hydrocarbon phases. This switch restores compatibility with the pre-99A treatment.
- 30. Controls how advance gas is to be used during reinjection. If:
  - =1 uses the mixing tank treatment where the advanced gas is mixed with the produced gas and gas from this mixing tank is reinjected. The advanced gas rate is added to the produced gas rate to form an available gas rate for reinjection subject to fuel and sales gas commitments.
  - =2 also uses the mixing tank treatment, but the advanced gas rate is not added to the produced gas rate to form the available gas rate prior to fuel and sales gas commitments. This was the default 99A advanced gas treatment.
- 31. If > 0 well and group names are not internally converted to upper case.
- 32. This switch overrides some corrections made to the well calculation for the 99A release, restoring compatibility with earlier releases to allow you to assess the importance of the changes. If:
  - = 1 the injection well potential calculation reverts to its pre-99A state, when a THP limit imposed on an injection well was used to set the potential flow rate if the THP value at the BHP limiting potential flows was **less** than this limit. For the 99A release this calculation has been corrected, with the THP limit now acting as an **upper** bound for injection wells. This correction only affects runs with injection wells which have THP limits set and are subject to group control, since the default well guide rates are set equal to their potential rates.
  - =2 the group and field liquid compositions revert to the pre-99A state, when they were calculated by summing the well component volume rates instead of the well component molar rates. The change affects the reported group and field liquid component mole fractions.
  - =10 both the above revert to their pre-99A state.
- 33. If > 0 the error message associated with calculating a [FACTLI](#) value less than 0.9 or greater than 1.1 when using compositional equilibration option 1 (10<sup>th</sup> item in [EQUIL](#) keyword) is downgraded to a warning, allowing the run to proceed.
- 34. If > 0 the multisegment well having this well number (wells are numbered in the order they are input) will take two extra steps to help converge when crossflowing. Firstly, the multisegment well primary variables at the start of each well calculation are initialized to the solution at the end of the last timestep. Secondly, during the solution of the flow control rate constraint, the search for the BHP puts extra weight on bisection rather than Newton. This may result in more iterations being taken to converge the well, but it helps convergence in difficult situations. If this item is set to 10000 then all multisegment wells use the above.
- 35. Not used.
- 36. This switch overrides some corrections made to the well calculation for the 2000A release, restoring compatibility with earlier releases to allow you to assess the importance of the changes. If

- =1 the top-up phase identification calculation reverts to its pre-2000A state, where a phase is assigned as the top-up phase if a group is under a voidage replacement or voidage rate control mode when injecting this phase. The 2000A method assigns a phase as the top-up phase if a group level voidage replacement or voidage rate injection limit or target is associated with this phase.
- =2 the simulator reverts to the pre-2000A treatment of completion D-factors entered using [COMPDAT](#) or [COMPDATL](#). This treatment applies the D-factors directly to the completions. The 2000A treatment of positive completion D-factors is to take them as applying to the well and scaling them to values appropriate to the completions.
- =3 the simulator reverts to the pre-2000A treatment of the end run flag in [WECON](#) and [GECON](#). If this flag is set to Y, the run is stopped only on violation of a minimum economic rate limit. The 2000A behavior is to stop the run if the well (or all the producers in the group) have been shut/stopped for **any** reason.
- =4 the simulator reverts to the pre-2000A treatment of well revival as controlled by [WTEST](#). If all the connections of the well are closed, the well will not be revived. The 2000A behavior is to open all connections shut by an automatic workover and compare these connection flows against well and connection economic ratio limits; if any connections now obey these limits, the well is declared open again.
- =5 the simulator reverts to the pre-2000A treatment of a well's bottom hole pressure reference depth that is defaulted in [WELLSPEC](#), [WELSPECS](#) or [WELSPECL](#). This reference depth is set equal to the center depth of the grid block containing the first connection defined for this well. The 2000A behavior is to use the center depth of the grid block containing the topmost connection of the well if the bottom hole pressure reference depth is defaulted.
- =6 the simulator reverts to the pre-2000A treatment for closing a well that is unable to flow, that is the well is stopped. The 2000A behavior uses item 9 in the [WELSPECS](#) keyword to determine whether the well is shut or stopped, with the default action (which applies if the well is specified with the [WELLSPEC](#) keyword) being to shut the well.
- =7 the simulator reverts to the pre-2000A treatment for switching a group to a passive control mode because it cannot meet its target without all its subordinate groups and wells first moving onto individual control. The 2000A treatment improves the behavior of the group control facility in handling subordinate wells or groups which are instructed to produce at a higher rate than a group's target.
- =8 the simulator reverts to the pre-2000A treatment of not applying a D-Factor term to the water flow equation for an injecting completion in a crossflowing gas injector. The 2000A treatment applies the D-Factor mobility multiplier to all the injecting phases, which is consistent with the calculation in ECLIPSE 100.
- =9 the simulator reverts to the pre-2000A treatment of the injection system, whereby the calculation is performed once per Newton iteration. The 2000A treatment has iterative loops over the injection calculation when advance or make-up gas is present or availability limits have been requested (see keywords [WAVAILIM](#) and [GCONTROL](#)).
- =10 the simulator reverts to the pre-2000A treatment of cases where the source of injection gas is a single separator stage (see [GINJGAS](#) item 5) and there are fuel or sales targets that take precedence over injection (see [WTAKEGAS](#)). Previously, the fuel and sales gas composition was that of the complete separator, whereas in reality the composition must change to reflect the fact

that an amount of injection gas with the composition of a single stage has been removed. The new treatment allows for this change in composition, by performing the injection calculation first at a rate that is limited by higher priority fuel and sales requirements.

Setting the switch to 100 activates **all** the above reversions.

37. If > 0 the simulator reverts to the pre-2000A treatment of the [DPCDT](#) keyword, in which the limiting of the capillary pressure changes occurs after table look-up. The 2000A treatment limits the capillary pressure associated with each phase.
38. If >0 the DPCDT limiting applies to both explicit and implicit cells, which was the pre-2000A treatment. The 2000A default is to only have the DPCDT limiting on explicit cells.
39. Reserved for internal use. Do not use this.
40. Enables screening of the oil, water and gas saturations from a [GETSOL](#) (Thermal option).
41. If > 0 this disables the 2000A treatment of hydrocarbon-water relative permeabilities, where the end-points of the gas and oil-water curves are scaled before interpolation based on the Li correlation (see "[Near critical oil and gas relative permeabilities](#)" in the *ECLIPSE Technical Description*).
42. This switch controls options that may aid convergence in dual porosity cases. It is possible to reach a position where one phase's potential gradient goes from matrix to fracture and another phase's goes from fracture to matrix. This becomes a problem if the upwind mobilities of the respective phases are small or zero. Typically these situations occur rarely, but they can cause severe convergence difficulties. If:
  - =1 invokes an option to set the matrix pressure change over a Newton iteration to the fracture value.
  - =2 the transmissibility between matrix and fracture is lowered for a single timestep to allow convergence. Note that in principle this slightly modifies the resulting solution, but this modification is unlikely to be significant in most field examples.
43. This switch overrides some corrections made to the well calculation for the 2001A release, restoring compatibility with earlier releases to allow you to assess the importance of the changes. If:
  - =1 the defaulting for Kh (permeability x thickness) in the [COMPDAT](#) keyword reverts to its pre-2001A state, where an unset Kh value is calculated from the grid block data regardless of whether the connection transmissibility factor is set. The 2001A method calculates an unset Kh value from a given connection transmissibility factor and geometric denominator term calculated from grid block data. Furthermore in 2001A, if both Kh and the connection transmissibility factor have been set, the geometric denominator term is calculated from these two values.
  - =2 no warning or error messages are generated when a well completed in an LGR is specified in keywords that require connection values and are not designed for LGR wells. The connection values are assumed to refer to the simulation grid with the LGR positioned below the global grid. The 2001A behavior is to generate an error message in this situation unless the connection values are all defaulted and the action of the keyword thus applies to every connection in the well. From 2010.1 onwards this error message has been replaced by a warning message and the offending well is skipped.
  - =3 groups that were set under the control of a higher level group ( ' GR ' ) with keywords [GRUPPROD](#) or [GRUPINJE](#), but did not have a guide rate explicitly set (using [GRUPGR](#)), are **not** reset to a passive state and are reported as under ' GR ' control. This reported mode does not accurately reflect the way the group is solved by ECLIPSE 300. The 2001A behavior is to report a group that has been set under ' GR ' control without a user set guide rate as a passive group. This switch

also reverts ECLIPSE 300 to assigning the default group guide rate to group's potential. The default value for group guide rates in 2001A is zero (which means 'undefined'), and groups only have guide rates if they are set explicitly. This is now consistent with ECLIPSE 100.

Setting the switch to 100 activates **all** the above reversions.

44. This switch may be used to control the calculation of explicit hydrostatic heads, either segmented (see item 12 of [WELSPECS](#) keywords) or averaged (see item 1 of this keyword).

The explicit head is calculated at the start of each timestep and remains constant over the timestep.

- If set > 0, the head is also averaged with its value of the previous timestep, to damp out any oscillations that may be caused by the use of explicit quantities. The averaging depends on the value n of this switch:  $H(\text{used}) = (H(\text{current}) + nH(\text{previous})) / (n + 1)$
- If set=0, the head is averaged as above with n=2
- If set<0, no averaging takes place.

45. This switch may be used to control various aspects of how wells are solved under THP control.

In the 2001A release of ECLIPSE 300 a predictor has been incorporated that estimates the solution for a THP controlled well by finding the intersection between the latest linear inflow performance relationship (IPR) for the well and the cross section of the VFP curve at the target THP and the well's latest water and gas fractions. This prediction can often speed up the full solution of the well.

In addition to introducing a predictor, a new scanning mechanism was introduced in the 2001A release. A scan is called when the THP control algorithm struggles to find a solution (this is usually when the well is near to the point of being unable to flow under THP control). A successful scan supplies two BHP values that result in two THP values that straddle the target THP; this then makes the full solution of the well much easier. The old scanning mechanism attempted to find straddling THP values by numerous well solutions over a spread of BHP values. This technique can be expensive, especially for the Multisegment Well Model. The new scan only solves the well at flow values that correspond to those in the VFP table. This accurately models the point at which the well is unable to flow without resorting to too many well solutions.

You may switch the predictor on and off and switch between the old and new scanning techniques as follows, if:

- =1 the predictor is not used, but the new scanning technique will be used if necessary. This may be used if the prediction appears unreliable.
- =2 the predictor is used, but no scan is called should the THP algorithm struggle to find a solution. This should be quicker than the default case, with the decision to close a well (because it is unable to flow on THP control) being based on the predictor.
- =3 the predictor is used and if necessary both new and old scanning mechanisms are used. This should slower than the default case, but the well may flow a little longer under THP control before closing (if the timestepping resolution allows this to be seen).
- =4 the predictor is not used and the old scanning mechanism used if necessary. This then reverts the THP control algorithm to the 2000A state.

46. A positive value sets the number of Newton iterations within a timestep in which a well can be revived after being closed because it is unable to flow given the current reservoir conditions. The default behavior for the 2001A release when not using the Thermal option is to revive such a well only during the first [NUPCOL](#) Newton iterations. When the Thermal option is used, the default is to allow 21

revivals within a timestep before the well is closed. If this switch is set to a negative value, no well revivals are permitted. If however the switch is set to -999 the simulator reverts to the pre-2001A treatment, whereby the number of revivals permitted within a timestep was fixed at 21.

47. Number of network balancing iterations in which a well can be revived after being closed because it cannot operate against its current THP.

If set = 0, this defaults to max (4, NETBAL/2) where NETBAL is the maximum number of network balancing iterations allowed (see the [NETBALAN](#) keyword).

48. This option will turn off either the gravity or the porosity-stress relation in the rock stress calculation of the ECLIPSE 300 Geomechanics option. If:

=4 the gravity term is inactive in the stress equations

=6 the porosity-stress relation is inactive and porosity remains constant

=10 this is equivalent to both of the above.

49. Activates prototype group control logic that may help in problematic runs when wells and/or groups have significant flows that are unavailable for higher group control.

50. Reserved for use by FrontSim.

51. Governs the frequency at which the well potentials are recalculated during network coupling iterations. The potentials are used to calculate well and group guide rates, which govern the apportioning of group flow targets unless they are to be handled by automatic chokes. If:

=0 this defaults to recalculating the potentials at every network coupling iteration. The potentials will thus remain consistent with the latest THP limits from the balanced network.

=1 the potentials are calculated only once in each of the first NUPCOL Newton iterations of the timestep, before each set of network coupling iterations begin. This is the same as the frequency for recalculating the well potentials when there is no network; however, when a network is present the potentials are not fully consistent with the latest balanced THP limits.

52. In 2001A and later releases, the horizontal thermal transmissibility is based on the full cell cross-sectional area and does not include a net-to-gross factor. If this option is set to 1, the pre-2001A calculation, which includes net-to-gross, is used.

53. Activates a simple algorithm, using direct table lookup values, for oil relative permeabilities that are used when calculating the blocking factor in the Generalized Pseudo Pressure option (see the [PSEUPRES](#) keyword). By default in 2001A and later releases, the oil relative permeabilities used in the blocking factor calculation are found from a full three-phase calculation in the same manner as grid cell permeabilities. Should this more accurate calculation prove prohibitively expensive, the simpler method may be used by setting this option to 1. (This uses an internal version of [SOF3](#) for  $k_{rog}$  and  $k_{row}$  values that are combined using the default model for three-phase oil relative permeability as described in "[Saturation Functions](#)" in the *ECLIPSE Technical Description*.)

54. This switch overrides some corrections made to the well calculation for the 2002A release, restoring compatibility with earlier releases to allow you to assess the importance of the changes. If

=1 for wells connected to the innermost grid block of a radial grid, the connection transmissibility factor is calculated using the innermost grid block radius. By default, the wellbore radius is used in this calculation.

- =2 for wells with THP limits set, in some circumstances, the potential rates will be calculated at the well's BHP limit even though the rates at the THP limit are lower and thus should be assigned as the well's actual potential. By default, the well potentials are correctly calculated.
55. Not used at present.
56. If  $\geq 1$ , then in black oil mode, the oil formation volume factor and the viscosities are interpolated in  $1/b_o$  and  $1/(b_o.V_o)$  as in ECLIPSE.
- If =2, and using `PVDG`, the gas formation volume factor and viscosities are also interpolated in  $1/b_g$  and  $1/(b_g.V_g)$ . This option has no effect on `PVTG`, where the formation volume factor is interpolated in  $1/b_g$  but the viscosity is interpolated directly.
57. If =1, then the pre-2002A equilibration behavior is restored.
- If =2, then the pre-2012.1 equilibration behavior is restored: if a saturation pressure calculation fails the results are still used to determine the vapor composition below the gas-oil contact or the oil composition above the gas-oil contact.
58. Controls the time truncation error (tte) based timestep selection:
- >0 then the timestep is based on the  $\sqrt{\text{target}/\text{tte}}$  rather than  $\text{target}/\text{tte}$ .
  - <3 then the calculation is based on (normalized) mass change.
  - =3 then the calculation is based on the saturation change
  - >3 then the calculation is based on both masses and saturation.
59. If set >0, in runs using flux boundary conditions certain error conditions are reduced to warnings to allow the run to proceed.
- If set >0, in a full field `DUMPFLUX` run, any error messages about wells connecting to multiple flux regions are replaced by warnings. These remain strict errors in the reduced flux `USEFLUX` run when wells connect both inside and outside the `USEFLUX` region. This switch is useful in cases with many flux regions where it is known a priori which flux region numbers constitute the `USEFLUX` region (using `FLUXREG` in the reduced run) and that there is no problem with the placing of wells in the reduced run.
60. This option can be used with the `SKIPSTAB` keyword. The simulator performs a rigorous one-phase stability check on every  $n^{\text{th}}$  non-linear iteration. Therefore a value of 1 switches the `SKIPSTAB` option off and a value of 0 switches it back on again.
61. Restores pre-2002A convergence behavior of the linear solver.
62. This option must be set in the `RUNSPEC` section. If set >0, all wells declared throughout the simulation that are not multisegment wells are internally converted to single segment multisegment wells. The Multisegment Well Model is thus used in preference to the standard well model; this has been found to improve numerical convergence, and thus reduce timestep chopping, in some simulations.
63. If set = 1, this prevents extrapolation of the VFP tables in THP, WFR, and GFR during the calculation of the branch pressure drop in the Network Option. If a value lies outside the range of the VFP table, the branch pressure drop is calculated at the nearest tabulated value.
- Otherwise, the VFP table is extrapolated linearly in these quantities if they are outside the range of the table.

64. Reserved for Geomechanics
65. This switch may be used to change the type of density calculation for the wellbore hydrostatic head (see item 12 of the [WELSPECS](#) keyword) as follows, if:
- =1 the default method is set to 'AVG'. This was the default prior to the 2002A release.
  - =2 all wells have their wellbore density calculation method changed to 'SEG'. This switch applies to all currently defined wells and all wells to be defined in the remainder of the simulation, and overrides item 12 in the [WELSPECS](#) keyword.  
  
This override switch would be useful when running from a pre-2002A flexible restart in which all the wells, by default, use the 'AVG' density calculation method.
  - =3 all wells have their wellbore density calculation method changed to 'AVG'. This switch applies to all currently defined wells and all wells to be defined in the remainder of the simulation, and overrides item 12 in the [WELSPECS](#) keyword.
66. If set >0 this switch reverts to the 2001A linear solver. From 2002A onwards the default linear solver for serial and parallel runs is WARP. The use of this linear solver does not affect the results, only the performance, which normally improves.
67. This switch may be used to change the pressure convergence tolerance in the well model. When solving a well under flow rate or THP control, the well's BHP is adjusted such that the flow rate or THP of the well approaches the target value. The well is deemed to be solved when changes in its BHP are less than this pressure tolerance.  
  
The default pressure tolerance is divided by ten to the power of the value set in this switch. So setting this switch to 2 tightens the convergence tolerance by a factor of one hundred. Setting a negative value slackens this convergence tolerance.  
  
Tightening this tolerance may be necessary if flow rate targets are not being accurately met or if the target is small enough to result in well drawdowns that are similar to the default pressure tolerance (0.01psia).
68. If set > 0, this switch turns on non-linear speed-up due to Gain.  
  
Note that this is also affected by the setting of Item 19. Both items must be set to 'on' for the non-linear speed-up due to Gain to be used (so, by default, Gain is generally 'off').
69. If set >0 this switch restores the 2001A tunings, that is restores changes made to default values of the [TSCRIT](#) and [AIMCON](#) keywords. The 2002A setting are equivalent to having the AIM1 argument set in the [TOPT](#) keyword in the 2001A release. The changes made are
- 11th item in keyword [TSCRIT](#) has changed, this limits the timestep size after well modifications. For AIM runs this is now set to 40, thus allowing one-month timesteps, which is often desirable and achievable in history-matching data sets.
  - The default procedure for selection of implicit cells during an AIM run has changed, that is, the default setting of the [AIMCON](#) keyword has changed. The new setting often chooses fewer implicit cells for the early time in a history-matching case (water-injection), and more implicit cells during a gas-injection prediction phase.  
  
These settings are believed to produce better answers more efficiently.
70. This switch changes the behavior of the [ACTNUM](#) keyword in dual porosity cases. By default inactivating a cell in either matrix or fracture has the effect of inactivating both cells. Setting this

switch to >0 means that only the cell specified is inactivated. This was the default behavior prior to the 2002A release.

One exception to the new behavior is when a fracture cell contains a numerical aquifer (see keyword AQUNUM). In that case, inactivating the corresponding matrix cell does not automatically inactivate the fracture cell with the aquifer inside.

71. Reserved for Geomechanics
72. Base IMPSAT timesteps on the average throughput rather than the maximum.
73. Use throughput when selecting implicit cells in IMPSAT cases. If
  - =1 recalculates the vector suns only (null check)
  - =2 uses the throughput to set implicit cells.
74. Uses a more rigorous calculation of the saturation pressure. This calculation is significant slower than the default calculation, but gives more accurate answers for fluids near the critical point.
75. By default, all solution data requested under the RPTSOL keyword will be output for any local grid refinements present. Setting this switch to > 0 implies that the local grid output will not be output for the SOLUTION section.
76. If set >0 this switch reverts to the 2002A treatment of combined hysteresis and miscible flooding for the calculation of relative permeabilities. In this previous treatment the critical saturation for the immiscible part was based on the drainage curve rather than on a scanning curve if relevant. Also the critical point of the miscibility curve was assumed to be zero, which may not be the case if the MISCNUM keyword is used.

For models with the relative permeability hysteresis option (see HYKR keyword) or the MISCNUM option, setting this value >0 also reverts to pre-2005A\_1 behavior for the calculation of the effect of the surface tension on the relative permeability scaling end points.

77. Requests output of the computed gradients of all optimization constraints specified in keyword OPTCONS, while skipping the actual Reservoir Optimization process. The gradients are stored in files (see keyword SOPG in "Optimization State Files" in the ECLIPSE File Formats Reference Manual) available to any optimization software running outside of ECLIPSE.
78. Resets the PVT region number for all wells. In runs with more than one PVT region (see item 2 of the TABDIMS keyword), the 2004A simulator sets a PVT region number for each well, according to the PVT region number of the completion cells. This option allows the user to override this PVT region number, and set a new PVT region number for all wells. Prior to 2004A the properties of fluids in the wells were calculated using a PVT region number of 1. Therefore setting this item to 1 will give the pre-2004A behavior.
79. This switch overrides some corrections and improvements made to the well calculation for the 2004A release, restoring compatibility with earlier releases to allow assessment of the importance of the changes. If:
  - =1 when a group becomes passive, wells and groups at a lower level will become subject to rate control from groups at a higher level even if the passive group was set 'not free to respond to a higher level production rate target' (see item 8 in GCONPROD or GCONINJE). The default behavior in 2004A is that the 'not available for higher level rate control' restriction remains in effect even if the group to which it is applied becomes passive.
  - =2 when performing the top-up phase injection calculations for a group, any group flows in the non-top-up phase are treated as unavailable for group control flows (that is in the same manner as

satellite group flows). The default behavior in 2004A is to follow the ECLIPSE 100 methodology and directly reduce the group's voidage target by the non-top-up phase flows - this is a simpler and more robust approach.

- =3 when summing over wells to form a group's potential flow rates, well efficiency factors are not taken into account. The default behavior in 2004A is to multiply each well's potential rate by its efficiency factor when forming group values.

Setting the switch to 100 activates **all** the above reversions.

- 80. Reserved for ComSim
- 81. Reserved for ComSim
- 82. This switch allows you to change the way in which Forchheimer effects are incorporated in the Generalized Pseudo-Pressure calculation for a well when item 4 of [PICOND](#) is set to YES. If:
  - =1 the Forchheimer flow multiplier is calculated using a B-parameter equation based on the fluid properties of the connected cell (see [Non-Darcy flow](#) in the *ECLIPSE Technical Description*). By default the B-parameter is calculated using the fluid properties and saturations at each pressure point in the pseudo-pressure integral.
  - =2 Forchheimer effects in the Generalized Pseudo-Pressure calculation are switched off and only Capillary Number velocity-dependent relative permeability effects are incorporated in this calculation. This was the behavior of pre-2004A releases.
- 83. Post 2007.1 the Multisegment Well Model uses the modified solution update method by default. The modified method can improve convergence for difficult problems, but may be slower in more straightforward cases. If
  - =1 the pre-2007.1 multisegment well update method is restored.
- 84. Number of times a single timestep can be consecutively chopped because a well has switched from rate control to pressure control and died in the same timestep. If:
  - =0 defaults to 1.
  - = negative prevents timestep being chopped for this reason.
- 85. If set to 1, use the high mobility injection well model for all injectors. See [WELSPECS](#) item 16.
- 86. If set to 1, revert to pre-2004A weighting of average phase potentials by hydrocarbon volume rather than phase saturation. The calculations of phase potentials are detailed in "[Potential Calculations](#)" in the *ECLIPSE Technical Description*.
- 87. If set to 1, revert to pre-2004A behavior if [JFUNC](#) and [PCW](#) or [PCG](#) are present in the dataset.
- 88. This switch overrides some corrections and improvements made to the well calculation for the 2005A release, restoring compatibility with earlier releases to allow assessment of the importance of the changes. If:
  - =1 connection voidage rates are calculated at the reference pressure for the well (see item 13 of [WELSPECS](#)). The default behavior in 2005A is that a connection's voidage rate is calculated at the reference pressure for the fluid-in-place region of the connected grid block.
  - =2 derivatives of the voidage control well residual are calculated in the pre-2005A manner.

=3 a number of improvements to the segmented wellbore pressure head calculation for crossflowing injections wells are disabled.

Setting the switch to 100 activates **all** the above reversions

- 89. If set to 1, enable the Finite Difference stress calculation to run with corner-point geometry.
- 90. If set to 1, enable SAMG solver convergence statistics to be printed in the debug file.
- 91. If set to 1, revert to pre-2005A linear solver control. This is not recommended.
- 92. Alternative timestepping strategy will be implemented.

In thermal runs (2006.1 onward) this option is automatically selected and can be turned off by setting a positive value

- 93. If set to 1, do not scale by the fracture gas saturation in the sorption rate equation for a Coal Bed Methane Model.
- 94. If set to 1, revert back to the pre-2006.1 well name and well list template matching.
- 95. This switch controls how the gas fuel and sales will be scaled back if the sum of the fuel, sales and reinjection exceeds the amount of gas available. If:
  - =0 (default) the sales and fuel are both scaled back by the same amount. If [WAVAILIM](#) is not used then no scaling back takes place.
  - =1 the priority order specified in [WTAKEGAS](#) is used to decide which of the fuel and sales to scale back first.
  - =2 there is no scaling back of the fuel and sales.
  - =3 the sales and fuel are both scaled back by the same amount whether [WAVAILIM](#) is not used or not.
  - =4 the priority order specified in [WTAKEGAS](#) is used to decide which of the fuel and sales to scale back first. If [WAVAILIM](#) is not used, then no scaling back takes place.
- 96. This switch controls some options related to the calculation of the velocity dependent skin factor (see "[Forchheimer models](#)" in the *ECLIPSE Technical Description* for more information). If:
  - =0 (default), the pressure equivalent radius term is not included (see "[Forchheimer parameter based well D-factors](#)" in the *ECLIPSE Technical Description* is used), and the new unit-dependent constants are used.
  - =1 the pressure equivalent radius term is included (see "[Forchheimer parameter based well D-factors](#)" in the *ECLIPSE Technical Description* is used), and the new unit-dependent constants are used.
  - =2 the pressure equivalent radius term is not included (see "[Forchheimer parameter based well D-factors](#)" in the *ECLIPSE Technical Description* is used), and the pre-2006.1 unit-dependent constants are used. Use this value to revert to the pre-2006.1 behavior.
  - =3 the pressure equivalent radius term is included (see "[Forchheimer parameter based well D-factors](#)" in the *ECLIPSE Technical Description* is used), and the pre-2006.1 unit-dependent constants are used.

97. This switch limits the timestep taken by the simulator after a multisegment well changes control mode. If set to 1 the pre-2006.1 limit of 5 days is applied, otherwise no limit is enforced.
98. Relax the monotonicity restriction of the [ROCKTAB](#) keyword; warnings are suppressed for non-monotonic pore volume and transmissibility multiplier values.
99. If set to non-zero, and the **original** CN model for velocity dependent relative permeabilities is being used, then the behavior returns to the pre-2006.1 use of velocity dependent relative permeability calculations in the generalized pseudo-pressure calculations. Pre-2006.1, the velocity dependent correction to the relative permeability was performed after the iterations to determine the generalized pseudo-pressure. At 2006.1 the velocity dependent correction to the relative permeability is performed within the iterations to determine the generalized pseudo-pressure. This switch also reverses some bug fixes in the original CN model for back compatibility with pre-2006.1 results.  
  
If set non-zero, and the **alternative** CN model for velocity dependent relative permeabilities is being used, then the pre-2007.1 behavior is used. See "[Alternative model for capillary number effects](#)" in the *ECLIPSE Technical Description* for a description of the pre- and post-2007.1 behavior.
100. Reserved for future development.
101. If set to 1, then the test for zero thickness blocks in the X- and Y-direction is removed. Doing this can improve the pore volume calculation for nasty grids, for example, XY in map feet; IJ orientation with I up the page, J across.
102. Reserved for future use.
103. If this switch is non-zero, the connate gas saturation is allowed to be non-zero. This can be used in cases where non-zero connate gas is required and also provides back compatibility with pre-2004A behavior for dual porosity equilibration.
104. If this switch is non-zero, then the PBGS surface volume production balancing group control mode balances the *produced* surface gas volume, instead of the *excess* surface gas volume, with the specified fraction (or multiple) of the injected surface gas volume.
105. Restores pre-2006.2 behavior regarding tilted aquifer equilibration and calculation of the block equilibration pressures. If:
  - > 0 pre-2006.2 behavior is restored with the equilibration tilt correction not being applied to numerical aquifers and the equilibration block pressure taken as an average pressure over the sampling points specified by item 9 of the [EQUIL](#) keyword.
  - =0 tilt correction is applied to numerical aquifers if item 9 of the [EQUIL](#) keyword is positive and the block equilibration pressure is taken as the central pressure.
  - <0 tilt correction is applied to numerical aquifers if item 9 of the [EQUIL](#) keyword is positive but the block equilibration pressure is taken as the average pressure.
106. If set above 5000, this increases the maximum number of internal allocatable arrays to the value specified. This option is intended for use in special circumstances, for example when there are a large number of equilibration regions and the previously hard-wired limit of 5000 is insufficient. A message will be output by the simulator indicating when you should use this option.
107. Restores pre-2007.1 behavior of the drift flux model for small flows and hold-ups. If:
  - > 0 the 2006.2 behavior is restored, this affects the drift flux calculations in the presence of small values of flow rate and hold-up.

- > 1 the pre-2006.2 behavior is restored, this only affects the reporting of segment phase volume flow rates and velocities for small hold-ups
108. By default, gas injected during the surface gas production balancing group control mode is reported as reinjected gas, and the reported excess and export gas is based on this injected gas (not just gas formally reinjected during a reinjection group control mode). If this switch is non-zero, then this production balancing injected gas is **not** treated as reinjected gas. This affects the reporting of reinjected, excess and export gas in the gas accounting tables in the PRT file, and also in the values of these quantities written to the summary files.
109. For developer use.
110. This switch can used to revert to 2006.1 behavior. It is used internally to correct the saturations if the oil saturation becomes negative. In that case the gas-water capillary pressure is used, and the new behavior handle situations where the gas-water capillary pressure becomes negative.
111. In black oil simulations, with both dissolved gas and vaporized oil, the condition  $1 - R_{ssat} \times R_{vsat} < 0$  should hold. If it does not hold, the black oil flash may not be able to determine whether a single phase fluid is oil or gas. If set to 1, the pre-2007.1 behavior is used where single phase fluids default to oil. If set to 2, single phase fluids default to gas.
112. This option must be set in the RUNSPEC section. If set to a non-zero value, this reverts to the pre-2007.1 default behavior of reporting mass rates and totals in **long tons** (instead of **short tons**).
113. If set to various non-zero values, this restores aspects of the pre-2007.1 behavior regarding injection of gas and mixtures.
- If divisible by 2, use the pre-2007.1 calculation of availability of items in mixtures specified using [WINJORD](#).
  - If divisible by 3, use availability fractions when calculating mixture requirements. (These availability fractions are not used from 2007.1, instead a new calculation of the availability is performed.)
  - If divisible by 5, use the pre-2007.1 calculation of mixture potentials when calculating the availability fractions for mixture requirements. (Bugs were fixed in this calculation in 2007.1 to prevent crashes.)
  - If divisible by 7, use the pre-2007.1 treatment of gas specified using the injected fluid nature ' GAS ' in the [GINJGAS](#), [GRUPINJE](#), [WELLINJE](#), [WINJGAS](#), [WINJMIX](#) and [WINJORD](#) keywords. From 2007.1 these are internally converted to injection fluid nature ' GV ' with its source being the field separator (which has better gas accounting and r-injection behavior).
  - If divisible by 11, use the pre-2007.1 treatment of reinjection for mixture items from a separator stage. Before 2007.1, these mixture items were effectively ignored in complex gas accounting (that is, where there is fuel and/or sales gas, with intermediate separator stage gas reinjection).
  - If divisible by 13, complex gas accounting (that is, where there is fuel and/or sales gas, with intermediate separator stage gas reinjection) uses the pre-2007.1 treatment of reinjection in calculations of excess and export gas.
  - If divisible by 17, gas from a satellite group is not reported as separator stage 1 gas for the group.
114. If set to a non-zero value, a simpler form of the max NaCl solubility in water is used for the [CO2STORE](#) option.
115. If set to 1, the default values of the water formation volume factor of the solubility table used in the [CO2SOL](#) option are calculated using the pre-2007.1 method. This affects the water density calculation.

116. If set to a non-zero value the pre-2007.1 implementation of the [BRINE](#) model is restored. This affects the equilibration of the initial solution.
117. If set to a nonzero value the [NTG](#) values will also apply to the calculation of the rock volumes. This is the pre-2007.1 behavior.
118. If set to a non-zero value various aspects of the pre-2007.1 [ACTION](#) ([ACTIONG](#), [ACTIONR](#), [ACTIONW](#), [ACTIONS](#), [ACTIONX](#)) implementation are restored. The default behavior from 2007.1 onwards is that [ACTION](#) ([ACTIONR](#), [ACTIONX](#)) conditions involving regions are evaluated using the summary quantities from the current timestep, the maximum timestep length after a well modification is respected, and the summary data is output before processing the [ACTION](#) ([ACTIONG](#), [ACTIONR](#), [ACTIONW](#), [ACTIONS](#), [ACTIONX](#)) conditions. If set to:
  - 1 the pre-2007.1 behavior of the [ACTION](#) ([ACTIONG](#), [ACTIONR](#), [ACTIONW](#), [ACTIONS](#), [ACTIONX](#)) keywords is restored. Specifically, the [ACTION](#) ([ACTIONR](#), [ACTIONX](#)) conditions are tested before the region summary quantities such as [ROIIP](#) are updated, and before the summary quantities are output. As a result summary data from the previous timestep can be overwritten when an [ACTION](#) ([ACTIONG](#), [ACTIONR](#), [ACTIONW](#), [ACTIONS](#), [ACTIONX](#)) is triggered. In addition the maximum timestep length after a well modification is not imposed, see item 11 of [TSCRIT](#) keyword, and item 10, record 1 of the [TUNING](#) keyword. If the user defined quantity feature is active then these quantities will also be calculated before the region summary quantities are updated.
  - 1 the pre-2007.1 timestepping sequence can be recovered. Specifically, the 2007.1 order of evaluating the [ACTION](#) ([ACTIONG](#), [ACTIONR](#), [ACTIONW](#), [ACTIONS](#), [ACTIONX](#)) conditions and the output of the summary data is followed, but the maximum timestep length after a well modification is not imposed.
119. If set to 1, the water properties of water analytic aquifers are calculated using the PVT tables for the [GASWAT](#), [CO2STORE](#), [CO2SOL](#) or [COMPW](#) options.
  - For [GASWAT](#) or [CO2STORE](#), this was the pre-2007.1 method. By default, the water properties are currently calculated using the EoS.
  - For the multi-component water option ([COMPW](#)), this was the pre-2008.1 method. By default, the water properties are currently calculated using the water components data.
  - For the [CO2SOL](#) option, this was the pre-2008.1 method. By default, the water properties are currently calculated using the solubility table.
120. If set to a positive number, the pre-2006.2 handling of a dual porosity system is restored. Otherwise, active matrix cells that are connected to inactive fracture cells (because of a [MINPV](#) criterion) are inactivated.
121. If set to a positive number, that number is taken as an upper limit for the blocking factor calculated by the generalized pseudo-pressure special inflow equation. If a zero (that is default), or negative value is specified, then no limit is applied. This can be used to prevent convergence problems when blocking factors greater than unity are generated. See "[Generalized pseudo-pressure in ECLIPSE 300](#)" in *ECLIPSE Technical Description* for more information.
122. Generates warning messages from the [AQUANCON](#) keyword when cells cannot be connected to the aquifer because there is an active cell on the aquifer side of the current cell.
123. If a zero (that is default), or negative value is specified, then no normalization is applied. If set to 1, then normalization of the track tracers concentration is applied for each well and the calculation of injected track tracers concentration is also performed. This can be used to prevent discrepancy

problems between field tracers' characteristics and field characteristics. The injected track tracers' concentration can be monitored in a similar way as ordinary track tracers. The naming of the injected tracers is done automatically in a similar manner (for example, AI1, BI2). If the 'REGONLY' option is used then the tracer AI1 refers to region A and injected component 1, BI2 to region B and injected component 2, and so on. For example, mnemonic FTTLBI2 can be used in the summary section to monitor FTTL for the injected tracer BI2.

124. If set to a positive number, a better hysteresis model for water capillary pressure is activated.
125. If set to a positive number the phase stability check is modified slightly in order to prevent the H<sub>2</sub>O-rich phase, in a GASWAT run, being labeled as gas (default from 2008.1). The pre-2008.1 behavior is achieved by putting the value to -1.
126. If set to a non-zero value, the pre-2007.1 behavior when the [INTPC](#) option for integrated capillary pressure is used with the alternative gravity drainage model specified by [GRAVDRM](#) is restored. Although [INTPC](#) was previously allowed with [GRAVDRM](#), the pre-2007.1 behavior did not lead to the correct final recovery in this case, whereas the 2007.1 behavior should do so.
127. If set to a non-zero value the block-by-block inter-region flowing fractions calculation for the table [GPTABLEN](#) look up is activated. By default, the inter-region flowing fractions are calculated using the region-averaged values.
128. If set to a non-zero value the pre-2007.2 tolerances used to calculate the derivatives of immobile fluids are restored. This can lead to large elements in the Jacobian and affect the convergence of the solution.
129. If set to a non-zero value, the pre-2008.1 behavior for scale deposition is set. Scale deposition will only be applied to producing completions (which could belong to producers or crossflowing injectors).
130. This option controls three features of the gas accounting used when there is reinjection of a fluid from a separator stage, either as part of a mixture or alone.
  - If set to 1,3,5 or 7 the pre-2004A behavior for gas accounting is used when there is reinjection of a mixture fluid (that is, one defined using the [WINJMIX](#) or [WINJORD](#) keywords) in which a mixture item comes from a separator stage.
  - If set to 2, 3, 6 or 7 the pre-2007.2 behavior for gas accounting is used when there is reinjection of separator stage fluid (defined using [GINJGAS](#)), with sales and/or fuel targets (defined using [GRUPSALE](#) or [GRUPFUEL](#)) not being respected appropriately in some circumstances.
  - If set to 4, 5, 6 or 7 the pre-2007.2 behavior for sales and fuel target checks is restored, with tighter checks on these targets in place in most circumstances.
131. This option controls the composition of water in analytic aquifers.
  - For the [GASWAT](#) or [CO2STORE](#) options, if set to 1, the pre-2007.2 behavior for water analytic aquifers is used where the water leaving / entering the reservoir is made up entirely of the "H<sub>2</sub>O" component.
  - For the multi-component water option ([COMPW](#)), if set to 1, the pre-2008.1 behavior is used where the water leaving / entering the reservoir is made up entirely of the last water component.
  - For the [CO2SOL](#) option, if set to 1, the pre-2008.1 behavior is used where the water leaving / entering the reservoir is made up entirely of the "WATER" component.
132. This option controls a number of changes to the generalized pseudo-pressure calculation.
  - If set to a non-zero value divisible by 2 the pre-2007.2 behavior for generalized pseudo-pressure is applied. This restores minor bugs in the evaluation of the mobility integral.

- If set to a non-zero value divisible by 3 the mobility at drainage radius used in the denominator of the blocking factor calculation is calculated in the same way as the integral mobility. The default behavior is to take the bulk cell mobility. This may be useful for some cases, but can lead to instabilities in the blocking factor calculation.
  - If set to a non-zero value divisible by 5 the pre-2008.1 behavior for generalized pseudo-pressure is applied. The mobility calculated for the blocking factor integral at pressures above drainage radius pressure and below completion pressure include velocity dependent relative permeability effects at these limiting pressures - before 2008.1 these effects were ignored. This only affects the calculation if capillary number model 1 is used: see [VELDEP](#).
  - If set to a non-zero value divisible by 7 the pre-2008.1 behavior for velocity dependent relative permeability in the generalized pseudo-pressure calculation is applied for radial grids. This only affects the calculation if capillary number model 1 is used: see [VELDEP](#).
133. If set to 1, the residual in the WARP linear solver is calculated with greater numerical accuracy.
134. If set to 1, the flows output by the [RPTRST](#), [RPTSCHED](#) and [RPTSOL](#) keywords are calculated at the start of the timestep rather than the end. This was the pre-2008.1 behavior.
135. If set to 1, an alternative implementation for predicting the energy density in the [HEATER](#) algorithm is activated.
136. If set to a non-zero value, apply the restrictive well-reservoir convergence check.
137. If set to a positive value, do an extra flash at the end of an accepted timestep (updates the fluid properties for reporting).
- If set to a negative value, do not perform this extra flash in [TRACER](#) runs (for pre-2008.1 back compatibility).
138. If set to a non-zero value, this reverts to the pre-2008.1 method when determining the light and heavy components for the saturation chop calculation (equation of state mode).
139. This option alters the behavior of gas accountancy, reverting various elements to pre-2008.1 behavior.
- If non-zero and divisible by 2 the pre-2008.1 calculation of reinjection fraction method is used for separator stage reinjection.
  - If non-zero and divisible by 3 the pre-2008.1 calculation of advance gas amount with [WINJORD](#) or [WINJMIX](#) is used. This causes advanced gas to be applied for each separator stage used instead of once for the source group or well. It also changes the calculation of injection composition with [WINJMIX](#) and the priority of advance gas injection.
  - If non-zero and divisible by 5 the pre-2008.1 behavior of basic gas accountancy is recovered. This changes the calculation of sales, fuel and reinjection amounts if sales or fuel gas is specified for groups beneath a reinjection source group in the group tree.
  - If non-zero and divisible by 7 the pre-2008.1 behavior of partial gas reinjection with sales or fuel gas is recovered. This changes the calculation of injection rate target to the reinjection fraction applied to available gas before sales and fuel deductions and before advance gas additions. This only applies to the reinjection of gas mixtures defined using [WINJORD](#) or [WINJMIX](#).
  - If non-zero and divisible by 11 the pre-2008.1 behavior of [QDRILL](#) with sales or fuel gas is recovered. This changes the point at which new gas injection wells are drilled. This only applies to the reinjection of gas mixtures defined using [WINJORD](#) or [WINJMIX](#).
140. If set to a non-zero value the pre-2007.2 calculation for the lumped tracer connection phase flow, which does not include a Li correlation factor in the wellbore flash, will be used.

141. If set to a nonzero value the segmented well head calculation in **BLACKOIL** mode reverts to pre-2007.2 behavior. This uses fluid densities for PVT region 1 irrespective of the well PVT region number.
142. This element controls the specification of bottom hole depth. If set to:
- 1 the bottom hole depth of a well is calculated using the pre-2008.1 algorithm if **WELSPECS** element 5 is defaulted. This sets the bottom hole depth to the depth of the center of the vertically highest completed block.
  - 2 the bottom hole depth of a well is calculated using the 2008.1 algorithm if **WELSPECS** element 5 is defaulted. This may not give the expected result in some circumstances.
143. When modeling oil-wet systems with the end point scaling option activated, it is advantageous to be able to scale the water-oil capillary pressure at the maximum water saturation (using keyword **PCW**) rather than at the entry (connate) water saturation (where the water saturation equals **SWLPC**). This switch caters for this situation. Of rather less interest, but for completeness, it is possible to scale the gas-oil capillary pressure (keyword **PCG**) at connate rather than maximum gas saturation using this option switch. If **OPTIONS3** (143) is non-zero and divisible by 2 then the water-oil capillary pressure is scaled at the maximum water saturation; and if **OPTIONS3** (143) is non-zero and divisible by 3 then the gas-oil capillary pressure is scaled at the connate gas saturation. If **OPTIONS3** (143) is set to 1, then any water capillary pressure curves for which  $P_{cow}$  is entirely positive are chosen as water-wet and scaled at the entry saturation **SWLPC** while any for which  $P_{cow}$  is entirely negative are scaled at the maximum saturation **SWU**. For mixed wettability curves, it would be a bit of an illusion to arbitrarily choose which end point to scale at, so setting this option switch to 1 does nothing for such curves. When the **SWATINIT** keyword is used to match an initial water distribution then the scaling on  $P_{cow}$  is more sensible if **OPTIONS3** (143)=1 when the rocks are either water wet or oil wet (but no mixed wettability rocks). When the **SWATINIT** keyword is used to match an initial water distribution for mixed wettability rocks and positive capillary pressure dominated then the scaling on  $P_{cow}$  is more sensible if **OPTIONS3** (143)=5 (minimum capillary pressure is fixed). When the **SWATINIT** keyword is used to match an initial water distribution for mixed wettability rocks and negative capillary pressure dominated then the scaling on  $P_{cow}$  is more sensible if **OPTIONS3** (143)=7 (maximum capillary pressure is fixed). Note that **OPTIONS3** (143)=5 and **OPTIONS3** (143)=7 are not scaling the capillary pressure above GOC, therefore, **SWATINIT** cannot be honored above GOC.
144. If set to 1, any errors resulting from checking the Z-factors are downgraded to warnings.
145. If set to 1, the pre-2008.1 handling of capillary pressure in analytic aquifers will be used.
146. Switch to activate one-phase selection method.
- 0 Li-criteria + minimum Gibbs free energy. (Default)
  - 1 Preferred phase is LIQUID.
  - 2 Preferred phase is Vapor.
  - 3 Minimum Gibbs free energy and Wilson K-values
  - 4 Minimum Gibbs free energy and Wilson K-values for pressures below 10 atma, otherwise Li-criteria
  - 5 Same as 0

## 6 Li- criteria (Pre-2008.1 default)

147. Reserved for developer use.
148. If set to 1, the pre-2008.1 handling of the SWATINIT calculation will be used.
149. If set to 1, the pre-2008.1 calculation of pressure equivalent radius for grid blocks at the center of radial grids is used.
150. If set to 1, the pre-2008.1 handling of WTEST after GECON shuts-in a group of production wells is used.
151. If set to 1, only the gas phase of a GASWAT or CO2STORE run is considered as hydrocarbon. This affects the calculation of the summary keywords FPR, FPRH and FPPO, as well as the fluid-in-place reports. By default, the water and gas phases are considered as hydrocarbon.
152. If set to 1, a minimum timestep that fails to converge is re-solved so that the solution accepted is the closest rather than just the last Newton iteration. This option will require more Newton iterations but can help a simulation through a very poor period of convergence.
153. From 2008.1, an improved vapor versus liquid density check is performed. If this item is set to a non-zero value, the pre-2008.1 behavior will be restored.
154. If set to a non-zero value, the pre-2008.1 behavior of analytic aquifer inflow equations is used. The 2008.1 behavior correctly calculates the flow from the reservoir to the aquifer in the case of connate water/gas. This change affects all analytical aquifers.
155. If set to a non-zero value, the pre-2008.1 behavior for tilted aquifer block equilibration is restored. The 2008.1 equilibration behavior uses the aquifer block properties instead of the tilted block geometrical properties for numerical aquifers associated with grid blocks of zero thickness.
156. If set to a non-zero value, the pre-2008.1 behavior for tilted block equilibration is restored. The 2008.1 equilibration behavior corrects the weighted sum calculation for tilted grid blocks, defined using corner point geometry, by adjusting the averaged inclination factors to prevent the planes representing the top and bottom faces based on these averaged inclination factors from intersecting within the grid block. This correction will typically apply to distorted grid blocks, for example, those for which one or more corners share the same or similar depth values for both the upper and lower faces.
157. If set to 1, an alternative implementation for the water density calculation algorithm is activated.
158. If set to 1, the Appleyard Chop is applied to components when they appear or disappear. This behavior is the default for simulations using the chemical reactions feature but can be disabled by setting to -1.
159. This option alters the behavior of gas accountancy, reverting various elements to pre-2008.2 behavior.
  - If set to a non-zero value divisible by 2, then if a well is set to reinject a group vapor source or a group is set to reinject a well vapor source (for example GINJGAS item 2 is set to WV) then no gas will be reinjected.
  - If set to a non-zero value divisible by 3, then make-up gas is not switched off when a group has a reinjection target set.
  - If set to a non-zero value divisible by 5, then the pre-2008.2 calculation of advance gas is used. This changes the calculation of advance gas if the WEFAC and/or GEFAC keywords are used.
  - If set to a non-zero value divisible by 7, then the pre-2008.2 calculation of availability limits is used. This changes the calculation of availability limit if the WEFAC and/or GEFAC keywords are used in conjunction with WAVAILIM.

- If set to a non-zero value divisible by 11, then the pre-2008.2 calculation of gas accounting is used. This changes the calculation of excess gas and reinjected gas if the GEFAC keyword is used.
160. If set to 1, the pre-2008.2 thermal non-linear damping is restored.
  161. If set to 1 an alternative procedure for simulations with rock-filled cells is activated. Mathematically this is a null change but variations due to numerical rounding may occur.
  162. If set to 1, this restores the pre-2008.1 behavior for equilibration options 2 and 3 when the reference depth is not set to GOC.
  163. If set to 1, an alternative memory allocation algorithm is enabled. It reduces the number of allocations/deallocations while increasing the maximum amount of memory used.
  164. If set > 0, this switch turns on Ezrokhi's formula for the water viscosity calculation in [CO2SOL](#) / [H2SSOL](#).
  165. If set to 1, this switch turns on Ezrokhi's formula for the water density calculation in [CO2SOL](#) / [H2SSOL](#).
  166. If set to 1, well constraints may be weakly violated in order to improve the convergence of the well model.
  167. If set > 0, this switch activates the single-phase splitting initialization algorithm for GFE minimization in the flash.
  168. If set to 1, the pre-2008.2 calculation of fluid in place is used, correctly accounting for satellite group injection and production fluids.
  169. The default behavior is for the emulsion viscosity model to be activated in keyword [WSEGSICD](#) and deactivated in keyword [WSEGAICD](#). If this switch is set equal to 1, the emulsion viscosity model is deactivated in keyword [WSEGSICD](#). If set equal to 2, the emulsion viscosity model is activated in keyword [WSEGAICD](#). If set equal to 3, the emulsion viscosity model is both deactivated in keyword [WSEGSICD](#) and activated in keyword [WSEGAICD](#).
  170. If set to 1, the pre-2009.1 behavior for the interpolation of the Carter-Tracy aquifer influence function tables is restored. If set to 2 the pre-2010.1 behavior for the default Carter-Tracy aquifer influence function table is restored.
  171. If set to 1, the pre-2009.1 MS well energy predictor is restored.
  172. If set to a non-zero value, the pre-2009.1 equilibration phase-labeling calculation is performed.
  173. If set to a non-zero value, the pre-2009.1 behavior of gas accounting is used. This changes how sales and/or fuel gas is calculated if a reinjection target greater than 1 is specified.
  174. If set to a non-zero value, the pre-2009.1 [FACTLI](#) calculation during solution initialization is used. The new calculation updates [FACTLI](#) based only on the single-phase cells.
  175. If set to a non-zero value, the pre-2006.2 defaulting of the D-factor (item 12 of the [COMPDAT](#) keyword, or item 13 of the [COMPDATL](#) and [COMPDATM](#) keywords) is restored. A bug was fixed in this defaulting at 2006.2. Prior to that version, the completion D-factor was recalculated each time one of these keywords was present with the D-factor defaulted.
  176. This option must be set in the RUNSPEC section. If set to a non-zero value the pre-2009.1 method for calculating region phase production totals (ROPT, RWPT and RGPT) is used. Pre-2009.1 these quantities were reported for the beginning of the timestep rather than the end.

177. If a multiple of 2, then the closure of history matched wells with zero production rates and banned crossflow will not automatically occur.
- If a multiple of 3, then the closure of injection wells with zero injection rates and banned crossflow will not automatically occur.
- If a multiple of 5, then the closure of history matched wells reverts to pre-2010.1 behavior. Specifically, reservoir volume rate controlled wells will be shut irrespective of their target rate if crossflow is banned.
178. This option controls the calculation of group production potentials. These are the sum of the well production potentials for all open wells in the group. If set to:
- 1 the pre-2008.3 reporting of group potentials is restored. Prior to this version, stopped well potentials were sometimes incorrectly included in the reported group potential
  - 2 the pre-2011.1 reporting of group potentials is restored. From 2008.3 until this release, shut well potentials were sometimes incorrectly subtracted from the reported group potential.
179. Between 2009.1 and 2013.1, the derivative of the pore volume with respect to pressure in the Palmer-Mansoori rock model (see the [ROCKPAMA](#) keyword) is modified for stability. This helps with some convergence problems encountered in previous releases. The default behavior is to ignore the volumetric strain effect if it dominates the pressure effect. If a value of 1 is used, the pre-2009.1 behavior for the Palmer-Mansoori rock model is restored. If a value of 2 is used then the volumetric strain effect in the derivative is ignored in all cases. From 2013.1 this option switch has no effect unless `OPTIONS3` item 295 is also set.
180. If set to a non-zero value, the pre-2009.1 behavior of allowing oil injection wells is restored.
181. If set to a non-zero value, the arguments `WXMF`, `WYMF` and `WZMF` of component `nn` in keyword [ACTIONW](#) are handled in the pre-2007.1 way: they should be written `WXMFnn`, `WYMFnn` and `WZMFnn`. The post-2007.1 way of writing these mnemonics is `WXMF_nn`, `WYMF_nn` and `WZMF_nn`.
182. If set to 1, this option ensures that the pre-2009.1 calculations for `FLOOIL` and `FLOGAS` are used for black-oil models.
183. If set to 1, this option ensures that the pre-2009.1 calculations for `FLOWAT` and `RWFR` are used for multi-component water models.
184. If set to 1, this option ensures that the pre-2009.1 calculation of well model for `CO2SOL` / `H2SSOL` case is used.
185. If set to a non-zero value, this option restores the 2008.1 behavior for equilibration option 3 when the reference depth is not set to GOC. Note that the pre-2008.1 behavior can be restored by setting item 162 of `OPTIONS3` to 1.
186. This affects various behavior related to the [WAVAILIM](#) keyword.
- From 2009.1 onwards, if a well is under availability control when an unlimited injection fluid source (for example stream) is specified (see [WINJGAS](#)), then the control mode is reset to the most recent one specified explicitly for that well. The pre-2009.1 behavior (which leaves the well on availability control) can be restored by setting `OPTIONS3` item 186 to a non-zero value which is a multiple of 2.
  - From 2009.1 onwards, if a group is under availability control (see [WAVAILIM](#)) when more than [NUPCOL](#) Newton iterations are required, the appropriate phase availability is restored for the group from the last `NUPCOL` calculated value. Previously the group phase availability limit

would always have been the last NUPCOL calculated availability for the **water** phase. The pre-2009.1 behavior can be restored by setting OPTIONS3 item 186 to a non-zero multiple of 3.

187. If set to a non-zero value, the pre-2009.1 reporting of segment phase velocities is restored. Prior to 2009.1 the phase velocities in segments where the drift flux slip model was not used were set equal to the segment mixture velocity. Post-2009.1 the phase velocity is set to zero if the phase saturation within the segment is zero.
188. If set to a non-zero value, the pre-2009.1 calculation of temperature variation with depth in the flash calculation is restored.
189. Options for a rigorous density inversion check and correction in flash. If set to:
  - 1 this switch inactivates a rigorous density inversion check for post-scalar flash.
  - 2 this switch activates a rigorous density inversion check during the vector flash as well as the post-scalar flash.
190. If set to a non-zero value, the pre-2009.1 setting of well enthalpies in thermal decks is activated. From 2009.1 onwards, the well enthalpies are set whenever an action is triggered.
191. If set to a non-zero value, the pre-2009.1 density gravity calculation method for MSWs is used.
192. If set to a non-zero value, the pre-2009.1 calculation of tracer concentration is used. The calculation of tracer concentration has been changed if a well or group efficiency factor has been set ([WEFAC](#) or [GEFAC](#)).
193. If set to a non-zero value, the pre-2009.2 minimum oil saturation calculation for the Stone 1 relative permeability model with either [SOMGAS](#) or [SOMWAT](#) specified is used. This omits a correction which has been introduced from 2009.2 onwards to handle situations where end-point scaling has been specified and the critical oil-in-gas ([SOGCR](#)) or critical oil-in-water ([SOWCR](#)) saturations have been set to zero.
194. If set to a positive value, pre-2009.2 [LAGTRAC](#) calculations are recovered.
  - If divisible by 2, streamline update and retrace times are calculated as they were for 2009.1.
  - If divisible by 3, streamline tracing uses the 2009.1 cell porosity calculation.
  - If divisible by 5, streamline tracing ignores rock compressibility.
  - If divisible by 7, streamline flowrates are calculated using the 2009.1 well/group efficiency method.
195. If set to a positive value, the pre-2009.2 [SORMW1](#) initial compositional is used. That composition consists of a [SORMW1](#) fraction of  $(x_i * m_i)$  where  $x_i$  is the liquid fraction and  $m_i$  is the molar density.
196. If set to a non-zero value, this restores the pre-2009.2 behavior for [VELDEP](#) models using radial geometry.
197. If set to 1, the pre-2009.2 behavior for the modification of non-neighbor connections in cells which have been coarsened is restored. For the 2009.2 version onwards, the handling of NNCs across x- and y-faults is much improved, and the transmissibility of all NNCs within coarsenings may be slightly altered.

If set to 2, the pre-2011.1 behavior for the transmissibility calculations for coarse cells in which some fine cells are active and others inactive is restored. For the 2011.1 version onwards, a single inactive fine cell in a coarse cell on the boundary of a coarsening will not zero the transmissibility into the adjacent fine cell.

This option should only be used to confirm that a particular change in behavior is due to the improved modeling in 2009.2 and later.

198. For developer use.
199. If set to 1, this enables an alternative Ezrokhi calculation.
200. If set to a non-zero value, this restores the pre-2010.1 FIP (fluid-in-place) calculations for any ECLIPSE 300 data set that does not contain `COAL` or `SOLID`.
201. This item affects the method used to calculate the summary keywords `BOIP`, `BGIP`, `BOIPL`, `BOIPG`, `BGIPL`, `BGIPG` and the vectors output in the restart file when using `SFIP` in `RPTRST`. By default summary keywords and vectors are calculated using the separator defined by `FIELDSEP`. If set to:
  - 1 the summary keywords and the vectors are calculated using the separators defined by `FIPSEP` and the regions defined by `FIPNUM`
  - 2 this reverts to the pre-2010.1 behavior where the summary keywords are calculated using the separators defined by `FIPSEP` and the vectors are calculated using the separator defined by `FIELDSEP`.
202. If set to a positive value, pre-2010.1 `LAGTRAC` calculations are recovered.
  - If divisible by 2 the pre-2010.1 method for solving `LUMPING` tracers is used.
  - If divisible by 3 the pre-2010.1 handling of well connections is used.
  - If divisible by 5 the pre-2010.1 streamline number calculation is used.
203. If set to a positive value then `LUMPING` tracers solved using `LAGTRAC` are renormalized using an alternative method. `LUMPING` tracers will be constrained to lie between the previous timestep solution and the un-renormalized solution for each cell, and therefore may not sum to the lumped carrier component density.
204. If set to a non-zero value, this enables the pre-2009.2 calculation method for segments whose pressure drop is defined using `VFP` tables.
205. If set to a positive value, this enables the pre-2009.2 behavior of `ACTIONX` with `WLISTDYN`.
206. Require that two successive Newton iterations converge.
207. If set to 1, this enables an alternative Jacobian construction for `CO2SOL` / `H2SSOL` / `GASSOL`.
208. If set to a non-zero value, the pre-2009.2 behavior is restored whereby the by `SPECHS` keyword need not be specified for thermal models with components exhibiting solid phases.
209. If set to 1, the pre-2010.1 behavior is restored. Items 4 and 5 of the `PINCH` keyword are disabled. The old behavior uses the new default values for these items.
210. If set to a non-zero value, the pre-2009.2 behavior of the well inflow performance relationship calculations is restored. This mainly affects Open ECLIPSE queries ending `IPRA`, `IPRB` or `IPRC` for wells with injecting connections.
211. If set to a non-zero value, the pre-2009.2 behavior of gas lift for wells drilled using the `QDRILL` keyword is used. If lift gas is specified for a closed well using `WCONPROD` prior to 2009.2 then no lift gas will be used if the well is opened using `QDRILL`.
212. If set to a positive value, the pre-2009.2 default behavior for rock volume calculation is activated. This applies to `COAL` Bed Methane cases that use the instant sorption model.

213. As explained in item 12 of [WELSPECS](#), the hydrostatic heads calculated using segmented densities in the wellbore are damped to reduce the likelihood of stability problems. This is done by combining values from the previous timestep with those of the current timestep in a weighted average. An error has been identified in the implementation of this damping which meant that more damping was being applied than intended. This error has been fixed in the 2010.1 version of the simulator but has not been made the default behavior as it may result in changes in simulation results. The correct damping can be applied by setting this item to a non-zero value.
214. If set to a non-zero value, this enables the pre-2009.2 John Appleyard Linear Solver ([JALS](#)) for thermal simulations.
215. If set to 1, this enables the alternative handling of the [ROCK](#) keyword and its functionality.
216. If set to a non-zero value this enables the pre-2010.1 [GRUPRIG](#) / [WDRILTIM](#) behavior.
217. If set to a non-zero value, the pre-2010.1 behavior for thermal heavy-oil equilibration will be restored.
218. If set to a non-zero value, the pre-2010.1 thermal temperature limits will be restored.
219. If set to a non-zero value, this enables the pre-2010.1 thermal rock-filled convergence method
220. Reserved
221. If set to a non-zero value, this enables the pre-2010.1 behavior for [BDENSITY](#).
222. If set to a non-zero value, this enables pre-2010.1 [WLISTARG](#) target value assignments.
223. Not used at present.
224. Prior to 2010.1, the termination of fluid import to or export from a segment using the [WSEGEXSS](#) keyword (by setting the import/export type to NONE) resulted in the termination of import to or export from all segments associated with the well defined using the [WSEGEXSS](#) keyword, if the termination was applied to the first segment previously defined for import or export. From 2010.1 onwards, if the termination is applied to the first segment, the import to or export from any other segments defined using this keyword is unaffected. Pre 2010.1 behavior can be restored by setting this item to a non-zero value.
225. If set to 1, this enables an alternative saturation pressure calculation in [GASWAT](#) cases.
226. Prior to 2010.1, the output of the input oil-water capillary pressure tabular data using the [EPSDEBUG](#) or [EPSDBGS](#) keyword reported the data in GRAF format with the sign reversed as compared to the input data. This sign reversal has now been removed but may be reinstated by setting this item to a non-zero value.
227. Prior to 2010.1 well fluid composition was set to zero internally for wells with no production. From 2010.1 well fluid composition is set from the well potential solution in this situation to facilitate the later calculation of reservoir fluid volume rate targets. The pre-2010.1 behavior may be recovered by setting this item to a non-zero value.
228. If set to 1 or 3, this restores the pre-2010.1 EoS cubic root selection method for the saturation pressure calculation in flash. If set to 2 or 3, this restores the pre-2010.1 EoS cubic root selection method for the single-phase molar density calculation in flash.
229. If set to a non-zero value, the pre-2010.1 calculation of availability limits is used. This changes the calculation of availability limit if the [WEFAC](#) and/or [GEFAC](#) keywords are used in conjunction with [WAVAILIM](#).

230. If set to a non-zero value, the pre-2010.1 use of the GEFAC keyword for transparent groups is applied. This changes group rate allocations of higher level targets if an intermediate, unconstrained group has a non-zero group efficiency factor.
231. If set to a non-zero value, the pre-2010.1 asphaltene deposition will be used. The new behavior improves the handling of the deposition model.
232. If set to 1, the pre-2010.1 density model for pure water is activated for CO2STORE. This model should not be used at higher temperatures (above 150 °C).
233. If set to a non-zero value, this enables the pre-2010.1 behavior for handling zero or negative DZ.
234. If set to a non-zero value, the pre-2010.1 default for the WELSEGS top segment effective wellbore volume is used.
235. The transmissibility and diffusivity for dual and multi porosity connections now use the simulation grid cell bulk volume and not the sum of the cell pore volume and cell rock volume. For most cases these will be equal, but for thermal and Coal Bed Methane runs, the assignment of rock volume might result in differences. The pre-2010.1 behavior can be restored by setting this item to 1.
236. The behavior when failing to converge in a thermal simulation has been improved. This includes not chopping on a minimum timestep until the maximum number of Newton iterations have been solved. The pre-2010.1 behavior can be restored by setting this item to 1.
237. If set to a non-zero value, region, production and injection rates do not include well and group efficiency factors (WEFAC and/or GEFAC) in their calculation.
238. If set to a non-zero value, the pre-2009.2 method for interpreting group injection inheritance rules will be restored. From 2009.2 onwards, the group injection inheritance linkage is automatically reevaluated when the injection fluid changes to ensure that the correct fluid properties are used.
239. If set to a non-zero value, the pre-2010.1 method for inferring injection gas composition from GINJGAS when using WCONINJH will be restored. In some cases, it has been found that the injection gas composition is not correctly inferred when using GINJGAS with WCONINJH and without group control. This has been rectified in 2010.1.
240. If set to a non-zero value, the pre-2010.2 version of the well solution predictor will be restored. For the 2010.2 version onwards, a correction has been made to the predictor to improve the handling of the situation when all flow terms are zero.
241. Two changes were made to the saturation pressure calculation for 2010.2: a modification to the ab-initio calculation and a change in the pressure range used for the Gibbs Free Energy minimization in the calculation. If this item is set to 1, this restores the pre-2010.2 behavior for both changes in the flash calculation. If set to 2, this only restores the pre-2010.2 ab-initio saturation pressure calculation. If set to 3, this only restores the pre-2010.2 pressure bracket for Gibbs Free Energy minimization in the saturation pressure calculation.
242. If set to 1, this restores the pre-2011.1 behavior for MULTFLT in the EDIT section. Prior to 2011.1 the fault multipliers were not properly applied to cross fault NNCs when MULTFLT was used in the EDIT section.
243. If set to 1, the pre-2010.2 version of the relative permeability hysteresis calculations, when used in combination with end-point scaling, will be restored. For the 2010.2 version onwards a correction has been made to the look-up of the maximum saturation and relative permeability table values which are used in the scaling of the hysteresis terms. This item should be specified in the RUNSPEC section.
244. If set to 1, the pre-2010.2 interpretation of the defaulting mechanism for the SWOF and SGOF / SLGOF (Family I) saturation function keywords will be restored. In some circumstances this can lead to the

- incorrect construction of the [SWFN](#), [SGFN](#) and [SOF3](#) (Family II) saturation function keywords, which are used internally for the saturation function calculations, when only one of the [SWOF](#) and [SGOF](#) / [SLGOF](#) keywords is defaulted for a given saturation table number. This item should be specified in the [RUNSPEC](#) section.
245. If set to 1, the pre-2010.2 usage of the process-dependent relative permeability and capillary pressure end-point tables [ENKRVT](#), [ENKRVC](#), [ENPCVT](#) and [ENPCVC](#) will be restored. This is not recommended but has been provided for backwards compatibility. For 2010.2 onwards, the internal sign of the water-oil capillary pressure has been corrected, when looked up from a process-dependent end-point table, and checks have been added to ensure that the end-point scaling arrays used to report the process-dependent end-points are allocated appropriately. This item should be specified in the [RUNSPEC](#) section.
  246. If set to 1, the pre-2011.1 method for calculating Stone's formula number 1 for oil relative permeability is used. This mainly affects the way end-point scaling is used with the minimum oil saturation tables ([SOMGAS](#) or [SOMWAT](#)).
  247. If set to 1, the pre-2011.1 handling of [SUMMARY](#) keywords [AAQR](#) and [AAQT](#) is restored. Before 2011.1, the list associated with these keywords could contain an element referring to a gas analytic aquifer. If the list was empty, all analytic aquifers including gas one were listed. From the 2011.1 version on, using these keywords with a gas analytic aquifer is not allowed. Additionally, the [ALL SUMMARY](#) keyword implies the keywords [AAQRG](#) and [AAQTG](#).
  248. If set to 1, duplicated records in the [FAULTS](#) keyword are ignored. If a fault is specified twice, any multipliers associated with it are applied twice.
  249. If set to 1, the pre-2011.1 interpretation of the removal of heat transfer coefficients to completions for the [WSEGHEAT](#) keyword will be restored. From 2011.1 onwards, the behavior has been modified to ensure that the heat transfer coefficient to the completion is removed when instructed by this keyword.
  250. If set to 1, the pre-2011.1 handling of non-neighbor connections between two regions which have an associated [MULTREGT](#) multiplier is restored. For certain geometries, these non-neighbor connections could have the multiplier applied to them twice. Use of this option is not recommended but it is provided for backward compatibility.
  251. If set to 1, the pre-2011.1 handling of [MULTPV](#) within an [EQUALS](#) keyword is restored. Use of this option is not recommended but is provided for backward compatibility. From 2011.1 onwards, the use of [MULTPV](#) within an [EQUALS](#) keyword generates an error.
  252. If set to 1, the pre-2011.1 model for the calculation of water relative permeability hysteresis for water as a non-wetting phase will be restored. This change only applies when the hysteresis control keywords [EHYSTR](#) or [EHYSTRR](#) have item 2 set to a value of 7. For the 2011.1 version a correction has been applied to the calculation for the case when the current water saturation is less than the maximum historical water saturation.
  253. If set to 1, the pre 2010.2 handling of inconsistent PVT table selection is restored such that, if there are any cells in the same equilibration region that use different PVT tables, this will result in a warning message only. For the 2010.2 version onwards, the default response is to issue an error message.
  254. If set to 1, this activates the pre-2011.1 treatment of inline NNC transmissibilities.
  255. If set to 1, the pre-2011.1 behavior is restored for the modeling of the two-phase relative permeability of oil to gas when using the [EHYSTR](#) or [EHYSTRR](#) keywords with item 2 set to 4 (Killough hysteresis applied to both wetting and non-wetting phases). In some cases it has been found that the two-phase relative permeability of oil to gas can exceed the maximum value specified in the drainage and imbibition oil saturation function tables, or the maximum value specified via the end-point scaling

- keywords [KRO](#) and [IKRO](#) (and their directional and irreversible variants) if [ENDSCALE](#) has been specified. Depending upon the choice of three-phase relative permeability model, this can result in the three-phase oil relative permeability also exceeding the maximum value from the tables or end-points. This has been addressed for the 2011.1 version by constraining the maximum value of the two-phase relative permeability of oil to gas to the maximum of the values specified in the drainage or imbibition tables or end-points. The two-phase oil relative permeability of oil to gas is combined with the two-phase oil relative permeability of oil to water to form the three-phase oil relative permeability. The constraint described here will apply to all three-phase oil relative permeability models available in ECLIPSE 300 with the exception of the [IKU3P](#) and [ODD3P](#) models.
256. If set to 1, the output generated by the [RPTRST](#) flow arguments [FLOCn](#), [FLOE](#), [FLOOIL](#), [FLOWAT](#), [FLOGAS](#) and [FLORES](#) is written to the restart file in the pre-2012.1 format, which outputs non-neighbor flows, including flows between local and global grids, in a single list. See "Restart Files" in the *ECLIPSE File Formats Reference Manual* for the default format. This option switch also restores the previous pre-2012.1 NNC order in the INIT file.
  257. If set to 1, the pre-2011.1 method for determining whether to make an aquifer connection for a particular cell is used. This treats adjacent cells which contain a local grid as if they were inactive. If this option is not specified or set to 0, they are treated as if they were active. The new method is compatible with ECLIPSE 100.
  258. If set to 1, a modified non-linear solver is used. The new non-linear solver is designed to tackle some convergence problems, such as flip-flopping. It does more work than the current default non-linear solver, and therefore will be a little slower in cases that already run well. However it can be much faster in some cases that do not run well with the default solver.
  259. If set to 1, the pre-2011.1 behavior of honoring THP limits for history match wells will be used.
  260. If set to 1, when using the thermal option, the surface gas density will be determined by a surface flash, rather than using the data from the [DENSITY](#) keyword.
  261. If set to 1, the pre-2011.1 behavior is restored for the deselection of hysteresis via the [NOHYST](#) keyword. Prior to 2011.1, hysteresis was not deselected by this keyword if specified after the [SATOPTS](#) keyword or if WAG hysteresis was specified via the [WAGHYSTR](#) keyword.
  262. If set to 1, the pre-2011.1 behavior is restored for the treatment of the [PPCWMAX](#) keyword. Prior to 2011.1, the maximum capillary pressure was not modified if this exceeded the value specified by item 1. This has now been rectified.
  263. If set to 1, an alternative calculation of inter-region and inter-block phase flow rates, based on a flash at surface pressure and temperature, is activated in non-thermal [CO2STORE](#) runs.
  264. If set to 1, the pre-2011.1 behavior is restored for the treatment of the [WELSEGS](#) keyword. Prior to 2011.1, in some circumstances, the redefinition of the segments in a multisegment well did not result in the re-initialization of the well. This has now been rectified.
  265. If set to 1, the pre-2011.1 behavior is restored for saturation pressure calculations. In 2011.1, a new method is used to determine whether two compositions are the same. The new method is consistent with that used in the flash stability check.
  266. Reserved.
  267. If set to -1, the pre-2012.1 method for solving network models is used.
  268. Reserved.

269. If set to 1, the pre-2012 handling of summary keywords starting with B, F, G, W with a defaulted component number is used. The current method is to store all components in the summary file. The former method stores only the last one.
270. If set to 1, the pre-2011.2 calculation of observed reservoir volume is used. The 2011.1 method did not account for NGL correctly.
271. If set to 1, the pre-2012.1 treatment for wells under WAG control is restored. For the 2012.1 version, when a well which is under WAG control is shut, the WAG control is deselected.
272. If set to 1, the pre-2012.1 treatment is restored for the defaulting behavior for the end-point scaling relative permeability keyword `KRORG` within a local grid when it is defaulted from the global grid.
273. If set to 1, the pre-2012.1 dual/multi-porosity diffusivity calculation is restored. (Not scaling the diffusivity with the porosity.)
274. With effect from the 2014.1 release, this item is no longer available.
275. If set to 1, the pre-2012.1 treatment is restored for the allocation of Equation of State regions for the generalized pseudo-pressure calculations (GPP). Prior to 2012.1, for models with two or more Equation of State regions, the Equation of State region number used for the calculation of the well properties associated with the GPP option was defaulted to 1.
276. If set to 1, the pre-2012.1 behavior for STEAM-GAS injection is restored to use a fixed gas molar density. In addition, the setting of this switch will also revert the improved `WINJTEMP` enthalpy calculation to pre-2012.1 behavior. If set to 2, the pre-2012.2 behavior for STEAM-GAS, STEAM-OIL, HCGAS and HCOIL injection is used when the surface flash detects a single phase with the wrong phase being injected. For additional information, refer to "[Calculation of molar rates in ECLIPSE 300](#)".
277. If set to 1, the pre 2012.1 treatment is restored for the output of the end-point scaling arrays to the INIT file via `FILLEPS`. Prior to 2012.1, the values for global grid blocks containing local grids were output as default values for end-point arrays not specified in the input data. For 2012.1 onwards, these values are now defaulted from the appropriate saturation functions.
278. If set to 1, the pre-2012.1 coal bed methane diffusion equation (for multi-porosity) is used. The coal volume will always be used.
279. If set to 1, the pre-2012.1 behavior for the reading and writing of restart records associated with the WAG hysteresis option (`WAGHYSTR` keyword) will be restored. For the 2012.1 version, the restart records have been restructured to permit the use of this option with parallel restarts. Additional checking of the pre-2012.1 WAG hysteresis restart records has also been introduced for 2012.1. In cases where the pre-2012.1 restart record is unsuitable, item 279 can be set to 2 to bypass the input restart record.
280. If set to 1, the pre-2012.1 behavior of wells with zero flow rate targets is used. This may return production wells with a negative production rate in some circumstances.
281. In 2012.1, the VFP table extrapolation for negative flows was changed in the network model, to provide continuous pressure drop around zero flow. If set to 1, the pre-2012.1 VFP table extrapolation in the network model is used.
282. In some cases it has been found that reading restarts which contain WAG hysteresis records created by the 2009.1 and 2009.2 versions fails with a message referring to an incorrect header record. This is associated with an attempt to read a UDA/UDQ restart record when none was defined. Under these circumstances item 282 of the `OPTIONS3` keyword may be set to 1 to bypass the reading of the non-existent UDA/UDQ record thereby resulting in the correct reading of the WAG hysteresis record.

(This does not address the problems associated with the incorrect size of the WAG hysteresis which can occur in some cases with restarts written by parallel runs using versions prior to 2012.1.)

283. If set to 1, the pre-2012.1 behavior for Killough hysteresis in water-oil black oil models is restored. For the 2012.1 version, modifications have been made to take account of the critical saturation for the non-wetting imbibition saturation function when this is greater than zero and also to the modeling of the non-wetting phase hysteresis.
284. Reserved.
285. If set to 1, the pre-2012.1 behavior for modeling velocity-dependent relative permeabilities with [VELDEP](#) item 5 for the generalized pseudo-pressure option is restored. For the 2012.1 version, checks have been added to handle negative capillary numbers.
286. If set to 1, the pre-2013.1 behavior is restored for the calculation of three-phase relative permeabilities when one of the VDRP models specified by item 5 of the [VELDEP](#) keyword is selected.
- For the 2013.1 version, the method of calculation of the three-phase gas and oil relative permeabilities has been modified both for the grid block properties calculation and also for VDRP effects upon the well generalized pseudo-pressure (GPP) calculation where this option has been selected. For the grid block calculation, the two-phase oil relative permeability to gas is now calculated from the two-phase gas relative permeability to oil.
- For versions prior to 2013.1, the two-phase oil relative permeability to gas was calculated from the three-phase gas relative permeability. For the GPP calculation, the three-phase gas and oil relative permeabilities are now calculated in an identical manner to that employed for the grid block; this involves firstly calculating the associated two-phase relative permeability pairs and combining these to form the three-phase relative permeabilities. For versions prior to 2013.1, the three-phase oil relative permeability was calculated directly from the three-phase gas relative permeability.
287. If set to 1, the pre-2013.1 behavior is restored when modeling directional relative permeabilities without end-point scaling. Prior to 2013.1, there were some circumstances where calculations related to directional relative permeabilities assumed that end-point scaling was also being modeled.
288. Reserved.
289. Reserved.
290. If set to 1, the pre-2012.2 behavior is restored when applying default values to the KRGR, KRWR, KRORG or KROWG end-points associated with the [ENKRVT](#) or [ENKRVC](#) keywords for temperature or composition dependence respectively. If set to 1, this will also restore the pre-2012.2 behavior for the reporting of the KRGR, KRWR, KRORG or KROWG end-point scaling arrays in the INIT file when [ENDSCALE](#) and [FILLEPS](#) have been specified.
- This should be specified in the RUNSPEC section.
291. If set to 1, the pre-2013.1 behavior of printing all warning messages regarding well connections to inactive grid blocks will be active. If not set, only the first five warnings will be printed and any further warnings will be suppressed.
292. If set to 1, the pre-2013.1 behavior of the algorithm solving group problems is recovered. From 2013.1 this algorithm was altered to improve robustness and speed.
293. If set to 1, the pre-2013.1 behavior of calculating drift velocities for downward sloping segments will be activated.
294. If set to 1, this reverts to the pre-2013.1 method of determining the directions of non-neighbor connections while multiplying their transmissibilities by [ROCKTAB](#) items 3 – 5, when keyword [RKTRMDIR](#) is also specified.

295. If set to 1, the pre-2013.1 [ROCKPAMA](#) / [ROCKPAME](#) calculations are used. The derivative modifications as specified by [OPTIONS3](#) item 179 are ignored from 2013.1.
296. If set to 1, the additional WAG hysteresis regions specified via the [WH2NUM](#) and [WH3NUM](#) keywords and the associated additional processing (which applies whether these have been specified or defaulted) will be ignored. This option is only relevant when the [WAGHYSTR](#) keyword has been specified.
- This should be specified in the [RUNSPEC](#) section.
297. If set to 1, the pre-2013.1 version of the debug output for the scaled saturation tables specified via either the [EPSDEBUG](#) and [EPSDBGS](#) keywords will be selected.
298. Reserved.
299. If set to 1, the pre-2013.1 handling of models with both generalized pseudo-pressure and rock compaction options active will be selected.
300. If set to 1, the pre-2013.1 handling of the calculation of water molar density and water fluid-in-place will be selected, for models where [SOLUBILS](#) is included. Otherwise, the default calculation now takes into account the salt concentration in each cell and uses the corresponding brine surface density which is interpolated from [SOLUBILS](#). Note that activating this back-compatibility option within the [SCHEDULE](#) section, and hence using a combination of both forms of water density calculation, may lead to convergence problems. It is advisable to select one calculation method for the entire simulation.
301. If set to 1, the pre-2013.1 behavior is restored for models with two-point end-point scaling where one or more of the keywords [KRWR](#), [KRGR](#), [KRORW](#) and [KRORG](#) or their imbibition counterparts have been specified. In addition, this will also revert corrections to the maximum attainable unscaled water and gas saturations.
302. If set to 1, the pre-2013.1 behavior is restored for the calculation of the oil and gas phase Forchheimer models specified via items 3 and 4 respectively of the [VELDEP](#) keyword.
303. If set to 1, the pre-2013.1 calculation of volumetric rates and fluid in place in thermal runs is selected, affecting various quantities, such as [OIPG](#), [GOR](#), [WCT](#) and others. It is recommended that this option is requested before the [SOLUTION](#) section in the dataset.
304. Reserved.
305. If set to 1, the pre-2013.1 calculation of equilibrium deviation terms for reactions set with [EQLDREAC](#) is restored.
306. If set to 1, the pre-2014.1 behavior will be restored for models with end-point scaling specified, where the saturations at which the end-points [KRWR](#), [KRGR](#), [KRORW](#) and [KRORG](#) (relative permeabilities at residual saturation of the displacing phase) occur are the same as the saturations at which [KRW](#), [KRG](#), [KRO](#) and [KRO](#) (relative permeabilities at maximum saturation) respectively occur. For the 2014.1 version, corrections have been made to prevent the maximum scaled relative permeabilities exceeding the maximum specified relative permeabilities under these circumstances. This also applies to the imbibition counterparts if hysteresis is being modeled.
307. If set to 1, warning messages will be issued for models which use the [ODD3P](#) coupled three-phase relative permeability and capillary pressure hysteresis option, where the oil-water or gas-oil primary capillary pressure curves cross the secondary (increasing) or tertiary (decreasing) hysteresis capillary pressure curves. This corresponds to pre-2013.2 behavior. If required this option should be set prior to the [PROPS](#) section.

308. If set to -1, unset LGR fracture coordinates will not be copied from the matrix even if [DPGRID](#) is specified. This was the default behavior prior to 2014.1.
309. If set to 1, this will revert to the pre-2013.2 behavior of the [COMPKRIL](#) keyword for defining user relative permeabilities for injector completions in locally refined grids.
310. If set to 1, this will revert to the pre-2013.2 behavior for the calculation of water relative permeability hysteresis in oil-wet systems. Prior to the 2013.2 version, water relative permeability hysteresis in oil-wet systems was only available for black oil reservoir models. For other models only the drainage curve was used.
311. If set to 1, the pre-2014.1 behavior for determining when a non-neighbor connection should be deleted based on its transmissibility, diffusivity and thermal transmissibility is restored. Additionally, values which are below the cutoff value for all of transmissibility, diffusivity and thermal transmissibility will be preserved provided that the NNC itself is preserved. Note that, if this option is used, the diffusivity and thermal transmissibility settings from the [MINNNCT](#) keyword will have no effect.
312. If set to 1, this will revert to the pre-2014.1 behavior for the calculation of the inverse lookup with endpoint scaling. If defaulted, inverse lookup will be performed with 3 points endpoint scaling.
313. If set to 1, this will revert to the pre-2014.1 behavior for the treatment of pressure by enumeration in cells where no value has been set, where such cells were assumed to have atmospheric pressure. If defaulted, it is an error to have an active global cell without an explicitly set pressure at the end of the SOLUTION section.
314. If set to 1, this will revert to the pre-2013.2 behavior for the modeling of water relative permeability hysteresis scanning curves for models using the [WAGHYSTR](#) keyword when end-point scaling has been specified and where the three-phase water relative permeability saturation table numbers have been specified via the [WH3NUM](#) keyword. For the 2013.1 version, in some cases, these curves were defaulted saturation tables specified via the [IMBNUM](#) keyword. This has been rectified for the 2013.2 version onwards.
315. If set to 1, this will revert to the pre-2014.1 behavior for the modeling of generalized pseudo pressure in models with more than one equation of state region. For the 2014.1 version, the generalized pseudo pressure calculations for a given well completion utilize the equation of state properties associated with the grid block containing the completion rather than those associated with the well. Prior to 2014.1, the equation of state region number associated with the well rather than the completion was used.
316. If set to 1, this will revert to the pre-2014.1 behavior for the modeling of Killough hysteresis in oil wet systems.
317. If set to 1, this will revert to the pre-2014.1 behavior for the calculation of well productivity indices. When this option is active, the effective radius derived from the connection transmissibility factor, [COMPDAT](#) item 8, may be greater than the well's drainage radius, [WELSPECS](#) item 7 in the productivity index calculation. For the ECLIPSE 100 equivalent please refer to [item 226](#) of the [OPTIONS](#) keyword.
318. If set to 1, the preferred phase of an injection well will be updated to match the actual injection phase. This is the default behavior in ECLIPSE 100. For the ECLIPSE 100 equivalent please refer to [item 227](#) of the [OPTIONS](#) keyword.
319. If set to 1, this will revert to the pre-2014.1 behavior for the application of the D-Factors for wells or well completions for which values have been specified via the [WDFAC](#) keyword, the [WDFACCOR](#) keyword or item 12 of the [COMPDAT](#) keyword (or item 13 of the [COMPDATL](#) keyword). For the 2014.1 version, an additional check has been added to avoid negative discriminants in the solution of

the quadratic in the flow rate used to calculate the D-Factor multiplier. In all other respects, the calculation itself has not been changed.

320. If set to 1, this will revert to the pre-2014.1 behavior for the defaulting of the hysteresis control parameters when hysteresis has been specified via the `HYSTER` option of the `SATOPTS` keyword in the `RUNSPEC` section but the `EHYSTR` keyword has been omitted from the `PROPS` section. For versions prior to 2014.1, neither relative permeability or capillary pressure hysteresis were selected correctly if, in addition to the `EHYSTR` keyword, none of the alternative keywords used for specifying hysteresis, for example, `HYKR`, `HYPC`, `HYST`, `HYSTJ` or `HYSTK` were specified. For the 2014.1 version, if hysteresis has been specified via the `HYSTER` option of the `SATOPTS` keyword but the `EHYSTR` keyword has been omitted, the hysteresis parameters will be assigned to the default values specified for the `EHYSTR` keyword and any alternative definitions associated with alternative hysteresis keywords will be superseded.
321. If set to 1, this will revert to the pre-2014.1 behavior for the specification of negative capillary pressure end-points via the `PCW` and `PCG` keywords and their imbibition counterparts. Prior to 2014.1, if negative values were specified, the values actually used would default to the corresponding saturation table end-point values. For the 2014.1 version, if negative `PCW` or `PCG` values are specified, these will be used instead of the saturation table end-point values. This change of behavior also applies to capillary pressure end-points calculated via the `JFUNC` and `JFUNCR` keywords.
322. If set to 1, the non-linear residual checks will not be output by the JALS linear solver.

## Examples

The examples show two ways to set items 21 and 34. The first example sets them on one line by defaulting the first 20 items, setting 21, defaulting the next 12 items and setting 34:

```
OPTIONS3
20* 2 12* 1 /
```

The second example sets the switches on two lines, by defaulting 20 items and setting item 21, then defaulting 33 items and setting item 34:

```
OPTIONS3
20* 2 /
OPTIONS3
33* 1 /
```

## OPTLOAD **Load optimization from a given iteration**

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE
x	OPTIMIZE

This keyword is used to hot-start a reservoir optimization simulation using the optimizer control parameter values from a specified optimization iteration.

In order to use this keyword, you must have a optimization state file, which contains the information from the reservoir optimizer at the required iteration. This file must be in the same directory as the simulation model file that uses the OPTLOAD keyword.

---

**CAUTION:** There is no guarantee of cross-version compatibility of the optimization state file. It is possible that an optimization state file generated by one version of the simulator will not load into another version of the simulator.

---

The optimization state file is output by the optimizer during each optimization iteration.

- The rootname of the optimizer state file is the rootname of the original optimization simulation file.
- The file extension for the optimization state file depends on the output requirements specified from the original optimization. The file extensions are shown in the table below:

Extension	Unified	Formatted
FOPT	Yes	Yes
OPT	Yes	No
K000#	No	Yes
J000#	No	No

Table 3.24: Optimization state file extensions

---

**Note:** When the optimizer is hot-started, only the control parameter values from the original optimization iteration are used, not the gradient values or line-search parameters. This is because any changes to the optimization problem (such as modifying the objective function, constraints or control parameters) between the original optimization and the hot-started optimization invalidates the stored optimization gradients.

---

### Example

This example shows how to restart an optimization using a previous optimization run from optimization iteration number 8. This example assumes that the required optimization state file has the rootname BASECASE and is in the same directory as the new (hot-starting) simulation model.

```
OPTLOAD
  'BASECASE' 8 /
```

## OPTODD3P Specify ODD3P relative permeability and capillary pressure hysteresis model options

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is used to specify options that control the operation of the ODD3P three-phase relative permeability and capillary pressure coupled hysteresis model.

The keyword is followed by a single record consisting of two integer items. The record is terminated with a slash (/):

1. Option for selecting which ODD3P model to use for the calculation of three-phase relative permeabilities and capillary pressures when the ODD3P option has been specified.
  - 1 2008.1 version of ECLIPSE 300 ODD3P option.
  - 2 2008.2 version of ECLIPSE 300 ODD3P option.
  - 3 2009.1 version of ECLIPSE 300 ODD3P option.
  - 4 Current version of ECLIPSE 300 ODD3P option.

DEFAULT: 4.

For the 2008.1 and earlier versions it has been found that, in some cases, the switching behavior when switching from primary to hysteresis curves was incorrect, in that the wrong hysteresis curve was selected. This has been rectified for the 2008.2 version onwards, which is used by default. However, the 2008.1 version of ODD3P has been retained for backwards compatibility.

For the 2009.1 version, some amendments have been made to the calculation of the derivatives associated with the relative permeability calculations. The 2008.2 version, which does not include these amendments, may be specified by setting this item to 2.

For the current version, some amendments have been made to the calculation of the derivatives associated with the scaling of the end-point saturations. The 2009.1 version, which does not include these amendments, may be specified by setting this item to 3.

2. Option for selecting which set of saturations is used to determine changes in saturation direction.
  - 1 Grid block saturations.
  - 2 Normalized saturations.

DEFAULT: 2.

For very small changes in saturations, instantaneous differences in saturation direction between the grid block saturations and the ODD3P normalized saturations for a given phase can occur. Given that the ODD3P model utilizes the normalized saturations for the hysteresis calculations, consistency is assured by using the normalized saturations for the detection of saturation direction changes and this method is used by default. The detection of saturation direction changes based upon grid block saturations is available for backwards compatibility. This was the only method available for the 2008.1 version of ODD3P.

This keyword is only relevant if the ODD3P three-phase relative permeability and capillary pressure hysteresis model has been selected and will otherwise be ignored. If this keyword is not specified with the ODD3P option, the default options described above will be selected automatically.

## Example

The example below selects the current `ODD3P` model and saturation direction switching based upon normalized saturations both of which are the defaults.

```
OPTODD3P  
2 2 /
```

## Specify optimization options

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE
x	OPTIMIZE

This keyword is used to specify options that control the operation of the optimizer.

The keyword is followed by a single record consisting of three integers. The record is terminated with a slash (/):

1. Flag indicating which method is to be used to calculate the search direction in the optimizer. A value of 1 indicates that the steepest descent method is to be used, while a value of 2 indicates that the conjugate gradient method is to be used.  
DEFAULT: 1
2. Flag indicating which method is to be used to determine the free/dependent parameter split used when handling active constraints.

A value of 1 indicates that the first parameters in the list should be taken as the dependent parameters at each time period - this was the behavior pre-2006.1. The use of this method means that the performance of the optimizer can be dependent on the order that the parameters are specified in the [OPTPARS](#) keyword.

A value of 2 indicates that the dependent parameters should be chosen as the ones for which the constraints have the greatest sensitivity at each time period. The use of this method should mean that the optimization is not dependent on the order that the parameters are specified in the [OPTPARS](#) keyword.

DEFAULT: 2

3. Flag indicating which formulation is to be used for calculating the Lagrangian gradients.

In the **original** formulation, as described in [Introducing Additional Constraints](#) in the *ECLIPSE Technical Description* is used to eliminate  $\underline{\Psi}$ .

In the **alternative** formulation, as described in [Introducing Additional Constraints](#) in the *ECLIPSE Technical Description* is used to eliminate  $\underline{\Phi}$ .

A value of 1 indicates that the (more expensive) alternative formulation should only be used when necessary, and the original formulation should be used otherwise. item 11 of the [OPTTUNE](#) keyword is used to decide when the switch between the two formulations is necessary.

A value of 2 indicates that the original formulation should always be used.

A value of 3 indicates that the alternative formulation should always be used.

A value of 4 indicates that the method used in the previous versions of the code should be used. This is the same as original formulation but with an attempt made to continue the optimization if insensitive constraints are encountered. This formulation is only present for back-compatibility. The mechanism used to continue the optimization has no mathematical or physical foundation and may only work for a small number of cases. It has been entirely superseded by the alternative formulation.

DEFAULT: 1

### Example

This example shows how to change the optimizer to use the conjugate gradient method, and also to use the specified [OPTPARS](#) parameter order for choosing the dependent parameters when handling constraints.

x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE
x	OPTIMIZE

This keyword is used to specify the control parameters to be varied in an optimization run of the simulator.

The keyword must be followed by a set of records, each specifying a parameter to be used in the optimization. Each record should be terminated with a slash (/) and the set of records must end with a slash. At least one record is required to perform an optimization.

This keyword should only appear once in the data file.

1. Control parameter.

Available control parameters are:

FOPR Field oil production rate

FWPR Field water production rate

FWIR Field water injection rate

FGPR Field gas production rate

FGIR Field gas injection rate

FLPR Field liquid production rate

GOPR Group oil production rate

GWPR Group water production rate

GWIR Group water injection rate

GGPR Group gas production rate

GGIR Group gas injection rate

GLPR Group liquid production rate

WBHP Well bottom hole pressure

WOPR Well oil production rate

WWPR Well water production rate

WWIR Well water injection rate

WGPR Well gas production rate

WGIR Well gas injection rate

WLPR Well liquid production rate

SCSA Segment cross sectional area (for parameterization of multisegment well segments defined using the [WSEGVAVL](#) keyword). The segment cross sectional area parameter is currently only available for producing multisegment wells, not injectors.

2. Unique identifier for the domain to which the parameter specified in the first item applies. This should be the name of a well or group that has already been defined in the SCHEDULE section. It is not possible to use wildcard characters to specify more than one well or group. Well lists, specified using the `WLIST` keyword, cannot be used as the domain identifier.

If the parameter is specific to a segment of a multisegment well (such as a specific valve control) then the segment number should also be provided in the form `NAME:XX` where `NAME` denotes the well name and `XX` the segment number. See the examples for more information.

3. The minimum permissible value of the control parameter during the optimization.  
DEFAULT: 0.0
4. The maximum permissible value of the control parameter during the optimization  
DEFAULT: 1.0E+20
5. Index of first report time at which this parameter may be varied.  
DEFAULT: 0 (or the first report index in a RESTART case)
6. Index of last report time at which this parameter may be varied.  
DEFAULT: The last report index requested in the SCHEDULE section.
7. Control mode to be used between the start and end report times of this parameter. This is only used for SCSA parameters (see item 1).

Since a well can only have one control mode, then if multiple SCSA parameters are specified on the same well at the same time, then the first control mode specified will be used for the well.

Available control modes are:

ORIG Original control from the base case

OIL Oil rate control

WAT Water rate control

GAS Gas rate control

LIQ Liquid rate control

BHP Bottom hole pressure control

THP Tubing head pressure control. (This control mode is only available if the well has an associated VFP table.)

DEFAULT: ORIG

## Notes

- The initial value of a parameter is taken as the value of the corresponding simulated value in the optimization base case simulation. For example, if a `WBHP` parameter is specified on a particular well, then the initial value for that parameter at each report period in the optimization is taken as the actual bottom hole pressure for that well in the base simulation.

The SCSA parameter is a special case here, because there is no concept of an “SCSA control mode” for a well. When an SCSA parameter is used, the well control mode can be specified in item 7. The target for the specified SCSA parameter control mode during optimization runs is taken as the actual value from the optimization base simulation, and all other targets and limits are removed from the well.

- If the 'ORIG' SCSA control mode is specified, then the well control (for example from the `WCONPROD` keywords) from the base case is kept for the optimization runs.
- The specified SCSA parameter well control mode will be ignored if there is a well parameter on the same well at the same time. This is because the well parameter specifies the control mode and this takes precedence over the segment SCSA control mode.
- When a parameter is specified, all other limits that might interfere with this are removed by the optimizer so that it has complete control over the effect of the parameter on the simulation. For example, if a WOPR parameter is specified for a particular well, then during the optimization simulations, all other limits (on rates, pressures and so forth) are removed and the well is removed from responding to any higher level group control. If other limits are required during optimization, then these should be specified using the `OPTCONS` keyword.

## Examples

This keyword is used to specify tuning parameters for an optimization run of the simulator. The keyword is optional.

The keyword is followed by a single record consisting of some or all of the following items.

1. The initial constraint tolerance used in the optimization run.  
DEFAULT: 0.05
2. The minimum constraint tolerance.  
DEFAULT: 0.05
3. The number of optimization iterations to allow for progression from the initial to the minimum constraint tolerance.  
DEFAULT: 10
4. Objective function convergence tolerance between optimization iterations.  
DEFAULT: 1.0e-06
5. Minimum objective function RMS gradient.  
DEFAULT: 1.0e-06
6. Parameter convergence tolerance between optimization iterations.  
DEFAULT: 1.0e-06
7. Parameter boundary relative tolerance.  
DEFAULT: 1.0e-03
8. Line search alpha convergence tolerance.  
DEFAULT: 1.0e-06
9. Line search alpha minimum.  
DEFAULT: 1.0e-03
10. Line search alpha maximum.  
DEFAULT: 1.0  
  
Note: Increase this number for a more aggressive optimization line search strategy.
11. The tolerance used to decide if the active constraints are insensitive to the dependent parameters. (This is only used if item 3 of [OPTOPTS](#) is set to 1.)  
DEFAULT: 1.0e-06

This keyword is used to declare a threshold orthogonality error for interfaces in the Z-direction to employ nine-point transmissibilities whenever the [MPFA](#) keyword is used to select the nine-point MPFA scheme.

See "[Tensor permeability](#)" in the *ECLIPSE Technical Description* for further information.

The keyword should be followed by a single positive real number, the dimensionless minimum orthogonality error in order to calculate nine-point transmissibilities for a Z-direction interface.

DEFAULT: 0.000000

The data must be terminated by a slash (/).

The keyword causes any interfaces in the Z-direction cell with an orthogonality error less than the input value to use the normal five-point transmissibilities.

### Example

```
ORTHERRZ
0.001 /
```

## OUTRAD

## Outer radius for radial geometry

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by a single positive real number denoting the outer radius of the reservoir, terminated by a slash (/).

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

If the outer radius is specified using OUTRAD, the program calculates a set of cell radii (or R-direction thicknesses), which observe the correct inner radius (see the INRAD keyword), outer radius and number of cells in the R-direction.

In addition, the keyword DRV may be used to specify the R-direction thicknesses of some of the cells. In this case, the program honors these input values and just calculates the DRV values of the remaining cells.

If an incomplete set of DRV values has been entered, the missing radii are supplied in a geometric series when OUTRAD is specified.

For instance, if there are NR cells in the R-direction, and  $i_L$  is the index of the first block for which the DRV value has **not** explicitly been entered, then the outer radii for blocks 1 to  $i_L-1$  are obtained by successively accumulating the sum of the DRV s and INRAD.

For the remaining blocks (that is, for  $i > i_L-1$ ), the outer radii of two neighboring blocks in the radial direction (the  $i^{\text{th}}$  and  $i-1^{\text{th}}$  grid blocks) will be related by

$$\frac{R_i}{R_{i-1}} = \left( \frac{\text{OUTRAD}}{R_{i_L-1}} \right)^{1/(\text{NR}-(i_L-1))} \quad \text{Eq. 3.137}$$

so that neighboring pairs of radii have the same ratio for all  $i > i_L-1$ .  $DR$  for the  $i^{\text{th}}$  cell is then given by  $DR_i = R_i - R_{i-1}$

If only INRAD and OUTRAD are specified, and no DRV values have been specified, then the grid block radii are calculated from the above formulae with  $i_L = 1$  and  $R_0$  defined equal to INRAD.

The following restrictions apply to the use of OUTRAD:

- It should only be used with radial geometry.
- OUTRAD should not be specified when the grid is defined by corner-point geometry using the keyword COORD.
- OUTRAD must be greater than INRAD.
- It is ignored if a complete set of DRV values (NR entries) has been input.

## Example

With NR=5:

```

INRAD
0.2 /
DRV
1.0 3.0 /
OUTRAD
500 /

```

## OUTSOL

## Controls solution output for GRAF and flexible restarts

See keyword [RPTRST](#), which has superseded the OUTSOL keyword.

---

**Note:** Although the old OUTSOL keyword is superseded, it is still recognized for back compatibility. If a data set contains both OUTSOL and RPTRST, the later one will determine the output to the Restart file.

This keyword specifies initial overburden boundary conditions when initial stress calculation INIT is specified with the keyword [GEOMECH](#) in the RUNSPEC section.

This keyword allows initial overburden on the top face. An overburden at the top face is a force/unit area. If this keyword is not specified, the overburden is defaulted to zero, which means the top face is free to move unless otherwise specified.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. A vertical overburden on Z+ face.  
UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)  
DEFAULT: 0
2. First block to be modified in the X direction  
DEFAULT: 1 if an X- face
3. Last block to be modified in the X direction  
DEFAULT: NX if an X+ face
4. First block to be modified in the Y direction  
DEFAULT: 1 if a Y- face
5. Last block to be modified in the Y direction  
DEFAULT: NY if a Y+ face

## Example

```
--Set a 3000 psi overburden

This keyword specifies initial overburden boundary conditions for an LGR when initial stress calculation INIT is specified with the keyword [GEOMECH](#) in the RUNSPEC section.

This keyword allows initial overburden on top face in a local grid refinement. An overburden at top face is a force/unit area. If this keyword is not specified, the overburden is defaulted to be zero which means the top face is free to move, unless otherwise specified.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. Name of the Local Grid Refinement
2. A vertical overburden on Z+ face.  
UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)  
DEFAULT: 0
3. First block to be modified in the X direction  
DEFAULT: 1 if an X- face
4. Last block to be modified in the X direction  
DEFAULT: NX if an X+ face
5. First block to be modified in the Y direction  
DEFAULT: 1 if a Y- face
6. Last block to be modified in the Y direction  
DEFAULT: NY if a Y+ face

### Example

```

-- For the local grid refinement LGR1 set a 3000 psi overburden
OVERBDIL
'LGR1' -3000 /

```

## OVERBURD **Rock overburden pressure tables**

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTROCC (see item 2 in keyword [ROCKCOMP](#) in the RUNSPEC section) tables of rock overburden data, each terminated by a slash (/). Each table consists of 2 columns of data:

- The depth.  
Values should increase monotonically down the column.  
UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)
- The overburden pressure values should increase monotonically down the column.  
UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NPPVT (see item 4 of keyword [TABDIMS](#) in the RUNSPEC section).

The NTROCC records correspond to the rock compaction table region numbers, which are set using keyword [ROCKNUM](#).

The OVERBURD keyword can be used if the rock compaction option is selected (keyword [ROCKCOMP](#) in RUNSPEC). The overburden pressure at the grid block depth is subtracted from the pore pressure to look up the pore volume and transmissibility multiplier values. If the keyword is not present then the overburden pressure is taken to be zero.

ECLIPSE by default tabulates the rock compaction multipliers against fluid pressure. But if the OVERBURD keyword is specified, the [ROCKTAB](#), [ROCKTABH](#) or [ROCK2D](#) and [ROCK2DTR](#) keywords tabulate the compaction multipliers against the effective fluid pressure instead ( $P_{\text{eff fl}} = P_{\text{fluid}} - \text{Overburden}$ ). If the overburden pressure is greater than the fluid pressure, as it usually is, then the effective fluid pressure (or stress) is negative. This leads to non-intuitive compaction tables with negative effective pressures in the first column.

The compaction tables can be input in a more intuitive manner by selecting the 'STRESS' option in the [ROCKOPTS](#) keyword before the [ROCKTAB](#), [ROCKTABH](#) or [ROCK2D](#) and [ROCK2DTR](#) keywords. In this case the pore volume and transmissibility multipliers are tabulated against the effective overburden pressure,

$$P_{\text{eff ov}} = \text{Overburden} - P_{\text{fluid}}, \text{ which is } - P_{\text{eff fl}}.$$

See also keywords [ROCKTAB](#), [ROCKTABH](#), [ROCK2D](#), [ROCK2DTR](#) and [ROCKOPTS](#), and "Rock compaction" in the *ECLIPSE Technical Description*.

### Example

With NTROCC=1 and NPPVT ≥5:

```
OVERBURD
 2000  600
 4000 1200
 6000 1800
 8000 2300
10000 2800
/
```

## Overwrite radial-direction transmissibilities

This keyword specifies a value to be overwritten on to the transmissibilities during the SCHEDULE section, for flow in the radial direction.

The value is applied to the transmissibility between the cell and its neighbor in the appropriate **positive** direction.

The default is to supply a value for each cell in the grid, that is each keyword should be followed by  $N_R \cdot N_\theta \cdot N_z$  values in natural order, with the R index changing fastest.

If values are defaulted or set negative, the transmissibilities for the corresponding cells are not modified.

These keywords will normally be used with [BOX](#) and [ENDBOX](#), when the number of values should be the number of cells in the current BOX.

The form of the input is analogous to that for the [OVERTX](#) keyword.

### Example

Set transmissibility values in a box to zero:

```

-- IX1-IX2 JY1-JY2 KZ1-KZ2
BOX
  5  5  3  8  4  6  /
OVERTR
  18*0.0 /
ENDBOX

```

The modified transmissibilities can be output to the Print file by using the mnemonic [MULT](#) in the [RPTSCHED](#) keyword.

---

**Note:** It is important to note that if the transmissibilities are also modified using transmissibility multiplier [MULTR](#), the resulting output takes into account both of these actions.

---

## OVERTTHT **Overwrite azimuthal-direction transmissibilities**

## Overwrite X-direction transmissibilities

This keyword specifies a value to be overwritten on to the transmissibilities during the SCHEDULE section, for flow in the X direction.

The value is applied to the transmissibility between the cell and its neighbor in the appropriate **positive** direction.

UNITS: cP.rm<sup>3</sup>/day/bars (METRIC), cP.rb/day/psi (FIELD), cP.rcc/hr/atm (LAB), cP.rm<sup>3</sup>/day/atm (PVT-M)

The default is to supply a value for each cell in the grid, that is each keyword should be followed by  $N_x \cdot N_y \cdot N_z$  values in natural order, with the X index changing fastest.

If values are defaulted or set negative, the transmissibilities for the corresponding cells will not be modified.

These keywords is normally used with [BOX](#) and [ENDBOX](#), when the number of values should be the number of cells in the current BOX.

### Example

Set transmissibility values in a box to 18.6:

```

-- IR1-IR2 JT1-JT2 KZ1-KZ2
BOX
  23 25 13 15 1 8 /
OVERTX
72*18.6 /
ENDBOX

```

The modified transmissibilities can be output to the Print file by using the mnemonic MULT in the [RPTSCHED](#) keyword.

**Note:** It is important to note that if the transmissibilities are also modified using transmissibility multiplier [MULTX](#), the resulting output will take into account both of these actions.

## Overwrite Y-direction transmissibilities

This keyword specifies a value to be overwritten on to the transmissibilities during the SCHEDULE section, for flow in the Y direction.

The value is applied to the transmissibility between the cell and its neighbor in the appropriate **positive** direction.

UNITS: cP.rm<sup>3</sup>/day/bars (METRIC), cP.rb/day/psi (FIELD), cP.rcc/hr/atm (LAB), cP.rm<sup>3</sup>/day/atm (PVT-M)

The default is to supply a value for each cell in the grid, that is each keyword should be followed by  $N_x \cdot N_y \cdot N_z$  values in natural order, with the X index changing fastest.

If values are defaulted or set negative, the transmissibilities for the corresponding cells will not be modified.

These keywords is normally used with [BOX](#) and [ENDBOX](#), when the number of values should be the number of cells in the current BOX.

### Example

Set transmissibility values in a box to 1.4:

```

-- IR1-IR2 JT1-JT2 KZ1-KZ2
BOX
  23  25  13  15  1  8 /
OVERTY
72*1.4 /
ENDBOX

```

The modified transmissibilities can be output to the Print file by using the mnemonic MULT in the [RPTSCHED](#) keyword.

---

**Note:** It is important to note that if the transmissibilities are also modified using transmissibility multiplier [MULTY](#), the resulting output takes into account both of these actions.

## Overwrite Z-direction transmissibilities

This keyword specifies a value to be overwritten on to the transmissibilities during the SCHEDULE section, for flow in the Z direction.

The value is applied to the transmissibility between the cell and its neighbor in the appropriate **positive** direction.

UNITS: cP.rm<sup>3</sup>/day/bars (METRIC), cP.rb/day/psi (FIELD), cP.rcc/hr/atm (LAB), cP.rm<sup>3</sup>/day/atm (PVT-M)

The default is to supply a value for each cell in the grid, that is each keyword should be followed by  $N_x \cdot N_y \cdot N_z$  values in natural order, with the X index changing fastest.

If values are defaulted or set negative, the transmissibilities for the corresponding cells will not be modified.

These keywords are normally used with [BOX](#) and [ENDBOX](#), when the number of values should be the number of cells in the current BOX.

### Example

Set transmissibility values in a box to 2.0:

```

-- IR1-IR2 JT1-JT2 KZ1-KZ2
BOX
  23  25  13  15  1  8 /
OVERTZ
72*2.0 /
ENDBOX

```

The modified transmissibilities can be output to the Print file by using the mnemonic MULT in the [RPTSCHED](#) keyword.

**Note:** It is important to note that if the transmissibilities are also modified using transmissibility multiplier [MULTZ](#), the resulting output takes into account both of these actions.

## **P**

This section contains an alphabetic listing of keywords starting with the letter P.

## PARACHOR **Component parachors**

	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

In a run with  $N_c$  components, this keyword associates a parachor with each component. These need only be entered if surface tensions are to be calculated (**MISCIBLE** option requested in **RUNSPEC**).

The keyword should be followed by  $N_c$  values.

The use of parachors is discussed in "[Evaluation of surface tensions](#)" in the *ECLIPSE Technical Description*.

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of keyword **TABDIMS**. The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

UNITS: (dynes/cm)<sup>1/4</sup>cc/gm-M (**METRIC**), (dynes/cm)<sup>1/4</sup>cc/gm-M (**FIELD**), (dynes/cm)<sup>1/4</sup>cc/gm-M (**LAB**), (dynes/cm)<sup>1/4</sup>cc/gm-M (**PVT-M**)

DEFAULT: There are no component-wise default values. The users are recommended not to default these to the internal default value.

### Example

```
PARACHOR
74.92 192.74 390.4 /
```

	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

Initiates a parallel run and sets options for domain decomposition.

This keyword should be followed by up to two items of data, followed by a slash (/).

1. The number of domains (NDMAIN).

DEFAULT: 1

2. The type of run.

SERIAL For the serial implementation of the parallel algorithm.

This activates the ECLIPSE 300 WARP solver

DISTRIBUTED For distributed memory machines.

DEFAULT: DISTRIBUTED

If the second item in the PARALLEL keyword is set to SERIAL, the parallel algorithm is executed on a single processor, without any message passing. Consequently no parallel speedup is observed. This option is for testing only, not for production runs.

See "[Parallel option](#)" in the *ECLIPSE Technical Description*.

### Example

```
PARALLEL
--NDMAIN MACHINE TYPE
   4      DISTRIBUTED /
```

## PARAOPTS Options affecting domain decomposition

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword is used to control a number of options that may improve performance in parallel runs.

The keyword should be followed by one record. The record contains one character string and a number of integers that allow some tuning of the parallel domain decomposition option (see "[Options to improve performance](#)" in the *ECLIPSE Technical Description*). The data should be terminated with a slash (/).

1. Method used for global reduction operations.

Either TREE or T caused a hypercube algorithm to be used for global sums and maximum operations.

Any other character string will cause the data to be collected on one processor and the sum computed there.

DEFAULT: TREE

2. Determines whether parallel code generates one Print (PRT) file for the run or one per slave. The same applies to debug (DBG), log (LOG) and message (MSG) files. The log file contains output that would otherwise be output to the screen on the master process. If one file is produced for each type some output from processes other than process 1 may be lost.

0 produces one file of each stated type. However, if one or several slave processes encounter an error or a bug condition, or a stop limit imposed by keyword `MESSAGES`, the files for each process will be created. Note that these files may not contain some initial information, in which case setting this item to 1 as explained below is still useful.

1 produces a file of each stated type for each process. No log file is produced for process 1 as this is the output that is sent directly to the screen.

DEFAULT: 0

3. Sets the size (in Megabytes) for the message passing buffers used in the MPI version.

ECLIPSE 100 will always use at least about 9.5 Megabytes. Therefore, values less than 10 will have no effect.

DEFAULT: 0

4. Sets the number of buffers to be used for sending messages in the MPI version. ECLIPSE 100 will always use at least 2 buffers.

DEFAULT: 2

5. Values greater than 0 may reduce the memory required for tracer calculations. Currently disabled.

DEFAULT: 0

6. Values greater than 0 cause coarsenings that cross domain boundaries to be split, and the cells in the shared plane left uncoarsened.

DEFAULT: 0

7. Values greater than 0 cause the inlining of NNCs in the outer solver direction to be turned off.

DEFAULT: 0

8. Values greater than 0 cause the reports in the PRT file controlled by the RPT keywords to be produced. Not producing these reports saves memory and decreases execution time.

DEFAULT: 0

9. Reserved.

## Example

```
PARAOPTS  
2* 10 3 /
```

## PARTTRAC Dimensions for the partitioned tracer option

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data consists of three items, giving data needed for the partitioned tracer option. This keyword must be used to activate the option. The option is available if either the environmental tracer option or the surfactant option is used (see "[Environmental tracers](#)" and "[Surfactant model](#)" in the *ECLIPSE Technical Description*).

The data must be terminated by a slash (/).

1. NPARTT: The maximum number of partitioned tracers, entered using keyword [TRACER](#) in the PROPS section.  
DEFAULT: 0
2. NKPTMX: The number of K(P) tables describing the partitioning, entered using keywords [TRACERKP](#) or [TRACERKM](#) in the PROPS section.  
DEFAULT: 0
3. NPKPMX: The maximum number of pressure points in each K(P) table, entered in keyword [TRACERKP](#).  
DEFAULT: 0

### Example

```
PARTTRAC
1 5 30 /
```

### Note

Partitioned tracers allow ECLIPSE 100 to solve a range of problems that could not be tackled otherwise. For example, if marked gas is injected into a reservoir it is possible that the marker may dissolve in the water; the partitioned tracer option can model this behavior. With a single phase tracer in, say, the gas phase, ECLIPSE solves a conservation equation for the total amount of tracer in a grid block, taking into account the inflow and outflow of gas. With a partitioned tracer, one or more additional phases can be nominated (in the [TRACER](#) keyword) into which the tracer may also dissolve. Please see the "[Environmental tracers](#)" chapter in the *ECLIPSE Technical Description*.

---

**Note:** This keyword cannot be used with two-phase tracers.

---

## Pathname aliases

This keyword allows aliases for pathname roots to be defined, to facilitate transfer between different working directories and to avoid unnecessarily long pathnames. The aliases can be used with the [INCLUDE](#), [IMPORT](#), [RESTART](#) and [GDFILE](#) keywords. See "File handling in ECLIPSE" in the *ECLIPSE Technical Description*.

The keyword should be followed by up to 100 records, each of which is terminated by slash (/). The list of aliases is terminated by a null record (that is a record with no data before the terminating slash). Each record consists of the following items of data.

1. ALIAS: Alias for the pathname or pathname root  
(up to 8 characters long and enclosed in quotes).
2. PATHNAME: Full pathname or pathname root to be substituted for the alias  
(up to 132 characters long and enclosed in quotes).

When using an alias in [INCLUDE](#), [IMPORT](#), [RESTART](#) or [GDFILE](#), it should be prefixed by a '\$' which identifies the following string as an alias. ECLIPSE then substitutes the string \$ALIAS by PATHNAME.

### Example

```

--Runspec section
PATHS
`GRIDS'  `/disk1/studies/grids' /
`HMATCH' `/disk1/pred/match' /
`VFP'   `/disk2/wells/vfp' /
/
---Grid section
INCLUDE
`$GRIDS/case1.grdecl' /

--Props section
IMPORT
`$HMATCH/endpoints/modell1.dat' /
/

```

## PBUB

## Initial bubble point pressure

x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword should only be used in a black oil run. The keyword should be followed by one real number for every grid block, specifying the initial bubble point pressure. The data field should be terminated by a slash (/).

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

Grid blocks are ordered with the X axis index cycling fastest (from 1 to NDIVIX), followed by the Y axis index (from 1 to NDIVIY ), and finally the Z axis index (from 1 to NDIVIZ). NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword [DIMENS](#). Repeat counts may be used for repeated values (for example 115\*2.893). Note that spaces must not be inserted on either side of the asterisk (\*).

This keyword is an alternative to the [RS](#) keyword for defining the initial dissolved gas distribution in runs with enumerated initial conditions.

When using explicit initialization, you must ensure that the initial solution is stable and physically reasonable.

See also the keywords [PRESSURE](#), [PRVD](#), [RV](#), [PDEW](#), [SWAT](#) and [SGAS](#) in the SOLUTION section.

## Example

With NDIVIX=8, NDIVIY=6 and NDIVIZ=2 specified in RUNSPEC keyword [DIMENS](#):

```
PBUB
48*3042
48*3063 /
```

## PBVD

## Bubble point versus depth tables for equilibration

The data comprises NTEQUL (see item 1 in keyword [EQLDIMS](#)) tables of bubble point pressure versus depth, one for each equilibration region. Each table consists of 2 columns of data, and must be terminated by a slash (/). Column:

1. Depth values.

The values should increase monotonically down the column.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

2. The corresponding values of the bubble point pressure ( $P_{\text{bub}}$ ).

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NDRXVD (see item 3 in keyword [EQLDIMS](#)).

This keyword is an alternative to the [RSVD](#) keyword, in which the dissolved gas-oil ratio is tabulated against depth for each equilibration region. See also keyword [EQUIL](#).

The PBVD keyword cannot be used in API tracking runs.

See "[Initializing the study](#)" in the *ECLIPSE Technical Description* for further information.

### Example

With NTEQUL=1 and NDRXVD  $\geq$ 3:

```
PBVD
7000 4000
8000 4020
9000 4045 /
```

## PCG, IPCG Scaled maximum gas capillary pressures

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword allows the maximum gas-oil capillary pressure to be scaled on a grid block by grid block basis. The keyword can only be used when the end-point scaling option is active (keyword [ENDSCALE](#) in the RUNSPEC section).

The capillary pressure is given by:

$$P_c = P_{ct} \left( \frac{PCG}{P_{cm}} \right) \quad \text{Eq. 3.138}$$

where

$P_{ct}$  Capillary pressure from the table

$P_{cm}$  Maximum  $P_c$  in the table - at  $S_g = 1 - S_{wco}$

PCG Maximum  $P_c$  from the PCG data.

The PCG keyword should be followed by one real number for each grid block in the current input box, specifying the maximum gas capillary pressure value. The data must be terminated by a slash(/).

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If the PCG keyword is omitted, the maximum gas  $P_c$  value defaults to the value used in the appropriate gas saturation function table.

If the hysteresis model is active (switch 'HYSTER' in keyword [SATOPTS](#)), then the PCG data will scale the drainage curve only. The imbibition curve can be scaled by using the equivalent IPCG keyword.

ECLIPSE 300

If the [ODD3P](#) relative permeability and capillary pressure hysteresis model is selected, this keyword will be ignored.

The PCG keyword should not be used in combination with the J-function option (keyword [JFUNC](#)). In this case, the J-function calculation always defines the water capillary pressure scaling and the input PCG array is ignored.

See also keywords [SGFN](#) and [SGOF](#) in the PROPS section.

Refer to "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for more information.

---

**Note:** The PCG data used to scale the capillary pressure must be consistent with the capillary pressure from the table. In particular PCG has to have the same sign as  $P_{cm}$  in order to avoid having a change in the wettability. If PCG and  $P_{cm}$  have different signs (for example PCG negative and  $P_{cm}$  positive) the scaling will not be performed. Moreover no scaling will be performed if  $P_{cm}$  is zero (see [item 74](#) in [OPTIONS](#) for a different scaling).

---

## Example

With ENDSCALE specified in RUNSPEC; and NDIVIX=1, NDIVIY=7 and NDIVIZ=3 specified in RUNSPEC keyword DIMENS):

```
PCG  
6*10.0  
6*12.0  
6*15.0 /
```

# PCG32D

## 2D table of gas/oil capillary pressure

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword together with keyword **SGF32D** is an alternative to keyword **SGFN**. It allows the three-phase gas/oil capillary pressure to be input directly as a function of oil and water saturations in a two-dimensional table. The gas relative permeability must be provided using keyword **SGF32D**.

The data comprises **NTSFUN** (see item 1 of keyword **TABDIMS** in the **RUNSPEC** section) tables of gas/oil capillary pressure, tabulated against both oil and water saturations, each terminated by a slash (/).

Each table consists of a number of records:

1. The oil saturation values

Values should be between 0 and 1 and should increase monotonically. The number of oil saturation values should not exceed **NSSFUN** (see item 3 of keyword **TABDIMS**).

Subsequent records (a maximum of **NSSFUN** records):

- The water saturation.
- Followed by the gas/oil capillary pressure values for this water saturation at all the corresponding oil saturations entered in Record 1.

The gas/oil capillary pressures should be monotonically decreasing,. The number of gas/oil capillary pressure values should not exceed the number of oil saturation values entered in Record 1.

UNITS: bars (**METRIC**), psi (**FIELD**), atm (**LAB**), atm (**PVT-M**)

The columns of data must also comply with the following constraints:

- The water saturation (the first item in the second and subsequent records) should increase monotonically down the column. The gas/oil capillary pressure for each oil saturation should decrease monotonically down the column.
- Default values may not be placed within the table.

The entire table may be defaulted provided that the table is not the first. Defaulted tables are replaced with a copy of the previous table.

The keyword cannot be used with the end-point scaling, hysteresis or miscible options.

### Example

With **NTSFUN=1** and **NSSFUN ≥ 11**:

```

PCG32D

## PCODD3P

## Capillary pressure calculation control for ODD3P option

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTSFUN (see item 1 of keyword [TABDIMS](#) in the RUNSPEC section) tables of capillary pressure calculation control data, each terminated by a slash (/). Only one row per table should be entered. This keyword is only used with the [ODD3P](#) relative permeability and capillary pressure hysteresis option and is optional.

Each table consists of a single row containing 7 columns of data:

1. Capillary pressure functional dependence calculation control.

DEFAULT: 6

One of thirteen functional dependence relationships may be selected for the calculation of capillary pressure. These are numbered 0 to 12, with a value of 0 used to set the capillary pressures to zero. These functional dependences are described below.

2. Constant  $\delta_g$  in gas saturation dependent capillary pressure weighting function.

DEFAULT: 0.0

This parameter is only used if the value of the functional dependence calculation control parameter defined in column 1 is assigned a value between 1 and 8 inclusive. The use of these weighting functions is described below.

3. First exponent  $\alpha_g$  in gas saturation dependent capillary pressure weighting function.

DEFAULT: 1.0

This parameter is only used if the value of the functional dependence calculation control parameter defined in column 1 is assigned a value between 1 and 8 inclusive. The use of these weighting functions is described below.

4. Second exponent  $\beta_g$  in gas saturation dependent capillary pressure weighting function.

DEFAULT: 1.0

This parameter is only used if the value of the functional dependence calculation control parameter defined in column 1 is assigned a value between 1 and 8 inclusive. The use of these weighting functions is described below.

5. Constant  $\delta_w$  in water saturation dependent capillary pressure weighting function.

DEFAULT: 0.0

This parameter is only used if the value of the functional dependence calculation control parameter defined in column 1 is assigned a value between 1 and 8 inclusive. The use of these weighting functions is described below.

6. First exponent  $\alpha_w$  in water saturation dependent capillary pressure weighting function.

DEFAULT: 1.0

This parameter is only used if the value of the functional dependence calculation control parameter defined in column 1 is assigned a value between 1 and 8 inclusive. The use of these weighting functions is described below.

7. Second exponent  $\beta_w$  in water saturation dependent capillary pressure weighting function.

DEFAULT: 1.0

This parameter is only used if the value of the functional dependence calculation control parameter defined in column 1 is assigned a value between 1 and 8 inclusive. The use of these weighting functions is described below.

The capillary pressure weighting functions  $H(S_g)$  and  $F(S_w)$  are calculated as shown below:

$$H(S_g) = \frac{\delta_g S_g^{\alpha_g}}{S_g^{\alpha_g} + (1 - S_g)^{\beta_g}}$$

and

$$F(S_w) = \frac{\delta_w S_w^{\alpha_w}}{S_w^{\alpha_w} + (1 - S_w)^{\beta_w}}$$

The *representative* capillary pressures, that is, the values obtained from table look-up using the normalized saturations are corrected according to the following equations:

$$P_{cow} = \hat{P}_{cow} + HR$$

$$P_{cgo} = \hat{P}_{cgo} + FR$$

$$R = \hat{P}_{cgo} - \hat{P}_{cgo} - \hat{P}_{cow}$$

where the capillary pressure terms  $\hat{P}_{cij}$  denotes the representative capillary pressures obtained from table look-up as a function of normalized hysteresis saturation  $\tilde{S}_i$  or  $\tilde{S}_j$ . The capillary pressures may be made functions of one of two normalized saturations as shown below:

Saturation Dependence	Oil-Water System	Gas-Oil System	Gas-Water System
1	$\hat{P}_{cow}(\tilde{S}_o)$	$\hat{P}_{cgo}(\tilde{S}_g)$	$\hat{P}_{cgo}(\tilde{S}_g)$
2	$\hat{P}_{cow}(\tilde{S}_w)$	$\hat{P}_{cgo}(\tilde{S}_o)$	$\hat{P}_{cgo}(\tilde{S}_w)$

Table 3.25: Saturation dependencies

The functional dependence calculation control parameter defined above in column 1 of the PCDODD3P keyword selects the method used to calculate the capillary pressures as shown below:

Relationship type	Calculation of oil-water and gas-oil capillary pressure	
0	$P_{cow} = 0.0$	$P_{cgo} = 0.0$
1 and 2	$P_{cow} = \hat{P}_{cow}(\tilde{S}_o) + HR$	$P_{cgo} = \hat{P}_{cgo}(\tilde{S}_g) + FR$
3 and 4	$P_{cow} = \hat{P}_{cow}(\tilde{S}_o) + HR$	$P_{cgo} = \hat{P}_{cgo}(\tilde{S}_o) + FR$
5 and 6	$P_{cow} = \hat{P}_{cow}(\tilde{S}_w) + HR$	$P_{cgo} = \hat{P}_{cgo}(\tilde{S}_g) + FR$
7 and 8	$P_{cow} = \hat{P}_{cow}(\tilde{S}_w) + HR$	$P_{cgo} = \hat{P}_{cgo}(\tilde{S}_o) + FR$

Relationship type	Calculation of oil-water and gas-oil capillary pressure
9	$P_{cow} = \hat{P}_{cow}(\tilde{S}_o)$ <span style="float: right;"><math>P_{cgo} = \hat{P}_{cgo}(\tilde{S}_w) - \hat{P}_{cow}(\tilde{S}_o)</math></span>
10	$P_{cow} = \frac{S_g}{S_g + S_o} \hat{P}_{cgo}(\tilde{S}_w) + \frac{S_o}{S_g + S_o} \hat{P}_{cow}(\tilde{S}_w)$ $P_{cgo} = \frac{S_w}{S_o + S_w} \hat{P}_{cgo}(\tilde{S}_g) + \frac{S_o}{S_o + S_w} \hat{P}_{cgo}(\tilde{S}_g)$
11	$P_{cow} = \frac{S_g}{S_g + S_o} \hat{P}_{cgo}(\tilde{S}_w) + \frac{S_o}{S_g + S_o} \hat{P}_{cow}(\tilde{S}_w) \quad P_{cgo} = \hat{P}_{cgo}(\tilde{S}_g)$
12	$P_{cow} = \frac{S_g(S_o[\hat{P}_{cgo}(\tilde{S}_w) - \hat{P}_{cgo}(\tilde{S}_g)] + S_w[\hat{P}_{cgo}(\tilde{S}_w) - \hat{P}_{cgo}(\tilde{S}_g)]) + S_o(S_o + S_w)\hat{P}_{cow}(\tilde{S}_w)}{S_o(S_g + S_o + S_w)}$ $P_{cgo} = \left[ \frac{S_o}{(S_o + S_w)} + \frac{S_g S_w}{(S_o + S_w)(S_g + S_o + S_w)} \right] \cdot \hat{P}_{cgo}(\tilde{S}_g) +$ $\left[ \frac{S_w}{(S_o + S_w)} + \frac{S_g S_w^2}{S_o(S_o + S_w)(S_g + S_o + S_w)} \right] \cdot \hat{P}_{cgo}(\tilde{S}_g) -$ $\left[ \frac{S_g S_w}{(S_g + S_o + S_w)} \right] \cdot \hat{P}_{cgo}(\tilde{S}_w) - \left[ \frac{S_w}{(S_g + S_o + S_w)} \right] \cdot \hat{P}_{cow}(\tilde{S}_w)$

Table 3.26: Functional relationships for the calculation of capillary pressure

R is calculated according to the value of the capillary pressure functional dependence calculation control parameter (column 1) for values between 1 and 8 above as shown below:

Relationship type	Calculation of value R
1	$R = \hat{P}(\tilde{S}_g) - \hat{P}_{cgo}(\tilde{S}_g) - \hat{P}_{cow}(\tilde{S}_o)$
2	$R = \hat{P}_{cgo}(\tilde{S}_w) - \hat{P}_{cgo}(\tilde{S}_g) - \hat{P}_{cow}(\tilde{S}_o)$
3	$R = \hat{P}_{cgo}(\tilde{S}_g) - \hat{P}_{cgo}(\tilde{S}_o) - \hat{P}_{cow}(\tilde{S}_o)$
4	$R = \hat{P}_{cgo}(\tilde{S}_w) - \hat{P}_{cgo}(\tilde{S}_o) - \hat{P}_{cow}(\tilde{S}_o)$
5	$R = \hat{P}_{cgo}(\tilde{S}_g) - \hat{P}(\tilde{S}_g) - \hat{P}_{cow}(\tilde{S}_w)$
6	$R = \hat{P}_{cgo}(\tilde{S}_w) - \hat{P}_{cgo}(\tilde{S}_g) - \hat{P}_{cow}(\tilde{S}_w)$
7	$R = \hat{P}_{cgo}(\tilde{S}_g) - \hat{P}_{cgo}(\tilde{S}_o) - \hat{P}_{cow}(\tilde{S}_w)$
8	$R = \hat{P}_{cgo}(\tilde{S}_w) - \hat{P}_{cgo}(\tilde{S}_o) - \hat{P}_{cow}(\tilde{S}_w)$

Table 3.27: Functional relationship types and the calculation of R

Capillary pressure functional dependence calculation control parameter options 9, 10 and 11 correspond to cases where R is equal to 0.0. For options 10, 11 and 12 the saturation weightings are obtained from the grid block saturations  $\tilde{S}_i$ . Option 12 incorporates saturation weighting based upon all three grid block saturations (S-Weighted Model). This model has been developed by StatoilHydro ASA see [Ref. 104].

If the `PCODD3PG` keyword is specified, the parameters in columns 2, 3 and 4 which are used to calculate the function  $H(S_g)$  are ignored and the values of this function are obtained from the tabulated data specified by the keyword `PCODD3PG`.

Similarly, if the `PCODD3PW` keyword is specified, the parameters in columns 5, 6 and 7 which are used to calculate the function  $F(S_w)$  are ignored and the values of this function are obtained from the tabulated data specified by the keyword `PCODD3PW`.

The values assigned to items 2 to 7 and the optional superseding of these values by the specification of the keywords `PCODD3PG` and `PCODD3PW` are only relevant if, for a given saturation region, the capillary pressure functional dependency (item 1) has been set to an option between 1 and 8.

Default values (represented by 1\*) may be inserted as required in columns 1 to 7. When the table is read in, these defaults are replaced by the default values specified above.

The second and subsequent tables may be defaulted entirely. Defaulted tables are replaced with a copy of the previous table.

Only the tables associated with the primary saturation region numbers defined using the `PSTNUM` keyword are used. Tables associated with the secondary and tertiary hysteresis saturation region numbers defined using the `ISTNUM` and `DSTNUM` keywords respectively are ignored and may be defaulted.

See "[Saturation functions](#)" in the *ECLIPSE Technical Description* for a description of the method used to compute the oil relative permeability in blocks where all three phases are present.

See also the keywords `EPSODD3P`, `PCODD3PG` and `PCODD3PW`.

## Example

With `NTSFUN=3`

```
PCODD3P
6 1.0 0.1 0.2 1.0 0.11 0.3 /
9 6* /
2 1.3 0.1 0.2 1.5 0.13 0.34 /
```

## PCODD3PG Capillary pressure calculation gas saturation function

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTSFUN (see item 1 of keyword [TABDIMS](#) in the RUNSPEC section) tables of capillary pressure calculation gas saturation functions, each terminated by a slash (/). This keyword is only used with the [ODD3P](#) relative permeability and capillary pressure hysteresis option and is optional. If specified, this keyword replaces the gas saturation function  $H(S_g)$  defined by the parameters specified in the keyword [PCODD3P](#) with the tabulated function defined here.

Each table consists of 2 columns of data:

1. The gas saturation.

Values should be between 0.0 and 1.0 inclusive and should increase monotonically down the column. The first and final values should be 0.0 and 1.0 respectively.

2. The corresponding values for the function  $H(S_g)$ .

Values should be between 0.0 and 1.0 and should be level or increasing down the column. The first and final values should be 0.0 and 1.0 respectively.

Default values (represented by 1\*) may be inserted as required in column 2. When the table is read in, defaults are replaced by values computed by linear interpolation.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (see item 3 of keyword [TABDIMS](#)).

The entire table may be defaulted provided the table is not the first. Defaulted tables are replaced with a copy of the previous table.

Only the tables associated with the primary saturation region numbers defined using the [PSTNUM](#) keyword are used. Tables associated with the secondary and tertiary hysteresis saturation region numbers defined using the [ISTNUM](#) and [DSTNUM](#) keywords respectively are ignored and may be defaulted.

See "[Saturation functions](#)" of the *ECLIPSE Technical Description* for a description of the method used to compute the oil relative permeability in blocks where all three phases are present.

See also the keywords [EPSODD3P](#), [PCODD3P](#) and [PCODD3PW](#).

### Example

With NTSFUN=1 and NSSFUN ≥ 8:

```
PCODD3PG
0.0000 0.000
0.2000 0.030
0.3000 0.050
0.4000 0.150
0.5000 0.240
0.8000 0.670
0.9000 0.800
1.0000 1.000 /
```

1.0000 1.000 /
```

## PCRIT

## Critical pressures

In a run with  $N_c$  components, this keyword associates a critical pressure with each component.

The keyword should be followed by  $N_c$  values.

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of keyword `TABDIMS`. The use of multiple EoS regions is discussed in "Equations of state regions" in the *ECLIPSE Technical Description*.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: There are no component-wise default values. The users are recommended not to default these to the internal default value.

## Example

For a four-component system:

```
PCRIT
1050 1300 1500 1803 /
```

## PCW, IPCW Scaled maximum water capillary pressures

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword allows the maximum water-oil (or water-gas) capillary pressure to be scaled on a grid block by grid block basis. The keyword can only be used when the End Point Scaling option is active (keyword [ENDSCALE](#) in the RUNSPEC section).

The capillary pressure is given by:

$$P_c = P_{ct} \left( \frac{PCW}{P_{cm}} \right) \quad \text{Eq. 3.139}$$

where

$P_{ct}$  Capillary pressure from the table

$P_{cm}$  Maximum  $P_c$  in the table - at  $S_w = S_{wco}$ , connate water

PCW Maximum  $P_c$  from the PCW data.

The PCW keyword should be followed by one real number for each grid block in the current input box, specifying the maximum water capillary pressure value. The data must be terminated by a slash(/).

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If the PCW keyword is omitted, the maximum water  $P_c$  value defaults to the value used in the appropriate water saturation function table.

If the Hysteresis model is active (switch 'HYSTER' in keyword [SATOPTS](#)), then the PCW data scales the drainage curve only. The imbibition curve can be scaled by using the equivalent IPCW keyword.

---

**Note:** The PCW keyword should not be used in combination with the J-function option (keyword [JFUNC](#)). In this case, the J-function calculation always defines the water capillary pressure scaling and the input PCW array is ignored. The maximum capillary pressure for each cell is reported to the INIT file. This is shown as the PCW property in the 3D Viewer.

---

ECLIPSE 300

If the [ODD3P](#) relative permeability and capillary pressure hysteresis model is selected, this keyword will be ignored.

See also keywords [SWFN](#), [SWOF](#) and [SWATINIT](#) in the PROPS section.

Refer to "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for more information.

---

**Note:** The PCW data used to scale the capillary pressure must be consistent with the capillary pressure from the table. In particular PCW has to have the same sign as  $P_{cm}$  in order to avoid having a change in the wettability. If PCW and  $P_{cm}$  have different sign (for example PCW negative and  $P_{cm}$  positive) the scaling will not be performed. Moreover no scaling will be performed if  $P_{cm}$  is zero (see [item 74](#) of [OPTIONS](#) and [item 143](#) of [OPTIONS3](#) for a different scaling).

---

## Example

With ENDSCALE specified in RUNSPEC; and NDIVIX=1, NDIVIY=7 and NDIVIZ=3 specified in RUNSPEC keyword [DIMENS](#):

```
PCW  
6*78.0  
6*20.0  
6*150.0 /
```

# PCW32D

## 2-D table of water/oil capillary pressure

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword together with keyword **SWF32D** is an alternative to keyword **SWFN**. It allows the three-phase water/oil capillary pressure to be input directly as a function of oil and gas saturations in a two dimensional table. The water relative permeability must be provided using **SWF32D** keyword.

The data comprises **NTSFUN** (see item 1 of keyword **TABDIMS** in the **RUNSPEC** section) tables of water/oil capillary pressure, tabulated against both oil and gas saturations, each terminated by a slash (/).

Each table consists of a number of records:

1. The oil saturation values

Values should be between 0 and 1 and should increase monotonically. The number of oil saturation values should not exceed **NSSFUN** (see item 3 of keyword **TABDIMS**).

Subsequent records (a maximum of **NSSFUN** records):

- The gas saturation.
- Followed by the water/oil capillary pressure values for this gas saturation at all the corresponding oil saturations entered in Record 1.

The water/oil capillary pressures should be monotonically increasing, from an initial value of zero. The number of water/oil capillary pressure values should not exceed the number of oil saturation values entered in Record 1.

UNITS: bars (**METRIC**), psi (**FIELD**), atm (**LAB**), atm (**PVT-M**)

The columns of data must also comply with the following constraints:

- The gas saturation (the first item in the second and subsequent records) should increase monotonically down the column. The water/oil capillary pressure for each oil saturation should increase monotonically down the column.
- Default values may not be placed within the table.

The entire table may be defaulted provided that the table is not the first. Defaulted tables are replaced with a copy of the previous table.

The keyword cannot at present be used with the end-point scaling, hysteresis or miscible options.

### Example

With **NTSFUN=1** and **NSSFUN≥11**:

```

PCW32D
-----SOIL-----
--SGAS
0.01  0.27  0.32  0.37  0.42  0.47  0.52  0.57  0.72  0.77  0.78 /

## Initial dew point pressure

This keyword should only be used in a black oil run. The keyword should be followed by one real number for every grid block, specifying the initial vapor oil-gas ratio. The data field should be terminated by a slash (/).

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

Grid blocks are ordered with the X axis index cycling fastest (from 1 to NDIVIX), followed by the Y axis index (from 1 to NDIVIY ), and finally the Z axis index (from 1 to NDIVIZ). NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword [DIMENS](#). Repeat counts may be used for repeated values (for example 115\*0.00377). Note that spaces must not be inserted on either side of the asterisk (\*).

This keyword is an alternative to the [RV](#) keyword for defining the initial vaporized oil distribution in runs with enumerated initial conditions.

When using explicit initialization, you must ensure that the initial solution is stable and physically reasonable.

See also the keywords [PRESSURE](#), [PRVD](#), [RS](#), [PBUB](#), [SWAT](#) and [SGAS](#) in the SOLUTION section.

### Example

With NDIVIX=8, NDIVIY=6 and NDIVIZ=2 specified in RUNSPEC keyword [DIMENS](#):

```
PDEW
48*6123
48*6098 /
```

## PDIVX

## Dew point versus depth tables for equilibration

The data comprises NTEQUL (see item 1 in keyword [EQLDIMS](#)) tables of dew point pressure versus depth, one for each equilibration region.

Each table consists of 2 columns of data, and must be terminated by a slash (/).

1. Depth values.

The values should increase monotonically down the column.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

2. The corresponding values of the dew point pressure ( $P_{\text{dew}}$ ).

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NDRXVD (see item 3 in keyword [EQLDIMS](#)).

This keyword is an alternative to the [RVVD](#) keyword, in which the vaporized oil-gas ratio is tabulated against depth for each equilibration region. See also keyword [EQUIL](#).

See "[Initializing the study](#)" in the *ECLIPSE Technical Description* for further information.

### Example

With NTEQUL=1 and NDRXVD≥3:

```
PDVD
7000 3000
8000 3020
9000 3045 /
```

## PEBI

## Specifies a Pebi/Petra grid is to be used

This keyword instructs ECLIPSE that an unstructured Pebi/Petra grid is used. The grid is expected to be generated by FloGrid.

The keyword is followed by the following items, terminated with a slash (/).

**Note:** ECLIPSE will not itself generate grid files from a simulation that includes the PEBI keyword, so they should not be deleted unless the user is prepared to regenerate them from the original source.

1. Flag to allow negative transmissibilities. (ECLIPSE 100 only.)

YES Allow negative transmissibilities

NO Disallow negative transmissibilities

DEFAULT: NO

2. Flag to avoid grid calculations in ECLIPSE, and to perform data checks appropriate to unstructured grid data.

YES Assume the pore volumes and transmissibilities are all supplied and skip attempting to calculate them

NO Perform pore volume and transmissibility calculations

DEFAULT: NO

**Note:** ECLIPSE 300 does not support any Pebi grid that includes [DUALPORO](#) or [DUALPERM](#).

## Example

## PECOEFS

## Coefficients for petro-elastic model

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data in this keyword consists of a row for each **PENUM** region in the model. Each row consists of at least eight items but may contain values for other items if they are not defaulted. These items describe the coefficients in each **PENUM** region for the Petro-elastic Model. The first ten items are real numbers and the last item is an integer.

Each row of data must be terminated by a slash (/). Empty rows (containing just their terminating slash) default to a copy of the previous row.

1. The salinity of water,  $S$ , in the region.

UNITS: ppm (METRIC), ppm (FIELD), ppm (LAB)

This is used in the calculation of bulk modulus of brine in the Petro-elastic Model.

2. The temperature,  $T$ , in the region.

UNITS: °C (METRIC), °F (FIELD), °C (LAB)

This is used in the calculation of the bulk modulus of oil, water and gas in the Petro-elastic Model. A negative value is not permitted for this item.

3. The combined density of the minerals (for example sand, shale, silt) in the region.

UNITS: kg/m<sup>3</sup> (METRIC), lb/ft<sup>3</sup> (FIELD), gm/cc (LAB)

4. The first order coefficient of effective porosity,  $\phi_{eff}$ , in the calculation of the bulk modulus of the mineral material in the region. This is the  $C_1$  term in equation 3.140:

$$K_{minerals} = C_1 \phi_{eff} + C_0 \quad \text{Eq. 3.140}$$

UNITS: barsa (METRIC), psia (FIELD), atma (LAB)

5. The zero<sup>th</sup> order coefficient of effective porosity,  $\phi_{eff}$ , in the calculation of the bulk modulus of the mineral material in the region. This is the  $C_0$  term in equation 3.140.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB)

6. The coefficient of the mineral bulk modulus in the calculation of the bulk modulus of the frame in the region. This is the  $C_K$  term in equation 3.141. To make the frame bulk modulus independent of the mineral bulk modulus, this value should be set to zero.

$$K_{frame}^{\alpha} = C_K K_{minerals}^{\alpha} + \sum_{i=0}^{\alpha} C_{K,i}(P) \phi_{eff}^i \quad \text{Eq. 3.141}$$

where  $\alpha$  is the **item 9** and the  $C_{K,i}(P)$  tables are specified using the keyword **PEKTABx**.

UNITS: dimensionless

7. The coefficient of the mineral shear modulus in the calculation of the shear modulus of the frame in the region. This is the  $C_G$  term in equation 3.142. To make the frame shear modulus independent of the mineral shear modulus, this value should be set to zero.

$$G_{frame}^{\alpha} = C_G G_{minerals}^{\alpha} + \sum_{i=0}^7 C_{G,i}(P) \phi_{eff}^i \quad \text{Eq. 3.142}$$

where  $\alpha$  is defined in the previous item,  $G_{minerals}$  is defined in the next item, and the  $C_{G,i}(P)$  tables are specified using the keyword `PEGTABx`.

UNITS: dimensionless

8. The shear modulus of the mineral,  $G_{minerals}$ , in the region.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB)

9. The exponent of the mineral bulk/shear modulus in the calculation of the bulk/shear modulus of the frame in the region. This is the  $\alpha$  term in equations 3.141 and 3.142. Typical values for this are +1 (so that the mineral term is simply added to the pore volume terms to generate the frame term) and -1 (so that a harmonic style addition is used). A value of zero is not allowed for this item.

DEFAULT: 1

UNITS: dimensionless

10. The exponent in the calculation of bulk modulus of fluid. This is the  $e$  term in equation 3.143.

$$K_{fluid} = (K_{liquid} - K_g)(1 - S_g)^e + K_g \quad \text{Eq. 3.143}$$

where

$K_{fluid}$  is the bulk modulus of fluid (mixture of oil, water and gas),

$K_g$  is the bulk modulus of gas,  $S_g$  is the gas saturation and

$K_{liquid}$  is given by equation 3.144.

Note that this item will be ignored if item 11 is 0.

$$\frac{S_o + S_w}{K_{liquid}} = \frac{S_o}{K_o} + \frac{S_w}{K_w} \quad \text{Eq. 3.144}$$

DEFAULT: 1

UNITS: dimensionless

11. Switch between the two available methods for calculating the fluid bulk modulus. These methods are a generalized form of Wood's law for the oil, water and gas as given by equation 3.145,

$$\frac{1}{K_{fluid}} = \frac{S_o}{K_o} + \frac{S_w}{K_w} + \frac{S_g}{K_g} \quad \text{Eq. 3.145}$$

and the standard Wood's law for the oil and water with Brie et al (SPE 30595) used for the addition of the gas term, as given in equation 3.143. This switch is an integer value. It can only take the values 0 and 1.

- A value of 0 indicates that equation 3.145 is to be used in the region
- A value of 1 indicates that equations 3.143 and 3.144 are to be used.

DEFAULT: 0

## Example

The following example shows the `PECOEFS` for a model which has `FIELD` units and has 4 `PENUM` regions. The number of `PENUM` regions is specified by item 1 of the `PEDIMS` keyword in the `RUNSPEC` section.

In this example, the third and fourth rows have been left blank, so the data for these rows is copied from the second row.

```
PECOEFS
      3.0E4 201.0 165.0 -2.8E6 2.2E6 0.5 1.0 0.9E6 1 2 1 /
      3.0E4 210.0 168.0 -2.7E6 2.2E6 0.5 1.0 1.1E6 1 2 1 /
/
/
```

## PEDTUNE

## Set non-default Pedersen viscosity tuning parameters

	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword provides a mechanism for modifying the default tuning parameters used for the calculation of the mixture molecular weight and the rotational coupling factors in the Pedersen et al. viscosity correlation. It is only relevant if the Pedersen et al. viscosity calculations have been selected by including the `PEDERSEN` keyword in the `PROPS` section; otherwise it will be ignored.

The data consist of six items. items 1 and 2 are for the tuning mixture molecular weight and items 3 to 6 are for the rotational coupling factors.

1. Tuning parameter 1:  
 DEFAULT: 1.0  
 Minimum: 0.1  
 Maximum: 10.0
2. Tuning parameter 2:  
 DEFAULT: 1.0  
 Minimum: 0.1  
 Maximum: 10.0
3. Tuning parameter 3:  
 DEFAULT: 1.847  
 Minimum: -100.0  
 Maximum: 100.0
4. Tuning parameter 4:  
 DEFAULT: 0.5173  
 Minimum: -1000.0  
 Maximum: 1.5
5. Tuning parameter 5:  
 DEFAULT: 7.378E-03  
 Minimum: -0.015  
 Maximum: 0.1
6. Tuning parameter 6:  
 DEFAULT: 3.1E-02  
 Minimum: -0.2  
 Maximum: 1.1

The data must be terminated with a slash (/).

Using this keyword only one set of tuning parameters is required. Alternatively, if multiple equation of state regions have been specified, the `PEDTUNER` keyword may be used to specify these tuning parameters separately for each equation of state.

For the Pedersen viscosity correlation, the mixture molecular weight is given by:

$$M_{w,mix} = c_1 \cdot 1.304 \times 10^{-4} (\bar{M}_w^{c_2 \cdot 2.303} - \bar{M}_n^{c_2 \cdot 2.303}) + \bar{M}_n$$

where

$\bar{M}_w$  and  $\bar{M}_n$  are the weight average and number average mole weights respectively, and

$c_1$  and  $c_2$  are the tuning parameters 1 and 2 respectively, specified using this keyword.

For the Pedersen viscosity correlation, the rotational coupling factors are given by:

$$\alpha_{mix} = 1 + c_5 \cdot (\rho_{r,mix})^{c_3} \cdot (M_{w,mix})^{c_4}$$

$$\alpha_o = 1 + c_6 \cdot (\rho_{r,mix})^{c_3}$$

where

$\rho_{r,mix}$  is the reduced density, and

$c_3$ ,  $c_4$ ,  $c_5$  and  $c_6$  are the tuning parameters 3, 4, 5 and 6 respectively, specified using this keyword.

## Example

Select a single set of non-default tuning parameters for the entire reservoir model:

```
PEDTUNE
1.001 1.005 1.847 0.5173 7.378E-03 3.1E-02 /
```

## PEDTUNER **Set non-default Pedersen viscosity tuning parameters for multiple EoS regions**

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword provides a mechanism for modifying the default tuning parameters used for the calculation of the mixture molecular weight and the rotational coupling factors in the Pedersen et al. viscosity correlation. This is done separately for each equation of state (EoS) region, the number of which is specified using item 9 in [TABDIMS](#). This keyword is only relevant if the Pedersen et al. viscosity calculations have been selected by including the [PEDERSEN](#) keyword in the PROPS section and will otherwise be ignored.

The data consists of six items followed by a slash (/) for each equation of state region. items 1 and 2 are for tuning the mixture molecular weight. items 3 to 6 are for the rotational coupling factors.

1. Tuning parameter 1:  
 DEFAULT: 1.0  
 Minimum: 0.1  
 Maximum: 10.0
2. Tuning parameter 2:  
 DEFAULT: 1.0  
 Minimum: 0.1  
 Maximum: 10.0
3. Tuning parameter 3:  
 DEFAULT: 1.847  
 Minimum: -100.0  
 Maximum: 100.0
4. Tuning parameter 4:  
 DEFAULT: 0.5173  
 Minimum: -1000.0  
 Maximum: 1.5
5. Tuning parameter 5:  
 DEFAULT: 7.378E-03  
 Minimum: -0.015  
 Maximum: 0.1
6. Tuning parameter 6:  
 DEFAULT: 3.1E-02  
 Minimum: -0.2  
 Maximum: 1.1

The data must be terminated with a slash (/).

For the Pedersen viscosity correlation, the mixture molecular weight is given by:

$$M_{w,mix} = c_1 \cdot 1.304 \times 10^{-4} (\bar{M}_w^{c_2 \cdot 2.303} - \bar{M}_n^{c_2 \cdot 2.303}) + \bar{M}_n$$

where

$\bar{M}_w$  and  $\bar{M}_n$  are the weight average and number average mole weights respectively, and

$c_1$  and  $c_2$  are the tuning parameters 1 and 2 respectively, specified by this keyword.

For the Pedersen viscosity correlation, the rotational coupling factors are given by:

$$\alpha_{mix} = 1 + c_5 \cdot (\rho_{r,mix})^{c_3} \cdot (M_{w,mix})^{c_4}$$

$$\alpha_o = 1 + c_6 \cdot (\rho_{r,mix})^{c_3}$$

where

$\rho_{r,mix}$  is the reduced density, and

$c_3$ ,  $c_4$ ,  $c_5$  and  $c_6$  are the tuning parameters 3, 4, 5 and 6 respectively, specified using this keyword.

If only one set of tuning parameters is required, the [PEDTUNE](#) keyword may be used to specify these tuning parameters for the entire reservoir.

## Example

Select non-default tuning parameters for a model with two equation of state regions:

```
PEDTUNER
1.001 1.005 1.847 0.5173 7.378E-03 3.1E-02 /
1.002 1.006 1.84 0.5173 7.378E-03 3.15E-02 /
```

## PEGTABx

## Pressure table for shear modulus of frame

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

These keywords specify the tables which contain the coefficients of a polynomial in effective porosity  $\phi_{eff}$  to be used in the calculation of the **shear** modulus of the frame in the petro-elastic model. Each of these tables specifies a coefficient as a function of pressure  $P$  for each **PENUM** region.

The general version of shear modulus of frame,  $G_{frame}$  is

$$G_{frame}^{\alpha} = C_G G_{mineral}^{\alpha} + \sum_{i=0}^7 C_{G,i}(P) \phi_{eff}^i$$

where

$C_G$ ,  $G_{mineral}$  and  $\alpha$  are the constants defined by keyword **PECOEFS** in the **PROPS** section,

$\phi_{eff}$  is the effective porosity and

the  $C_{G,i}(P)$  terms are the following keywords recognized by ECLIPSE:

PEGTAB0 Table of  $C_{G,0}(P)$  against pressure  $P$

PEGTAB1 Table of  $C_{G,1}(P)$  against pressure  $P$

PEGTAB2 Table of  $C_{G,2}(P)$  against pressure  $P$

PEGTAB3 Table of  $C_{G,3}(P)$  against pressure  $P$

PEGTAB4 Table of  $C_{G,4}(P)$  against pressure  $P$

PEGTAB5 Table of  $C_{G,5}(P)$  against pressure  $P$

PEGTAB6 Table of  $C_{G,6}(P)$  against pressure  $P$

PEGTAB7 Table of  $C_{G,7}(P)$  against pressure  $P$

Each keyword consists of a number of tables. The number of tables is determined by item 1 of keyword **PEDIMS** in the **RUNSPEC** section, there being one table for each **PENUM** region. The number of entries in a single table should not exceed item 2 of keyword **PEDIMS**. Each table must be terminated by a slash (/).

If a keyword is not present, all its tables are assumed to be zero.

Each table consists of the following items of data.

1. The pressure  $P$

The pressure values - these must be monotonically increasing for each table.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB)

2. The value of  $C_{G,i}(P)$

UNITS: barsa<sup>a</sup> (METRIC), psia<sup>a</sup> (FIELD), atma<sup>a</sup> (LAB)

Empty tables (containing just their terminating slash) default to a copy of the previous table.

## Example

If the information in the `PEDIMS` keyword specifies that there are 3 `PENUM` regions and at least 4 points in each table, then the `PEGTAB7` keyword could be as shown:

```
PEGTAB7
1800 1.0E+5
2000 3.1E+5
2100 2.8E+5
2480 2.7E+5 /
1500 0.8E+5
2500 4.2E+5
3000 2.9E+5 /
/
```

In this example, the table for the third `PENUM` region is defaulted to be the same as that for the second region.

## PEKTABx

## Pressure table for bulk modulus of frame

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

These keywords specify the tables which contain the coefficients of a polynomial in effective porosity  $\varphi_{eff}$  to be used in the calculation of the **bulk** modulus of the frame in the petro-elastic model. Each of these tables specifies a coefficient as a function of pressure  $P$  for each **PENUM** region.

The general version of bulk modulus of frame,  $K_{frame}$ , is

$$K_{frame}^{\alpha} = C_K K_{mineral}^{\alpha} + \sum_{i=0}^7 C_{K,i}(P) \varphi_{eff}^i \quad \text{Eq. 3.146}$$

where

$K_{mineral}$  is the bulk modulus of mineral material making up rock,

the constants  $C_K$  and  $\alpha$  are defined in the keyword **PECOEFS** in the **PROPS** section,

$\varphi_{eff}$  is the effective porosity and

the  $C_{K,i}(P)$  terms are the following keywords recognized by ECLIPSE:

PEKTAB0 Table of  $C_{K,0}(P)$  against pressure  $P$

PEKTAB1 Table of  $C_{K,1}(P)$  against pressure  $P$

PEKTAB2 Table of  $C_{K,2}(P)$  against pressure  $P$

PEKTAB3 Table of  $C_{K,3}(P)$  against pressure  $P$

PEKTAB4 Table of  $C_{K,4}(P)$  against pressure  $P$

PEKTAB5 Table of  $C_{K,5}(P)$  against pressure  $P$

PEKTAB6 Table of  $C_{K,6}(P)$  against pressure  $P$

PEKTAB7 Table of  $C_{K,7}(P)$  against pressure  $P$

Each keyword consists of a number of tables. The number of tables is determined by item 1 of keyword **PEDIMS** in the **RUNSPEC** section, there being one table for each **PENUM** region. The number of entries in a single table should not exceed item 2 of keyword **PEDIMS**. Each table must be terminated by a slash (/).

If a keyword is not present, all its tables are assumed to be zero.

Each table consists of the following items of data.

1. The pressure  $P$

The pressure value. These must monotonically increase for each table.

UNITS: barsa (**METRIC**), psia (**FIELD**), atma (**LAB**)

2. The value of  $C_{K,i}(P)$

UNITS: barsa<sup>a</sup> (METRIC), psia<sup>a</sup> (FIELD), atma<sup>a</sup> (LAB)

Empty tables (containing just their terminating slash) default to a copy of the previous table.

## Example

If the information in the `PEDIMS` keyword specifies that there are 3 `PENUM` regions and at least 4 points in each table, then the `PEKTAB4` keyword could be as shown:

```
PEKTAB4
1240 0.1E+6
2357 2.0E+6
2450 1.1E+6 /
1000 4.4E+6
2000 2.6E+6
2500 2.7E+6
3000 3.0E+6 /
/
```

In this example, the table for the third `PENUM` region is defaulted to be the same as that for the second region.

## PENUM

x	ECLIPSE 100

## Petro-elastic region numbers

The keyword should be followed by one integer for every grid block in the current input box specifying the region to which it belongs.

---

**CAUTION:** You must specify a value for each grid block in the model.

---

The region number should not be less than 1 nor greater than the first entry in the keyword [PEDIMS](#). The data must be terminated by a slash (/).

The petro-elastic region number specifies which set of petro-elastic coefficients and frame bulk/shear modulus functions (input using [PECOEFS](#), [PEKTABx](#) and [PEGTABx](#) in the [PROPS](#) section) should be used to calculate the petro-elastic properties in each grid block.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

See also the petro-elastic function keywords [PEDIMS](#), [PECOEFS](#), [PEKTABx](#) and [PEGTABx](#) in the [PROPS](#) section.

### Example

With [NDIVIX=10](#), [NDIVIY=10](#), [NDIVIZ=3](#) specified in [RUNSPEC](#) keyword [DIMENS](#) and no input [BOX](#) set, the following example would specify that the top layer is in petro-elastic region 1, the middle layer is in region 2, and the third layer is in region 3:

```
PENUM
100*1 100*2 100*3 /
```

## PERMAVE

**Permeability averages for transmissibility**

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword may optionally be used to modify the way the adjacent grid block permeabilities are averaged when ECLIPSE calculates the interblock transmissibilities.

The keyword should be followed by three real numbers, to specify the exponents used in the power law expression for averaging block permeabilities in each direction. These replace the default weighted harmonic averages of block permeabilities employed when calculating interblock transmissibilities. The three numbers represent the exponents for the permeability averages in the I, J and K directions respectively. The data should be terminated by a slash (/).

Each exponent is defaulted to -1.0, which reproduces the usual weighted harmonic averages of block permeabilities. A value of 1.0 produces a weighted arithmetic average, while a value of 0.0 produces a weighted geometric average. If the exponent is less than -10.0 (or greater than 10.0), then the minimum (or maximum) block permeability respectively is used as the average.

If the [LINKPERM](#) keyword is specified as well as PERMAVE, then the interface permeability implied by LINKPERM overrides any average indicated by PERMAVE.

The forms taken by the various options are described in "[Transmissibility Calculations](#)" in the *ECLIPSE Technical Description*.

**Example**

The default transmissibilities are used in the X direction, while Y direction permeabilities use a geometric average and arithmetic averaging is used for the Z direction permeabilities.

```
PERMAVE
1* 0.0 1.0 /
```

## PERMMF

## PERMSTAB Geomechanics permeability multiplier as a tabular function of rock stress

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

A permeability multiplier may be specified in table form as a function of maximum and minimum principal stress. This keyword is only valid if the geomechanics option is chosen (see [GEOMECH](#) in the RUNSPEC section).

The data comprises NGMYRG (first item in keyword [GEODIMS](#) in the RUNSPEC section) tables, each terminated by a slash (/), where NGMYRG is the number of geomechanics regions in the model.

The first record sets the values of the maximum principal stress,  $\sigma_1$ . These must be monotonically increasing. This record must end with a slash (/).

Record 1             $\sigma_{1,1}$     $\sigma_{1,2}$    ...    $\sigma_{1,NGMPTC}$

The next NGMPTR records set the values of the minimum principal stress,  $\sigma_3$  followed by the table data for the permeability multipliers,  $PM$ . A value of 1 for a multiplier means the phase mobilities are unchanged. Values of the minimum principal stress must be monotonically increasing; that is, subsequent records must have increasing  $\sigma_3$ . Repeat counts may be used with the multipliers, but not with the maximum/minimum principal stresses.

Record 2             $\sigma_{3,1}$     $PM_{1,1}$    ...    $PM_{1,NGMPTC}$

Record 3             $\sigma_{3,2}$     $PM_{2,1}$    ...    $PM_{2,NGMPTC}$

... ..

... ..

Record NGMPTR    $\sigma_{3,NGMPTR}$     $PM_{NGMPTR,1}$    ...    $PM_{NGMPTR,NGMPTC}$   
+1

Records 2 through NGMPTR must end with a slash (/).

---

**Note:** If the permeability multiplier is only a function of the maximum principal stress, then set or default the number of rows, NGMPTR, to be 1. In this case, the first value in Record 2,  $\sigma_{3,1}$ , is ignored. Similarly, if the multiplier is only a function of the minimum principal stress, then set or default the number of columns, NGMPTC, to be 1. Again, in this case the first value in Record 1,  $\sigma_{1,1}$ , is ignored.

---

The set of records is ended by a blank record, containing only a slash.

The permeability multipliers are not checked for monotonicity. If input maximum and minimum principal stresses from the simulation model lie outside the range of the above table, constant slope extrapolation is used.

See also "[Geomechanics](#)" in the *ECLIPSE Technical Description*.

### Example

With NGMYRG=1, NGMPTC=4, NGMPTR=3:

```
PERMSTAB
-- Maximum principal stresses
   5000  7000  9000  11000  /
-- Minimum principal stress, permeability multipliers
5000  2*1      1.1  1.3  /
6000  1       1.1  1.2  1.4  /
8000  1.1     1.3  1.6  1.9  /
/
```

## PERMTHT

## PERMXY-ZZ Specifies off-diagonal tensor permeability coefficients

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The PERMXY, PERMYZ, PERMZ, PERMXX, PERMY and PERMZZ keywords specify the components of the permeability tensor. The basis in which the tensor is defined is given by the MPFA keyword. The permeability tensor  $K$  is assumed to be symmetric and is specified by its components  $K_{11} = \text{PERMX}$ ,  $K_{22} = \text{PERMY}$ ,  $K_{33} = \text{PERMZ}$ ,  $K_{12} = K_{21} = \text{PERMXY}$ ,  $K_{23} = K_{32} = \text{PERMYZ}$  and  $K_{31} = K_{13} = \text{PERMZ}$ .

The diagonal terms are aliased: PERMXX to [PERMX](#), PERMY to [PERMY](#) and PERMZZ to [PERMZ](#).

The keyword should be followed by one real number for every grid block in the current input box specifying the X-direction permeability. The data must be terminated by a slash (/).

UNITS: mD (METRIC), mD (FIELD), mD (LAB), mD (PVT-M)

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*208.4). Note that spaces must not be inserted on either side of the asterisk.

Keyword MPFA must be specified to enable the use of tensor permeabilities.

Any tensor values not entered are defaulted to zero (0.0).

### Example

```

## Imports grid from a .GSG

This keyword allows the grid geometry to be imported from either a Generic Simulation Grid (GSG) file.

This type of file format has to be imported using Petrel.

ECLIPSE will read a .GSG file. The root extension **must** be provided.

ECLIPSE cannot generate a GRID / EGRID output file when the geometry is read from a GSG file with the PETGRID keyword. If an EGRID / GRID is required, export it from Petrel.

### .GSG files

The .GSG file can contain grid geometry for both global and local grids. Either corner point geometry with straight pillars or corner point geometry with curved or truncated pillars can be imported.

For any .GSG file containing LGRs, it is important to note that the [PETOPTS](#) keyword, together with the LGRSIMGD argument, must be set in the RUNSPEC section of the data file. This helps in the preprocessing of the LGRs within the simulators.

For straight pillar geometry, non-neighbor connections and transmissibilities can be determined by the simulators, but if values are present in the .GSG file then they will be used and no calculations will be performed. For curved or truncated pillar geometry they must be specified in the .GSG file. All other grid-cell based global and local properties for the GRID, EDIT, PROPS, REGIONS and SOLUTION sections can be imported. This includes any necessary [DUALPORO](#) and [DUALPERM](#) cell based properties, for instance the multiplier to be used in determining the matrix-fracture coupling transmissibilities.

---

**Note:** Where the transmissibilities are imported from the .GSG file rather than calculated, any keywords which would have been used in their initial calculation in the GRID section will have no effect. If transmissibility multipliers are required, they should be specified in the EDIT section.

---

Since the .GSG file is exported from Petrel, it is advisable that the geometry be viewed there. ECLIPSE will **not** output any kind of GRID file if the PETGRID keyword is present in the dataset. A warning message will be issued if GRID file output is requested when the PETGRID keyword is used.

### .OPF files

---

**Attention:** The PETGRID keyword was introduced in 2005A in order to import the .OPF file format which was introduced for the FrontSim simulator. From the 2008.1 release, this file format was no longer supported in ECLIPSE. From the 2012.1 release, the file format support is withdrawn. An alternate method must be chosen, for instance, using the .GSG format, importing GRID files and/or using ECLIPSE keywords.

---

## Specifying PETGRID keyword and data

The PETGRID keyword should be followed by a single data item specifying the complete name, including any suffix, of the .GSG file containing the required grid information.

The PETGRID keyword is incompatible with auto refinement. The grid should be altered inside Petrel in this case.

The data should be terminated by a slash (/).

---

**CAUTION:** This keyword is also not recommended for use with the vertical equilibrium option.

---

## Example

In this example, ECLIPSE reads the geometric grid data and cell properties from the GSG file called MODEL1.GSG.

```
PETGRID  
MODEL1.GSG /
```

## PETOPTS

## Options for Petrel runs

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by some or all of the following data items, which typically set options for simulator runs started by Petrel. The data should be terminated by a slash (/).

**Note:** Refer to Petrel documentation and release notes for additional information.

**CAUTION:** The LGRSIMGD, TRANPORV, NOFLTNNC and NOPINCHC arguments should never be edited by hand - they are written by Petrel to reflect the data contained in the .GSG file. Altering them by hand is likely to lead to invalid results.

### PETOPTS data items

#### Simulator input options

**Note:** The following options affect simulator input. They must correspond with the contents of the geometry file in order for the simulator to function correctly. **They should never be added or removed manually.**

**LGRSIMGD** The geometry file imported using the [PETGRID](#) keyword contains local grid refinements. This mnemonic is necessary for the simulators to read and process the local grid data during the pre-sweep of all the keywords in the entire data file. Without it, the simulators will fail to process the LGR data correctly, resulting in error messages and failure to simulate.

**TRANPORV** The geometry file(s) imported from Petrel contains transmissibilities and pore volumes, and also non-neighbor connections due to faults and pinchouts. For ECLIPSE Thermal models, rock volumes, heat transmissibilities and thermal conductive non-neighbor connections will also be exported. The TRANPORV mnemonic will be output by Petrel if curved or listric pillars are exported in the .GSG file. Typically, this geometry is complex so Petrel is best placed to define the necessary non-neighbor connections, transmissibilities, pore volumes (and rock volumes). For simpler corner point geometries, this mnemonic is not needed as the simulators are able to calculate all the essential grid geometry and grid cell volume information needed. However, the more complex geometries (curved or listric pillars) may cause ECLIPSE to miscalculate these quantities. It is recommended that the [RPTGRID](#) and [RPTGRIDL](#) keywords are used with mnemonics ALLNNC, PORV, TRANX / TRANY / TRANZ, ROCKV and HEATTX / HEATTY / HEATTZ for further investigation.

#### Simulator output options

**Note:** The following options affect simulator output and can be specified by the user as required.

**INITNNC** By default, the simulators will **not** output any kind of grid file if the [PETGRID](#) keyword is used. If the run contains non-neighbor connections, INITNNC enables the NNC index information to be defined in the .INIT file together with the TRANNNC information and the CORSNUM information. If you have chosen a combination of settings which mean that a

grid file is being output, then this information will be defined both in it and in the .INIT file.

- TINYINIT** Output only the pore volume array and the transmissibility arrays (and the non-neighbor connection information if requested by **INITNNC**) to the .INIT file. If this option is not specified, the output to the .INIT file will remain unchanged.
- EDITSUPP** Suppress warning messages that could be output due to non-neighbor connections not being found while reading **EDITNNC** or **EDITNNCR** data.
- NEWTRAN** Force ECLIPSE 300 to use a corner-point type calculation of transmissibilities. This is equivalent to the ECLIPSE 100 **NEWTRAN** keyword, and is intended to allow calculation of X and Y fault transmissibilities in coarsened regions. In ECLIPSE 100, this mnemonic is permitted but has no effect.
- ECLIPSE 300 only* **OLDORNNC** Within the .INIT file, output the data for non-neighbor connections between global cells in the order used pre-2010.1. If this option is omitted, then the order matches that used in the restart and .FLUX files.
- NOCOMPIN** Output values for all grid blocks to the .INIT file, not just active grid blocks.

---

**Note:** When this mnemonic is specified in ECLIPSE 100, the simulator will run in **NOSIM** mode with all cells treated as active cells in order to generate the required .INIT file. If other output files are required, save the uncompressed .INIT file, remove the **NOCOMPIN** mnemonic, and rerun.

---

- ECLIPSE 100 only* **NOSWATIN** Suppress the output of the **SWATINIT** array to the if this array is not specified in the input data file. By default this array is written to the .INIT file as undefined values if not specified in the input data file.

DEFAULT: None of the above

## Obsolete options

The following options are obsolete and should not be added to datasets:

- **NOFLTNNC**: Simulator fault non-neighbor connection calculations are always suppressed if the **TRANPORV** mnemonic is specified.
- **NOPINCHC**: Simulator pinchout non-neighbor connection calculations are always suppressed if the **TRANPORV** mnemonic is specified.

## Example

Allow non-neighbor connection index information to be output to the .INIT file, and import transmissibilities and pore volumes from the .GSG file.

```
PETOPTS
INITNNC TRANPORV /
```

## PICOND

## Controls calculation of generalized pseudo-pressure option

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword controls the calculation of the generalized pseudo-pressure option for modeling the effects of condensate dropout on the fluid mobilities at producing well connections (see "Special inflow equations" in the *ECLIPSE Technical Description*). The PICOND keyword is optional, as suitable defaults are applied in its absence.

The option is activated in gas condensate runs for individual wells by entering GPP in item 8 of keyword WELSPECS. In ECLIPSE 300 the option may also be activated for all wells by entering the PSEUPRES keyword.

The keyword should be followed by some or all of the following data items, terminated with a slash (/).

1. The maximum interval between pressure quadrature points below the dew point pressure, in the calculation of the generalized pseudo-pressure integral.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

DEFAULT: 4 times atmospheric pressure

2. The maximum interval between pressure quadrature points above the dew point pressure, in the calculation of the generalized pseudo-pressure integral.

If a zero or negative quantity is entered, the quadrature points are the same as the pressure points input in the PVTG table.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

DEFAULT: 0.0

DEFAULT: 10 times atmospheric pressure

3. Damping coefficient, PPDAMP, for the blocking factor.

This value must lie between 0.0 and 1.0. It provides a means of damping oscillations that may result from the explicit calculation of the blocking factor  $\beta$  (which is calculated at the beginning of each timestep), by averaging it with its value from the previous timestep according to the formula

$$\beta_{\text{used}} = \text{PPDAMP}\beta_{\text{calculated}} + (1-\text{PPDAMP})\beta_{\text{previous}}$$

DEFAULT: 1.0

4. Allow Velocity Dependent Relative Permeability (VDRP) and Forchheimer effects in the pseudo-pressure calculation?

- Either YES or NO

If this data item is set to YES, both Capillary Number VDRP and Forchheimer effects are included in the pseudo-pressure calculation. The VDRP option must be activated with keyword VELDEP. Properties of the Capillary Number and Forchheimer models are set with keywords VDKRO, VDKRG and VDKRGC.

DEFAULT: NO

5. Multiplicative factor, PPBFAC, to generate the lower bound in the construction of the generalized pseudo-pressure integral table.

$$p_L = (\text{PPBFAC}) \times p_{\text{completion cell}}$$

ECLIPSE 100

ECLIPSE 100

ECLIPSE 300

ECLIPSE 300 only

ECLIPSE 300 only

This lower bound is the  $p_L$  base pressure described in "[Generalized pseudo-pressure in ECLIPSE 300](#)" in the *ECLIPSE Technical Description*. It should be chosen so that the required range of cell and well pressures will be covered by the pseudo-pressure integral.

This is a dimensionless value which must lie between 0.0 and 0.95.

DEFAULT: 0.0

- ECLIPSE 300 only* 6. Multiplicative factor, PPAFAC, to generate the upper bound in the construction of the generalized pseudo-pressure integral table.

$$p_U = (\text{PPAFAC}) \times p_{\text{completion cell}}$$

This upper bound should be chosen so that the required range of cell and well pressures will be covered by the pseudo-pressure integral.

This is a dimensionless value which must lie between 1.05 and 2.0.

DEFAULT: 1.1

- ECLIPSE 300 only* 7. Dimensionless number, PPSWLM, giving the fractional change in water saturation in the completion grid block necessary to force a recalculation of the generalized pseudo-pressure integral table.

DEFAULT: 0.1

- ECLIPSE 300 only* 8. Dimensionless number, PPPSLM, giving the fractional decrease in saturation pressure in the completion grid block necessary to force a recalculation of the generalized pseudo-pressure integral table. An increase in saturation pressure always forces a recalculation.

DEFAULT: 0.1

- ECLIPSE 300 only* 9. Dimensionless number, PPCMLM, giving the fractional change in composition necessary to force a recalculation of the generalized pseudo-pressure integral table. If any one component shows this fractional change then the table is recomputed.

DEFAULT: 0.01

- ECLIPSE 300 only* 10. Maximum time between recalculations of generalized pseudo-pressure integral table. If this is set to a negative value then no limit is imposed.

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

DEFAULT: -1 (that is no limit)

- ECLIPSE 300 only* 11. Adaptive ordinate error. When calculating the generalized pseudo-pressure integral table, if this value is positive more ordinates are placed where the mobility is non-linear, and fewer ordinates are placed where the mobility is linear. This item determines how many ordinates are used. If the area defined by three ordinates is different from the area defined by the outer two by more than this fraction, an extra ordinate will be added between the first two ordinates. A reasonable value for this item would be between 0.001 and 0.05.

DEFAULT: -1 (that is use regular ordinates)

- ECLIPSE 300 only* 12. Adaptive ordinate minimum spacing. This is the minimum possible distance between any pair of ordinates when the adaptive ordinate spacing scheme is active.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

DEFAULT: 0.1 atm

End the data record with a slash (/).

## Notes

- ECLIPSE 300 only* • The lower and upper bound factors (items 5 and 6) can be used to reduce the size of the pressure range covered by the generalized pseudo-pressure integral. In conjunction with the intervals in items 1 and 2, this can be used to increase the accuracy of the integration without having to use too many quadrature points (which can be computationally expensive otherwise). Unfortunately there is no good rule for selecting these bounds so the defaults should be used unless they are leading to problems.
- ECLIPSE 300 only* • The generalized pseudo-pressure integration table recalculation limits (items 7, 8, 9 and 10) may be used if certain anomalous behaviors are encountered in production. One example is if a well BHP drops sharply, but then recovers then an inappropriate table may have generated an anomalously high blocking factor. If this is suspected, setting any of items 7, 8, 9 or 10 to 0.0 will force a recalculation every step. This may fix the problem, but slow down the simulation considerably. Finding an intermediate value should remove any problem and retain much of the default performance. Unfortunately there is no good rule for selecting these limits so the defaults should be used unless they are leading to problems.
- ECLIPSE 300 only* • On occasion a rapidly changing blocking factor may occur. Significant damping of such a blocking factor (that is small values of item 3) can lead to inaccurate results (for example, a kink in the well BHP). If this problem is encountered try setting the damping coefficient (item 3) to 1.0 (or as large a value as possible). If this still does not resolve the issue then setting the well to be a single-segment multisegment well (see [item 62](#) in OPTIONS3) may fix the problem.

## Example

```
PICOND  
30.0 0.0 0.5 /
```

## PIMTDIMS

## PI scaling table dimension data

	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data consists of two items, describing the number of tables of PI scaling factor versus maximum water cut, and the maximum number of entries in any table. The tables are entered in the SCHEDULE section by keyword `PIMULTAB`.

The data consists of two integers terminated by a slash (/).

1. The number of PI Scaling tables to be entered in the `PIMULTAB` keyword.  
DEFAULT: 0
2. The maximum number of entries in any one of the PI scaling tables.  
DEFAULT: 0

## Example

```
PIMTDIMS
2 8 /
```

## PIMULTAB Tables of well PI multiplier versus max water cut

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword may be used to input PI multiplier tables, which scale a well's connection factors according to the maximum water cut it has so far achieved. The tables defined here are allocated to individual wells with the [WPITAB](#) keyword. The facility may be useful in approximating performance decline due to backflow of water.

The keyword is followed **exactly** by NTPIMT tables, each containing two columns and no more than NPPIMT rows of data. The dimensions NTPIMT and NPPIMT are entered in the RUNSPEC section keyword [PIMTDIMS](#). Each table should be terminated with a slash (/).

1. Maximum water cut values.

The values should increase monotonically down the column.

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

2. The corresponding values of the PI scaling factor.

Empty tables (containing just their terminating slash) default to a copy of the previous table. Extrapolation outside the range of a table returns the value of the nearest point in the table.

See also keywords [WPITAB](#) and [WPIMULT](#) (the latter may be used to scale well PIs by a constant factor).

---

**Note:** The PI scaling tables are **not** written to the Restart files. Accordingly they must be present in any restarted data set. Thus it is also possible to change the tables at a restart.

---

### Example

With NTPIMT=2. NPPIMT must have been set  $\geq 5$ :

```
PIMULTAB
-- max    PI
-- WCT    mult
  0.0     1.0
  0.1     0.95
  0.15    0.85
  0.4     0.55
  0.8     0.43 /

  0.0     1.0
  0.01    0.92
  0.04    0.85
  0.12    0.44
  0.4     0.32 /
```

## PINCH

## Generates connections across pinched-out layers

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by some or all of the following items, which define the pinchout threshold thickness in the z-direction and the threshold gap between adjacent layers. The data record should be terminated by a slash (/).

- Pinchout threshold thickness.  
UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)  
DEFAULT: 0.001 (all unit sets)
- Option controlling generation of pinchouts when a minimum pore volume has been set using [MINPV](#) or [MINPVV](#).

**GAP** Allow NNCs across cells that are inactive due to MINPV even if the thickness exceeds the threshold.

**NOGAP** The threshold thickness is strictly observed whether or not the pinched-out cells are inactive due to MINPV.

DEFAULT: GAP

---

**Note:** Regardless of the value of this argument, any cells with a pore volume less than 0.000001 (in all unit sets) are automatically considered to have a negligible pore volume available for flow and only allow a pinchout NNC across them if the threshold thickness entered as the first item is not exceeded.

---

*ECLIPSE 300 only*

---

**Note:** If the thermal option has been selected, the cell's rock volume is also considered, and a cell is only considered to have a negligible pore volume available for flow if both the pore volume and rock volume are less than 0.000001 (in all unit sets).

---

- Maximum empty gap allowed between cells in adjacent grid layers for a non-zero transmissibility to exist between them.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: Infinity (1.0E20 in all unit sets)

- Option for calculating the pinchout transmissibility.

**TOPBOT** The pinchout transmissibility is formed from the half-cell Z-direction transmissibilities of the active cells on either side of the pinched-out layer(s).

**ALL** The pinchout transmissibility is a harmonic average of the Z-direction transmissibilities of all the cells between the active cells on either side of the pinched-out layer(s). In ECLIPSE 300, this option is only available for Cartesian corner-point geometry.

DEFAULT: TOPBOT

- Option for accounting for [MULTZ](#) through a pinched-out column, if item 4 has been set to TOPBOT. If item 4 has been set to ALL, any value specified for item 5 is ignored and TOP is used.

**TOP** The transmissibility multiplier applied to the pinchout is the MULTZ for the active cell at the top of the pinchout.

ALL The transmissibility multiplier applied to the pinchout is the minimum of the MULTZ values for the active cell at the top of the pinchout and all the inactive cells in the pinched-out column. This replaces OPTIONS keyword switch 17. In ECLIPSE 300, this option is only available for Cartesian corner-point geometry.

DEFAULT: TOP

---

**Note:** In a run, the transmissibility multipliers for all cells not included in the loaded flux region are set to zero. Pinchouts will therefore not be created across any cells not in the active flux regions when the ALL option of item 5 is specified.

---

Pinched-out layers are represented in the grid as layers of inactive cells of zero thickness. The presence of a layer of inactive cells would normally prevent flow from crossing it, between the active cells immediately above and below.

If the keyword PINCH is entered, ECLIPSE will automatically generate non-neighbor connections between the active cells on either side of the pinched-out layer(s), allowing fluid to flow across it. Generally, the layer or layers of inactive cells are deemed to be pinched-out if their overall cell thickness is less than the specified threshold value.

When PINCH has been specified and if keyword MINPV or MINPVV has been used to set the minimum pore volume a cell must have to be active, then by default, a column of cells may be pinched-out if the pore volumes are less than the minimum value, even if the overall thickness exceeds the threshold thickness. If MINPV or MINPVV is used to switch off cells with small pore volumes (to enhance the convergence of the solver), these cells will not act as a barrier to vertical flow unless the second item equals NOGAP and/or the pore volume is less than 0.000001 (in all unit sets), and the overall thickness exceeds the threshold set in the first item. If the second item equals GAP, cells with pore volume of less than 0.000001 (in all unit sets) will only act as a barrier if that individual cell's thickness exceeds the threshold set in the first item.

By default, the pinchout connection reflects the Z-transmissibility multiplier (MULTZ) specified in the upper of the two connected cells. item 5 can be set to modify this behavior such that the minimum value of MULTZ for all pinched out cells is used.

If the third item is defaulted or omitted, then a non-zero transmissibility exists between two adjacent active cells in the same vertical column, whatever the size of the empty gap between the cells, and when MULTZ is not zero for the upper of the two cells. Otherwise, if this gap exceeds the threshold empty gap, then the transmissibility is always set to zero. For a prospective pinchout connection, no NNC is formed if the sum of the empty gaps between all adjacent layers of inactive cells in the pinchout exceeds this threshold.

The PINCH keyword only affects pinchouts between layers, i.e. in the z-direction. To control generation of pinchouts within a layer, i.e. in the x or y direction, use PINCHXY.

## Notes

- Non-neighbor connections are not generated if the keyword NONNC has been entered in the RUNSPEC section.
- Pinchout connections are only formed across inactive cells, whatever the value set for the threshold thickness; there is no connection across active cells.
- The default method (TOPBOT in item 4) to calculate the transmissibility of a non-neighbor connection due to a pinchout uses a harmonic average of the half-cell Z-direction transmissibilities for the active cells on either side of the pinched-out layer(s). For block-centered geometry with OLDTRAN (see

"Transmissibility Calculations" in the *ECLIPSE Technical Description*) the pinchout transmissibility between top and bottom cells  $t$  and  $b$  is

$$Tr = \frac{1}{\frac{1}{Tr_t} + \frac{1}{Tr_b}} MULTZ_t$$

where

$$Tr_t = CDARCY \frac{2PERMZ_t DX_t DY_t}{DZ_t}$$

is the half-cell transmissibility for the top cell, etc.

The case of corner-point geometry with `NEWTRAN` is analogous (see "Transmissibility Calculations" in the *ECLIPSE Technical Description*). If `item 5` is set to `ALL`, then the multiplier used is the minimum value of `MULTZ` between all cells in the pinched-out column (that is  $\min(MULTZ_i)$  for  $i = t, \dots, b-1$ ).

If the flag `ALL` is specified in `item 4`, then the pinchout transmissibility is calculated as a harmonic average

$$Tr = \frac{n}{\sum \frac{1}{TRANZ_i}}$$

where

the sum is over all cells  $i = t, \dots, i = b-1$  in the column between  $t$  and  $b$ ,

$n$  is the number of cells being summed over, and

each transmissibility  $TRANZ_i$  is calculated as described in "Transmissibility Calculations" in the *ECLIPSE Technical Description*. In this case, `item 5` is ignored.

- In corner-point geometry, the total thickness of inactive layers in the pinchout (compare `item 1`) is computed as the maximum difference in corner-point depths between the active cells on either side of the pinched-out layer(s), for each of the four coordinate lines surrounding the column.

In corner-point geometry, the thickness of the empty gap between two adjacent cells (see `item 3`) is taken as minimum difference in corner-point depths between the appropriate coordinate lines.

- When `item 5` is set to `ALL`, note that the transmissibility multiplier for the cell at the top is not itself changed when calculating the multiplier to be used for the pinchout.

## Example

```
PINCH
--Threshold   Gap or
--thickness   No Gap
              0.1   'GAP' /
```

## PINCHNUM Identifies pinchout regions

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The `PINCHNUM` keyword identifies regions for calculation of pinchouts. The threshold thickness and options for calculating the pinchouts should be supplied for each `PINCHNUM` region using the `PINCHREG` keyword.

To use this keyword, `NRPIN` must be set greater than zero in item 3 of the `RUNSPEC` section keyword `GRIDOPTS`, to define the maximum number of `PINCHNUM` regions.

The `PINCHNUM` keyword should be followed by one integer for each grid cell, specifying the region number to which it belongs. The data must be terminated by a slash (/).

Any cells not explicitly assigned a value of `PINCHNUM` are taken to be in region 1.

See also keywords `PINCHREG` and `PINCH`.

In ECLIPSE 100:

- For use with the dual porosity option, only the matrix cells or the fracture cells need to be input. The cell values in the other porosity will be copied automatically. If the user wants to specify matrix cells and fracture cells separately, then [item 117](#) in `OPTIONS` should be set greater than 1. This will also affect use of the `MULTNUM`, `FLUXNUM` or `OPERNUM` keywords.
- The `PINCHNUM` keyword cannot be used inside a `CARFIN/RADFIN...ENDFIN` bracket.

### Example

To define 4 separate regions in a 4\*4\*3 field, with `NRPIN`=4:

```
PINCHNUM
1 1 2 2
1 1 2 2
3 3 4 4
3 3 4 4
1 1 2 2
1 1 2 2
3 3 4 4
3 3 4 4
1 1 2 2
1 1 2 2
3 3 4 4
3 3 4 4
/
```

## PINCHOUT

**Generates connections across pinched-out layers**

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This is a less flexible (and older) alternative to the [PINCH](#) keyword, which also generates connections across pinched-out layers. The difference is that the `PINCH` keyword allows you to specify a maximum threshold thickness for pinched-out cells, whereas if you use the `PINCHOUT` keyword the threshold thickness is fixed at 0.001 (in all unit sets).

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

See the `PINCH` keyword for more information on generating pinch-out connections.

When cells are inactive due to [MINPV](#) or [MINPVV](#), pinchout connections are formed regardless of the threshold thickness, analogously to using the `PINCH` keyword.

The `PINCHOUT` keyword has no associated data.

**Example**

```
PINCHOUT
```

## PINCHREG **Generates connections across pinched-out layers within regions**

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword supplies data for calculating pinchouts in multiple regions. The regions should be identified using keyword [PINCHNUM](#). If [PINCHNUM](#) is not specified, then [PINCHREG](#) applies to flux regions defined by [FLUXNUM](#). If neither [PINCHNUM](#) nor [FLUXNUM](#) is specified then [PINCHREG](#) is ignored.

The [PINCHREG](#) keyword should be followed by [NRPINC](#) records (item 3 of keyword [GRIDOPTS](#)) when using [PINCHNUM](#), or [NTFREG](#) records (item 4 of keyword [REGDIMS](#)) when using [FLUXNUM](#), with each record terminated by a slash (/).

Each record refers to a separate [PINCHNUM](#) or [FLUXNUM](#) region and consists of some or all of the items, detailed below, which are the same as in the [PINCH](#) keyword. If the record is defaulted for a region, then no pinchouts are generated in that region. When calculating a pinchout between cells in different regions, the [PINCHREG](#) data is taken from the region containing the upper of the two cells.

- Pinchout threshold thickness.
 

UNITS: m ([METRIC](#)), ft ([FIELD](#)), cm ([LAB](#)), m ([PVT-M](#))

DEFAULT: 0.001 (all unit sets)
- Option controlling generation of pinchouts when a minimum pore volume has been set using [MINPV](#) or [MINPVV](#).
 

**GAP** Allow NNCs across cells that are inactive due to [MINPV](#) even if the thickness exceeds the threshold.

**NOGAP** The threshold thickness is strictly observed whether or not the pinched-out cells are inactive due to [MINPV](#).

DEFAULT: **GAP**
- Maximum empty gap allowed between cells in adjacent grid layers for a non-zero transmissibility to exist between them.
 

UNITS: m ([METRIC](#)), ft ([FIELD](#)), cm ([LAB](#)), m ([PVT-M](#))

DEFAULT: Infinity (1.0E20 in all unit sets)
- Option for calculating the pinchout transmissibility.
 

**TOPBOT** The pinchout transmissibility is formed from the half-cell Z-direction transmissibilities of the active cells on either side of the pinched-out layer(s).

**ALL** The pinchout transmissibility is a harmonic average of the Z-direction transmissibilities of all the cells between the active cells on either side of the pinched-out layer(s).

DEFAULT: **TOPBOT**
- Option for accounting for [MULTZ](#) through a pinched-out column, if item 4 has been set to **TOPBOT**. This item is ignored if item 4 is set to **ALL**.
 

**TOP** The transmissibility multiplier applied to the pinchout is the [MULTZ](#) for the active cell at the top of the pinchout.

ALL The transmissibility multiplier applied to the pinchout is the minimum of the MULTZ values for the active cell at the top of the pinchout and all the inactive cells in the pinched-out column. This replaces [item 17](#) in OPTIONS.

DEFAULT: TOP

See the [PINCH](#) keyword for further information.

## Example

With NRPINC=4

```
PINCHREG
--Threshold  Gap or   Empty
--thickness  No Gap   Gap
             0.1    1*    10.0  /
             0.2    1*    20.0  /
             1.0    'NOGAP' /
```

## PINCHXY

## Generates horizontal pinchout connections

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by up to two real numbers, which define the X-direction and Y-direction pinchout threshold widths. The data record should be terminated by a slash (/).

1. Threshold width in the X or R direction for horizontal pinchouts  
UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)  
DEFAULT: 0.001 (all unit sets)
2. Threshold width in the Y or THETA direction for horizontal pinchouts  
UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)  
DEFAULT: 0.001 (all unit sets)

Columns which are pinched-out in the X (or Y) direction are represented in the grid as columns of inactive cells of zero width in the X (or Y) direction. The presence of such a column of inactive cells would normally prevent flow from crossing it in the X (or Y) direction, between the active cells on either side of it.

If the keyword PINCHXY is entered, ECLIPSE automatically generates X (or Y) direction horizontal non-neighbor connections between the active cells on either side of the pinched-out column(s), allowing fluid to flow through it in the X (or Y) direction. Columns are deemed to be pinched-out in the X (or Y) direction if their overall cell width in the X (or Y) direction is less than the specified threshold value.

The X (or Y) direction pinch-out connection reflects the X (or Y) direction transmissibility multiplier ([MULTX](#) or [MULTY](#)) specified in the left most (or backmost) of the two connected cells.

### Notes

- Non-neighbor connections are not generated if the keyword [NONNC](#) has been entered in the RUNSPEC section.
- Pinchout connections are only formed across inactive cells, whatever the value set for the threshold thickness.
- Only horizontal pinchouts in the global grid will be generated. Currently, no local grid PINCHXY connections will be calculated.

*ECLIPSE 300 only*

### Example

```
PINCHXY
1* 0.1 /
```

## PLMIXNUM Polymer mixing regions

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The PLMIXNUM keyword is used with the Polymer flooding option to define regions with different polymer characteristics. The region number entered with this keyword is used to determine the Todd-Longstaff mixing and/or the maximum polymer and salt concentrations used in the mixing parameter calculation of fluid component viscosity. See keywords [PLMIXPAR](#) and [PLYMAX](#). The keyword should be followed by one integer for each grid cell in the matrix. The data entries should not exceed NPLMIX entered using keyword [REGDIMS](#) (item 10) in the RUNSPEC section. The data must be terminated by a slash (/).

If the keyword is not present all matrix cells are assigned a value of unity.

### Example

A 4\*4\*3 grid with differing mixing characteristics in the middle layer of the reservoir:

```

PLMIXNUM
16*1
16*2
16*1 /

```

## PLMIXPAR Polymer Todd-Longstaff mixing parameter

	SUMMARY
x	SCHEDULE

The data comprises NTSFUN (see item 1 in RUNSPEC keyword [TABDIMS](#)) tables of polymer adsorption functions, each terminated by a slash (/), describing the adsorption of polymer by the rock formation. Each table consists of 2 columns of data:

1. The local polymer concentration in the solution surrounding the rock. The values should increase monotonically down the column.  
  
UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB)
2. The corresponding saturated concentration of polymer adsorbed by the rock formation. This quantity is therefore the mass of adsorbed polymer per unit mass of rock.

These values should increase monotonically down the column.

UNITS: kg/kg (METRIC), lb/lb (FIELD), gm/gm (LAB)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (item 3 in RUNSPEC keyword [TABDIMS](#)).

---

**CAUTION:** The first row in the adsorption tables should consist of a pair of zeroes.

---

See "[Polymer flood model](#)" in the *ECLIPSE Technical Description* for further information.

Polymer adsorption functions can also be specified using the [ADSORP](#) and [PLYADSS](#) keywords.

## Notes

- Changes made in the SCHEDULE section will not be honored in a restart run unless the re-specification is also included in the restart data file. This may be done either by placing the new data for PLYADS in the PROPS section or by leaving the SCHEDULE section keywords in place and using the [SKIPREST](#) keyword.
- When the temperature option (keyword [TEMP](#)) is activated, it is possible to specify this keyword multiple times with different values for different temperatures by using the [PLYATEMP](#) keyword before each occurrence of PLYADS to specify the relevant temperature.

## Example

With NTSFUN=2 and NSSFUN≥4:

```

PLYADS
.0000 .00000
.0003 .00005
.0005 .00007
.0008 .00008
.0010 .00008 /
.0000 .00000
.0010 .00010 /

```

## PLYADSS

## Polymer adsorption functions varying with salinity

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword should only be used for polymer studies where the salt-sensitivity option has been activated (keyword [BRINE](#) in [RUNSPEC](#)).

The data comprises [NTSFUN](#) (see item 1 in [RUNSPEC](#) keyword [TABDIMS](#)) tables of polymer adsorption functions, each terminated by a slash (/), describing the adsorption of polymer by the rock formation.

Each table consists of up to [NSSFUN](#) elementary sets of records, each corresponding to a given solution polymer concentration. In the first record of each set, there are two items:

1. The local polymer concentration in the solution surrounding the rock.  
UNITS: kg/sm<sup>3</sup> ([METRIC](#)), lb/stb ([FIELD](#)), gm/scc ([LAB](#))
2. The corresponding saturated concentration of polymer adsorbed by the rock formation, for the solution polymer concentration specified by item 1, and the salt concentration given by item 1 in the corresponding [ADSALNOD](#) table. This quantity is therefore the mass of adsorbed polymer per unit mass of rock.

UNITS: kg/kg ([METRIC](#)), lb/lb ([FIELD](#)), gm/gm ([LAB](#))

In subsequent records of the set, for record N (where N runs from 2 to a value not greater than [NSSFUN](#), which is item 3 in [RUNSPEC](#) keyword [TABDIMS](#)) there is a single data item, specifying the adsorbed polymer concentration at the solution polymer concentration specified in record 1, and the salt concentration specified by item N in the corresponding [ADSALNOD](#) table.

Each set of records for a solution polymer concentration value should be terminated by a slash (/) and each table should be terminated by an additional slash.

There must be the same number of entries in each column of a given table, which should not be less than 2 or greater than [NSSFUN](#) (item 3 in [RUNSPEC](#) keyword [TABDIMS](#)). The number of salinity concentration entries should also be the same for each solution polymer concentration record, and correspond to the number of entries in the corresponding [ADSALNOD](#) table.

---

**CAUTION:** The first solution polymer concentration value in each table, and all corresponding adsorbed concentrations at all salinities, should be zero.

---

**Note:** When the temperature option (keyword [TEMP](#)) is activated, it is possible to specify this keyword multiple times with different values for different temperatures by using the [PLYATEMP](#) keyword before each occurrence of [PLYADSS](#) to specify the relevant temperature.

---

See "[Polymer flood model](#)" in the *ECLIPSE Technical Description* for further information.

Polymer adsorption functions can also be specified using the [ADSORP](#) keyword.

### Example

```

## PLYATEMP Polymer adsorption table temperatures

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword should only be used for polymer studies. It allows for temperature dependence of the polymer adsorption tables (keywords [PLYADS](#) or [PLYADSS](#)) in the [PROPS](#) section). If it is used, multiple adsorption tables can be used, with each table giving the adsorption data at one temperature. In this case, the keyword [PLYATEMP](#) is used to give the temperature value of the adsorption table which follows it. Adsorption data for intermediate temperatures is calculated by interpolation between the tables. Adsorption data for temperatures outside the range specified by the [PLYATEMP](#) keywords is defined using the adsorption values for the maximum or minimum [PLYATEMP](#) temperature value, as appropriate.

The data for each occurrence of this keyword consists of a series of temperature values, one for each [SATNUM](#) region used, which give the region temperatures for the following polymer adsorption table:

1. Temperature.

UNITS: °C ([METRIC](#)), °F ([FIELD](#)), °C ([LAB](#))

The temperatures should be followed by a slash to terminate the record.

The sequence of [PLYATEMP](#)/[PLYADS](#) or [PLYATEMP](#)/[PLYADSS](#) keyword pairs should be in order of increasing temperature.

A maximum number of [NTSFUN](#) (see [TABDIMS](#)) temperatures can be provided in each instance of [PLYATEMP](#).

A maximum number of [NSSFUN](#) (see [TABDIMS](#)) temperatures per [SATNUM](#) region can be specified using [PLYATEMP](#) and hence a maximum number of [NSSFUN](#) instances of [PLYATEMP](#) can be provided.

If [PLYATEMP](#) is not used, only one [PLYADS](#) or [PLYADSS](#) table can be provided and the adsorption data is then independent of temperature.

See “[Polymer flood model](#)” in the *ECLIPSE Technical Description* for further information.

## PLYCAMAX Specifies maximum polymer adsorption values for the Polymer Flood Model

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is optional, and is used to customize data for the Polymer Flood Model on a cell-by-cell basis. See "[Polymer flood model](#)" in the *ECLIPSE Technical Description* for further information.

The keyword should be followed by one real number for each cell in the current input box. The values denote the maximum polymer adsorption value that is to be used in the calculation of the resistance factor for the aqueous phase in the Polymer Flood Model. The data must be terminated by a slash (/).

Note that a zero value should not be used even if a zero adsorption isotherm has been defined.

Any cells which do not have an individual value set using this keyword will use the value for their rock type which is set in item 5 of the [PLYROCK](#) keyword.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0.00012). Note that spaces must not be inserted on either side of the asterisk (\*).

The keyword can be used in conjunction with the [EQUALS](#), [ADD](#) and [MULTIPLY](#) keywords, and the [OPERATE](#) and [OPERATER](#) keywords.

---

**Note:** Only cells which have had a valid individual PLYCAMAX value set will be affected by these data manipulation keywords. Cells which will use a value from PLYROCK will be unaffected.

---

UNITS: kg/kg (METRIC), lb/lb (FIELD), gm/gm (LAB), kg/kg (PVT-M)

See also keywords [PLYKRRF](#) and [PLYRMDEN](#).

### Example

```

----- IX1-IX2 JY1-JY2 KZ1-KZ2
BOX

x	SCHEDULE

This keyword describes the thermal degradation of polymer due to temperature. The data comprises NTPVT (see item 2 in RUNSPEC keyword [TABDIMS](#)) tables of polymer thermal degradation functions, each terminated by a slash (/). Each table consists of the following columns of data:

- The local temperature in the solution.  
The values should increase monotonically down the column.  
UNITS: °C (METRIC), °F (FIELD), °C (LAB)
- The corresponding half-life of the polymer.  
UNITS: day (METRIC), day (FIELD), hr (LAB)  
There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NPPVT (item 4 in RUNSPEC keyword [TABDIMS](#)).

**Note:** Changes made in the SCHEDULE section will not be honored in a restart run unless the re-specification is also included in the restart data file. This may be done either by placing the new data for PLYDHFLF in the PROPS section or by leaving the SCHEDULE section keywords in place and using the [SKIPREST](#) keyword.

See the "[Polymer flood model](#)" in the *ECLIPSE Technical Description* for further information.

### Example

With NTPVT=2 and NPPVT≥5:

```
PLYDHFLF
  0.0  365.0
  50.0  240.0
 100.0  180.0
 150.0  150.0

## Effective salinity coefficient for polymer

This keyword may only be used when the multi-component brine model (keyword [BRINE](#) in conjunction with keyword [ECLMC](#) in the RUNSPEC section) is active in conjunction with the polymer option (keyword [POLYMER](#) in the RUNSPEC section).

The PLYESAL keyword activates the effective salinity calculation for polymer adsorption and defines the parameter,  $\alpha^P$ , in the expression for the effective salinity

$$C_{SEP} = C_- + (\alpha^P - 1)C_{++} \quad \text{Eq. 3.147}$$

where

$C_{SEP}$  denotes the effective salinity for the polymer

$C_-$  denotes the anion concentration

$C_{++}$  denotes the divalent cation concentration

$\alpha^P$  denotes the effective salinity parameter

See "[Brine Tracking](#)" in the *ECLIPSE Technical Description* for details of this option.

The keyword should be followed NTSFUN records of data (see item 1 in keyword [TABDIMS](#)), each containing a single non-negative real number. Each record must be terminated by a slash (/).

UNITS: dimensionless

DEFAULT: 0.0

### Example

For NTSFUN=2:

```
PLYESAL
-- alpha
  10 /
  15 /
```

## PLYMAX

## Polymer/salt concentrations for mixing calculations

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The data comprises NPLMIX (see item 10 in RUNSPEC keyword [REGDIMS](#)) rows of maximum polymer and salt concentrations that are to be used in the mixing parameter calculation of the fluid component viscosities. Each table consists of the following items of data:

1. The value of the polymer concentration in the solution which is to be used in the calculation of the maximum polymer fluid component viscosity.

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB), kg/sm<sup>3</sup> (PVT-M)

2. The value of the salt concentration in the solution which is to be used in the calculation of the maximum polymer fluid component viscosity. This item is ignored if the salt-sensitivity keyword [BRINE](#) is not specified in the RUNSPEC section.

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB), kg/sm<sup>3</sup> (PVT-M)

---

**Note:** Changes made in the SCHEDULE section will not be honored in a restart run unless the re-specification is also included in the restart data file. This may be done either by placing the new data for PLYMAX in the PROPS section or by leaving the SCHEDULE section keywords in place and using the [SKIPREST](#) keyword.

---

See "[Polymer flood model](#)" in the *ECLIPSE Technical Description* for further information.

### Example

With NPLMIX=2:

```
PLYMAX
.0100 .0500 /
.0050 .0300 /
```

## PLYOPTS

## Polymer options

This keyword sets optional parameters for the ECLIPSE 300 polymer model. See the "[Polymer flood model](#)" in the *ECLIPSE Technical Description* for further information.

1. The minimum water saturation for polymer effects.

DEFAULT: 1e-6

For cells with small water saturations, a small amount of polymer will give a high concentration of polymer in the water phase, which could have a large effect on the water phase viscosity. To prevent numerical errors effecting the solution, polymer concentrations are disregarded for cells where the minimum water saturation is below a threshold given by this item.

### Example

```
PLYOPTS
2.0e-6 /
```

## PLYROCK Specifies the polymer-rock properties

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTSFUN (see item 1 in RUNSPEC keyword [TABDIMS](#)) rows specifying the rock properties which are required for the Polymer Flood Model. Each table should be terminated by a slash (/) and requires the following items of data:

- The dead pore space for this rock type.  
The value specified should be greater than or equal to 0, less than the maximum water saturation and less than unity.
- The residual resistance factor for this rock type.  
This quantity must be greater than or equal to 1 and represents the decrease in the rock permeability to the aqueous phase when the maximum amount of polymer has been adsorbed.
- The mass density of this rock type at reservoir conditions.

This quantity is used in the calculation of the polymer loss due to adsorption.

If the surfactant model is active, then the mass density of the rock supplied in the PLYROCK keyword is used, and the value supplied in [SURFROCK](#) is ignored.

UNITS: kg/rm<sup>3</sup> (METRIC), lb/rb (FIELD), gm/rcc (LAB), kg/rm<sup>3</sup> (PVT-M)

- The adsorption index to be used for this rock type.  
Possible values for the adsorption index are 1 or 2. If a value of 1 is selected, then the polymer adsorption isotherm is retraced whenever the local polymer concentration in the solution decreases. If a value of 2 is selected, then no polymer desorption may occur.  
DEFAULT: 1
- The maximum polymer adsorption value that is to be used in the calculation of the resistance factor for the aqueous phase.

Note that a zero value should not be used even if a zero adsorption isotherm has been defined.

UNITS: kg/kg (METRIC), lb/lb (FIELD), gm/gm (LAB), kg/kg (PVT-M)

See "[Polymer flood model](#)" in the *ECLIPSE Technical Description* for further information.

---

**Note:** When non-zero initial polymer concentrations are specified via the [SPOLY](#) keyword, the concentration specified in that keyword will be honored and extra adsorbed polymer is added to the rock so that it is in equilibrium with the input fluid concentration.

---

### Related keywords

Polymer-rock properties can be modified in SCHEDULE using the [PLYROCKM](#) keyword.

### Example

With NTSFUN=2 specified in keyword [TABDIMS](#):

```
PLYROCK
 0.13 1.75 1880 2 0.00012 /
 0.16 1.95 2010 1 0.00014 /
```

## PLYROCKM Specifies modifiers for polymer-rock properties

	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The data comprises NTSFUN (see item 1 in RUNSPEC keyword [TABDIMS](#)) rows specifying modifiers for the rock properties which are required for the polymer flood model (see [PLYROCK](#) for a more detailed description of each of the properties).

- The dead pore space for this rock type.
 

The value specified should be greater than or equal to 0, less than the maximum water saturation and less than unity. This replaces the previous value entered using [PLYROCK](#) or [PLYROCKM](#) and is an absolute value rather than a multiplier.

DEFAULT: Previous value entered using [PLYROCK](#) or [PLYROCKM](#).
- The residual resistance factor for this rock type.
 

Acts as a multiplier on the values entered using [PLYROCK](#) or [PLYKRRF](#). Multipliers are not cumulative.

DEFAULT: 1
- The mass density of this rock type at reservoir conditions.
 

Acts as a multiplier on the values entered using [PLYROCK](#) or [PLYRMDEN](#). Multipliers are not cumulative.

DEFAULT: 1
- The adsorption index to be used for this rock type.
 

This replaces the previous value entered using [PLYROCK](#) or [PLYROCKM](#).

DEFAULT: Previous value entered using [PLYROCK](#) or [PLYROCKM](#).
- The maximum polymer adsorption value that is to be used in the calculation of the resistance factor for the aqueous phase.
 

Acts as a multiplier on the values entered using [PLYROCK](#) or [PLYCAMAX](#). Multipliers are not cumulative.

DEFAULT: 1

---

**Note:** Changes made in the [SCHEDULE](#) section will not be honored in a restart run unless the re-specification is also included in the restart data file. This may be done either by placing the new data for [PLYROCK](#) in the [PROPS](#) section or by leaving the [SCHEDULE](#) section keywords in place and using the [SKIPREST](#) keyword.

---

### Example

With NTSFUN=2:

```
PLYROCKM
0.13 1.15 0.9 2 1.5 /
0.16 1.0 1.0 1 1.2 /
```

## PLYSHEAR Polymer shear thinning/thickening data

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used to activate the polymer shear thinning/thickening option and to supply the shear effect data. The keyword is optional, and if omitted no shear effect calculations are performed.

For shear thinning, a positive feedback effect is possible whereby increased flow speed leads to reduced viscosity which in turn produces more increase in flow speed. If the shear thinning multiplier is too small, this will produce a runaway condition producing convergence problems. An alternative option for the input of shear-thinning multipliers is available via the [PLYSHLOG](#) keyword, which may reduce this effect by controlling the logarithmic derivative of the multiplier. This alternative may be more appropriate if the shear-thinning data shows log-log behavior. The PLYSHEAR multiplier can also be controlled as described in "Notes".

The data comprises NTPVT (see item 2 in RUNSPEC keyword [TABDIMS](#)) tables of polymer shear thinning/thickening data, each terminated by a slash (/). The data is supplied as a shear multiplier that is applied in the update of the effective water and polymer viscosities and thus in the update of the water phase and polymer flows. This multiplier is tabulated as a function of water phase/polymer flow velocity.

Each table consists of 2 columns of data:

1. The water phase/polymer flow velocity.

By default this velocity is calculated taking into account the mobile water saturation. The pre-2014.1 velocity calculation, which omits the mobile water saturation, may be activated by setting [OPTIONS](#) keyword [item 228](#) to 1.

The values should increase monotonically down the column. The first entry should be 0.0.

UNITS: m/day (METRIC), ft/day (FIELD), cm/hr (LAB)

2. The corresponding factor applied to the effective water and polymer viscosities (entered using [PVTW](#) with [PLYVISC](#), [PLYVISCS](#), [PLYVISCT](#) or [PLYVSCST](#)) due to shear thinning/thickening of the polymer.

Usually the first entry would be 1.0.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NPPVT (see the RUNSPEC keyword [TABDIMS](#)).

---

**Note:** Changes made in the SCHEDULE section will not be honored in a restart run unless the re-specification is also included in the restart data file. This may be done either by placing the new data for PLYSHEAR in the PROPS section or by leaving the SCHEDULE section keywords in place and using the [SKIPREST](#) keyword.

---

The resulting shear viscosities of the water and polymer, at a given polymer concentration and flow velocity, are:

$$\mu_{w,sh} = \mu_{w,eff} Z_w^*, \quad \mu_{p,sh} = \mu_{p,eff} Z_p^*$$

where each viscosity multiplier is calculated in the form

$$Z = \frac{1 + (P - 1)M}{P}$$

and

$\mu_{w,sh}$  is the shear water viscosity

$\mu_{p,sh}$  is the shear polymer viscosity

$\mu_{w,eff}$  is the effective water viscosity

$\mu_{p,eff}$  is the effective polymer viscosity

$P$  is the viscosity multiplier assuming no shear effect (entered using the PLYVISC, PLYVISCS, PLYVISCT, or PLYVSCST keywords).

$M$  is the shear effect multiplier supplied in the PLYSHEAR keyword.

Note that for  $M = 1$ , or no shear effect, we recover the effective component viscosities, and for  $M = 0$ , or maximum shear thinning, the shear viscosities are

$$\mu_{w,sh} = \frac{\mu_{w,eff}}{P}, \quad \mu_{p,sh} = \frac{\mu_{p,eff}}{P}$$

which corresponds to the minimum viscosity that can be obtained. If the polymer concentration is zero ( $P=1$ ) we recover the effective component viscosities again, which, in that particular case equal the pure water viscosity.

## Notes

- If the shear effect is not significant, the PLYSHEAR keyword should be omitted, as the calculation of the velocity-dependent viscosity increases the run time.
- The positive feedback effect noted above for shear thinning will occur for  $P$  significantly larger than 1.0 if the gradient of the PLYSHEAR data,  $\frac{d(\log(M))}{d(\log(v))} < -1$ . When  $P$  is near 1.0 (on a cell-by-cell or well/well-segment basis) this condition may be relaxed but should be monitored on a case-by-case basis. The simulator will warn if the data in PLYSHEAR violates this condition. It is recommended to keep the PLYSHEAR data within this bounding condition.
- In versions of ECLIPSE before 2012.1, shear thinning only was allowed and multiplier values in column 2 were required to decrease monotonically down the column. This has now been relaxed to allow shear thickening; however, in some cases, convergence problems may result. Currently, there is one case in which the cause of these problems is known. If a well is set not to allow crossflow (WELSPECS item 10) then oscillation in the temporary closure pattern of well connections due to a backflow condition can cause the well not to converge. Note that crossflow is allowed now for polymer, and it is preferred to use crossflow as this is the physical condition. If it is required that crossflow is disallowed, then shear effects can exacerbate non-convergence. In this case consider using [item 198](#) in OPTIONS which closes back-flowing connections in the event of non-convergence (but not for multisegment wells).

See the "[Polymer flood model](#)" in the *ECLIPSE Technical Description* for further information.

## Example

With NTPVT=1 and NPPVT≥4 specified in keyword [TABDIMS](#):

## PLYSHLOG Polymer shear thinning/thickening logarithmic model

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used to activate the alternative (logarithm-based) polymer shear thinning/thickening option and to supply the required shear effect data. The keyword is optional and, if omitted, no shear effect calculations are performed. This keyword therefore activates a variant of the polymer shear thinning/thickening model activated by keyword [PLYSHEAR](#).

The data comprises NTPVT (see item 2 in RUNSPEC keyword [TABDIMS](#)) tables of polymer shear thinning/thickening data. Each table consists of two records, each terminated by a slash (/). The data is supplied as a shear effect multiplier, tabulated as a function of water phase/polymer flow velocity, for a specified set of reference conditions. Note that if keyword [SHRATE](#) is specified then the multipliers are instead tabulated as a function of water/polymer flow shear rate.

### Record 1

Three items of data:

- The reference polymer concentration that is associated with the shear data provided.  
UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB)  
Note that this item cannot be defaulted and must take a positive value.
- The reference salinity, if appropriate, that is associated with the shear data provided.  
UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB)  
Note that this item must be specified if either of the [PLYVISCS](#) or [PLYVSCST](#) keywords are used, and should otherwise remain defaulted.
- The reference temperature, if appropriate, that is associated with the shear data provided.  
UNITS: °C (METRIC), °F (FIELD), °C (LAB)  
Note that this item must be specified if either of the [PLYVISCT](#) or [PLYVSCST](#) keywords are used, and should otherwise remain defaulted.

### Record 2

A table consisting of two columns of data that correspond to the reference conditions specified in Record 1.

- The water phase/polymer flow velocity or shear rate (shear rate if [SHRATE](#) is included),  $X$ .  
By default this velocity is calculated taking into account the mobile water saturation. The pre-2014.1 velocity calculation, which omits the mobile water saturation, may be activated by setting [OPTIONS](#) keyword [item 228](#) to 1.  
The values must increase monotonically down the column. The first entry  $X_1 = \varepsilon$  must be a small positive value in the range  $0 < \varepsilon \leq 10^{-6}$ .  
UNITS (velocity): m/day (METRIC), ft/day (FIELD), cm/hr (LAB).  
UNITS (shear rate): 1/day (METRIC), 1/day (FIELD), 1/hr (LAB).
- The corresponding shear effect multiplier,  $Z^{ref}$ .

These values must be positive and the first multiplier, which therefore corresponds to the minimal velocity (or shear rate), must be equal to 1.0.

UNITS: Dimensionless.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NPPVT (see the RUNSPEC keyword TABDIMS).

---

**Note:** Changes made in the SCHEDULE section will not be honored in a restart run unless the re-specification is also included in the restart data file. This may be done either by placing the new data for PLYSHLOG in the PROPS section or by leaving the SCHEDULE section keywords in place and using the SKIPREST keyword.

---

ECLIPSE takes each velocity (or shear rate),  $X_i$ , entered in the PLYSHLOG table and calculates a corresponding viscosity multiplier,  $Z_i$ , as follows:

$$Z_i(X_i) = \frac{1 + (P-1)M_i^{ref}(X_i)}{P}$$

where

$M_i^{ref}$  is calculated based on the reference conditions specified in PLYSHLOG.

$P$  is the viscosity multiplier assuming no shear effect and is interpolated, based on the current polymer concentration (and salt and temperature, if applicable), from the relevant polymer viscosity keyword (PLYVISC, PLYVISCs, PLYVISCt or PLYVSCSt). The value of  $P$  must be greater than or equal to unity.

Taking natural logarithms of the input velocities (or shear rates in the case of SHRATE),  $X_i$ , and the corresponding viscosity multipliers,  $Z_i$ , gives a discrete set of points  $(\ln X_i, \ln Z_i)$  through which a piecewise linear function,  $f$ , is constructed. Within this function, the straight line joining two consecutive points  $(\ln X_i, \ln Z_i)$  and  $(\ln X_{i+1}, \ln Z_{i+1})$  may be written as:

$$\ln X_i \ln Z_{i+1} + \ln \frac{X_{i+1}}{X_i} \ln Z = \ln Z_i \ln X_{i+1} + \ln \frac{Z_{i+1}}{Z_i} \ln X$$

The shear water and shear polymer viscosities are then calculated as follows:

$$\mu_{w,sh} = \mu_{w,eff} Z_w^*, \quad \mu_{p,sh} = \mu_{p,eff} Z_p^*$$

where:

$\mu_{w,sh}$  is the shear water viscosity following shear thinning/thickening

$\mu_{p,sh}$  is the shear polymer viscosity following shear thinning/thickening

$\mu_{w,eff}$  is the effective water viscosity

$\mu_{p,eff}$  is the effective polymer viscosity

$Z_w^*$  is the shear effect multiplier that lies at the intersection of the piecewise linear function,  $f$ , and the straight line  $\ln X_0 = \ln X + \ln Z$  where  $X_0$  is the water phase flow velocity (or shear rate) prior to shear thinning/thickening.

$Z_p^*$  is as above albeit  $X_0$  in this case is the polymer flow velocity (or shear rate) prior to shear thinning/thickening.

Shear thinning/thickening is not applied in those cases where:

- The value of  $X_0$  is less than the minimum velocity (or shear rate) specified in PLYSHLOG.
- There is no significant effect due to the polymer concentration (case where  $P = 1$ )

In such cases, the shear viscosities are equal to the effective component viscosities, that is,  $Z_w^* = Z_p^* = 1$ .

Note that the data entered for PLYSHLOG must satisfy the constraint

$$\frac{d(\ln M^{ref})}{d \ln X} = \frac{\ln M_{i+1}^{ref} - \ln M_i^{ref}}{\ln X_{i+1} - \ln X_i} > -1$$

## Notes

- If the shear effect is not significant, the PLYSHLOG keyword should be omitted, as the calculation of the velocity-dependent viscosity increases the run time.
- Models are sensitive to the shear data used and so care must be taken when using this keyword.
- In versions of ECLIPSE before 2012.1, shear thinning only was allowed. This has now been relaxed to allow shear thickening.

See the "[Polymer flood model](#)" in the *ECLIPSE Technical Description* for further information.

## Example

With NTPVT=1 and NPPVT≥6 specified in keyword [TABDIMS](#) and keyword PLYVSCST present:

```

PLYSHLOG
-- reference conditions
-- polymer          salinity          temperature
   0.5              0.0              0.0
/
-- velocity         multiplier
-- m/day           dimensionless
   0.000001        1.0
   0.1             1.2
   1.0             1.6
  10.0            1.7
 100.0           1.8
1000.0          1.8
/

```

## PLYTRRF

## Polymer residual resistance factor temperature dependence

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword should only be used for polymer studies. It describes the temperature dependence of the residual resistance factor given by the second data item of keyword [PLYROCK](#) or by [PLYKRRF](#).

The data comprises NTSFUN (see RUNSPEC keyword [TABDIMS](#)) tables of polymer residual resistance factor multiplier functions, each terminated by a slash (/), describing the effect on the residual resistance factor for adsorbed polymer due to increasing temperature. Each table consists of 2 columns of data:

1. Temperature.

The values should increase monotonically down the column.

UNITS: °C (METRIC), °F (FIELD), °C (LAB)

2. The corresponding factor by which the residual resistance factor (entered using the [PLYROCK](#) or [PLYKRRF](#) keywords) has to be multiplied to give the temperature-dependent residual resistance factor of adsorbed polymer.

If [PLYTRRFA](#) is specified, then for a given grid cell temperature T, the value of the temperature multiplier will be the value in column 2 for the first temperature in column 1 that is equal to or below T. Otherwise, the multiplier will be linearly interpolated as usual between the column 2 values for the column 1 temperatures that form the range containing T.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (RUNSPEC keyword [TABDIMS](#)). If [PLYTRRFA](#) is specified, then this number should also be one more than the value specified first argument of [PLYTRRFA](#).

See "[Polymer flood model](#)" in the *ECLIPSE Technical Description* for further information.

### Example

With NTSFUN=1 and NSSFUN≥5 specified in keyword [TABDIMS](#):

```

PLYTRRF
 20.0   0.1
 50.0   0.5
100.0   2.5
150.0  10.0
200.0  20.0 /

```

## PLYTRRFA Polymer residual resistance factor temperature dependence controller

x	ECLIPSE 100
	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword should only be used for polymer studies. It controls the way the temperature dependence of the residual resistance factor given by `PLYTRRF` is interpreted.

If this keyword is absent, then `PLYTRRF` is interpreted as a piecewise linear specification of the temperature-dependent multiplier of the residual resistance factor (RRF) of the adsorbed polymer. The RRF is always calculated at the highest temperature experienced in the cell while polymer was present.

If this keyword is present, then `PLYTRRF` is interpreted as a histogram of this multiplier. The temperature range is divided into intervals by `PLYTRRF`, and the adsorbed polymer in each cell is divided into batches for each temperature interval.

This keyword has one data item:

1. `NBTRRF`: the number of intervals in the histogram version of `PLYTRRF`.  
`NBTRRF` must be greater than or equal to 2.

The keyword is terminated by a slash.

---

**Note:** There should be one more data line in `PLYTRRF` than in `NBTRRF`, to represent the upper limit of the table. Hence `NBTRRF = 2` will require 3 data lines in `PLYTRRF`.

---

See keyword `PLYTRRF` and the description of the "Polymer flood model" in the *ECLIPSE Technical Description* for further information.

### Example

For a 2-interval representation:

```
PLYTRRFA
 2 /
```

## PLYVISC

## Polymer solution viscosity function

The data comprises NTPVT (see RUNSPEC keyword [TABDIMS](#)) tables of polymer viscosity multiplier functions, each terminated by a slash (/), describing the effect on the viscosity of pure water of increasing the concentration of polymer in solution. Each table consists of 2 columns of data:

- The polymer concentration in the solution.  
The values should increase monotonically down the column.  
The first entry should be 0.0  
UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB), kg/sm<sup>3</sup> (PVT-M)
- The corresponding factor by which the water viscosity (entered using the PVTW keyword in ECLIPSE 100 or the corresponding "Water components" keywords in ECLIPSE 300) has to be multiplied to give the viscosity of the solution.

The first entry should be 1.0.

The values should be level or monotonically increasing down the column.

*ECLIPSE 100 only*

*ECLIPSE 100 only*

This keyword should only be used for polymer studies where the salt-sensitivity option has not been activated (using keyword [BRINE](#) in RUNSPEC). However, if multi-component brine option is activated (using both [BRINE](#) and [ECLMC](#) keywords in RUNSPEC), then the keyword PLYVISC should be used as Multi-Component Brine model cannot currently be used with salt-sensitive Polymer model.

*ECLIPSE 100 only*

---

**Note:** If the surfactant option is active, the viscosity multiplier applies to the water viscosity supplied in the [SURFVISC](#) keyword.

---

The keyword may be used in the SCHEDULE section where the effect of polymer on viscosity may change during the simulation, for example when considering thermal degradation but should be used with care. The keyword must first have been defined in the PROPS section before it can be used in the SCHEDULE section. In addition, the keyword will affect all polymer in the reservoir, not just polymer injected after the keyword has been used.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NPPVT (RUNSPEC keyword [TABDIMS](#)).

See "[Polymer flood model](#)" in the *ECLIPSE Technical Description* for further information.

### Example

With NTPVT=1 and NPPVT≥5:

```
PLYVISC
.0000  1.0
.0003 10.0
.0005 25.0
.0008 50.0
.0010 80.0 /
```

## PLYVISCS

## Polymer/salt solution viscosity function

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword should only be used for polymer studies when the salt- sensitivity option has been activated (in ECLIPSE 100 keyword [BRINE](#) in the RUNSPEC without [ECLMC](#), in ECLIPSE 300 the use of this keyword will activate the salt- sensitivity option).

The data comprises NTPVT (see item 2 in RUNSPEC keyword [TABDIMS](#)) tables of polymer viscosity multiplier functions, each terminated by a slash (/), describing the effect on the viscosity of pure water of increasing the concentration of polymer and salt in the solution. Each table consists of up to NPPVT (see RUNSPEC keyword [TABDIMS](#)) sets of data records. Each set of records within a table consists of up to NPPVT records of data items to allow the specification of a full two-dimensional polymer/salt solution viscosity function. The first record of each elementary set of records contains the following items of data:

1. The polymer concentration in the solution.

The values should increase monotonically down the column.

The first entry should be 0.0

UNITS: kg/sm<sup>3</sup> ([METRIC](#)), lb/stb ([FIELD](#)), gm/scc ([LAB](#))

2. The corresponding factor by which the water viscosity (entered using the [PVTW](#) keyword in ECLIPSE 100 or the corresponding "[Water components](#)" keywords in ECLIPSE 300) has to be multiplied to give the viscosity of a fully mixed solution of polymer/salt at a polymer concentration given by item 1 and a salt concentration given by item 1 in the corresponding salinity table ([SALTNODE](#) keyword in ECLIPSE 100 or [ESPNODE](#) keyword in ECLIPSE 300).

---

**Note:** The values should be greater than or equal to unity. Activating [item 208](#) in [OPTIONS](#) relaxes this constraint by allowing any positive value.

---

For record 2 and all subsequent records up to a maximum of NPPVT, there should be only 1 data item in the record. This item defines the corresponding factor by which the pure water viscosity has to be multiplied to obtain the viscosity of the polymer/salt solution whose polymer concentration is given in item 1 above and whose salt concentration is specified in the corresponding record in the [SALTNODE](#) keyword in ECLIPSE 100 or in the [ESPNODE](#) keyword in ECLIPSE 300.

The data for each table is terminated by a null record (that is a record with no data before the terminating slash).

See "[Polymer flood model](#)" in the *ECLIPSE Technical Description* for further information.

## Example

With NTPVT=1 and NPPVT=4:

```

PLYVISCS
.0000  1.0
        1.0
        1.0
        1.0 /
.0100  10.0
        8.0
        6.0
        4.0 /
.0200  25.0

# PLYVSCST Polymer/salt solution/temperature viscosity function

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword should only be used for polymer studies when the salt-sensitivity option has been activated (keyword **BRINE** in the RUNSPEC section) and when the temperature option has been activated (keyword **TEMP** in the RUNSPEC section).

The data comprises NTPVT (see item 2 in RUNSPEC keyword **TABDIMS**) tables of polymer viscosity multiplier functions, each terminated by a slash (/). These describe the effect on the viscosity of pure water of increasing the concentration of polymer and salt in the solution, and the temperature of the solution.

Each table consists of up to NPPVT (see RUNSPEC keyword **TABDIMS**) sets of data records, one for each polymer concentration. The set of records then has NPPVT subsets, one for each brine concentration value specified by the **SALTNODE** keyword, with each subset containing NPPVT records for each temperature specified by the **TEMPNODE** keyword.

In outline, the record structure for one table is shown below:

Column 1	Column 2
Polymer concentration value 1	multiplier at polymer concentration 1, brine concentration 1, and temperature 1
multiplier at polymer concentration 1, brine concentration 1, and temperature 2	
multiplier at polymer concentration 1, brine concentration 1, and temperature 3 /	<i>end of first record set (brine concentration 1) for polymer concentration 1</i>
multiplier at polymer concentration 1, brine concentration 2, and temperature 1	
multiplier at polymer concentration 1, brine concentration 2, and temperature 2	
multiplier at polymer concentration 1, brine concentration 2, and temperature 3 /	<i>end of 2nd record set (brine concentration 2) for polymer concentration 1</i>
/	<i>end of records for polymer concentration 1</i>
Polymer concentration value 2	multiplier at polymer concentration 2, brine concentration 1, and temperature 1
<i>Record sets repeat for remaining polymer concentration values</i>	
<i>/ one additional slash to terminate this table</i>	
<b>remaining tables (if any) have the same format</b>	

Table 3.28: PLYCSCST table structure for 2 SALTNODE values and 3 TEMPNODE values

In this table, there is only one column for the multiplier, except for the first record where the polymer concentration changes, where there are two columns: concentration and multiplier. *Italics show comments.*

Each elementary set of records refers to one polymer concentration and one salt concentration, and gives a single column of viscosity multipliers, one record for each temperature in the **TEMPNODE** keyword (except

where the polymer concentration changes, where the multiplier is in column 2). For successive sets of records, each set refers to a salt concentration specified by the `SALTNODE` keyword.

When the record set for the largest `SALTNODE` value has been completed, the next set of records refers to a new polymer concentration, and restarts at the first `TEMPNODE` and `SALTNODE` values. The multiplier is preceded by the polymer concentration value for this record only. In combination this allows the specification of a full three-dimensional polymer/salt solution/temperature viscosity function.

The multipliers should be greater than or equal to unity. Activating [item 208](#) in `OPTIONS` relaxes this constraint by allowing any positive value.

Note that:

The polymer concentration in the solution should increase monotonically down the table

The first entry should be 0.0

UNITS: kg/sm<sup>3</sup> (`METRIC`), lb/stb (`FIELD`), gm/scc (`LAB`)

The set of records for one polymer concentration is terminated by a null record (that is a record with no data before the terminating slash).

See the "[Polymer flood model](#)" in the *ECLIPSE Technical Description* for further information.

## Example

With `NTPVT=1` and `NPPVT ≥ 3`, for 2 `SALTNODE` and 3 `TEMPNODE` values (text after the slashes provides comments):

```

PLYVSCST
.0000  1.0
        1.0
        1.0 / set of records for salt concentration value #1
        1.0
        1.0
        1.0 / set of records for salt concentration value #2
/ end of records for polymer concentration 0.0000
.0100  10.0
        8.0
        6.0 / set of records for salt concentration value #1
        8.0
        4.0
        2.0 / set of records for salt concentration value #2
/ end of records for polymer concentration 0.0100
.0300  50.0
        25.0
        15.0 /
        40.0
        30.0
        18.0 /
/ end of records for polymer concentration 0.0300
/ end of table 1

```

## Pressure maintenance region numbers

The keyword should be followed by one integer for every grid block in the current box specifying the pressure maintenance region to which it belongs. The region number should not be less than 1 or greater than the number of pressure maintenance tables, specified with [TABDIMS](#).

Pressure maintenance region numbers are used to specify regions for pressure maintenance as described with the [GPMAINT](#) keyword.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices.

By default all cells are in PMANUM region 1.

### Example

```
PMANUM
100*1 100*2 /
```

## Maximum pressure in the simulation

The keyword should be followed by some or all of the following items, indicating the maximum pressure likely to be reached during the simulation and additional information governing total compressibility checks. The record should be followed by a slash (/).

**Note:** In ECLIPSE 300, this keyword is active only for Blackoil and Thermal Blackoil runs with dissolved gas (RS) or vaporized oil (RV).

1. The maximum pressure likely to be reached during the simulation

**Note:** This item is ignored in ECLIPSE 300.

This value is used only if live oil PVT properties are entered using keyword [PVCO](#). The information is used for two purposes. Firstly, the undersaturated parts of the oil PVT tables are automatically filled out in the form of the [PVTO](#) keyword, up to the pressure entered in [PMAX](#). Secondly, ECLIPSE carries out a check to see if compressibilities are changing too rapidly with  $P_{\text{pub}}$  so that the curves of undersaturated oil formation volume factor for two different values of  $R_s$  cross each other. A warning is printed if they cross at a pressure below the maximum pressure entered in [PMAX](#).

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: ERROR: this item must be entered with [PVCO](#) tables.

2. Maximum pressure value to extend the range of pressures for checking total compressibility of the system.

By default the total compressibility of the gas-oil system is checked across the range of pressures spanned by the bubble point pressures in the [PVTO](#) (or [PVCO](#)) tables (or plain pressure nodes in a [PVDO](#) table) in dead oil cases; and by the range of dew point pressures in the [PVTG](#) tables (or plain [PVDG](#) tables) in dry gas cases. The upper pressure limit for the total compressibility checks is then set to the maximum of the value entered here and the maximum saturation pressure specified in the input tables. This could be useful to check total compressibility errors arising from extrapolation above the highest entered  $R_s$  value in the [PVTO](#) table which would cause convergence difficulties. It is not necessary to use [PVCO](#) to enable this checking, as this also applies to [PVTO](#) tables. See "[Total compressibility checks](#)" in the *ECLIPSE Technical Description* for more information

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: 0.0 barsa

3. Minimum pressure value to extend the lower range of pressures for checking total compressibility of the system.

By default the total compressibility of the gas-oil system is checked across the range of pressures spanned by the bubble point pressures in the [PVTO](#) (or [PVCO](#)) tables (or plain pressure nodes in a [PVDO](#) table) in dead oil cases; and by the range of dew point pressures in the [PVTG](#) tables (or plain [PVDG](#) tables) in dry gas cases. The lower pressure limit for the total compressibility checks is then set to the minimum of the value entered here and the minimum saturation pressure specified in the input tables.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: 1.0E+20 barsa

4. The number of nodes used to span the range of pressures for checking total compressibility. See "[Total Compressibility Checks](#)" in the *ECLIPSE Technical Description* for more information. Up to 100 nodes may be used.

DEFAULT: 30

## Example

## PMISC

## Pressure-dependent miscibility tables

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The PMISC keyword is optional, and may only be used in miscible runs (see keyword [MISCIBLE](#)). It supplies tables that control the transition between immiscible and miscible displacement as a function of oil pressure. If this keyword is not present in miscible runs, miscible displacement is assumed to occur at all pressures; pressure having no effect on the miscibility. See "[Miscible flood modeling](#)" in the *ECLIPSE Technical Description*. Saturation functions for the immiscible fluid must be specified when PMISC is used in a miscible run.

If used in runs which use the Solvent Model in miscible mode (keywords [SOLVENT](#) and [MISCIBLE](#) in the RUNSPEC section) then see also the section entitled "[Using the Solvent Model](#)" in the *ECLIPSE Technical Description*.

The data comprises NTMISC (see keyword [MISCIBLE](#)) tables of the pressure dependent miscibility function, each terminated by a slash.

Each table consists of 2 columns of data:

1. The local oil phase pressure.  
Values should increase monotonically down the column.  
UNITS: barsa ([METRIC](#)), psia ([FIELD](#)), atma ([LAB](#)), atma ([PVT-M](#))
2. The corresponding miscibility, on a scale from 0.0 to 1.0.  
Zero corresponds to immiscible displacement and 1.0 to miscible displacement.  
The values should be level or increasing down the column.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSMISC (defined by keyword [MISCIBLE](#)).

## Example

With NTMISC=1 and NSMISC≥4:

```
PMISC
1000.0 0.0
4000.0 0.0
4100.0 1.0
8000.0 1.0 /
```

## POISSONR Poisson's ratio for rock stress balance

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword has no effect if **GEOMECH** is not specified in the RUNSPEC section.

The keyword should be followed by one non-negative real number for every grid block in the current input box, specifying the rock Poisson ratio. This parameter is dimensionless and must be greater than -1 and less than 0.5. The data must be terminated by a slash (/).

Grid blocks are ordered with the *X* axis index cycling fastest, followed by the *Y* and *Z* axis indices. Repeat counts may be used for repeated values (for example 115\*208.4). Note that spaces may not be inserted on either side of the asterisk.

---

**Note:** There is no default for the Poisson ratio. The simulation will stop if the **GEOMECH** keyword is specified but this data is not supplied.

---

### Example

```
POISSONR
324*0.3 /
```

## POLYMER

## Activates the Polymer Flood Model

This keyword activates the Polymer Flood Model (see "[Polymer flood model](#)" in the *ECLIPSE Technical Description*).

The keyword has no associated data.

ECLIPSE 300 only

The keyword should be followed by one non-negative real number for every grid block in the current input box, specifying the fractional porosity value for each cell.

Grid blocks whose pore volume is zero are treated by the program as inactive. Since the computing time and storage space requirements of a run depend primarily on the number of active grid blocks, it is important that inactive blocks should be unambiguously identified. This is best done by setting either `PORO` or `NTG` to zero in inactive blocks. It is also possible to set pore volumes directly (array `PORV` in the `EDIT` section), or to use the `ACTNUM` keyword.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example `115*0.127`). Note that spaces must not be inserted on either side of the asterisk.

The data must be terminated by a slash (/).

**Note:** For thermal runs both the rock volume and the pore volume should be zero for a cell to become inactive.

### Examples

#### Example 1

```

----- IX1-IX2 JY1-JY2 KZ1-KZ2

ENDBOX

```

#### Example 2

In this example, porosity values for a 10\*10 cross section are set, with an inactive third layer:

```

PORO
10*0.21 10*0.24 10*0.0 30*0.23 20*0.18 20*0.03 /

```

ECLIPSE 100

Every `PORO` value in the top plane (`K = 1`) must be specified in one way or another by the end of the `GRID` section. Values in lower planes (`K > 1`) which are not specified default to the value in the plane above.

# PORV

## Specifies the grid block pore volumes

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
x	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by one non-negative real number for every grid block in the current input box, specifying the grid block pore volumes.

This keyword is entirely optional. Any pore volumes that are not altered remain at the values calculated by the program from the GRID data.

Grid blocks whose pore volume is zero are treated by the program as inactive. Since the computing time and storage space requirements of a run depend primarily on the number of active grid blocks, it is important that inactive blocks should be unambiguously identified. This can be done either by using the PORV keyword (described here) to overwrite pore volumes directly in the EDIT section, or by setting [PORO](#) or [NTG](#) to zero in the GRID section. The [ACTNUM](#) keyword (in the GRID section) can also be used to identify inactive grid blocks.

In ECLIPSE 100 only, grid cells defined as inactive in the GRID section could be activated in the EDIT section using the PORV keyword. A warning message is issued in this case.

In ECLIPSE 300 only, grid cells defined as inactive in the GRID section using the ACTNUM keyword cannot be activated in the EDIT section. The use of the PORV keyword is ignored in this case.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*195.8). Note that spaces must not be inserted on either side of the asterisk.

UNITS:  $\text{rm}^3$  (METRIC), rb (FIELD), rcc (LAB),  $\text{rm}^3$  (PVT-M)

The data must be terminated by a slash (/).

ECLIPSE 100 only

---

**Note:** If a cell is defined with zero pore volume in the GRID section, then making it active by changing the pore volume in the EDIT section is not allowed with the polymer, surfactant, foam, temperature or environmental tracer options.

---

ECLIPSE 300 only

---

**Note:** For thermal runs both the rock volume and the pore volume should be zero for a cell to become inactive.

---

---

**Note:** It is not possible to give a non-zero pore volume to a cell which has a thickness of zero. An error message will be issued in this case (this can be reduced to a warning in ECLIPSE 300 by setting [item 233](#) in [OPTIONS3](#) to a non-zero value). Individual cell thicknesses can be adjusted with [ADDZCORN](#) if needed.

---

### Example

```

----- IX1-IX2 JY1-JY2 KZ1-KZ2
BOX      11  14   3   8   6   6   /
PORV
24*0 /
ENDBOX

```

## PPCWMAX

## Limits the calculated PCW values when SWATINIT is used

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used to limit the scaling of the capillary pressure curves when the [SWATINIT](#) keyword has been used to input an initial water distribution. Typically, if the input water saturation is above the connate saturation in blocks well above the transition zone, the scaling of the  $P_c$  curve leads to unphysically high capillary pressure values.

The keyword should be followed by NTSFUN (see item 1 of keyword [TABDIMS](#) in the RUNSPEC section) records, each terminated by a slash (/).

Each record consists of the following items of data:

1. The maximum capillary pressure for this saturation region; it must be greater than the maximum capillary pressure in the corresponding saturation function table.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

DEFAULT: Infinity (no limit)

2. Either YES or NO, indicating whether the connate saturation should be modified to honor the input water saturation when the capillary pressure limit is exceeded.

DEFAULT: NO

If a maximum capillary pressure is supplied via item 1 and item 2 is set to NO, the input water saturation (from SWATINIT) is not honored in grid blocks that exceed the maximum capillary pressure. In such cases, the rescaled maximum capillary pressure will be set to the maximum specified by PPCWMAX, and the initial water saturation will be adjusted to be consistent with this rescaling.

If a maximum capillary pressure is supplied via item 1, and item 2 is set to YES, the capillary pressure is reset using the values input via the saturation tables, and the connate saturation will be set to the SWATINIT value. In such cases, the maximum table capillary pressure remains unscaled and the effect of changing the connate saturation to the supplied SWATINIT value will be to adjust the initial water saturation to be consistent with the unscaled capillary pressure.

See also the SWATINIT and [PCW](#) keywords in the PROPS section.

### Example

With NTSFUN=2

```
PPCWMAX
 15.0      YES    /
 17.0      YES    /
```

## Reference pressures

This keyword can only be used with the THERMAL option (keyword [THERMAL](#) in the RUNSPEC section).

In a live-oil thermal run with  $N_c$  components, `PREF` specifies the reference pressures at which the hydrocarbon liquid densities are defined.

The expression used to calculate oil component liquid densities is the following:

$$\rho_c = \frac{\rho_{ref_c}}{\left[1 - c_{P_c}(P - P_{ref_c})\right] \left[1 + c_{T1_c}(T - T_{ref_c})\right]} \quad \text{Eq. 3.148}$$

where

$\rho_{ref,c}$  is the reference density, specified with keyword [DREF](#),

$c_{P_c}$  is the oil component liquid compressibility, specified with keyword [CREF](#),

$P_{ref_c}$  is the reference pressure, specified with this keyword,

$T_{ref_c}$  is the reference temperature, specified with keyword [TREF](#), and

$c_{T1_c}$  is the thermal expansion coefficient, specified with keyword [THERMEX1](#).

There should be one value for each component:

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: the standard pressure set with keyword [STCOND](#).

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

PREFW specifies the reference pressure used in calculating the water density and water viscosity for each of the  $N_w$  water components.

The water component densities, at pressure  $P$ , are calculated from:

$$\rho_w = \rho_{ref_w} \cdot (1 + X + X^2/2)$$

$$X = c_{P_w} \cdot (P - P_{ref_w})$$

where

$\rho_{ref_w}$  is the reference density, specified with keyword [DREFW](#),

$c_{P_w}$  is the water component compressibility, specified with keyword [CREFW](#)

$P_{ref_w}$  is the reference pressure, specified with this keyword

The water component viscosities are calculated from:

$$\mu_w = \mu_{ref_w} \cdot (1 + Y + Y^2/2)$$

$$Y = -c_{V_w} \cdot (P - P_{ref_w})$$

where

$\mu_{ref_w}$  is the reference viscosity, specified with keyword [VREFW](#)

$c_{V_w}$  is the viscosibility, specified with keyword [VREFW](#)

There should be one value for each component:

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: 1 atma.

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

See "[Water components](#)" in the *ECLIPSE Technical Description* for further details of the water component option.

ECLIPSE 100

This keyword is used to switch on the well prioritization option, and to set coefficients in the priority equations.

This method of limiting the group production rate is an alternative to the method of apportioning group production targets among the wells in proportion to their guide rates. In the prioritization option, wells are turned on in decreasing order of priority, the well with the highest priority flowing first, until a group's production rate limit is exceeded. The flowing wells operate at their individual targets or limits (see the keyword [WCONPROD](#)). But the well that exceeds the group's rate limit is cut back to meet the limit, and the wells with priority lower than this subordinate to that group do not flow. The low priority wells not selected for flow are priority-closed until they are eventually selected. In the well reports, priority-closed wells are indicated by "PSHT" or "PSTP" depending on whether they are shut or stopped, as requested in item 9 of keyword [WELSPECS](#). Wells that are closed manually by the user, or by violating economic limits, cannot be selected for flow, whatever their priority number is.

Optionally, the coefficients for a second priority formula can also be defined. In the [GCONPRI](#) keyword it is possible to select which of the two priority formulae should be used to obey each rate limit separately. For example, if a gas rate limit is exceeded you may wish to priority-close wells with a high GOR, whereas to obey a water rate limit the user may wish to close wells with a high water-cut. When there are two priority formulae defined, the procedure is slightly different to the single priority equation case. All the available (open or priority-closed) wells are opened initially, then if a group rate limit is violated ECLIPSE closes in turn the wells with the lowest priority according the formula chosen for that particular rate limit until the rate limit is no longer exceeded. The last well to be closed is then reopened and made to produce at a rate calculated to meet the limit. If the group exceeds two or more limits having different priority formulae, ECLIPSE determines which limit is broken by the largest fraction and uses the formula appropriate to that limit to select the lowest priority well to close. As each well is closed, the active formula may, of course, change.

The wells are prioritized at each Newton iteration of each timestep, in the first NUPCOL iterations. Any wells that flow with a reduced target calculated to meet a group's rate limit have their target rates recalculated to meet the group's limit exactly. During any subsequent iterations of each timestep, the on-off status and flow target of each well will be kept unchanged, to allow the iteration to converge. The value of NUPCOL is set by keyword [NUPCOL](#).

While a well has its flow rate cut back to meet a group's limit, its minimum rate limits set in keywords [WECON](#) and [WLIFT](#) are ignored. This is to prevent the well being prematurely closed or put on artificial lift when it is producing at a low rate so as not to exceed the group's production rate limit.

The priority numbers for each well are calculated from their potential production rates (see "[Well potentials](#)" in the *ECLIPSE Technical Description*) at regular intervals, using the general formula

$$\text{Priority} = \frac{A + BQ_o + CQ_w + DQ_g}{E + FQ_o + GQ_w + HQ_g} \quad \text{Eq. 3.149}$$

where

$Q_o$ ,  $Q_w$  and  $Q_g$  are the well's potential oil, water and gas production rates, and

A - H are 8 coefficients set with this keyword.

The equation allows the priority to be set equal to, for example, the potential oil rate, or the reciprocal of the potential gas rate, or the reciprocal of the water cut. Individual wells may also have their priorities set independently by the user, overriding the general formula (see keyword [WELPRI](#)).

The prioritization option can be applied to group and field production control, but not injection control (which is still handled by guide rates). When this option is used, the group production rate limits should be set using the keyword `GCONPRI`, not `GCONPROD`. Group limits can be applied at any level in the grouping tree.

It is possible to mix the two group control strategies - prioritization and guide rates - in a single run. Groups to be controlled by prioritization should have their rate limits set with keyword `GCONPRI`, while groups using the guide rate method have their rate limits set with keyword `GCONPROD`. A group can be changed from one method to the other simply by re-specifying its rate limits with the appropriate keyword. The mixing of the two methods, however, is subject to the following restriction: the guide rate method cannot be used by a group subordinate to a group using the prioritization method. Thus, for example, no groups can use the guide rate method if the field has a prioritization rate limit.

When the two group control strategies are mixed, the well rates are allocated according to the following method. First, the production wells subordinate to prioritization groups are solved, selecting the wells for flowing in decreasing order of their priorities. Next, the producers in the remaining parts of the grouping tree are solved, employing the standard guide rate method to apportion the flow rates between them to meet any `GCONPROD` group targets. If a prioritization group is subordinate to one with a `GCONPROD` rate target, the wells in the prioritization group already have had their flow rates set, and the remaining wells have their rates set to make up the rest of the `GCONPROD` group's target. Wells from the drilling queue (keyword `QDRILL` or `WDRILPRI`) that are not subordinate to a prioritization group will be opened when necessary to meet the `GCONPROD` group's rate target. The drilling queue is **not** used for opening wells subordinate to prioritization groups, as the prioritization algorithm itself handles the opening and closing of these wells.

The `PRIORITY` keyword is followed by some or all of the following items of data, terminated with a slash (/). The record may be terminated early with a slash; the remaining items assume their default values. The items are:

Item 1 The minimum time interval between well priority calculations

Wells have their priorities calculated from the formula above at the beginning of each timestep that starts after the specified interval has elapsed since the previous calculation.

A zero value causes the priorities to be recalculated every timestep. This may result in oscillations with some wells alternately switching on and off.

UNITS: day (`METRIC`), day (`FIELD`), hr (`LAB`), day (`PVT-M`)

Items 2 - The coefficients A - H in the first priority formula.

9

None of the coefficients can have negative values.

At least one of the first four coefficients (A - D) must be non-zero, and similarly at least one of the last four coefficients (E - H) must be non-zero.

DEFAULT: Zero

*ECLIPSE 100 only*

Items The coefficients A - H in the second priority formula.

10-17

None of the coefficients can have negative values.

A second priority formula will be defined if one or more of these coefficients is non-zero. In this case, at least one of the first four coefficients (A - D) must be non-zero and at least one of the last four coefficients (E - H) must be non-zero.

DEFAULT: Zero

## Examples

This keyword can optionally be used to define a specific sequence of actions to be performed if a group fails to meet its production rate target set in keyword [GCONPROD](#). A full description of these actions can be found under "[Group production rules](#)" in the *ECLIPSE Technical Description*.

The keyword consists of two records of data, each terminated by a slash (/).

### Record 1

This should contain a list of some or all of the following action mnemonics, terminated with a slash. The order in which the mnemonics are entered determines the order in which the actions are performed. Thus, whenever a group cannot make its [GCONPROD](#) production rate target, initially the first action in the list is performed. When no more actions of this type can be performed, ECLIPSE commences the second action in the list, and so on. The actions are:

**DRILL** Open new wells from the drilling queue.

The drilling queue must be set up with either keyword [QDRILL](#) or [WDRILPRI](#), containing production wells declared as [SHUT](#) in keyword [WCONPROD](#). Restrictions on the rate at which wells can be drilled may be imposed by declaring the time taken to drill each well (keyword [WDRILTIM](#)) and defining drilling rigs (keyword [GRUPRIG](#)). Wells in the Sequential Drilling Queue (keyword [QDRILL](#)) will be drilled in the sequence in which they are placed in the queue. Wells in the Prioritized Drilling Queue (keyword [WDRILPRI](#)) are drilled in decreasing order of their drilling priority. The order in which wells are drilled may be affected by drilling rig constraints.

**REPERF** Open new connections on [AUTO](#) in existing wells.

The connections must be placed on automatic opening by specifying 'AUTO' in item 6 of keyword [COMPDAT](#) (or in keyword [WELOPEN](#)). Wells are worked over in turn to open these connections. Restrictions on the rate at which wells can be worked over may be imposed by declaring the time taken to perform a workover (keyword [WORKLIM](#)) and defining workover rigs (keyword [GRUPRIG](#)). When a group needs more production, ECLIPSE will examine its subordinate wells that have connections on [AUTO](#) and are not prevented from being worked over by rig constraints. The well with the largest sum of [connection factor \* phase mobility] of its remaining connections on [AUTO](#) is selected, and the next connection in its [AUTO](#) queue is opened.

**THP** Reduce each well's THP limit to a specified lower value.

Secondary well THP limits should be specified in item 8 of keyword [WLIFT](#). If a decrement value is entered in item 11 of [WLIFT](#), the well's THP is decreased to its secondary limit in stages, a decrement at a time. When a group needs more production, ECLIPSE examines its subordinate wells operating on THP control that have secondary THP limits waiting to be applied. The well that gives the biggest increase in flow when switched to its secondary THP limit (or when given its next THP decrement towards this limit) is selected, and its current THP limit is replaced by its secondary THP limit (or decremented by the amount specified in item 11).

**RETUBE** Change VFP table numbers (for example to model a retubing operation).

Secondary VFP table numbers should be specified for wells in item 4 of keyword [WLIFT](#). When a group needs more production, ECLIPSE will examine its subordinate wells operating

on THP control that have secondary VFP tables waiting to be used. The well that gives the biggest increase in flow when switched to its secondary VFP table is selected, and its current VFP table number is replaced by its secondary VFP table number.

LIFT Change ALQ values (that is apply a fixed amount of artificial lift).

Secondary ALQ values should be specified for wells in item 5 of keyword WLIFT. If an increment value is entered in item 10 of WLIFT, the well's ALQ is increased to its secondary value in stages, an increment at a time. A new well efficiency factor can also be defined in item 6 of keyword WLIFT if required, which comes into effect when the new ALQ value (or the first ALQ increment) is applied. Restrictions on the total amount of lift applied in any group may be specified with keyword GLIFTLIM. When a group needs more production, ECLIPSE examines its subordinate wells operating on THP control that have secondary ALQ values waiting to be applied and are not prevented from applying them by group lift capacity constraints. The well that gives the biggest increase in flow when switched to its secondary ALQ value (or when given its next ALQ increment towards this value) is selected, and its current ALQ value is replaced by the new value (or incremented by the amount specified in item 10).

The effect of this mnemonic is different if the Gas Lift Optimization facility is being used (see "[Gas Lift Optimization](#)" in the *ECLIPSE Technical Description*). Secondary ALQ values must **not** be specified with WLIFT, and GLIFTLIM must **not** be used. Instead, ECLIPSE automatically allocates lift gas to the wells until group production targets are met or other operating limits are reached. Gas lift allocations are calculated at specified intervals, or during the first NUPCOL Newton iterations of each timestep, depending on the instructions in keyword LIFTOPT, (regardless of the presence or absence of the LIFT mnemonic in PRORDER). By default, all the requested production rule actions will be attempted **before** gas lift is allocated. However, if LIFT is entered in the PRORDER keyword, gas lift allocation takes precedence over any production rule actions whose mnemonics are entered after LIFT. Thus, for example, it is possible to specify that drilling new wells should only be attempted if group targets cannot be met by applying gas lift. Essentially, all production rule actions entered after LIFT are only performed immediately after a gas lift optimization calculation, and not at any other time or Newton iteration, if a group production target still cannot be met. In this case it is best to configure LIFTOPT so that gas lift is optimized during each of the first NUPCOL iterations of every timestep.

COMP Switch on, or increase power of, compressors linked to this group.

This option is only available if the Extended Network Model is in use (see "[The extended network model](#)" in the *ECLIPSE Technical Description*). The compressors must be defined with the NETCOMPA keyword, to be turned on when a nominated group cannot meet its target production rate of a specified phase. When the group needs more production, ECLIPSE turns on the compressors responding to the specified phase production of that group. If the group has more than one compressor responding to it, the compressors are turned on in increasing order of their switching sequence number (item 12 of keyword NETCOMPA). Multi-level compressors (see NETCOMPA item 10) have their power increased by one stage at a time until the group's rate target is satisfied or the compressor is fully on and another compressor is tried.

A blank record, containing just the terminating slash, results in none of the above remedial actions being performed when a group cannot make its target rate (except for gas lift optimization, if this facility has been turned on). No drilling is performed, even if a drilling queue has been set up.

## Record 2

The second record consists these data flags, terminated by a slash (/). These are flags that control the application of the production rules. Both may be defaulted.

1. This item is a flag to control the application of the production rules when wells are treated as being shut for a given length of time during drilling or workovers (that is when item 3 of keyword `WDRILTIM` is set to YES). This flag has no effect if `WDRILTIM` item 3 is set to NO for all producers.

The item consists of the characters YES or NO, specifying whether or not further actions are allowed before the full benefits of a DRILL or REPERF action are felt.

**YES** Allow further actions to take place in the timestep while a well is shut during a drilling or workover process, if the group cannot immediately make its target rate. This may result in further actions being performed before they are permanently needed.

**NO** When a production well is drilled or worked over to increase the flow rate in a group, and the well is treated as shut for the (non-zero) duration of this process, do not allow **any** further production rule actions to take place within this group until the next timestep that begins after the process has been completed.

Setting this item to NO has a similar effect to the QDRILL command in keyword `WDRILTIM`, except that this item restricts **all** the group production rule actions and not just drilling.

DEFAULT: YES

2. This item is a flag to control the order in which the actions in keyword `WLIFT` are performed when triggered by individual wells rather than by group behavior (that is when a well dies under THP control it will be revived after an action is performed, or an action can be performed when a well's flow rate or water cut violates a limit specified in item 2 or 7 of keyword `WLIFT`). The actions may either be performed in the same sequence as specified in record 1 of keyword `PRORDER`, or in the original sequence given in `WLIFT`.

The item consists of the characters YES or NO, specifying whether the original order in `WLIFT` should be overridden.

**YES** Apply the three actions (lower the THP, retube or apply lift) in the same order as specified in record 1 of keyword `PRORDER`.

**NO** Apply the actions in the original order given in keyword `WLIFT`, that is first THP, then RETUBE, then LIFT.

DEFAULT: YES

## Notes

- The production rules apply to all groups (including the FIELD) that have guide rate group control targets (keyword `GCONPROD`). They do **not** apply to groups under prioritization control (keyword `GCONPRI`).
- With the THP, RETUBE and LIFT actions, secondary values of the THP, VFP table number and ALQ must be supplied in keyword `WLIFT`. The `WLIFT` keyword will also apply these values to wells individually when their production rate falls below a specified limit, or their water cut or gas-liquid ratio exceeds a specified limit, or when the well dies under THP control. If you wish these secondary

values to be applied only via the group production rules to help meet a group target, or if a well dies under THP control, then you must give the rate, water cut and GLR limits in items 2, 7 and 9 of keyword `WLIFT` a default, zero or negative value.

- The THP action has no effect within groups that are part of a network (see "[Network option](#)" in the *ECLIPSE Technical Description*), since the wells have their THP limits set according to their group's nodal pressure.
- If the gas lift optimization facility is being used (see "[Gas Lift Optimization](#)" in the *ECLIPSE Technical Description*), by default all the requested production rule actions are attempted **before** gas lift is allocated. But if `LIFT` is entered in Record 1, any production rule actions entered after `LIFT` will only be performed immediately after a gas lift optimization calculation, if a group production target still cannot be met. The frequency of gas lift optimization calculations is governed by the `LIFTOPT` keyword, and is not affected by the presence or absence of the `LIFT` mnemonic in `PRORDER`.
- If the `PRORDER` keyword is not present then, for back compatibility, only the `DRILL` action will be applied (if a drilling queue has been set up), followed by the `COMP` action (in an Extended Network Model containing automatic compressors).
- If compressors have been defined in the extended network model with the `NETCOMPA` keyword (see "[The extended network model](#)" in the *ECLIPSE Technical Description*), they are used regardless of whether the `PRORDER` keyword is entered or if the `COMP` option is missing from the `PRORDER` keyword. By default, the compressors are used as a last resort to increase a group's production rate if it fails to meet its target. Once a compressor has been defined, then, it is ultimately used when more flow is required; the `PRORDER` keyword just instructs ECLIPSE to turn the compressors on before some of the other options to increase the flow have been tried.
- When the network option is in use, by default all actions except for `COMP` will be performed in any network balancing iteration when a flow target is not met. Thus it is possible, for example, that a well may be opened from the drilling queue prematurely because an intermediate network balancing iteration has high nodal pressures. The exception is the `COMP` action, which is only performed if more flow is required once the network has converged. It is possible to instruct ECLIPSE to prevent any of the other production rule actions from being performed before the network balancing iterations have converged, by using the `WAITBAL` keyword (see "[Network option](#)" in the *ECLIPSE Technical Description*). Then if more flow is required once the network has converged, an appropriate production rule action is performed and the network must be balanced again. Using this option therefore requires more network balancing iterations in total.

## Example

```
PRORDER
DRILL THP REPERF /
NO /
```

causes the following actions to take place whenever a group cannot make its `GCONPROD` production target. Firstly, ECLIPSE searches the drilling queue for a suitable well to open. If no wells can be drilled, it examines the wells having secondary THP values and reduce the THP of the well that it selects. If it cannot reduce any THP values, it examines the wells having connections on `AUTO` opening, and opens the next `AUTO` connection in the well that it selects.

## Initial pressure versus depth tables

This keyword can be used as an alternative to the [PRESSURE](#) keyword to specify the initial pressure for an enumerated initial solution.

The data comprises NTEQUL (see keyword [EQLDIMS](#)) tables of initial oil pressure versus depth, one for each equilibration region. Each table consists of 2 columns of data, and must be terminated by a slash (/).

1. Depth values.

The values should increase monotonically down the column.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

2. The corresponding values of oil pressure.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NDRXVD (see keyword [EQLDIMS](#)).

See also keywords [SWAT](#), [SGAS](#), [RS](#), [PBUB](#), [RV](#) and [PDEW](#) in the SOLUTION section.

### Example

With NTEQUL=1 and NDRXVD≥4:

```
PRVD
 7000 2310.0
 8000 2640.0
 9000 2990.0
10000 3390.0 /
```

## PSEUPRES

**Activate the generalized pseudo-pressure option in ECLIPSE 300**

	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword requests that the Generalized Pseudo-Pressure (GPP) option be activated for the well inflow calculations in ECLIPSE 300.

The keyword should be specified early in the SCHEDULE section before any well operations keywords or timestepping keywords are specified. Alternatively this option can be activated for individual wells by entering GPP in item 8 of [WELSPECS](#).

For details of the GPP model, see "[Special inflow equations](#)" in the *ECLIPSE Technical Description*.

See also keyword [PICOND](#).

## PSGRO

## Primary residual gas saturation in gas-oil system

x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies the residual gas saturation in a gas-oil system within each grid cell for the primary saturation tables. This is only required when the [ODD3P](#) option is being used and when saturation table end-point scaling has been specified by the [ENDSCALE](#) keyword in the RUNSPEC section.

Each PSGRO keyword should be followed by one real number for each grid cell in the current input box specifying the residual saturation within the grid cell. The saturation should be in the range of 0.0 to 1.0 inclusive. If the value of PSGRO is omitted for any grid cell in a model for which [ENDSCALE](#) has been specified, the residual saturation will be obtained from the critical saturation in the appropriate saturation table.

See "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for further details.

See also the [PSORG](#), [PSORW](#), [PSWRO](#), [PSGRW](#) and [PSWRG](#) keywords.

## Example

With [NDIVIX](#)=3, [NDIVIY](#)=4 and [NDIVIZ](#)=5 specified in RUNSPEC keyword [DIMENS](#) and no input BOX set:

```
PSGRO
60*0.1/
```

## PSGRW

This is an optional keyword associated with the [PARALLEL](#) keyword. It specifies possible partitions arising from domain decomposition in the X-direction. It is envisaged that the data will be collected from the output of the PART argument in the [RPTSOL](#) keyword, which outputs all potential splits for a given dataset.

This keyword is a multiple record version of the now-redundant [PDIVX](#) keyword. The purpose of this keyword is to specify all possible partitions in a particular direction without having to edit the dataset.

The keyword is followed by multiple records each having  $N_{px}$  integer items (where  $N_{px}$  is the number of processors in the X-direction; if the number of processors specified by the [NPROCX](#) keyword matches the entries in a particular record, then this record is used for domain decomposition). Each integer specifies the last x-index for the particular processor. The last item must have the value  $N_x$ .

See also "[Parallel option](#)" in the *ECLIPSE Technical Description*.

### Example

```

DIMENS
30 20 3 /
PSPLITX
 15 30 / --NPROCX= 2 LOAD BALANCED (%) = 95.41
 11 19 30 / --NPROCX= 3 LOAD BALANCED (%) = 94.59

This keyword uses the saturation pressure calculation to assign single phase hydrocarbon states as oil or gas, rather than the Li correlation. This gives a more precise state identification although this involves the extra cost of the  $P_{\text{sat}}$  evaluation.

There is no data associated with this keyword.

## PSTEADY

## Turns on the pseudo steady-state calculation

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword advances the simulator to a steady state. Read the notes at the end of the keyword. The keyword is followed by the following items of data, denoting the day, month and year of the date required for the **end** of the simulation. This is the date that is given to the restart file, from which further predictive runs take place; and it is only used for output to the restart file. Further data specifies the criteria for the determination of whether steady-state has been reached. The keyword is terminated with a slash (/).

## 1. Day

Day of the month (an integer between 1 and 31).

## 2. Month

Name of the month (JAN, FEB, MAR, APR, MAY, JUN, JUL, AUG, SEP, OCT, NOV, DEC).

For July, the abbreviation JLY is a valid alternative.

## 3. Year

The year (a four-figure integer).

DEFAULT: Is the date given in the [START](#) keyword if that has been given previously? There is no default if the [START](#) keyword is not present before this keyword; this item cannot be defaulted in this situation.

4. Measure of ‘closeness’ to steady-state where *i* refers to grid blocks, *PV* is the pore volume and *Q* represents all of pressure and the three saturations (if appropriate) and the scaling factor *S* is 1 for the saturations and brine and is the field average pressure for the pressure.

$$\text{MAXABS} \quad \frac{\text{Max}}{i} \frac{|Q_i^{n+1} - Q_i^n|}{S \cdot \Delta t}$$

$$\text{L2} \quad \frac{\sqrt{\sum_i (PV(Q_i^{n+1} - Q_i^n))^2}}{\Delta t \sum_i PVQ_i^{n+1}}$$

DEFAULT: MAXABS

5. Tolerance for determining if pressure has reached steady-state.
6. Tolerance for determining if the oil saturation has reached steady-state.
7. Tolerance for determining if the water saturation has reached steady-state.
8. Tolerance for determining if the gas saturation has reached steady-state.
9. Tolerance for determining if the brine concentration has reached steady-state.

DEFAULT: If the chosen norm is MAXABS the defaults are  $1.0 \times 10^{-3}$  for the saturations and brine concentration and  $1.0 \times 10^{-2}$  for pressure. If the norm is L2 then the defaults are all  $1.0 \times 10^{-6}$ .

## 10. Upper limit for timestepping to ensure that the calculation doesn't run for ever if the steady state not found. The run will end when the simulation reaches this time.

DEFAULT: 365000

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

11. Lower limit for timestepping to ensure that the calculation doesn't end too soon. The run will not end before the simulation reaches this time.

DEFAULT: 0

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

12. Option to improve the initial equilibration of the model when analytic aquifers, such as [AQUCHWAT](#), [AQUCHGAS](#), [AQUFETP](#) and [AQUCT](#), are used in the solution section. This option should help to obtain a better estimate of the steady-state and therefore reduce the simulation time needed to reach a steady-state.

Either YES or NO

DEFAULT: NO

## Notes

When this keyword is used ECLIPSE reads the data set up to the first timestepping keyword. The simulator is run up to a maximum amount of time specified in item 10 or it automatically stops when it believes, based on items 4-9, that a steady-state has been reached. SUMMARY section keywords PSSPR, PSSS(PSSSO, PSSSW, PSSSG) output the logarithm of the error and switch 77 of the [DEBUG](#) keyword outputs the actual errors. At the end of a successful run a restart file is produced (usually number 1 but check the print file to be sure) and this restart file is dated with the date given in items 1-3 regardless of what time the simulator is reporting as being current.

While timestepping keywords are ignored the SCHEDULE section is read, and honored, up to the first timestepping keyword. This means that steady-states can be generated with wells producing. **However, steady-states may not exist in all cases.** If wells are changing controls a steady-state will not be achieved. If it is desired to have a steady state with a well that is open, but the well can only flow near the steady-state solution then there is a problem as the well cannot be opened later in the SCHEDULE section as no more timestep keywords will be read. There are two options. The keyword option means ensuring that the well is tested for opening by using the [WTEST](#) keyword, or the [ACTIONX](#) keyword can be used to open the well at a date sufficiently later that it can operate. item 11 can be helpful to ensure the code doesn't end before the ACTION is triggered.

A restart file will be produced in all cases so it is necessary to check in the print file that steady-state was successfully accomplished.

---

**Note:** PSTEADY cannot be used in a restart run or a parallel run.

---

## Example

```
PSTEADY

## PSTNUM

## Primary saturation function region numbers

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by one integer for every grid block in the current input box specifying the primary saturation function region to which it belongs. This keyword is used together with [ISTNUM](#) and [DSTNUM](#) if the [ODD3P](#) relative permeability and capillary pressure hysteresis model has been selected in the PROPS section. The region number should not be less than 1 or greater than NTSFUN (see keyword [TABDIMS](#)). The data must be terminated by a slash (/).

The primary saturation function region number specifies which set of saturation functions (input using [SOF3](#), [SGF3](#), and [SWF3](#) in the PROPS section) should be used to calculate the primary relative permeabilities and capillary pressures in each grid block.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

For grid blocks for which the primary saturation function region numbers are not specified, the region numbers will be assigned a value of 1. The [ODD3P](#) model is implicitly hysteretic. However, hysteresis may be deselected on a per grid block basis by setting the secondary and tertiary hysteresis saturation region numbers equal to the primary saturation region numbers.

See also the saturation function keywords [SOF3](#), [SGF3](#) and [SWF3](#) in the PROPS section and the secondary and tertiary hysteresis saturation region numbers [ISTNUM](#) and [DSTNUM](#) in the REGIONS section.

### Example

With NTSFUN=2 specified in keyword [TABDIMS](#); NDIVIX=8, NDIVIY=6 and NDIVIZ=5 specified in RUNSPEC keyword [DIMENS](#); and no input BOX set:

```
PSTNUM
144*1 96*2 /
```

## PSTRBC

## Principal stress boundary conditions coupled stress and fluid flow

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY

This keyword is being replaced by a new keyword for setting stress boundary conditions. Please refer to keyword [GMPSTBC](#).

This keyword specifies principal stress boundary conditions when a rock stress calculation is specified. It is only applicable when the keyword [GEOMECH](#) has been specified in the RUNSPEC section.

Use of this keyword allows the full set of three principal stress vectors to be specified on all boundaries. This is sufficient information to fully define the stress tensor at the chosen boundary. Alternatively, tractions or displacements may be specified using the [TRACTBC](#) or [DISPBC](#) keywords.

Note that the principal stress vectors should, by definition, be mutually orthogonal. If non-orthogonal vectors are provided, ECLIPSE 300 issues a warning message and orthogonalizes the vectors provided using the Gram-Schmidt process.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. A character string specifying the boundary to which the principal stress boundary condition is applied

This must be one of the following:

I+ Specify the boundary condition on the outer I+ edge

I- Specify the boundary condition on the outer I- edge

J+ Specify the boundary condition on the outer J+ edge

J- Specify the boundary condition on the outer J- edge

K+ Specify the boundary condition on the outer K+ edge

K- Specify the boundary condition on the outer K- edge

DEFAULT: There is no default for this item; it must be specified.

The K- boundary is the top boundary of the simulation, K+ is the bottom.

2. The X component of the first principal stress vector.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

DEFAULT: 0

3. The Y component of the first principal stress vector.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

DEFAULT: 0

4. The Z component of the first principal stress vector.  
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)  
DEFAULT: 0
5. The X component of the second principal stress vector.  
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)  
DEFAULT: 0
6. The Y component of the second principal stress vector.  
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)  
DEFAULT: 0
7. The Z component of the second principal stress vector.  
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)  
DEFAULT: 0
8. The X component of the third principal stress vector.  
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)  
DEFAULT: 0
9. The Y component of the third principal stress vector.  
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)  
DEFAULT: 0
10. The Z component of the third principal stress vector.  
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)  
DEFAULT: 0
11. First block to be modified in the I direction  
DEFAULT: 1 if an I- face
12. Last block to be modified in the I direction  
DEFAULT: NX if an I+ face
13. First block to be modified in the J direction  
DEFAULT: 1 if a J- face
14. Last block to be modified in the J direction  
DEFAULT: NY if a J+ face
15. First block to be modified in the K direction  
DEFAULT: 1 if a K- face
16. Last block to be modified in the K direction  
DEFAULT: NZ if a K+ face

## Example

```
-- Principal stress vectors:
-- P1=(-2000,0,0), P2=(0,-2500,200), P3=(0,0,0)

This keyword is being replaced by new keyword for setting displacement boundary conditions. Please refer to keyword [GMPSTBCL](#).

This keyword specifies principal stress boundary conditions when a finite volume or finite element rock stress calculation is specified. It is only applicable when the keyword [GEOMECH](#) has been specified in the RUNSPEC section.

Use of this keyword allows the full set of three principal stress vectors to be specified on all boundaries in a local grid refinement. This is sufficient information to fully define the stress tensor at the chosen boundary. Alternatively, tractions or displacements may be specified using the [TRACTBCL](#) or [DISPBCL](#) keywords.

Note that the principal stress vectors should, by definition, be mutually orthogonal. If non-orthogonal vectors are provided ECLIPSE 300 issues a warning message and orthogonalizes the vectors provided using the Gram-Schmidt process.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. A character string specifying the boundary to which the principal stress boundary condition is applied

This must be one of the following:

I+ Specify the boundary condition on the outer I+ edge

I- Specify the boundary condition on the outer I- edge

J+ Specify the boundary condition on the outer J+ edge

J- Specify the boundary condition on the outer J- edge

K+ Specify the boundary condition on the outer K+ edge

K- Specify the boundary condition on the outer K- edge

DEFAULT: There is no default for this item; it must be specified.

The K- boundary is the top boundary of the simulation, K+ is the bottom.

Name of local grid refinement

2. The X component of the first principal stress vector.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

## PSWRG

## Primary residual water saturation in water-gas system

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies the residual water saturation in a water-gas system within each grid cell for the primary saturation tables. This is only required when the [ODD3P](#) option is being used and when saturation table end-point scaling has been specified by the [ENDSCALE](#) keyword in the RUNSPEC section.

Each `PSWRG` keyword should be followed by one real number for each grid cell in the current input box specifying the residual saturation within the grid cell. The saturation should be in the range of 0.0 to 1.0 inclusive. If the value of `PSWRG` is omitted for any grid cell in a model for which `ENDSCALE` has been specified, the residual saturation will be obtained from the critical saturation in the appropriate saturation table.

See "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for further details.

See also the [PSORG](#), [PSGRO](#), [PSORW](#), [PSWRO](#) and [PSGRW](#) keywords.

### Example

With `NDIVIX=3`, `NDIVIY=4` and `NDIVIZ=5` specified in RUNSPEC keyword [DIMENS](#) and no input BOX set:

```
PSWRG
60*0.1/
```

## PSWRO

## Primary residual water saturation in water-oil system

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies the residual water saturation in a water-oil system within each grid cell for the primary saturation tables. This is only required when the [ODD3P](#) option is being used and when saturation table end-point scaling has been specified by the [ENDSCALE](#) keyword in the RUNSPEC section.

Each [PSWRO](#) keyword should be followed by one real number for each grid cell in the current input box specifying the residual saturation within the grid cell. The saturation should be in the range of 0.0 to 1.0 inclusive. If the value of [PSWRO](#) is omitted for any grid cell in a model for which [ENDSCALE](#) has been specified, the residual saturation will be obtained from the critical saturation in the appropriate saturation table.

See "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for further details.

See also the [PSORG](#), [PSGRO](#), [PSORW](#), [PSGRW](#) and [PSWRG](#) keywords.

### Example

With [NDIVIX](#)=3, [NDIVIY](#)=4 and [NDIVIZ](#)=5 specified in RUNSPEC keyword [DIMENS](#) and no input BOX set:

```
PSWRO
60*0.1/
```

## PVCDO

## Dead oil PVT properties (with constant compressibility)

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTPVT (see item 2 of keyword [TABDIMS](#) in the RUNSPEC section) records, one for each PVT table. Each record must be terminated by a slash (/).

Each record consists of the following items of data:

- The reference pressure ( $P_{\text{ref}}$ ) for items 2 and 4.  
UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)
- The oil formation volume factor at the reference pressure,  $B_o(P_{\text{ref}})$   
UNITS:  $\text{rm}^3/\text{sm}^3$  (METRIC), rb/stb (FIELD), rcc/scc (LAB),  $\text{rm}^3/\text{sm}^3$  (PVT-M)
- The oil compressibility

$$C = -\left(\frac{dB_o}{dP}\right)\bigg|_{B_o}$$

UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB), 1/atm (PVT-M)

- The oil viscosity at the reference pressure  $\mu_o(P_{\text{ref}})$ .  
UNITS: cP (METRIC), cP (FIELD), cP (LAB), cP (PVT-M)
- The oil “viscosibility”

$$C_v = \left(\frac{d\mu_o}{dP}\right)\bigg|_{\mu_o}$$

UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB), 1/atm (PVT-M)

ECLIPSE calculates  $B_o$  using:

$$B_o(P) = B_o(P_{\text{ref}})e^{-X} \quad \text{Eq. 3.150}$$

where

$$X = C(P - P_{\text{ref}})$$

and the product  $B_o\mu_o$  using:

$$B_o\mu_o P = B_o P_{\text{ref}}\mu_o P_{\text{ref}}e^{-Y} \quad \text{Eq. 3.151}$$

where

$$Y = (C - C_v)(P - P_{\text{ref}})$$

See also keyword [PVDO](#).

### Example

With NTPVT=1:

```
PVCDO  
3600 1.12 1.6e-5 0.88 0.0 /
```

## PVCO

## PVT properties of live oil in compressibility form (with dissolved gas)

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword offers a simpler method of entering tables of live oil PVT properties than with the [PVTO](#) keyword. The difference between the two keywords is that the [PVCO](#) keyword assumes that undersaturated oil with a particular  $R_s$  value has a compressibility that is independent of the pressure, and that the viscosity of undersaturated oil has a pressure-independent derivative. Thus there is no need to provide tables of undersaturated oil formation volume factor and viscosity versus pressure.

The data comprises NTPVT (see keyword [TABDIMS](#) in the [RUNSPEC](#) section) tables of live oil PVT functions. A single table consists of at least 2 and up to NRPVT (keyword [TABDIMS](#)) rows of 6 columns. Each table is terminated by a slash (/).

The columns are:

1. The bubble point pressure ( $P_{\text{bub}}$ ) for oil with the dissolved gas-oil ratio given by column 2.

Within each table, the pressure values should increase monotonically down the column.

UNITS: barsa ([METRIC](#)), psia ([FIELD](#)), atma ([LAB](#)), atma ([PVT-M](#))

2. The dissolved gas-oil ratio ( $R_s$ ) of saturated oil with bubble point given by column 1.

The values should increase monotonically down the column.

UNITS:  $\text{sm}^3/\text{sm}^3$  ([METRIC](#)), Mscf/stb ([FIELD](#)), scc/scc ([LAB](#)),  $\text{sm}^3/\text{sm}^3$  ([PVT-M](#))

3. The formation volume factor of saturated oil at  $P_{\text{bub}}$ .

UNITS:  $\text{rm}^3/\text{sm}^3$  ([METRIC](#)), rb/stb ([FIELD](#)), rcc/scc ([LAB](#)),  $\text{rm}^3/\text{sm}^3$  ([PVT-M](#))

4. The viscosity of saturated oil at  $P_{\text{bub}}$ .

UNITS: cP ([METRIC](#)), cP ([FIELD](#)), cP ([LAB](#)), cP ([PVT-M](#))

5. The compressibility of undersaturated oil with a dissolved gas-oil ratio given by column 2:

$$C = -\left(\frac{dB_o}{dP}\right) \Big| B_o$$

UNITS: 1/bars ([METRIC](#)), 1/psi ([FIELD](#)), 1/atm ([LAB](#)), 1/atm ([PVT-M](#))

6. The “viscosibility”, or viscosity compressibility, of undersaturated oil with a dissolved gas-oil ratio given by column 2:

$$C_v = \left(\frac{d\mu_o}{dP}\right) \Big| \mu_o$$

UNITS: 1/bars ([METRIC](#)), 1/psi ([FIELD](#)), 1/atm ([LAB](#)), 1/atm ([PVT-M](#))

ECLIPSE 300

**Note:** When the [PVCO](#) keyword is used within a thermal model to set the oil viscosity pressure dependence, only columns 1 and 4 need to be entered. Other columns are not used and should be defaulted. See "[Thermal option](#)" in the *ECLIPSE Technical Description*

ECLIPSE 300

The sixth column can be ignored by setting [item 24](#) in [OPTIONS3](#) to -1. It may be left out entirely if item 24 in [OPTIONS3](#) is set > 0, which restores the pre-99A five-column format of this keyword.

There must be the same number of entries in each column of a given table. This should not be less than 2 or greater than NRPVT (keyword [TABDIMS](#)).

Default values (represented by 1\*) may be inserted as required in columns 2 to 6. When a table is read in, defaults are replaced by values computed by linear interpolation. To input a constant compressibility (or viscosibility) for the whole table, enter the value of this quantity in the first row and enter defaults for the remaining items in the column. If all the items in the viscosibility column are defaulted, a value of zero will be assumed.

ECLIPSE 100

If the [PVCO](#) keyword is used, the maximum pressure expected in the simulation must also be entered with keyword [PMAX](#). This information is used for two purposes. Firstly, the undersaturated parts of the oil PVT tables are automatically filled out in the form of the [PVTO](#) keyword, up to the pressure entered in [PMAX](#).

ECLIPSE 100

---

**Note:** The undersaturated parts of the oil PVT tables are extrapolated over NRPVT pressure nodes (see item 4 of keyword [TABDIMS](#) in the [RUNSPEC](#) section) between the bubble point pressure and the maximum pressure entered in [PMAX](#). This means that interpolation between pressure nodes will vary slightly depending on the number of nodes used and will affect the simulation results accordingly. To avoid extrapolation, the keyword [PVTO](#) should be used instead of [PVCO](#).

---

Secondly, ECLIPSE carries out a check to see if compressibilities are changing too rapidly with  $P_b$  so that the curves of undersaturated oil formation volume factor for two different values of  $R_s$  cross each other. A warning is printed if they cross at a pressure below the maximum pressure entered in [PMAX](#).

ECLIPSE 100

---

**Note:** ECLIPSE 100 linearly interpolates the **reciprocals** of  $B_o$  and  $(B_o\mu_o)$  between data points, rather than the values themselves. This should be taken into account when comparing the results of ECLIPSE with those of other simulators, by ensuring the data points are not distributed too sparsely.

---

ECLIPSE 300

---

**Note:** ECLIPSE 300 linearly interpolates both  $B_o$  and  $\mu_o$  directly. If [item 56](#) of the [OPTIONS3](#) keyword is set greater than 0, then [PVCO](#) data will be interpolated in the same way as ECLIPSE 100.

---

ECLIPSE 100

---

**Note:** When using the API Tracking option (keyword [API](#) in the [RUNSPEC](#) section), the set of tables must be entered in increasing order of surface density (or decreasing order of API gravity).

---

See also keyword [PVTO](#).

## Example

With NTPVT=2. NRPVT must have been set  $\geq 14$ :

## PVDG

## PVT properties of dry gas (no vaporized oil)

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTPVT (item 2 in keyword `TABDIMS` in the `RUNSPEC` section) tables of dry gas PVT functions, each terminated by a slash (/).

Each table consists of 3 columns of data:

- The gas phase pressure.  
Values should increase monotonically down the column.  
UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)
- The corresponding gas formation volume factor.  
Values should decrease down the column.  
UNITS:  $\text{rm}^3/\text{sm}^3$  (METRIC), rb/Mscf (FIELD), rcc/scf (LAB),  $\text{rm}^3/\text{sm}^3$  (PVT-M)
- The corresponding gas viscosity.  
Values should be level or increasing down the column.  
UNITS: cP (METRIC), cP (FIELD), cP (LAB), cP (PVT-M)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NPPVT (item 4 in keyword `TABDIMS`).

See also keyword `PVZG`.

ECLIPSE 100

ECLIPSE 100

---

**Note:** ECLIPSE 100 linearly interpolates the **reciprocals** of  $B_g$  and  $(B_g \mu_g)$  between data points, rather than the values themselves. This should be taken into account when comparing the results of ECLIPSE with those of other simulators, by ensuring the data points are not distributed too sparsely.

---

ECLIPSE 300

---

**Note:** ECLIPSE 300 linearly interpolates both  $B_g$  and  $\mu_g$  directly. If item 56 of the `OPTIONS3` keyword is set to 2, then PVDG data (as well as oil property data) will be interpolated in the same way as ECLIPSE 100.

---

## Example

With one pressure table:

```
PVDG
400.000 5.90000 .01300
800.000 2.95000 .01350
1200.00 1.96000 .01400
1600.00 1.47000 .01450
2000.00 1.18000 .01500
2400.00 .98000 .01550
2800.00 .84000 .01600
3200.00 .74000 .01650
3600.00 .65000 .01700
4000.00 .59000 .01750
4400.00 .54000 .01800
4800.00 .49000 .01850
5200.00 .45000 .01900
5600.00 .42000 .01950
```

## PVDO

## PVT properties of dead oil (no dissolved gas)

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTPVT (see item 2 of keyword [TABDIMS](#) in the RUNSPEC section) tables of dead oil PVT functions, each terminated by a slash (/).

Each table consists of 3 columns of data:

1. The oil phase pressure.

Values should increase monotonically down the column.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

2. The corresponding oil formation volume factor.

Values should decrease down the column.

UNITS:  $\text{rm}^3/\text{sm}^3$  (METRIC), rb/stb (FIELD), rcc/scc (LAB),  $\text{rm}^3/\text{sm}^3$  (PVT-M)

3. The corresponding oil viscosity.

Values should be level or increasing down the column.

UNITS: cP (METRIC), cP (FIELD), cP (LAB), cP (PVT-M)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NPPVT (item 4 of keyword [TABDIMS](#)).

See also keyword [PVCDO](#).

## ECLIPSE 100

---

**Note:** ECLIPSE 100 linearly interpolates the **reciprocals** of  $B_o$  and  $(B_o\mu_o)$  between data points, rather than the values themselves. This should be taken into account when comparing the results of ECLIPSE with those of other simulators, by ensuring the data points are not distributed too sparsely.

---

## ECLIPSE 300

---

**Note:** ECLIPSE 300 linearly interpolates both  $B_o$  and  $\mu_o$  directly. If item 56 of the [OPTIONS3](#) keyword is set greater than 0, then PVDO data will be interpolated in the same way as ECLIPSE 100.

---

## Example

With NTPVT=2 and NPPVT≥8:

```
PVDO
 400 1.012 1.16
 1200 1.0040 1.164
 2000 0.9960 1.167
 2800 0.9880 1.172
 3600 0.9802 1.177
 4400 0.9724 1.181
 5200 0.9646 1.185
 5600 0.9607 1.19 /
 800 1.0255 1.14
 1600 1.0172 1.14
 2400 1.0091 1.14
 3200 1.0011 1.14
 4000 0.9931 1.14
 4800 0.9852 1.14
 5600 0.9774 1.14 /
```

## PVDS

## PVT properties of the solvent

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword may be used with the solvent or coal bed methane model as described in "Solvent model" and "Coal bed methane model" in the *ECLIPSE Technical Description*. The solvent is a second gas phase within the reservoir. The PVT data required is essentially a second dry gas table, analogous to the PVDG table.

The data comprises NTPVT (see keyword `TABDIMS`) tables of solvent PVT functions, each terminated by a slash (/). Each table consists of 3 columns of data:

1. The solvent gas phase pressure.

Values should increase monotonically down the column.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

2. The corresponding solvent formation volume factor.

Values should decrease down the column.

UNITS:  $\text{rm}^3/\text{sm}^3$  (METRIC),  $\text{rb}/\text{Mscf}$  (FIELD),  $\text{rcc}/\text{scc}$  (LAB),  $\text{rm}^3/\text{sm}^3$  (PVT-M)

3. The corresponding solvent viscosity.

Values should be level or increasing down the column.

UNITS: cP (METRIC), cP (FIELD), cP (LAB), cP (PVT-M)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NPPVT (see keyword `TABDIMS`).

## Example

With `NTPVT=1` and `NPPVT≥14`

```

-- PGAS  BGAS  VISGAS

## PVTG

## PVT properties of wet gas (with vaporized oil)

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTPVT (see item 2 in keyword [TABDIMS](#) in the RUNSPEC section) tables of wet gas PVT functions. A single table consists of at least 2 and up to NPPVT (item 4 in keyword [TABDIMS](#)) records each terminated by a slash (/). Each record gives PVT data for a particular gas phase pressure ( $P_g$ ). A table is terminated by a null record (that is a record with no data before the terminating slash). This table may be generated by PVT *i*.

Most records contain the following items of data and a terminating slash:

- The gas phase pressure ( $P_g$ ).  
Within a table, records should be arranged in order of increasing  $P_g$ .  
UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)
- The vaporized oil-gas ratio for saturated gas at pressure  $P_g$ .  
UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/Mscf (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)
- The gas formation volume factor for saturated gas at  $P_g$ .  
UNITS:  $\text{rm}^3/\text{sm}^3$  (METRIC), rb/Mscf (FIELD), rcc/scc (LAB),  $\text{rm}^3/\text{sm}^3$  (PVT-M)
- The gas viscosity for saturated gas at  $P_g$ .  
UNITS: cP (METRIC), cP (FIELD), cP (LAB), cP (PVT-M)

However some records (optionally all) contain additional data that defines the properties of under-saturated gas at the specified value of  $P_g$ . This extra data **must** be specified for the highest  $P_g$  in each table. The additional data takes the form of 3 columns which continue from items 2, 3 and 4 above.

Each column may have up to NRPVT (item 6 in keyword [TABDIMS](#)) entries.

Column 2 The vaporized oil-gas ratio ( $R_v$ ).

Values of  $R_v$  must decrease down the column (starting from the value for saturated gas).

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/Mscf (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

Column 3 The gas formation volume factor ( $B_g$ ) corresponding to  $R_v$  and  $P_g$ .

UNITS:  $\text{rm}^3/\text{sm}^3$  (METRIC), rb/Mscf (FIELD), rcc/scc (LAB),  $\text{rm}^3/\text{sm}^3$  (PVT-M)

Column 4 The gas viscosity ( $\mu_g$ ) corresponding to  $R_v$  and  $P_g$ .

UNITS: cP (METRIC), cP (FIELD), cP (LAB), cP (PVT-M)

There must be the same number of entries in each column. If no additional data is supplied for a particular value of  $P_g$ , ECLIPSE locates the next higher value of  $P_g$  for which undersaturated PVT data is available, and takes a scaled copy of the FVF and viscosity curves supplied there.

## Notes

- Data for undersaturated gas **must** be provided for the highest  $P_g$  in the table.

- ECLIPSE 100 linearly interpolates the **reciprocals** of  $B_g$  and  $(B_g\mu_g)$  between data points, rather than the values themselves. This should be taken into account when comparing the results of ECLIPSE 100 with those of other simulators, by ensuring the data points are not distributed too sparsely.
- ECLIPSE 300
- ECLIPSE 300 linearly interpolates the **reciprocals** of  $B_g$  but  $\mu_g$  is interpolated directly.

## Example

With NTPVT=2. NRPVT must have been set  $\geq 2$  and NPPVT $\geq 7$ :

```

PVTG
 30 0.00014 0.0523 0.0234

## PVT-M

## PVT-metric units are to be used

	<b>ECLIPSE 100</b>
x	<b>ECLIPSE 300</b>
	<b>SPECIAL</b>
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies that PVT-metric units are to be used for the input data. These are essentially the same as METRIC units, but with pressures measured in atmospheres. Note that the default units are METRIC.

See "[Units](#)" in the *ECLIPSE Technical Description* for further details.

There is no data associated with this keyword.

## PVTNUM

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

## PVT region numbers

The keyword should be followed by one integer for every grid block in the current input box specifying the PVT region to which it belongs. The region number should not be less than 1 or greater than NTPVT (item 2 in keyword [TABDIMS](#)). All grid blocks within a particular equilibration region (see keyword [EQLNUM](#)) must have the same PVT region number. The data must be terminated by a slash (/).

The PVT region number specifies which set of PVT tables (input using [DENSITY](#), [PVDG](#), [PVDO](#), [PVTG](#), [PVTO](#), [PVCO](#), [PVTW](#) and [ROCK](#) in the PROPS section) should be used to calculate PVT properties of fluids in each grid block for a black oil model.

For a compositional model, PVTNUM is only used to reference the water properties defined via [DENSITY](#), [PVTW](#) or [WATERTAB](#) and the rock compressibility specified by [ROCK](#) if required.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

## Example

With NTPVT=4 specified in keyword [TABDIMS](#); NDIVIX=8, NDIVIY=6 and NDIVIZ=5 specified in RUNSPEC keyword [DIMENS](#); and no input BOX set:

```
PVTNUM
8*1 16*2 8*3 16*4
8*1 16*2 8*3 16*4
8*1 16*2 8*3 16*4
8*1 16*2 8*3 16*4
8*1 16*2 8*3 16*4 /
```

## PVTO

## PVT properties of live oil (with dissolved gas)

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTPVT (see item 2 of keyword [TABDIMS](#) in the RUNSPEC section) tables of live oil PVT functions. A single table consists of at least 2 and up to NRPVT (item 6 of keyword [TABDIMS](#)) records each terminated by a slash (/). Each record gives PVT data for a particular dissolved gas-oil ratio ( $R_s$ ). A table is terminated by a null record (that is a record with no data before the terminating slash).

Most records contain the following items of data and a terminating slash:

1. The dissolved gas-oil ratio ( $R_s$ ).

Within a table, records should be arranged in order of increasing  $R_s$ .

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), Mscf/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

2. The bubble point pressure ( $P_{\text{bub}}$ ) for oil with dissolved gas-oil ratio given by item 1.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

3. The oil formation volume factor for saturated oil at  $P_{\text{bub}}$ .

UNITS:  $\text{rm}^3/\text{sm}^3$  (METRIC), rb/stb (FIELD), rcc/scc (LAB),  $\text{rm}^3/\text{sm}^3$  (PVT-M)

4. The oil viscosity for saturated oil at  $P_{\text{bub}}$ .

UNITS: cP (METRIC), cP (FIELD), cP (LAB), cP (PVT-M)

However some records (optionally all) contain additional data which defines the properties of under-saturated oil at the specified value of  $R_s$ . This extra data **must** be specified for the highest  $R_s$  in each table. The additional data takes the form of 3 columns that continue from items 2, 3 and 4 above. Each column may have up to NPPVT (see item 4 in keyword [TABDIMS](#)) entries.

Column 2 The oil phase pressure ( $P_o$ ). Values of  $P_o$  must increase down the column (starting from  $P_{\text{bub}}$ ).

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

Column 3 The oil formation volume factor ( $B_o$ ) corresponding to  $R_s$  and  $P_o$ . Values of  $B_o$  must decrease down the column.

UNITS:  $\text{rm}^3/\text{sm}^3$  (METRIC), rb/stb (FIELD), rcc/scc (LAB),  $\text{rm}^3/\text{sm}^3$  (PVT-M)

Column 4 The oil viscosity ( $\mu_o$ ) corresponding to  $R_s$  and  $P_o$ . Values of  $\mu_o$  do not normally decrease down the column.

UNITS: cP (METRIC), cP (FIELD), cP (LAB), cP (PVT-M)

There must be the same number of entries in each column. If no additional data is supplied for a particular value of  $R_s$ , ECLIPSE locates the next higher value of  $R_s$  for which undersaturated PVT data is available, and takes a scaled copy of the FVF and viscosity curves supplied there. The scaling is done in such a way that the compressibility and ‘viscosibility’,

$$\left( \frac{d\mu_o}{dP_o} \right) / \mu_o \quad \text{Eq. 3.152}$$

are preserved.

Note that data for undersaturated oil **must** be provided for the highest  $R_s$  in the table.

## Notes

- ECLIPSE 100*
  - ECLIPSE 100 linearly interpolates the **reciprocals** of  $B_o$  and  $(B_o\mu_o)$  between data points, rather than the values themselves. This should be taken into account when comparing the results of ECLIPSE 100 with those of other simulators, by ensuring the data points are not distributed too sparsely.
- ECLIPSE 300*
  - ECLIPSE 300 linearly interpolates the **reciprocals** of  $B_o$  but  $\mu_o$  is interpolated directly. If [item 56](#) of the OPTIONS3 keyword is set greater than 0, then PVTO data will be interpolated in the same way as ECLIPSE 100.
  - When using the API Tracking option (keyword [API](#) in the RUNSPEC section), the set of tables must be entered in increasing order of surface density (or decreasing order of API gravity).

See also keyword [PVCO](#).

## Example

With NTPVT=2. NRPVT must have been set  $\geq 11$  and NPPVT $\geq 6$ :

```

PVTO
0.165  400  1.012  1.17  /
0.335  800  1.0255 1.14  /

## Water PVT functions

The data comprises NTPVT (see item 2 of keyword [TABDIMS](#) in the RUNSPEC section) records, each terminated by a slash (/).

Each record consists of the following items of data:

- The reference pressure ( $P_{\text{ref}}$ ) for items 2 and 4.  
UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)  
DEFAULT: ERROR (ECLIPSE 100), 1 atma = 14.7psia (ECLIPSE 300).
- The water formation volume factor at the reference pressure,  $B_w(P_{\text{ref}})$   
UNITS:  $\text{rm}^3/\text{sm}^3$  (METRIC),  $\text{rb}/\text{stb}$  (FIELD),  $\text{rcc}/\text{sc}$  (LAB),  $\text{rm}^3/\text{sm}^3$  (PVT-M)  
DEFAULT: 1.0 (in all units)
- The water compressibility

$$C = -\left(\frac{dB_w}{dP}\right) / B_w \quad \text{Eq. 3.153}$$

UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB), 1/atm (PVT-M)  
DEFAULT: 0 (ECLIPSE 100), 4.0e-5 1/atm (ECLIPSE 300)

- The water viscosity at the reference pressure  $\mu_w(P_{\text{ref}})$ .  
UNITS: cP (METRIC), cP (FIELD), cP (LAB), cP (PVT-M)  
DEFAULT: 0.5 cP (ECLIPSE 100), 0.3 cP (ECLIPSE 300).
- The water “viscosibility”

$$C_v = \left(\frac{d\mu_w}{dP}\right) / \mu_w \quad \text{Eq. 3.154}$$

UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB), 1/atm (PVT-M)  
DEFAULT: 0.0

## ECLIPSE 100

ECLIPSE 100 calculates  $B_w$  using:

$$B_w(P) = \frac{B_w(P_{\text{ref}})}{1 + X + (X^2/2)} \quad \text{Eq. 3.155}$$

where

$$X = C(P - P_{\text{ref}})$$

ECLIPSE 100 calculates the product  $B_w\mu_w$  using:

$$B_w\mu_w(P) = \frac{B_w(P_{\text{ref}})\mu_w(P_{\text{ref}})}{1 + Y + (Y^2/2)} \quad \text{Eq. 3.156}$$

where

$$Y = (C - C_v)(P - P_{\text{ref}})$$

## ECLIPSE 300

ECLIPSE 300 calculates  $B_w$  using equation 3.155.  $\mu_w$  is calculated similarly:

$$\mu_w(P) = \frac{\mu_w(P_{\text{ref}})}{1 + Y + (Y^2/2)} \quad \text{Eq. 3.157}$$

where

$$Y = (-C_v)(P - P_{\text{ref}})$$

## ECLIPSE 300 Thermal option

In the thermal option there are several ways of defining  $B_w$  and  $\mu_w$ , which are described in "Water density" and "Water viscosity" in the *ECLIPSE Technical Description*. By default, most of the data given by this keyword is ignored.

## Example

With NTPVT=2:

```
PVTW
3600.0000  1.00341  3.00E-06  0.52341  0.00E-01  /
3900      1      2.67E-06  0.56341  1.20E-07  /
```

	SUMMARY
	SCHEDULE

This keyword supplies the water PVT data for runs in which the Brine option is active (keyword [BRINE](#)). The keyword is used in place of the [PVTW](#) keyword.

The surface density of brine can be set for each PVTWSALT table using the [BDENSITY](#) keyword. This supplies surface densities at the values of salt concentration specified in the PVTWSALT keyword. If [BDENSITY](#) is missing, the surface density of brine is taken from the water surface density specified in [DENSITY](#), for all salt concentrations.

In ECLIPSE 100 only, if the [ECLMC](#) keyword is selected, the [BRINE](#) keyword activates the multi-component brine model. In this case, salt effects on the water density are ignored and the keyword [PVTW](#) should be used instead.

In the present version of ECLIPSE 100 it is not possible to use this keyword with the polymer flood model. (See the [PLYVISCS](#) keyword for further information.)

The data comprises NTPVT (see keyword [TABDIMS](#)) tables. Each table consists of two records, each terminated by a slash (/).

### Record 1

Two items of data:

- The reference pressure ( $P_{ref}$ ) for this table.  
UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)
- The reference salt concentration for stock tank water,  $c_{s\ ref}$ .  
UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB), kg/sm<sup>3</sup> (PVT-M)  
DEFAULT: Minimum salt concentration specified in record 2 (typically zero).

### Record 2

A table consisting of 5 columns of data.

The number of entries in the table should not exceed NPPVT (see keyword [TABDIMS](#)).

---

**Note:** In ECLIPSE 300 the number of entries must equal NPPVT. In ECLIPSE 100 a minimum of one entry is needed (which effectively gives constant properties).

---

- The salt concentration,  $c_s$ .  
Values should increase monotonically down the column.  
UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB), kg/sm<sup>3</sup> (PVT-M)
- The water formation volume factor at the reference pressure as a function of salt concentration,  $B_w(P_{ref}, c_s)$ .  
Values should be level or decreasing down the column.  
UNITS: rm<sup>3</sup>/sm<sup>3</sup> (METRIC), rb/stb (FIELD), rcc/scc (LAB), rm<sup>3</sup>/sm<sup>3</sup> (PVT-M)

3. The water compressibility as a function of salt concentration,

$$C(c_s) = -\left(\frac{dB_w}{dP}\right) \Big| B_w \quad \text{Eq. 3.158}$$

UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB), 1/atm (PVT-M)

4. The water viscosity at the reference pressure as a function of salt concentration,  $\mu_w(P_{ref}, c_s)$ .

UNITS: cP (METRIC), cP (FIELD), cP (LAB), cP (PVT-M)

5. The water “viscosity” as a function of salt concentration,

$$C_v(c_s) = \left(\frac{d\mu_w}{dP}\right) \Big| \mu_w \quad \text{Eq. 3.159}$$

UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB), 1/atm (PVT-M)

## ECLIPSE 100

ECLIPSE first calculates the values of  $B_w$ ,  $C$ ,  $\mu_w$ ,  $C_v$  as functions of the salt concentration at the previous timestep by linear interpolation in salt concentration for  $C$  and  $C_v$  and on the reciprocals of  $B_w$  and  $B_w\mu_w$ . Then it calculates  $B_w$  and  $B_w\mu_w$  at the current pressure  $P$  as follows:

$$B_w(P, c_s) = \frac{B_w(P_{ref}, c_s)}{1 + X + (X^2/2)} \quad \text{Eq. 3.160}$$

where

$$X = C(P - P_{ref})$$

$$B_w(P, c_s)\mu_w(P, c_s) = \frac{B_w(P_{ref}, c_s)\mu_w(P_{ref}, c_s)}{1 + Y + (Y^2/2)} \quad \text{Eq. 3.161}$$

where

$$Y = (C - C_v)(P - P_{ref})$$

## ECLIPSE 300

ECLIPSE 300 calculates  $B_w$  using equation 3.160.  $\mu_w$  is calculated similarly:

$$\mu_w(P, c_s) = \frac{\mu_w(P_{ref}, c_s)}{1 + Y + (Y^2/2)}$$

where

$$Y = -(C_v)(P - P_{ref})$$

## Example

With NTPVT=2, NPPVT≥4:

```

PVTWSALT
--
-- Reference Pressure      Reference concentration

```

```

--          5000          0.0          /
--
-- Salt conc      Bw      Cw          Vw      Cv
--
--   0.0          1.01    3.00E-06    0.52    0.0
--   2.0          1.00    3.00E-06    0.52    0.0
--   5.0          0.98    3.00E-06    0.52    0.0
--  20.0          0.95    3.00E-06    0.52    0.0    /
--
-- Reference Pressure

## PVZG

## PVT properties of dry gas (using Z-factors)

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTPVT (see item 2 of keyword [TABDIMS](#) in the RUNSPEC section) tables of dry gas PVT functions. Each table consists of two records, each terminated by a slash (/).

## Record 1

One item of data:

1. The reference temperature for this table.

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

The temperature is used to convert the Z factor into a formation volume factor.

## Record 2

A table consisting of 3 columns of data:

1. The gas phase pressure.

Values should increase monotonically down the column.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

2. The corresponding compressibility (Z) factor.

3. The corresponding gas viscosity.

Values should be level or increasing down the column.

UNITS: cP (METRIC), cP (FIELD), cP (LAB), cP (PVT-M)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NPPVT (item 4 in keyword [TABDIMS](#)).

The Z factor is related to the formation volume factor  $B_g$ , reference temperature  $T_{ref}$  and pressure P by

$$B_g = Z \times \left( \frac{T_{ref} + T_{base}}{T_s + T_{base}} \right) \times \frac{P_s}{P} \quad \text{Eq. 3.162}$$

where  $P_s$  and  $T_s$  denote pressure and temperature at standard conditions, taken as

$P_s = 1.01325$  barsa (METRIC), 14.7 psi (FIELD), 1.0 atma (LAB)

$T_s = 15.56 \times C$  (METRIC),  $60 \times F$  (FIELD), 15.56 °C (LAB)

and  $T_{base}$  is the absolute temperature at base measured temperature given by

$T_{base} = 273.105$  K (METRIC),  $459.598 \times R$  (FIELD), 273.105 K (LAB).

See also keyword [PVDG](#).

## Example

With NTPVT=1 and NPPVT≥8:

```
PVZG

## Places wells in the sequential drilling queue

The keyword should be followed by a list of up to 50 well names, terminated with a slash (/).

The wells are placed in the sequential drilling queue, to be opened in sequence when they are needed to maintain a group rate target under group control by guide rate ([GCONPROD](#), [GCONINJE](#), [GCONSALE](#)). These wells may also be opened in sequence from the drilling queue in ECLIPSE 100 should they be needed to maintain a group's production potential ([GDRILPOT](#)). If the drilling queue already contains some wells, the new list of wells is added to the end of the queue. Note that there is only one drilling queue - each time QDRILL is entered it appends its wells to the end of this queue. Thus, if there are more than 50 wells to go into the queue, the remainder can be added to the queue by using the keyword a second time. Wells can be removed from the drilling queue, if required, by declaring them OPEN with keyword [WCONPROD](#), [WCONINJE](#) or [WELOPEN](#).

If a group (including the field) cannot meet its production target, the first production well in the queue that is subordinate to that group, and not subordinate to any other group under the same mode of production control, is opened automatically. If a group cannot meet its injection target, the first injection well in the queue that is subordinate to that group, and not subordinate to any other group under injection control for the same phase, is opened automatically.

Well opening may be delayed by constraints on the rate of drilling new wells (see keyword [WDRILTIM](#)), the availability of drilling rigs (keyword [GRUPRIG](#)) and, in ECLIPSE 100, on the maximum number of open wells in any group (item 9 of keyword [GECON](#)). If a well cannot currently be drilled because of any of these constraints, the subsequent wells in the drilling queue will be examined in turn to see if there is another suitable well that can be drilled instead.

An alternative to the sequential drilling queue is the prioritized drilling queue, from which wells are opened in decreasing order of their drilling priority (see keyword [DRILPRI](#)). Wells are placed in the prioritized drilling queue using the keyword [WDRILPRI](#). Only one type of drilling queue may exist at any given time in the run; the two types of queue cannot operate together.

The drilling queue facility should not be confused with the automatic opening option (AUTO in item 2 of keyword [WCONPROD](#) and item 3 of keyword [WCONINJE](#) for example). They are two completely separate facilities. Wells in the drilling queue are opened only when needed to maintain group production and injection targets. Wells on AUTO will be opened as soon as allowed by constraints on drilling rate and number of open wells per group, irrespective of group flow rates.

---

**Note:** The wells must have been fully specified as shut or stopped producers or injectors under independent or group control.

---

---

**Note:** The drilling queue is not used for opening wells belonging to groups under prioritization group control (keyword [GCONPRI](#)), as the prioritization algorithm itself handles the opening and closing of these wells.

---

See also keywords [WDRILRES](#), [WELSOMIN](#), [PRORDER](#) and [WDRILPRI](#).

This keyword is used to define the downstream stream rating table boundary condition of a river.

The keyword is followed by NRATTA tables with a maximum of MXRATE entries in each. These numbers are set with the RIVRDIMS keyword. Each table is terminated with a slash (/).

Each table consists of 2 columns of data:

1. Massflow

The first entry in a table must be 0.0

UNITS: m<sup>3</sup>/day (METRIC), ft<sup>3</sup>/day (FIELD), cc/hr (LAB)

2. Depth of the river at the massflow given in item 1

UNITS: m (METRIC), ft (FIELD), cm (LAB)

There is a minimum of two rows of data per table. End the table with a slash (/). After the first tables subsequent tables may be defaulted to the previous table by just entering a slash.

### Example

```

## QMOBIL

## Controls the mobile end-point correction in an LGR

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

QMOBIL may be used in LGR runs to switch the mobile end-point correction facility on or off within individual local grid refinements. It should be placed between the keyword that sets up the LGR ([CARFIN](#) or [RADFIN](#)) and the corresponding [ENDFIN](#) keyword.

The keyword operates in an analogous manner to the 'MOBILE' option in the [EQLOPTS](#) keyword in the RUNSPEC section, which turns on the mobile end-point correction facility in the global grid. By default, if the 'MOBILE' option is switched on, then the mobile end-point correction facility will operate in all local grids as well as in the global grid. Conversely, if the option is not enabled in RUNSPEC, the facility is turned off in the global grid and by default in all local grids. The QMOBIL keyword may be used to override the default setting in individual local grids.

If the mobile end-point correction facility is turned on in any local grid, but is not turned on in the global grid, then the endpoint scaling option must be enabled with the keyword [ENDSCALE](#) in the RUNSPEC section.

The QMOBIL keyword is followed by a record containing one item of data, terminated with a slash, which relates to the local grid system introduced in the preceding [CARFIN](#) or [RADFIN](#) keyword:

### 1. Mobile end-point correction flag

YES Mobile end-point correction is required in the local grid

NO Mobile end-point correction is not required in the local grid.

DEFAULT:

YES If the mobile fluid correction is activated for the global grid using [EQLOPTS](#) in the RUNSPEC section.

NO Otherwise

## Example

If the mobile fluid correction is activated using [EQLOPTS](#) in RUNSPEC, and you want to turn the facility off in the local grid [NOQMOB](#).

```

CARFIN
NOQMOB 1 2 1 2 1 2 4 4 4 /
QMOBIL
NO /
ENDFIN

```

## **R**

## RADFIN4

## Specifies a four-column radial local grid refinement

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

RADFIN4 sets up a single radial local grid refinement inside a given box of four columns of global grid cells. The box is identified by its global grid coordinates  $I1 - I2, J1 - J2, K1 - K2$ . The dimensions of the refined grid within this box of four columns are specified as NR, NTHETA, NZ.

Local grid refinement is described in "[Local grid refinement and coarsening](#)" in the *ECLIPSE Technical Description*.

The keyword is followed by the following items of data, terminated with a slash.

1. Name of the local grid refinement - up to 8 characters enclosed in quotes.
2.  $I1$  lower I-coordinate of the column in the global grid.
3.  $I2$  upper I-coordinate of the box in the global grid.

This must be  $I2 = I1 + 1$

4.  $J1$  lower J-coordinate of the box in the global grid.
5.  $J2$  upper J-coordinate of the box in the global grid.

This must be  $J2 = J1 + 1$

6.  $K1$  minimum K-coordinate of the box in the global grid.
7.  $K2$  maximum K-coordinate of the box in the global grid.
8. NR number of radial divisions in the refined grid.
9. NTHETA number of angular segments in the refined grid

Allowed values are  $NTHETA = 4$  or  $8$ .

If a corner point host grid is specified using [COORD / ZCORN](#), then only  $NTHETA = 8$  is allowed.

By default, the circle is completed. (Use [COORDSYS](#) if you wish to override this.)

10. NZ Number of vertical divisions in the refined grid.
11. NWMAX Maximum number of wells this local refined grid will contain.

DEFAULT: 1 (which is the normal value in a radial refinement).

The actual number of wells in any local grid, or amalgamation of local grids, must not exceed NWGMAX, in item 4 of the [WELLDIMS](#) keyword in the RUNSPEC section.

Any other GRID section keywords (for example [INRAD](#) and [COORDSYS](#)) following this keyword are taken to apply to this local refined grid, until an [ENDFIN](#), [CARFIN](#), [REFINE](#), [RADFIN](#) or another RADFIN4 keyword is encountered.

See also keywords [RADFIN](#), [HRFIN](#), [NZFIN](#).

---

**Note:** The inner radius of the radial refinement **must** be specified using keyword [INRAD](#) between the [RADFIN4](#) and [ENDFIN](#) keywords.

The outer radius may be specified using keyword [OUTRAD](#) but this is not compulsory. If the outer radius is not specified using `OUTRAD`, it defaults to  $RMAX/3$  where `RMAX` is the maximum radius of a circle contained within the four cells containing the radial refinement.

---

## Example

```
RADFIN4
-- NAME      I1 I2  J1 J2  K1 K2  NR  NTHETA  NZ    NWMAX
   'SOUTH'   7  8   8  9   3  5   6   8       18  /

INRAD
0.2 /
ENDFIN
```

## RADFIN

## Specifies a single-column radial local grid refinement

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The RADFIN keyword sets up a single radial local grid refinement inside a given column of global grid cells. The column is identified by its global grid coordinates I, J, K1, K2. The dimensions of the refined grid within this column are specified as NR, NTHETA, NZ. Local grid refinement is described in "[Local grid refinement and coarsening](#)" in the *ECLIPSE Technical Description*.

This keyword contains the following items of data, terminated with a slash (/):

1. Name of the local grid refinement - up to 8 characters enclosed in quotes.
2. I I-coordinate of the column in the global grid.
3. J J-coordinate of the column in the global grid.
4. K1 Minimum K-coordinate of the column in the global grid.
5. K2 Maximum K-coordinate of the column in the global grid.
6. NR Number of radial divisions in the refined grid.
7. NTHETA Number of angular segments in the refined grid.

Allowed values:

- 1 - For a 2-D radial grid
- 4 - For a 3-D radial grid.

If a corner point host grid is specified using [COORD](#) / [ZCORN](#), then only NTHETA = 4 is allowed.

*ECLIPSE 100 only*

8. NZ Number of vertical divisions in the refined grid.
9. NWMAX Maximum number of wells this local refined grid contains (not used in ECLIPSE 300)  
DEFAULT: 1 (Which is the normal value in a radial refinement.)

*ECLIPSE 300 only*

10. Inner radius of refinement  
UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)  
DEFAULT: 0.5 ft = 0.1524 m

*ECLIPSE 300 only*

11. Outer radius of refinement  
UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)  
DEFAULT: 1/3 of largest circle that can be inscribed in the column of cells

*ECLIPSE 300 only*

12. Minimum  $\Delta R$  value allowed in the refinement  
UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)  
DEFAULT: 5 ft = 1.524 m

13. Name of parent LGR (for nested refinements in ECLIPSE 300 only) - up to 8 characters. This item may be set to either a null string or to 'GLOBAL' to indicate that the parent grid is global (that is, this is not a nested refinement).

The sides and central axis of the radial refinement are assumed vertical as described in "[Radial refinements](#)" in the *ECLIPSE Technical Description*. Departures from this are allowed, but may generate warnings. See "[Current restrictions](#)" in the *ECLIPSE Technical Description*.

*ECLIPSE 300 only* Nested refinements may be used in ECLIPSE 300. If the parent grid is already an LGR then the name of the parent LGR should be specified. The range of I-, J- and K- indices should then refer to the parent grid. If the parent grid is the global grid, then the range of I-, J- and K- indices refers to the global grid.

*ECLIPSE 100 only* Nested refinements cannot be used in ECLIPSE 100. This item should be left defaulted or may be set to either a null string or 'GLOBAL'

DEFAULT: 'GLOBAL'

*ECLIPSE 100* The actual number of wells in any local grid, or amalgamation of local grids, must not exceed NWGMAX, in item 4 of the [WELLDIMS](#) keyword in the RUNSPEC section.

*ECLIPSE 100* items 10-13 are unused in ECLIPSE 100 and are ignored. The functionality can however be duplicated using the [INRAD](#), [OUTRAD](#) and [HRFIN](#) keywords.

Any other GRID section keywords (for example, [INRAD](#) and [PORO](#)) following this keyword are taken to apply to this local refined grid, until an [ENDFIN](#), [CARFIN](#), [REFINE](#), [RADFIN4](#) or another [RADFIN](#) keyword is encountered.

See also keywords [RADFIN4](#), [HRFIN](#), [NZFIN](#).

## Notes

*ECLIPSE 100*

- The inner radius of the radial refinement **must** be specified using keyword [INRAD](#) between the [RADFIN](#) and [ENDFIN](#) keywords.

The outer radius may be specified using keyword [OUTRAD](#) but this is not compulsory. If the outer radius is not specified using [OUTRAD](#), it will default to  $RMAX/3$  where  $RMAX$  is the maximum radius of a circle contained within the cell containing the radial refinement.

- When the grid is a dual or (in ECLIPSE 300) a multi-porosity grid, then the box of the parent grid is specified in the matrix only. The number of refined cells in the Z-direction is specified in the same way as for the [DIMENS](#) keyword in RUNSPEC - namely that  $NZ$  (item 8) gives the total number of Z-direction cells in all porosities, so that  $NZ$  must be a multiple of the number of porosities. An error will be posted if this is not the case. For example, for a dual porosity case,  $NZ$  should be a multiple of 2 and  $NZ/2$  should give the number of Z-direction refined cells in the matrix.

*ECLIPSE 300*

- Although the inner radius can be specified using item 10 of the [RADFIN](#) keyword, the inner radius value can also be overwritten using the [INRAD](#) keyword between the [RADFIN](#) / [ENDFIN](#) bracket.

## Example

```

RADFIN
-- NAME      I  J  K1  K2  NR  NTHETA  NZ  NWMAX
   'SOUTH'   7  8  3  5  6      4  18      /
INRAD
  0.2 /
ENDFIN

```

## Completing the circle

By default, non-neighbor connections are generated to complete the circle for each radial refinement. These connections act between the last cell in the theta-direction, and the first cell, for each layer and ring of cells, in the radial-direction.

By default, the circle is completed for `NTHETA = 4` refinements.

*ECLIPSE 300 only*

If the circle is **not** required to be completed, then the keyword `NOCIRCLE` should be used within the `RADFIN / ENDFIN` bracket.

*ECLIPSE 100 only*

If the circle is **not** required to be completed, use the `COORDSYS` keyword between the `RADFIN/ENDFIN` bracket. Refer to these keywords for more information.

## RADIAL

x	<b>ECLIPSE 100</b>

## Indicates that the run uses radial geometry

This keyword specifies that radial geometry is to be used. Cell coordinates are specified in terms of R-theta-Z values. Cell dimensions, permeabilities and transmissibilities may then be specified using radial alias keywords, and are interpreted as being in the radial geometry coordinate system.

One additional keyword is required in the GRID section for the radial case is [INRAD](#), which is used to specify the inner radius of the grid.

For ECLIPSE 100, if the radial grid completes a full circle, the [COORDSYS](#) keyword in the GRID section must be used to tie the two edges of the grid together with non-neighbor connections.

The RADIAL keyword has no associated data.

## RAINFALL

## Specifies a monthly varying flux rate for a constant flux aquifer

The keyword should be followed by the following data items and be terminated with a slash.

**Note:** No entry may be defaulted.

Negative 'influxes' are allowed.

Timesteps are chosen to honor the monthly intervals. This may mean that the minimum timestep given in [TUNING](#) is ignored.

### 1. Aquifer identification number

This should be a number between 1 and the maximum number of aquifers, set in the keyword [AQUDIMS](#) and must refer to an [AQUFLUX](#) type aquifer.

### 2. January aquifer flux

This is the water inflow rate per unit area of connected cell face for the month of January.

UNITS:  $\text{sm}^3/\text{day}/\text{m}^2$  (METRIC),  $\text{stb}/\text{day}/\text{ft}^2$  (FIELD),  $\text{scc}/\text{hr}/\text{cm}^2$  (LAB)

### 3. February aquifer flux

This is the water inflow rate per unit area of connected cell face for the month of February.

UNITS:  $\text{sm}^3/\text{day}/\text{m}^2$  (METRIC),  $\text{stb}/\text{day}/\text{ft}^2$  (FIELD),  $\text{scc}/\text{hr}/\text{cm}^2$  (LAB)

### 4. March aquifer flux

This is the water inflow rate per unit area of connected cell face for the month of March.

UNITS:  $\text{sm}^3/\text{day}/\text{m}^2$  (METRIC),  $\text{stb}/\text{day}/\text{ft}^2$  (FIELD),  $\text{scc}/\text{hr}/\text{cm}^2$  (LAB)

### 5. April aquifer flux

This is the water inflow rate per unit area of connected cell face for the month of April.

UNITS:  $\text{sm}^3/\text{day}/\text{m}^2$  (METRIC),  $\text{stb}/\text{day}/\text{ft}^2$  (FIELD),  $\text{scc}/\text{hr}/\text{cm}^2$  (LAB)

### 6. May aquifer flux

This is the water inflow rate per unit area of connected cell face for the month of May.

UNITS:  $\text{sm}^3/\text{day}/\text{m}^2$  (METRIC),  $\text{stb}/\text{day}/\text{ft}^2$  (FIELD),  $\text{scc}/\text{hr}/\text{cm}^2$  (LAB)

### 7. June aquifer flux

This is the water inflow rate per unit area of connected cell face for the month of June.

UNITS:  $\text{sm}^3/\text{day}/\text{m}^2$  (METRIC),  $\text{stb}/\text{day}/\text{ft}^2$  (FIELD),  $\text{scc}/\text{hr}/\text{cm}^2$  (LAB)

### 8. July aquifer flux

This is the water inflow rate per unit area of connected cell face for the month of July.

UNITS:  $\text{sm}^3/\text{day}/\text{m}^2$  (METRIC),  $\text{stb}/\text{day}/\text{ft}^2$  (FIELD),  $\text{scc}/\text{hr}/\text{cm}^2$  (LAB)

## 9. August aquifer flux

This is the water inflow rate per unit area of connected cell face for the month of August.

UNITS:  $\text{sm}^3/\text{day}/\text{m}^2$  (METRIC),  $\text{stb}/\text{day}/\text{ft}^2$  (FIELD),  $\text{scc}/\text{hr}/\text{cm}^2$  (LAB)

## 10. September aquifer flux

This is the water inflow rate per unit area of connected cell face for the month of September.

UNITS:  $\text{sm}^3/\text{day}/\text{m}^2$  (METRIC),  $\text{stb}/\text{day}/\text{ft}^2$  (FIELD),  $\text{scc}/\text{hr}/\text{cm}^2$  (LAB)

## 11. October aquifer flux

This is the water inflow rate per unit area of connected cell face for the month of October.

UNITS:  $\text{sm}^3/\text{day}/\text{m}^2$  (METRIC),  $\text{stb}/\text{day}/\text{ft}^2$  (FIELD),  $\text{scc}/\text{hr}/\text{cm}^2$  (LAB)

## 12. November aquifer flux

This is the water inflow rate per unit area of connected cell face for the month of November.

UNITS:  $\text{sm}^3/\text{day}/\text{m}^2$  (METRIC),  $\text{stb}/\text{day}/\text{ft}^2$  (FIELD),  $\text{scc}/\text{hr}/\text{cm}^2$  (LAB)

## 13. December aquifer flux

This is the water inflow rate per unit area of connected cell face for the month of December.

UNITS:  $\text{sm}^3/\text{day}/\text{m}^2$  (METRIC),  $\text{stb}/\text{day}/\text{ft}^2$  (FIELD),  $\text{scc}/\text{hr}/\text{cm}^2$  (LAB)

The water flow rate into a grid block from a constant flux aquifer is given by:

$$Q_w = F_w \cdot A \cdot M \quad \text{Eq. 3.163}$$

$F_w$  is the flux, entered in item 2

$A$  is the area of the connected cell face

$M$  is the aquifer influx multiplier (item 10 of the `AQUANCON` keyword or item 11 of the `AQANCONL` keyword), which defaults to 1.0.

where

The area is calculated directly from the connected cell geometry, and is not affected by item 9 of the `AQUANCON` keyword or item 10 of the `AQANCONL` keyword.

The aquifer flux can be modified at any time during the simulation by re-entering the `RAINFALL` keyword in the `SCHEDULE` section. The keyword replaces any flux entered in the `AQUFLUX` keyword.

## Example

```
RAINFALL
1
0.1
0.11
0.2
0.15
0.07
0.03
0.02
0.08
0.09
```

0.12  
0.15  
0.2 /

## RBEDCONT Tables of river bed/grid-block contact area data

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is used to define the contact area of a river with a grid-block as a function of the depth.

The keyword is followed by MXTBGR tables with a maximum of MXDPTB entries in each. These numbers are set with the RIVRDIMS keyword. Each table is terminated with a slash (/).

Each table consists of 2 columns of data:

1. Depth

The values should increase monotonically down the table

The first entry should be 0.0

UNITS: m (METRIC), ft (FIELD), cm (LAB)

2. Contact area at this depth

The values should increase monotonically down the table.

UNITS: m<sup>2</sup> (METRIC), ft<sup>2</sup> (FIELD), cm<sup>2</sup> (LAB)

There is a minimum of two rows of data per table. End the table with a slash (/). After the first tables subsequent tables may be defaulted to the previous table by just entering a slash.

### Example

To define a single table giving a constant contact area:

```
RBEDCONT
0.0 100.0
10.0 100.0/
```

## RCMASTS

## Sets minimum length for timesteps restricted by flow change

	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword may be used in a Reservoir Coupling master run to set a minimum length for timesteps restricted by a group's limiting flow rate fractional change (see item 4 in keyword [GRUPMAST](#)). If any groups have a limiting flow rate fractional change set, it is advisable to set a minimum timestep length that this restriction can impose, as the fractional flow changes can be large when the flows are small and wells are being opened or closed in the slave reservoirs.

The keyword is followed by a record containing a single number, terminated with a slash (/). The number represents the minimum timestep length that can be imposed by a group's limiting flow rate fractional change.

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

DEFAULT: TSMINZ in keyword [TUNING](#)

### Example

```

## REACT

**Activation molar energy in chemical reaction rates**

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The rate  $R_r$  of a chemical reaction depends on a rate constant ([REACRATE](#)), porosity ([REACPORD](#)), component concentrations ([REACCORD](#)), component phases ([REACPHA](#)), and temperature  $T$ :

$$R_r \propto e^{\left(-\frac{E_r}{RT}\right)}$$

where

$R$  is the gas constant and

$E_r$  is the activation molar energy of the reaction.

This keyword is followed by one item for each reaction defined by the [REACTION](#) keyword, each item representing the activation molar energy for the corresponding reaction. The list of items is terminated with a slash (/).

UNITS: kJ/kg-M ([METRIC](#)), Btu/lb-M ([FIELD](#)), J/gm-M ([LAB](#)), kJ/kg-M ([PVT-M](#))

DEFAULT: 0

See "[Chemical reactions](#)" in the *ECLIPSE Technical Description*.

**Example**

For two reactions with activation energies 19500 kJ/kg-M and 13700 kJ/kg-M respectively:

```
REACT
19500 13700 /
```

## REACCORD Order of component terms in chemical reaction rates

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The rate  $R_r$  of a chemical reaction depends on a rate constant ([REACRATE](#)), the temperature ([REACTACT](#)), porosity ([REACPORD](#)), component phases ([REACPHA](#)) and the concentration of reactants:

$$R_r \propto (m_c)^{n_c}$$

where

$m_c$  is the concentration of component  $c$  in the reacting phase and

$n_c$  is the index or order of the component term defined by this keyword.

The keyword is followed by one record for each reaction defined by the [REACTION](#) keyword. Each record contains  $N_{hc} + N_w$  items, one for each hydrocarbon component and one for each water component in the model. Each item represents the order of the component term for the corresponding reaction. Each record is terminated with a slash (/).

DEFAULT: 0 for each item.

For reactants the order must be non-negative. non-zero orders can be entered for components that are not reactants - in which case, when the component concentration  $m_c > 1$ , the component acts as a catalyst (or inhibitor if the order is negative).

If the order for a component is set to zero the reaction rate is independent of the concentration of that component. This is not recommended for reactants, unless keyword [EQLDREAC](#) is also used.

See "[Chemical reactions](#)" in the *ECLIPSE Technical Description*.

### Example

For a run with four components  $C_{12}H_{26}$ ,  $C_3H_8$ ,  $O_2$ ,  $CO_2$ , and water, and two reactions

and

The following example specifies that the reaction rate of the first reaction depends on the concentration of the first and third components, while the reaction rate of the second reaction depends on the concentration of the second and third components:

```

REACCORD
--HEAVY  LIGHT  O2    CO2  H2O
  1      0      1     0    0  /
  0      1      1     0    0  /

```

## REACCRIT Reaction rate interpolation criteria

	ECLIPSE 100

This keyword can be used in Thermal simulations to improve stability when modeling combustion processes.

When calculating the chemical reaction rate, certain terms can be interpolated between their values at the current timestep and the previous timestep, for example, temperature:

$$T = \theta \cdot T_n + (1-\theta) \cdot T_{n-1}, 0 < \theta \leq 1$$

where  $\theta$  is an interpolation parameter.

The keyword is followed by the following items of data, terminated with a slash.

1. Interpolation parameter for temperature used in the reaction rate Arrhenius term  
DEFAULT: 0.5
2. Interpolation parameter for oil saturation used in the reaction rate  
DEFAULT: 1 (that is, fully implicit)

See "[Chemical reactions](#)" in the *ECLIPSE Technical Description*.

### Example

```
REACCRIT
1* 0.5 /

## REACHES **Defines the reaches within a river**

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used to define the reach structure of a river. The river must previously have been introduced with the [RIVERSYS](#) keyword.

The keyword can only be used on one river at a time, so it must be specified more than once if there is more than one river.

The keyword is followed by a number of data records to describe the reach properties and geometry of the (possibly multibranching) river. Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing just a slash.

The data items in each record are:

### Record 1

The first record identifies the river, sets some general flags, and sets the properties to be associated with the river mouth. This reach is labeled reach number 1 and is reserved for internal use by ECLIPSE.

1. Name of the river
2. x-coordinate of the river mouth. (Downstream end of river)  
UNITS: m (METRIC), ft (FIELD), cm (LAB)
3. y-coordinate of the river mouth. (Downstream end of river)  
UNITS: m (METRIC), ft (FIELD), cm (LAB)
4. z-coordinate of the river mouth. (Downstream end of river)  
UNITS: m (METRIC), ft (FIELD), cm (LAB)
5. Length down the river to the river mouth  
This item can be used if the river being modeled within the simulator is not a complete river and it is wished to offset the distances from the true river mouth to the position defined in items 2-4.  
UNITS: m (METRIC), ft (FIELD), cm (LAB)  
DEFAULT: 0.0
6. Type of length and depth information entered in the subsequent records of this keyword  
INC The length and depth values entered in subsequent records refer to the incremental changes of these quantities along each reach.  
ABS The length and depth values entered in subsequent records refer to the absolute values of the tubing length and depth at the reach nodes.  
DEFAULT: There is no default; this item **must** be set.

End the data record with a slash (/).

### Each subsequent record

The subsequent records define the properties of all the river's reaches except for the top reach. The reaches must be numbered between 2 and MXREAC (entered in the RUNSPEC section keyword [RIVRDIMS](#)). Reaches may be entered in any order, and neighboring reaches need not be numbered consecutively;

ECLIPSE reorders them internally. A contiguous set of reaches having the same properties can be entered together in a single record as a range. The reaches within a range must have consecutively increasing numbers.

1. Reach number at the start of the range (nearest the river mouth)

An integer between 2 and MXREAC.

2. Reach number at the far end of the range

An integer between 2 and MXREAC, not less than item 1.

The remaining items in this record set the properties of the reaches in this range. To enter properties for a single reach, set items 1 and 2 equal.

3. Number of the reach to which the reach at the start of the range (item 1) is joined, that is its neighbor in the direction of the riverhead. This is its **outlet reach**; the convention being that production flows are positive.

4. The branch name

5. If item 6 of Record 1 is INC:

The length of each reach in the range, that is the distance between its nodal point and that of its neighbor in the direction of the river mouth.

Or, if item 6 of Record 1 is ABS:

The length down the river (from the river mouth) at the nodal point of the **last** reach in the range. ECLIPSE divides the length between this point and the node of the range's outlet reach (item 3) into *n* equal lengths, where *n* is the number of reaches in this range.

UNITS: m (METRIC), ft (FIELD), cm (LAB)

6. If item 6 of Record 1 is INC:

Depth change along each reach in the range, that is the depth of its nodal point minus the depth of its outlet reach's nodal point.

Or, if item 6 of Record 1 is ABS:

The depth of the nodal point of the **last** reach in the range. ECLIPSE calculates the depths of any other reaches in this range by interpolating between this depth and the depth of the range's outlet reach (item 4), linearly according to their length down the tubing.

UNITS: m (METRIC), ft (FIELD), cm (LAB)

7. Channel profile table number

DEFAULT: 1

8. Manning's roughness coefficient

9. If item 6 of Record 1 is INC:

The length of each reach in the range projected onto the X-axis, that is the X coordinate of its nodal point minus that of its neighbor in the direction of the river head.

Or, if item 6 of Record 1 is ABS:

X coordinate of the nodal point of the last reach in the range, relative to the origin of the grid.

ECLIPSE calculates the X coordinates of any other reaches in this range by interpolating between this

value and the X coordinate of the range's outlet reach (item 4), linearly according to their length down the tubing.

The X and Y coordinates of the reach nodes are stored on the restart or graphics files to enable graphics applications to produce plots of the river path. The data is not used for any other purpose and may be left defaulted if path plots are not required.

UNITS: m (METRIC), ft (FIELD), cm (LAB)

DEFAULT: 0.0

10. If item 6 of Record 1 is INC:

The length of each reach in the range projected onto the Y-axis, that is the Y coordinate of its nodal point minus that of its neighbor in the direction of the river head.

Or, If item 6 of Record 1 is ABS:

Y coordinate of the nodal point of the last reach in the range, relative to the origin of the grid. ECLIPSE calculates the Y coordinates of any other reaches in this range by interpolating between this value and the Y coordinate of the range's outlet reach (item 4), linearly according to their length down the reach.

UNITS: m (METRIC), ft (FIELD), cm (LAB)

DEFAULT: 0.0

11. If item 6 of Record 1 is INC:

The number of refined REACHES within this reach.

DEFAULT: 1

12. If item 6 of Record 1 is INC:

Item 6 for depth change of next REACH listed downstream. This item is only required with river refinement. This is item 6 of the next record.

DEFAULT: No Default.

End the data record with a slash (/).

End the set of data records with a slash.

## Example

To define a single channel that has two named branches; one having the same name as the river:

```

REACHES
'THUMB' 0.0 0.0 0.0 0.0 inc /
2 8 1 'THUMB' 200 5 1 0.01 2* /
9 13 8 'EYE' 200 5 1 0.02 2* /

```

## REACLIMS Pressure and temperature limits for calculating chemical reaction rates

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The REACLIMS keyword specifies the pressure and temperature limits used when calculating chemical reaction rates. Block pressures and temperatures outside the range specified are modified to the minimum or maximum values accordingly prior to calculating the reaction rates, see "Chemical reactions" in the *ECLIPSE Technical Description*.

The keyword is followed by one record for each reaction defined by the REACTION keyword. Each record should contain the following items of data and be terminated with a slash (/).

- Minimum pressure  
UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)  
DEFAULT: No minimum
- Maximum pressure  
UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)  
DEFAULT: No maximum
- Minimum temperature  
UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)  
DEFAULT: No minimum
- Maximum temperature  
UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)  
DEFAULT: No maximum

### Example

For a simulation with two reactions, constraining the pressure used to calculate the rate in the first reaction and the temperature in the second:

```

REACLIMS
--MIN P  MAX P  MIN T  MAX T
  30      70    2*     /
  2*     100   300    /

```

## REACOPS Options for chemical reaction models

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The REACOPS keywords specifies options used in the chemical reactions model, see "Chemical reactions" in the *ECLIPSE Technical Description*.

The keyword is followed by three items of data and terminated with a slash (/).

1. Convergence criteria for the sum of the non-linear residual. The timestep will only be accepted if the non-linear residual is less than this value. The sum of the non-linear residual can be output in the SUMMARY section by including the NLRESSUM keyword. This constraint ensures conservation between reacting components. The constraint can be disabled by specifying a negative value.

DEFAULT: 1e-4

2. Convergence criteria for the maximum element of the non-linear residual. The timestep will only be accepted if the maximum element of the non-linear residual is less than this value. The sum of the non-linear residual can be output in the SUMMARY section by including the NLRESMAX keyword. In a similar manner to the first item, this constraint ensures conservation between reacting components. The constraint can be disabled by specifying a negative value.

DEFAULT: Disabled

3. Limit the reaction rates such that only reactants present at the start of the timestep can be consumed within the timestep. Note with this simplification a component produced by one reaction cannot be consumed by another until the next timestep. Similarly a reactant flowing into a block cannot be consumed until the next timestep.

YES or NO

DEFAULT: NO

4. Scaling factor to ensure that the reaction rate of zero-order reactants tends to zero as the reactant disappears. In equilibrium deviation reactions (see the [EQLDREAC](#) keyword) if a reaction rate is independent of the concentration of a reactant, then the rate is multiplied by a factor  $m / (m + s)$  where  $m$  is the molar density of the reactant and  $s$  is given by this item. Please note that the default value is an experimental value and may be adjusted to ensure that the scaling factor  $m / (m + s)$  tends to zero with the concentration of the reactant.

DEFAULT: 1.0

---

**Note:** Prior to 2008.1 the convergence criteria on the non-linear residual was not applied. To obtain back compatibility the first item of REACOPS should be set negative.

---

---

**Note:** Simulations containing chemical reactions can be very sensitive. Modifying the items in the REACOPS keyword is likely to modify the results of the simulation.

---

### Example

Tighten the tolerance on the sum of the non-linear residual.

```
REACOPS
1e-5 /
```

## REACPHA Phase of component terms in chemical reaction rates

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The rate  $R_r$  of a chemical reaction depends on a rate constant ([REACRATE](#)), the temperature ([REACTACT](#)), porosity ([REACPORD](#)), and component concentrations ([REACCORD](#)) and component phases. This keyword allows the phase of each component in the reaction to be specified.

The keyword is followed by one record for each reaction defined by the [REACTION](#) keyword. Each record contains  $N_c$  items, one for each component, or  $N_c + 1$  items if water is included in the model. Each item can be one of 6 values:

ALL if all phases react

OIL if only the oil phase reacts

GAS if only the gas phase reacts

GPP if only the gas phase reacts and the rate depends on the gas partial pressure

WAT if the component is water in the water phase

NONE if the reaction rate is independent of the component.

Each record is terminated with a slash (/).

The default value is ALL. Phases are ignored for components with zero order ([REACCORD](#)).

If a component can react in two phases, and the reaction rate depends on the phase, then two reactions can be defined with the same stoichiometry, [STOREAC](#) and [STOPROD](#), but with different rates [REACRATE](#).

See "[Chemical reactions](#)" in the *ECLIPSE Technical Description*.

### Example

For a run with four components  $C_{12}H_{26}$ ,  $C_3H_8$ ,  $O_2$ ,  $CO_2$  and water, and two reactions with the same stoichiometry:

that proceed at different rates depending on whether  $C_3H_8$  is in the oil or gas phase, the keyword is used to distinguish the two reactions:

```
REACPHA
--HEAVY LIGHT O2 CO2 H2O
 1* OIL GAS 1* 1* /
 1* GAS GAS 1* 1* /
```

**Note:** In this example the phase of some components have been defaulted (to ALL) even though they are not reactants. This is because the component phase value is not used when the reaction rate is independent of a component.

## REACPORD **Order of porosity term in chemical reaction rates**

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The rate  $R_r$  of a chemical reaction depends on a rate constant ([REACRATE](#)), the temperature ([REACTACT](#)), component concentrations ([REACCORD](#)), component phases ([REACPHA](#)) and the porosity  $\theta$ :

$$R_r \propto \theta^{n_p}$$

where  $n_p$  is the index or order of the porosity term defined by this keyword.

The keyword is followed by one item for each reaction defined by the [REACTION](#) keyword, each item representing the order of the porosity term for the corresponding reaction. The list of items is terminated with a slash (/).

The default value depends on the component orders entered with the [REACCORD](#) keyword. It is chosen so that the reaction rate depends on the component concentrations per unit cell volume.

This keyword can be used to make a reaction rate independent of porosity by setting the order to zero. In this case the rate depends on the component concentration per unit pore volume.

See "[Chemical reactions](#)" in the *ECLIPSE Technical Description*.

### Example

For a run with four reactions that are independent of porosity:

```
REACPORD
--1  2  3  4
  0  0  0  0 /
```

## REACRATE Reaction rate constant

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The rate  $R_r$  of a chemical reaction depends on the temperature ([REACT](#)), porosity ([REACPOD](#)), component concentrations ([REACCORD](#)) and phases ([REACPHA](#)) and a constant term  $A_r$ :

$$R_r \propto A_r$$

defined by this keyword.

The keyword is followed by one item for each reaction defined by the [REACTION](#) keyword, each item representing the rate constant for the corresponding reaction. The list of items is terminated with a slash (/).

DEFAULT: 0

The units of  $A_r$  are not fixed, but are chosen so that the units of  $R_r$  are correct. Therefore the units of  $A_r$  depend on values entered for the component concentration orders ([REACCORD](#)). See "[Reaction rate units](#)" in the *ECLIPSE Technical Description*.

### Example

For two reactions with rates  $1 \times 10^6$  and  $0.3 \times 10^6$  respectively:

```
REACRATE
 1.0E6  3.0E5 /
```

## REACSMAX Maximum solid saturation in chemical reaction rates

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

In chemical reactions involving solid components, the rate  $R_r$  of a chemical reaction depends on the solid saturation  $\hat{S}_s$ :

$$R_r \propto \left(1 - \frac{\hat{S}_s}{\hat{S}_{smax}}\right)^{n_s}$$

where

$\hat{S}_{smax}$  is the limiting solid saturation, defined by this keyword and

$n_s$  is the order of the solid term defined by the [REACSORD](#) keyword.

If the solid saturation in a cell exceeds the value  $\hat{S}_{smax}$ , the reaction rate in the cell is set to zero. Solid saturations can exceed this limit, because of solid expansion, caused by changes in pressure or temperature in the cell.

The keyword is followed by one item for each reaction defined by the [REACTION](#) keyword, each item representing the limiting solid saturation term  $0.1 < \hat{S}_{smax} \leq 1$  for the corresponding reaction. The default value is  $\hat{S}_{smax} = 1$ . The list of items is terminated with a slash (/).

See "[Reactions involving solid components](#)" in the *ECLIPSE Technical Description*.

### Example

For a run with four reactions:

```
REACSMAX
--1 2 3 4
 1 1 1 0.95 /
```

	SUMMARY
	SCHEDULE

In chemical reactions involving solid components the rate  $R_r$  of a chemical reaction depends on the solid saturation  $\hat{S}_s$ :

$$R_r \propto \left(1 - \frac{\hat{S}_s}{\hat{S}_{s \max}}\right)^{n_s}$$

where  $\hat{S}_{s \max}$  is the limiting solid saturation, defined by the [REACSMAX](#) keyword and  $n_s$  is the index or order of the solid term defined by this keyword.

The keyword is followed by one item for each reaction defined by the [REACTION](#) keyword, each item representing the order of the solid term for the corresponding reaction. The list of items is terminated with a slash (/).

The default values for  $n_s$  are explained in "[Reactions involving solid components](#)" in the *ECLIPSE Technical Description*.

### Example

For a run with four reactions:

```
REACSORD
--1 2 3 4
 1* 1* 1* 2 /
```

## REACTION **Number of chemical reactions**

	<b>ECLIPSE 100</b>
x	<b>ECLIPSE 300</b>
	<b>SPECIAL</b>
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The REACTION keyword defines the number of chemical reactions that will be simulated. It can only be used in fully implicit runs.

The keyword should be followed by some or all of the following items of data:

1. The number of reactions.
2. The total number of equilibrium deviation terms (see [EQLDREAC](#)).
3. The total number of equilibrium k-values (see [EQLDKVCR](#)).
4. The total number of tracer dependent rate terms (see [REACTRAC](#)).
5. The total number of equilibrium tables (see [EQLDTAB](#)).

See "[Chemical reactions](#)" in the *ECLIPSE Technical Description*.

---

**Note:** The CPR linear solver (see [CPR](#) keyword) has been found to improve performance for non-thermal models with Chemical Reactions. Please consider modifying the default linear solver for such models.

---

### Example

```
REACTION
2 /
```

## REACTRAC Tracer dependent reaction rates

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword is followed by a number of records, each specifying a tracer-dependent reaction rate. The number of records is specified by the fourth item in the [REACTION](#) keyword. Each record contains four items of data and is terminated by a slash (/).

1. The reaction number  $r$
2. The tracer name
3. The tracer phase  $p$ , which can be ALL, OIL, GAS or WAT  
DEFAULT: ALL
4. The reaction order  $n$   
DEFAULT: 1.0

The reaction rate for reaction  $r$  is multiplied by a factor

$$(\theta \cdot t \cdot c_c)^n$$

where

$\theta$  is the porosity

$t$  is the tracer concentration

and  $c_c$  is the concentration of the tracer carrier component  $c$  in the tracer phase  $p$

$c_c = m_c$  if the tracer phase is ALL

$c_c = b_o \cdot S_o \cdot x_c$  if the tracer phase is OIL

$c_c = b_g \cdot S_g \cdot y_c$  if the tracer phase is GAS

$c_c = b_w \cdot S_w$  if the carrier is water and the tracer phase is WAT

The tracer names and carrier components must be defined by the [TRACER](#) keyword.

See "[Chemical reactions](#)" in the *ECLIPSE Technical Description*

### Example

In this example the reaction rate for reactions 1 will be multiplied by

$$c_c = \theta \cdot t \cdot b_w \cdot S_w$$

where  $t$  is the concentration of tracer TRW. In this example, item 4 of [REACTION](#) is set to 1:

```

REACTRAC
-- R TRACER PHASE N
  1 TRW   WAT   1 /

```

## READDATA **Read input data from an external source**

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The READDATA keyword allows ECLIPSE to read files of SCHEDULE section data generated by an external source during the course of the simulation. This allows the engineer, either by hand or by using another program, to modify the SCHEDULE data in response to the simulation results.

The keyword should be followed by one item of data:

1. Data input method:

'FILE' Requests the input to be read from a file. This is the only form of data input.

DEFAULT: 'FILE'

### Input by file

After the READDATA keyword has been read, ECLIPSE will expect to read a file of SCHEDULE section data after each Restart file has been output, typically at each report time (see keyword [RPTRST](#)). The input file behaves exactly like an [INCLUDE](#) file, and can contain any keyword available in the SCHEDULE section. The file is a standard free format input file, and it must be named as follows

`root.i0034` or `ROOT.I0034` for report set 34 (for example).

The prefix is the root name of the run, and the suffix is numbered with the report number of the corresponding restart file. If the 3 character suffix system is used, the file names are as follows:

`root.i01` - `root.i99` for report numbers 1 to 99

`root.j00` - `root.j99` for report numbers 100 to 199

`root.k00` - `root.k99` for report numbers 200 to 299

To prevent ECLIPSE reading a file which has only been partly written, a lockout system is employed. ECLIPSE checks for the existence of an additional guard file: `root.ok` or `ROOT.OK`.

This guard file needs to be generated for every report step since its presence signals to ECLIPSE that it can now read the data file. If the guard file is not present in the current working directory, ECLIPSE waits until it is present. When the guard file exists, ECLIPSE reads the expected data file and then deletes the guard file.

### Example

Since FILE is the only form of data input, the above example requests the input to be read from a file, by default:

```
READDATA
/
```

## RECOVERY Recovery plant table

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword enables tables to be entered to control recovery plants. The recovery plant option is discussed in "[The recovery plant option](#)" in the *ECLIPSE Technical Description*.

The keyword has two items of data, followed by the table.

1. The lower component index used to define the heavy fraction.  
This defaults to the last component.
2. The upper component index used to define the heavy fraction.  
This defaults to the last component.
3. A table of  $N_c + 1$  columns, where  $N_c$  is the number of components in the run, listing the NGL recovery fractions of each component as a function of the heavy mole fraction.

The maximum number of rows of data in this item is specified using [GPTDIMS](#) item 3.

Each value of the heavy mole fraction should be followed by  $N_c$  values (where  $N_c$  is the number of components in the run). The recovery fraction is the number of moles of NGL per mole of feed for each component.

Thus there should be  $N_c + 1$  numbers for each value of the heavy mole fraction.

The defaults for items 1 and 2 imply that the recovery plant table is normally of recovery fractions against the mole fraction of the last component in the feed.

### Example

```

RECOVERY
9 9
--Z9 CO2 N2 C1 C2 C3 C4-6 CZ7 CZ8 CZ9
0.0 0.0 0.002 0.001 0.45 0.65 0.98 1.0 1.0 1.0 --NGL recov. at Z9=0
0.05 0.0 0.002 0.001 0.48 0.68 0.99 1.0 1.0 1.0 --NGL recov. at Z9=0.05
/

```

## Initiates data input for a named local grid

This keyword is used to indicate that subsequent data refers to a named local grid. The keyword is followed by the local grid name, terminated with a slash. Subsequent keywords, from the available sets described below, are taken to refer to the specified local grid, until either an [ENDFIN](#) or another REFINE keyword is entered.

Local grid refinement is described in "[Local grid refinement and coarsening](#)" in the *ECLIPSE Technical Description*.

The REFINE keyword is available in the GRID, EDIT, PROPS, REGIONS, SOLUTION and SCHEDULE sections.

ECLIPSE 100 imposes the following restrictions on the keywords that can be used with this keyword.

### GRID section

The REFINE keyword can be used in the GRID section to return to a local grid that has previously been introduced with [CARFIN](#) or [RADFIN](#), to make further modifications to its grid data or to supply additional data.

In addition, the [BOX](#), [COPY](#), [EQUALS](#), [MULTIPLY](#) and [COPYBOX](#) keywords can be used to set or modify GRID section keywords in regions of the local grid.

### EDIT section

The following grid arrays may be edited for a local grid:

```
PORV  TRANX  TRANR  DIFFX  DIFFR
DEPTH  TRANY  TRANTH  DIFFY  DIFFTH
      TRANZ          DIFFZ
```

In addition, the [BOX](#), [COPY](#) and [EQUALS](#) keywords can be used to set or modify the above keywords in regions of the local grid. If any grid block values are defaulted, the host global grid cell value is used.

### PROPS section

In end point scaling runs (keyword [ENDSCALE](#) in the RUNSPEC section) the following keywords and their directional equivalents are available:

```
SWL ,      SWCR ,      SWU
SG ,      SGCR ,      SGU
SOWCR ,   SOGCR
KRO ,     KRORW ,     KRORG
IKRO ,    IKRORW ,    IKRORG
KRW ,     KRWR ,     IKRW ,     IKRWR
```

KRG, KRGR, IKRG, IKRGR

SWATINIT

In vertical equilibrium runs, with vertical equilibrium in the local grid, the [VEFRACV](#) keyword is also available.

In addition, the [BOX](#), [COPY](#), [EQUALS](#) and [OPERATE](#) keywords can be used to set or modify the above keywords in regions of the local grid. If any grid block values are defaulted, the host global grid cell value is used.

## REGIONS section

The following keywords are available for local grid data input following the [REFINE](#) keyword:

PVTNUM

SATNUM

EQLNUM

KRNUMX KRNUMY KRNUMZ (Directional  $K_r$  cases)

KRNUMX- KRNUMY- KRNUMZ-

IMBNUM IMBNUMY IMBNUMZ (Hysteresis cases)

IMBNUMX IMBNUMY- IMBNUMZ-

IMBNUMX-

ROCKNUM (Rock crushing cases)

MISCNUM (Miscible cases)

WH2NUM WH3NUM (WAG hysteresis cases)

In addition, the [BOX](#), [COPY](#), [ADD](#) and [EQUALS](#) keywords can be used to set or modify the above keywords in regions of the local grid. If any grid block values are defaulted, the host global grid cell value is used.

## SOLUTION section

In the [SOLUTION](#) section, the [REFINE](#) keyword can be used when the run is initialized by enumeration, to specify the initial conditions in the local grid cells. If the initial conditions for the local grid cells are not set in this way, they default to the initial conditions in their global grid host cells.

The [REFINE](#) keyword can be followed by any of the enumeration keywords that specify initial conditions on a cell by cell basis:

PRESSURE

SWAT

SGAS

SSOL

SURF

SFOAM

RS or PBUB

RV or PDEW

*ECLIPSE 100 only*

The [BOX](#), [EQUALS](#), [ADD](#), [MULTIPLY](#), [COPY](#) and [OPERATE](#) keywords are not available in the SOLUTION section.

## SCHEDULE section

The [REFINE](#) keyword can be used in the SCHEDULE section to modify region data during a simulation, though modification of [SATNUM](#) or [PVTNUM](#) data during a simulation should be carried out with care and is **not** recommended in general.

The keyword may be used with the [BOX](#), [EQUALS](#), [ADD](#) or [COPY](#) modifiers.

The following keywords are available for local grid data input following the [REFINE](#) keyword:

PVTNUM

SATNUM

KRUNUMX    KRUNUMY    KRUNUMZ    (Directional  $K_r$  cases)

KRUNUMX-    KRUNUMY-    KRUNUMZ-

IMBNUM    IMBNUMY    IMBNUMZ    (Hysteresis cases)

IMBNUMX    IMBNUMY-    IMBNUMZ-

IMBNUMX-

ROCKNUM    (Rock crushing cases)

MISCNUM    (Miscible cases)

MULTX

MULTY

MULTZ

MULTPV

EXCAVATE

**Note:** If region numbers are modified for refined cells in the global grid, then this change is not reflected in the associated local grid cells unless the local grid region numbers are also modified using the REFINE/ ENDFIN pair.

The block of data initiated by the REFINE keyword is terminated by either an ENDFIN keyword or another REFINE keyword.

## Examples

### EDIT section example

```
REFINE
  'LGR1' /

```

## REGDIMS Regions dimension data

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data consists of some or all of the following items which describe the maximum number of regions associated with miscellaneous keywords in the GRID, EDIT, PROPS, REGIONS or SOLUTION section.

The data must be terminated by a slash (/).

1. The maximum number of fluid-in-place regions (NTFIP) defined with keyword `FIPNUM` in the regions section. A balance sheet showing all fluid movements between fluid-in-place regions can be generated at each report time. If additional sets of fluid-in-place regions have been defined with keyword `FIP`, the maximum region number in this keyword must also not exceed this number.

Since the fluid-in-place balance sheet reports region-to-region flows, the storage required is proportional to the square of NTFIP. Very large values of NTFIP should therefore be avoided, as excessive storage may be required and in addition the restart files will be very large.

This quantity may also be defined by item 5 of `TABDIMS`. If it is set in both places, the greater of the two settings is used. Additionally, if item 1 of `DYNRDIMS` is defined, the greatest of the three settings is used.

DEFAULT: 1

2. The number of sets of fluid-in-place regions (NMFIPR). The standard set is defined by `FIPNUM` in the REGIONS section. Any additional sets are defined by `FIPxxx` keywords in the REGIONS section.

DEFAULT: 1

*ECLIPSE 300*

---

**Note:** If dynamic regions are used in addition to additional sets of standard fluid-in-place regions, this value needs to be the actual number of specified sets of fluid-in-place regions, not the maximum number.

---

*ECLIPSE 100 only*

3. The maximum number of independent reservoir regions (NRFREG). (See "[Independent reservoir regions](#)" in the *ECLIPSE Technical Description* and the keyword `ISOLNUM` in the GRID section.)

DEFAULT: 0

4. The maximum number of flux regions for the Flux option (NTFREG); or the maximum number of regions used by the `FLUXNUM` keyword in the GRID section.

This quantity may also be defined by item 11 of `TABDIMS`; if it is set in both places, the maximum of the two is used.

DEFAULT: 0

*ECLIPSE 100 only*

---

**Note:** If this value is defaulted or set to 0 and the 2nd item of `GRIDOPTS` is also defaulted or set to 0, the simulator behaves as though all grid blocks are in `MULTNUM` region 1. This has no effect except that specifying multipliers for region 1 will not generate a warning or error, and is a side-effect of the default value for `MULTNUM` being 1.

---

*ECLIPSE 300 only*

5. The maximum number of user-defined regions to be used in the enhanced `TRACK` option.

DEFAULT: 0

---

**CAUTION:** This number should, if possible, be no larger than the actual number of regions to be used, as any 'surplus' represents, depending on how many components are to be tracked, a considerable overhead in terms of both storage and CPU.

---

6. Coal Bed Methane option: The number of Coal Bed Methane regions, NTCREG, as used by [COALNUM](#) in the GRID section.

DEFAULT: 1

7. The maximum number of user-defined regions used by the [OPERNUM](#) keyword in the GRID and REGIONS sections.

DEFAULT: 0

8. The maximum number of double-precision work arrays for use with the [OPERATE](#) and [OPERATER](#) keywords. An integer value between 1 and 9999 should be specified.

DEFAULT: 0

9. The maximum number of integer work arrays for use with the [OPERATE](#) and [OPERATER](#) keywords. An integer value between 1 and 999 should be specified.

DEFAULT: 0

*ECLIPSE 100 only*

10. The number of polymer flooding mixing regions, NPLMIX, as used by [PLMIXNUM](#) in the GRID section.

Default: 1

## Example

```
REGDIMS
5 5 0 1 /
```

## RESIDNUM **VE** residual flow region numbers

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is optional and should only be used in runs employing the vertical equilibrium option (keyword **VE** in the RUNSPEC section). The residual flow region number specifies which set of saturation function tables (input using **SGFN**, **SOF3** and related keywords in the PROPS section) should be used in the Vertical Equilibrium residual flow calculation.

The keyword should be followed by one integer for every grid block in the current input box, specifying the residual flow region to which it belongs. The region number should not be less than 1 or greater than NTSFUN (see keyword **TABDIMS**). The data must be terminated by a slash (/). Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

If the keyword is used, the usual vertical equilibrium flow (calculated using the SATNUM saturation function tables) is modified by adding a second flow component based on the cell saturation and the RESIDNUM relative permeability table.

If water floods a cell containing oil, then a residual oil saturation will be left below the contact. The residual flow calculation is intended to model the slow movement of this residual oil during the period after the initial water influx. The residual flow eventually reduces the residual oil values from the SATNUM value to that of the RESIDNUM table. The rate at which this reduction occurs depends on the value of the relative permeability between these two saturations. Typically the relative permeability values is zero for phases with no residual flow and small otherwise. A warning message is issued if the oil relative permeability exceeds 5% for any residual flow table.

Any capillary pressure values entered in the RESIDNUM saturation tables will be ignored.

See also the saturation function keywords **SGFN**, **SWFN**, **SOF2**, **SOF3**, **SOF32D**, **SGOF**, **SLGOF** and **SWOF**, and "**Vertical equilibrium**" in the *ECLIPSE Technical Description*.

### Example

With NTSFUN=3 specified in keyword **TABDIMS**; NDIVIX=8, NDIVIY=6 and NDIVIZ=5 specified in RUNSPEC keyword **DIMENS**; and no input BOX set:

```
RESIDNUM
240*3 /
```

## RESOPT

## Request a reservoir optimization simulation

This keyword activates the Reservoir Optimization license key. It requires no data.

For further information, see the "[Optimization](#)" chapter in the *ECLIPSE Technical Description*.

---

**Note:** The reservoir optimization feature is not currently available with the parallel option. A list of options that are not compatible with the reservoir optimization feature is given in the "[Screening your model for suitability](#)" in the *ECLIPSE Technical Description*.

---

## RESORB

## Coal Bed Methane re-adsorption factor

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is used to specify a re-adsorption factor for each component in a Coal Bed Methane run. Using a value other than unity scales the rate of re-adsorption of the gas. A zero value prevents gas re-adsorption.

A coal bed methane model can be divided into one or more regions. The number of regions is NTCREG and this number is input by REGDIMS item 6. Coal regions are input with the keyword COALNUM. There is one RESORB record for each coal region up to NTCREG records. Each record contains the re-adsorption factor for the total number of components defined by keyword NCOMPS.

1.  $r_1 r_2 r_3 \dots r_{ncomps}$

Values should be in [0,1]

DEFAULT: 1.0

Re-adsorption factors for coal region number 1.

2.  $r_1 r_2 r_3 \dots r_{ncomps}$

Re-adsorption factors for coal region number 2.

The number of records should equal the maximum number of coal regions.

## Example

```
RESORB
--For      N2 C1 CH4
           1.0 0.9 0.9 / -- coalnum=1
/
```

## RESTART

## Read solution from a restart or a save file

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by a line containing between 2 and 4 items of data, terminated by a slash (/).

1. The root name of the Restart file or Save file.
2. The number of the report from which the run is to be restarted.

---

**Note:** When using a restart file, the report number does not reset to zero after each 10000 reports (for example the restart file produced after '.X9999' is '.Y0000' but the report numbers are still 9999 and 10000 respectively). See the *ECLIPSE File Formats Reference Manual* for more details.

---

---

**Note:** If the run which generated the file referred to in item 1 had the `RPTRST` mnemonic `BASIC=6`, then each timestep in that run will have generated restart or save file information. In this case, the report number that needs to be entered here is the timestep number. This information can be obtained from the print file for that run.

---

*ECLIPSE 100 only*

3. If the time-dependent data is stored on the Save file instead of the Restart file, the string `SAVE` should be entered here.

Default this item if the time-dependent data is to be read from the Restart file.

*ECLIPSE 100 only*

4. A string denoting the formatted/unformatted status of the Save file from which the time-dependent data is to be read.

`UNFORMATTED` The `SAVE` file is unformatted

`FORMATTED` The `SAVE` file is formatted

This item is only relevant if the time-dependent data is to be read from the Save file (that is item 3 is `SAVE`).

DEFAULT: `UNFORMATTED`

See also keyword `SAVE` in the `RUNSPEC` section, and keywords `LOAD`, `RPTRST`, `RPTSCHED` and `SKIPREST`.

## Example

```
RESTART
BASE 11 /
```

causes the current run to restart from report time 11 of a previous run whose root file-name was `BASE`, reading the solution data from the Restart file.

For more information see "[Restarts](#)" in the *ECLIPSE Technical Description*

## RESVNUM **Initiates coordinate data input for a given reservoir**

## RIVDEBUG Controls on debug output for individual rivers

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used control debug output for individual rivers.

**Note:** This output is primarily intended as an aid to program development and debugging, and it should not be requested for normal program runs.

The keyword is followed by any number of lines, each containing the following data and each terminated with a slash (/). The last line must be followed by a line containing only a slash.

1. River name.
2. Debug output control.

This is a 4-figure integer:

The 1<sup>st</sup> figure controls debug from river flow and property calculations.

The 2<sup>nd</sup> figure controls debug from connection flow calculations.

The 3<sup>rd</sup> figure is currently unused.

The 4<sup>th</sup> figure controls debug from river terms in the solver.

A value of 1 or more turns the relevant debug output switch on. Higher integers result in greater quantities of debug output. A value of zero turns the debug output off.

### Example

```
RIVDEBUG
RIVER1 2120 /
RIVER2 1001 /
/
```

## RIVERSYS **Defines the branch structure and boundary conditions of a river**

x	ECLIPSE 100
	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used to define the branch structure of a river and the boundary conditions to be associated with those branches, if any. This keyword has the effect of introducing the river.

The keyword can only be used on one river at a time, so it must be specified more than once if there is more than one river.

The keyword is followed by a number of data records to describe the reach properties and geometry of the (possibly multi-branched) river. Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing just a slash.

The data items in each record are:

### Record 1

1. Name of the river.
2. Equation set to be solved
  - 'KINEMATI' Kinematic wave equations
  - 'DIFFUSIV' Diffusive wave equations
  - 'STEADYST' Steady-state wave equations
  - 'STVENANT' Time-dependent St. Venant equations

DEFAULT: No default.

End the data record with a slash (/).

### Each subsequent record

The subsequent records define the branch names.

1. Branch number.
 

An integer between 1 and MXBRR1. Branch 1 is reserved for main river, or assigned to a channel that is the same as main river.
2. Branch name, used for further referencing of branches.
 

DEFAULT: If defaulted the branch will be given a name that is the branch number concatenated with 'BRANCH'. For example, branch number 7 would be given a branch name 'BRANCH07'. Do not default branch names with branch numbers greater than 99.

The main channel/river must have a branch number of 1. Lateral branches should be numbered between 2 and MXBRR1. Lateral branches may also have subordinate branches; in this case each branch must have a higher branch number than its parent branch.

The remaining items in this record set the boundary conditions for this branch, if any, and can be entered in any order.

If the branch has a downstream boundary condition then one of the following can be input:

- DOWNSTREAM DEPTH TABLE=n (see keyword [DEPTHTAB](#))

- DOWNSTREAM RATING TABLE=n,m (see keyword [QHRATING](#), n is the table number to use when  $dh/dl > 0$  and m is the table number to use when  $dh/dl < 0$ . In this release they must be equal)
- DOWNSTREAM UNIFORM\_FLOW (This boundary condition requires no data and assumes uniform flow conditions at outflow.)

---

**Note:** There must be no spaces around the '=' or the ',' and the '\_' is significant.

---

If the branch has an upstream boundary condition then one of the following may be input:

- UPSTREAM MASSFLOW TABLE=n (see keyword [MASSFLOW](#))

End the data record with a slash (/).

End the set of data records with a slash.

## Examples

### Example 1

To define a single channel that has two named branches; one having the same name as the river:

```
RIVERSYS
'MYRIVER' /
1 MYRIVER DOWNSTREAM DEPTH TABLE=1 /
2 MYTRIB UPSTREAM MASSFLOW TABLE=1 /
/
```

### Example 2

To define a single channel that has just the one branch having the same name as the river:

```
RIVERSYS
'MYRIVER' /
1 MYRIVER DOWNSTREAM DEPTH TABLE=1 UPSTREAM MASSFLOW TABLE=1 /
/
```

## RIVRDIMS River dimension data

## RIVRPROP

**Modifies properties of river reaches**

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword may be used to modify properties of individual reaches in a river (see "Rivers" in the *ECLIPSE Technical Description*) during the simulation, as an alternative to reentering the reach data with keyword [REACHES](#).

The keyword is followed by a number of data records, each containing the following items of data. Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing just a slash.

1. River name

The river must previously have had its reaches defined with keyword [RIVERSYS](#).

2. Reach number at the start of the range

An integer between two and the maximum number of reaches defined by item two in the [RIVRDIMS](#) keyword.

3. Reach number at the end of the range

An integer between two and the maximum number of reaches defined by item two in the [RIVRDIMS](#) keyword.

The following reach properties in this record apply to all the reaches in the range. To enter properties for a single reach, set items two and three equal.

4. Manning roughness coefficient

UNITS: dimensionless

DEFAULT: unchanged from previous value

**Example**

```
RIVRPROP
-- Name      Reaches  Manning Coef
  RIVER1     15  17    0.03 /
  RIVER2     12  12    0.02 /
/
```

## RIVRXSEC Tables of river profile data

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is used to define the cross-section of a river as a function of the depth.

The keyword is followed by MXTBPR tables with a maximum of MXDPTB entries in each. These numbers are set with the RIVRDIMS keyword. Each table is terminated with a slash (/).

Each table consists of 3 columns of data:

### 1. Depth

The values should increase monotonically down the table

The first entry should be 0.0

UNITS: m (METRIC), ft (FIELD), cm (LAB)

### 2. Wetted perimeter at this depth

The values should increase monotonically down the table

UNITS: m (METRIC), ft (FIELD), cm (LAB)

### 3. Cross-sectional area at this depth

The values should increase monotonically down the table

The first entry should be 0.0

UNITS: m<sup>2</sup> (METRIC), ft<sup>2</sup> (FIELD), cm<sup>2</sup> (LAB)

There is a minimum of two rows of data per table. End the table with a slash (/). After the first tables subsequent tables may be defaulted to the previous table by just entering a slash.

## Example

To define two tables for a simple box section channel 5 metres wide; the second being identical to the first:

```
RIVRXSEC
0.0 5.0 0.0
10.0 25.0 50.0/
/
```

## RIVSALT

## Sets salt concentrations in the upstream flow of rivers branches

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used to specify the concentration of salt in an injection stream. Salt can be injected in the upstream flow of a river branch or in a specified reach. The keyword should only be used in runs with the brine option active (keyword **BRINE** in the RUNSPEC section). If the RIVSALT keyword does not appear in the SCHEDULE section, then concentration values of zero are assumed.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. River name
2. The concentration of salt in the injection stream.

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB), kg/sm<sup>3</sup> (PVT-M)

3. The branch name. If not specified, this item is defaulted to the main branch of the river, that is branch with the same name as the river.

If the item 4 is not specified or defaulted, salt is injected in the upstream flow of this branch with the concentration specified in item 2. This should be a branch with an upstream boundary condition.

4. The reach number. If this item is specified, salt is injected in this reach with the concentration specified in item 2. item 3 is then ignored.

End data record with a slash (/).

End the set of records with a blank record, containing just a slash (/).

### Example

In this example, we specify the salt concentration in the upstream flow of the main branch of RIV1. We specify the salt concentration in the upstream flow of the branch BR1 of RIV2 and inject salt in reaches number 5 and 15 of RIV2.

```
RIVSALT
RIV1 0.8 1*/
RIV2 0.8 BR1 /
RIV2 0.7 BR1 5/
RIV2 0.7 1* 15/
/
```

## RIVTRACE Sets tracer injection concentrations for rivers

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies the concentration of an injected tracer. If a tracer does not appear in the list of tracer names in the RIVTRACE keyword, a concentration of 0.0 is assumed.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. River name.

Each river must previously have been declared.

2. Name of the tracer

(Up to 3 characters)

3. Value of the tracer concentration  $T_{\text{conc}}$

If a cumulative tracer factor is specified in item 4, then  $T_{\text{conc}}$  is taken as the maximum tracer concentration.

4. The value of the cumulative tracer factor,  $T_{\text{cum}}$ .

The cumulative tracer factor allows the tracer concentration to be specified as a linear function of the total cumulative water flow.

If a cumulative tracer factor is specified, then the tracer concentration in the injection stream is given by:

$$T_c = \text{MIN}(CI \cdot T_{\text{cum}}, T_{\text{conc}}) \quad \text{Eq. 3.164}$$

where

CI Total cumulative water flow at the previous timestep

$T_{\text{cum}}$  Cumulative tracer factor

$T_{\text{conc}}$  Tracer concentration entered in item 3.

UNITS: 1/sm<sup>3</sup> (METRIC), 1/stb (FIELD), 1/scc(LAB), 1/sm<sup>3</sup> (PVT-M)

5. The branch name.

If no branch is specified the main branch is used.

If item 6 is not specified or defaulted, the tracer is injected in the upstream flow of this branch with the concentration set by items 2 and 3. This should be a branch with an upstream massflow boundary condition.

6. Reach number.

If this item is specified, the tracer is injected in this reach with the concentration set by items 2 and 3. The item 5 is then ignored.

End data record with a slash (/).

End the set of records with a blank record, containing just a slash (/).

## Example

In this example tracer WT1 is being injected through the main branch of river RIV1 and through branch BR2 of river RIV2. Tracer WT2 is injected in reaches 5 and 15 of river RIV2.

```
RIVTRACE
RIV1 WT1 1.0 3*/
RIV2 WT1 1.0 1* BR2 1*/
RIV2 WT2 1.0 1* BR2 5/
RIV2 WT2 1.0 1* 1* 15/
/
```

## RKPVMNMX Specify limits for pore volume multipliers in rock tables

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTROCC (see item 1 in keyword [ROCKCOMP](#) in the RUNSPEC section) tables of pore volume multiplier limits for hysteretic rock data, each terminated by a slash (/). Each table consists of 2 columns of data:

1. The minimum pore volume multiplier.  
UNITS: dimensionless
2. The maximum pore volume multiplier.  
UNITS: dimensionless

No default values are defined. Data must be provided for each column of a given table.

The NTROCC records correspond to the Rock Compaction table region numbers, which are set using keyword [ROCKNUM](#) (item 1).

The RKPVMNMX keyword cannot be used in [THERMAL](#) simulations. It can only be used if the Rock Compaction option is selected (keyword [ROCKCOMP](#) in the RUNSPEC section with item 1 set to the BOBERG option).

For the BOBERG model, elastic curves are provided in a tabular format using the [ROCKTABH](#) keyword, and based on these elastic curves, ECLIPSE defines the deflation and dilation curves.

Without this keyword, the dilation curve, for instance, is unbounded and so if the maximum pore volume multiplier in the [ROCKTABH](#) table is reached and the pressure continues to increase, then ECLIPSE performs a table extrapolation which can result in extremely high pore volume and transmissibility multipliers.

Use of the RKPVMNMX keyword is a way of preventing unlimited extrapolation of the deflation and dilation curves. For instance, when the maximum pore volume multiplier defined using this keyword is reached and the pressure continues to increase, the model does not dilate anymore, instead the elastic curves are used to describe the rock expansion for the current pressure.

Using the pore volume multipliers specified with this keyword, a corresponding minimum/maximum pressure is obtained in addition to a minimum/maximum transmissibility multiplier at these pressure values. If the current grid cell pressure is outside of the minimum/maximum pressure values, then a new pore volume multiplier and transmissibility multiplier is found using the elastic curves, otherwise the original [ROCKTABH](#) algorithm will be used.

See also keywords [ROCKOPTS](#), and "[Rock compaction](#)" in the *ECLIPSE Technical Description*.

### Example

With NTROCC =1

```
RKPVMNMX
0.3 0.8 /
```

## RKTRMDIR

## Allow ROCKTAB tables to contain directional transmissibility multipliers

x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTPVT (see keyword [TABDIMS](#) in the RUNSPEC section) records, each terminated by a slash (/).

Each record consists of the following items of data:

1. The reference pressure ( $P_{ref}$ ).

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: 1.0132 barsa (METRIC), 14.7 psia (FIELD), 1 atma (LAB and PVT-M).

2. The rock compressibility

$$C = \left( \frac{dV}{dP} \right) / V$$

where V is the pore volume.

UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB), 1/atm (PVT-M)

DEFAULT: 0.0

ECLIPSE 100

ECLIPSE 300

DEFAULT: 4.934E-5 1/bars (METRIC), 3.402E-6 1/psi (FIELD), 5.000E-5 1/atm (LAB and PVT-M).

---

**Note:** If the ECLIPSE 300 Geomechanics option is specified and the second porosity-stress model is used, this rock compressibility is interpreted as  $C_{pp}$ .

---

- Geomechanics only* 3. Rock matrix compressibility,  $C_R$

UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB), 1/atm (PVT-M)

- Geomechanics only* 4. Bulk compressibility,  $C_{bc}$

UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB), 1/atm (PVT-M)

- Geomechanics only* 5. Reference porosity  $\phi_0$  for estimating compressibility if items 3 or 4 are unset.

UNITS:  $m^3/m^3$  (METRIC),  $ft^3/ft^3$  (FIELD), cc/cc (LAB),  $m^3/m^3$  (PVT-M)

- Geomechanics only* 6. Reference Poisson's ratio  $\nu_R$  for estimating compressibility if item 4 is unset.

ECLIPSE adjusts the pore volumes using

$$V(P) = V(P_{ref}) \left( 1 + X + \frac{X^2}{2} \right) \quad \text{Eq. 3.165}$$

where  $X = C(P - P_{ref})$

and  $V(P_{ref})$  is the pore volume at the reference pressure.

The NTPVT records correspond to the PVT region numbers, which are set using keyword [PVTNUM](#).

If item 3 of the [ROCKOPTS](#) keyword is set to the string 'SATNUM', the ROCK data records associate with saturation function region numbers (set with keyword [SATNUM](#)) instead of PVT region numbers. In this case, the ROCK keyword data should comprise NTSFUN (see keyword [TABDIMS](#)) records, corresponding to the saturation region numbers.

If item 3 of the ROCKOPTS keyword is set to the string 'ROCKNUM', the ROCK data records associate with rock region numbers (set with keyword [ROCKNUM](#)) instead of PVT region numbers. In this case, the ROCK keyword data should comprise NTROCC (see keyword [TABDIMS](#)) records, corresponding to the rock region numbers.

The ROCK keyword must be used if the Rock Compaction option is not selected (keyword [ROCKCOMP](#) in the RUNSPEC section). If Rock Compaction is selected, keyword [ROCKTAB](#) should be used instead.

See keyword [ROCKTAB](#) for details of this option.

---

**Note:** In ECLIPSE,  $V(P_{ref})$  is taken to be the value of PORV which is calculated from the geometric information supplied in the GRID and EDIT sections. Thus PORV (and PORO) values must be regarded as being at the rock reference pressure. It should be borne in mind that other simulators will assume the geometric PORV represents reservoir pore volumes. The reservoir pore volume in ECLIPSE is calculated as  $V(p)$  as above.

---

## ECLIPSE 300

Setting item 2 of the ROCKOPTS keyword to 'STORE' implies that the initial equilibrated pressures are used as reference pressures in each grid block instead of the value of  $P_{ref}$  entered in the ROCK keyword. Then the input pore volume for a cell is defined as the reservoir pore volume at initial conditions rather than the pore volume at the reference pressure.

---

**Note:** If ECLIPSE 300 Geomechanics is specified together with the second porosity-stress relationship model, which is activated in the 4th item of keyword [GEOMECH](#), then the following relationships are used. If the bulk compressibility,  $C_{bc}$  is unset in item 4 above, then  $C_{bc} = \varphi_0 \cdot C_{pp} + (1 + \varphi_0 \cdot )C_R$  where  $C_{pp}$  is entered as item 2 above. If the rock matrix compressibility  $C_R$  is also unset in item 3 above, then  $C_R$  is

estimated from the Hashin-Shtrikman bounds to be  $C_R = \frac{C_{bc}}{1 + \frac{3(1-\nu_R)\varphi_0}{2(1-2\nu_R)(1-\varphi_0)}}$  if the reference Poisson ratio

$\nu_R$  is set in item 6 or  $C_R = \frac{C_{bc}}{1 + \frac{3\varphi_0}{2(1-\varphi_0)}}$  if it is not. Note that if  $C_{pp}$  is unset, then a default value of

0.00005 bars<sup>-1</sup> will be assumed. Also note that if the reference porosity  $\varphi_0$  is not entered in item 5, then a warning is generated and a value of 0.33 is assumed. Further information on these estimates can be found in Zimmerman, [Ref. 134]. You are responsible for ensuring that the above estimates for any defaulted compressibilities are reasonable.

---

**Note:** The rock formation volume factor  $B_r$ , used to relate rock volumes at reservoir conditions to standard conditions, is calculated from item 2 through  $C_r = -\left(\frac{dB_r}{dP}\right) / B_r$ .

---

## Example

With NTPVT=3:

```
ROCK
 3600.00 .40E-05 /
```

```
3600.00 .40E-05 /  
3000 0 /
```

## ROCK2D

## 2D rock compaction tables versus P and Sw

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTROCC (see keyword [ROCKCOMP](#) in the RUNSPEC section) tables of water induced compaction data, in the form of two-dimensional tables of pore volume multiplier versus pressure and water saturation increase.

Each table consists of up to NSSFUN (see keyword [TABDIMS](#) in the RUNSPEC section) records of data, and is terminated by a slash (/). Each record consists of up to NSSFUN data items, terminated by a slash, defining the two-dimensional function. Each record consists of the following data:

- Item 1            The pressure value.
- The pressure values must increase monotonically within the set of records defining a table.
- UNITS: barsa (METRIC), psia (FIELD), atma (LAB)
- Subsequent items    The pore volume multiplier corresponding to the pressure in item 1 and each saturation increase value in the corresponding [ROCKWNOD](#) table.
- Successive values within a record should be level or decreasing, and the number of entries should be equal to the number of entries in the corresponding [ROCKWNOD](#) table.
- The NTROCC tables correspond to the rock compaction table region numbers, which are set using keyword [ROCKNUM](#).

The [ROCK2DTR](#) keyword can optionally be used in conjunction with [ROCK2D](#) to specify the associated transmissibility modification as a function of both pressure and water saturation. If the [ROCK2DTR](#) keyword is absent the transmissibility is kept constant.

The behavior of the reservoir when the pressure in a grid block increases will depend on the first data item in the [ROCKCOMP](#) keyword in the RUNSPEC section. If the reversible option is selected the two-dimensional table will be looked up at the prevailing pressure. If the irreversible option is selected the table will be looked up using the minimum pressure that the grid block attains during the run.

If the overburden pressure supplied in the [OVERBURD](#) keyword is greater than the fluid pressure (which it often will be), the effective fluid pressure ( $P_{\text{eff fl}} = P_{\text{fluid}} - \text{Overburden}$ ) will be negative. In this case the [ROCK2D](#) table will have to be supplied with negative pressures in column 1. At present the [STRESS](#) option in the [ROCKOPTS](#) keyword is not available with [ROCK2D](#).

See also keywords [ROCKTABW](#), [ROCK2DTR](#), [ROCKWNOD](#), [ROCKOPTS](#) and [OVERBURD](#), and "[Rock compaction](#)" in the *ECLIPSE Technical Description*.

## Example

With NTROCC=1 and NSSFUN≥4:

```

## ROCK2DTR 2D transmissibility modifier tables for water induced rock compaction

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The ROCK2DTR keyword can optionally be used in runs where the water induced compaction model has been activated by the [ROCK2D](#) keyword, to specify the associated transmissibility modification as a function of both pressure and water saturation. If the ROCK2DTR keyword is absent (but ROCK2D is present) the transmissibility is kept constant.

The data comprises NTROCC (see keyword [ROCKCOMP](#) in the RUNSPEC section) tables of water induced compaction transmissibility multipliers, in the form of two-dimensional tables versus. pressure and water saturation increase.

Each table consists of up to NSSFUN (see keyword [TABDIMS](#) in the RUNSPEC section) records of data, and is terminated by a slash (/). Each record consists of up to NSSFUN data items, terminated by a slash, defining the two-dimensional function. Each record consists of the following data:

Item 1            The pressure value.

The pressure values must increase monotonically within the set of records defining a table.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB)

Subsequent items:    The transmissibility multiplier corresponding to the pressure in item 1 and each saturation increase value in the corresponding [ROCKWNOD](#) table.

The number of entries should be equal to the number of entries in the corresponding [ROCKWNOD](#) table.

The NTROCC tables correspond to the rock compaction table region numbers, which are set using keyword [ROCKNUM](#).

The behavior of the reservoir when the pressure in a grid block increases will depend on the first data item in the [ROCKCOMP](#) keyword in the RUNSPEC section. If the reversible option is selected the two-dimensional table will be looked up at the prevailing pressure. If the irreversible option is selected the table will be looked up using the minimum pressure that the grid block attains during the run.

If the overburden pressure supplied in the [OVERBURD](#) keyword is greater than the fluid pressure (which it often will be), the effective fluid pressure ( $P_{\text{eff fl}} = P_{\text{fluid}} - \text{Overburden}$ ) will be negative. In this case the [ROCK2D](#) table will have to be supplied with negative pressures in column 1. At present the [STRESS](#) option in the [ROCKOPTS](#) keyword is not available with [ROCK2D](#).

See also keywords [ROCKTABW](#), [ROCK2D](#), [ROCKWNOD](#), [ROCKOPTS](#) and [OVERBURD](#), and "[Rock compaction](#)" in the *ECLIPSE Technical Description*.

### Example

With NTROCC=1 and NSSFUN ≥4:

```

ROCK2DTR
  0.0  0.81
      0.80
      0.74
      0.73 /
1000.0 0.93
      0.92

```

```
          0.87  
          0.86 /  
9000.0   1.0  
          1.0  
          0.94  
          0.94 /  
/
```

## ROCKCOMP Enables the rock compaction option

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This indicates that the rock compaction option is to be used (see "Rock compaction" in the *ECLIPSE Technical Description*). Pressure dependent pore volume and transmissibility multipliers should be entered using the keyword [ROCKTAB](#) (or [ROCKTABH](#) for hysteretic rock compaction) in the PROPS section. For cases where the Palmer-Mansoori option is being used, the rock model data must be entered using [ROCKPAMA](#), [ROCKPAME](#) or [ROCKPMAT](#).

The keyword may be followed by the following items to specify whether rock compaction is irreversible or hysteretic, to supply the dimensions for rock compaction tables and to initiate the water induced compaction option. If the water induced compaction model is requested in data item 3, either the [ROCKTABW](#) or the [ROCK2D](#) and [ROCKWNOD](#) keywords should be entered in the PROPS section.

The data should be terminated by a slash (/).

### 1. Option for rock compaction hysteresis or irreversibility.

- |                         |   |
|-------------------------|---|
| REVERS                  | Rock compaction is fully reversible with increasing pressure.   |
| IRREVERS                | Rock compaction is irreversible; the pore space does not reinflate when the pressure increases.   |
| HYSTER                  | Rock compaction is hysteretic; the pore space deflates and reinflates elastically for pressures above an elastic limit given by the deflation curve. For cells on the deflation curve, the pore spaces will only reinflate partially when the pressure increases. Pressure-dependent pore volume and transmissibility multipliers should be entered using keyword <a href="#">ROCKTABH</a> in the PROPS section.  |
| BOBERG                  | Rock compaction is hysteretic; the pore space deflates and reinflates elastically for pressures above an elastic minimum given by the deflation curve and below an elastic maximum given by the dilation curve. For cells on the deflation curve, the pore spaces will only reinflate partially when the pressure increases. For cells on the dilation curve, the pore spaces will only deflate partially when the pressure decreases. Pressure-dependent pore volume and transmissibility multipliers should be entered using keyword <a href="#">ROCKTABH</a> in the PROPS section. |
| <i>ECLIPSE 100 only</i> | REVLIMIT This option is only available if the water induced compaction model is active (data item 3). Compaction is reversible up to a limit of the pore volume associated with the minimum pressure reached in a grid block and the initial water saturation. The aim is to model elastic/plastic behavior with only the elastic region being reversible.  |
|                         | PALM-MAN This option is only available with the Coal Bed Methane option (see <a href="#">COAL</a> ). The Palmer-Mansoori model ( <a href="#">[Ref. 78]</a> in the <i>ECLIPSE Technical Description</i> ) is used to calculate the pore volume and transmissibility multipliers. The parameters for the Palmer-Mansoori model should be entered using keyword <a href="#">ROCKPAMA</a> in the PROPS section.   |
| <i>ECLIPSE 300 only</i> | TPLM-MAN This option is only available with the THERMAL option (see <a href="#">THERMAL</a> ). The Thermal Palmer-Mansoori model ( <a href="#">[Ref. 78]</a> in the <i>ECLIPSE Technical Description</i> ) is used to calculate the pore volume and transmissibility multipliers. The parameters for the Palmer-Mansoori model should be entered using keyword <a href="#">ROCKPMAT</a> in the PROPS section.   |

NONE Turns off rock compaction. This is equivalent to not specifying the ROCKCOMP keyword, unless the water induced compaction model has been activated.

DEFAULT: REVERS

2. The number of rock compaction tables.

The number of tables (NTROCC) entered using [ROCKPAMA](#), [ROCKPMAT](#), [ROCKTAB](#) or [ROCKTABH](#) in the PROPS section.

ECLIPSE 300

The number of tables may also be entered using item 13 of the [TABDIMS](#) keyword. If both ROCKCOMP item 2 and TABDIMS item 13 are present, the greater of the two values is used.

Different rock compaction tables may be used in different parts of the reservoir if the keyword [ROCKNUM](#) is specified in the REGIONS section. The maximum number of pressure nodes in the table is specified by NPPVT (item 4 of TABDIMS).

DEFAULT: 1

ECLIPSE 100 only

3. Flag requesting the water induced compaction option.

YES Use the water induced compaction option

NO Do not use the water induced compaction option

DEFAULT: NO

ECLIPSE 300

4. Option to define a model which can be used to specify the dependence of transmissibility on porosity:

EXP Transmissibility is as exponential function of porosity. Please refer to keywords, [ROCKTRMX](#), [ROCKTRMY](#) and [ROCKTRMZ](#) for a fuller description.

CZ Transmissibility is a function of porosity via the Carmen-Kozeny type formula:

$$\frac{\kappa}{\kappa_0} = \frac{\varphi}{\varphi_0} \tau \left[ \left( \frac{1-\varphi_0}{1-\varphi} \right) \right]$$

where  $\tau$  is defined in item 5 below.

item 4 is available for use with the ROCKTAB and ROCKTABH keywords. It is currently not available for use with the ROCK keyword.

ECLIPSE 300

5. The exponent ( $\tau$ ) in the Carmen-Kozeny formula defined using item 4 above. The lower limit is 0, the upper limit is 10 and values are restricted to the integers.

DEFAULT: 0

## Example

Irreversible rock compaction with 2 rock compaction tables and no water induced compaction

```
ROCKCOMP
IRREVERS 2 /
```

## ROCKCON Connection data for cap and base rocks

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can only be used with the THERMAL option (keyword [THERMAL](#) in the RUNSPEC section).

ROCKCON connects cap and base rocks (declared using [ROCKPROP](#)) to one or more reservoir cells. The connection to the reservoir is set up by an arbitrary box defined with lower and upper I, J and K indices (refer to items 2-7 below). For each active grid block within the box, a rock connection is made to the face specified in item 8 if either of the following conditions are met:

- The face is on the outside of the reservoir, or
- The face adjoins an inactive cell.

Any number of records may be entered, each terminated with a slash (/). The set of records must be terminated with a blank record containing just a slash (/).

The items in each record are:

1. Rock type identification number  
This should be a number between 1 and the maximum number of rocks, entered using [ROCKDIMS](#) in the RUNSPEC section.
2. Lower I-location of connecting grid blocks
3. Upper I-location of connecting grid blocks
4. Lower J-location of connecting grid blocks
5. Upper J-location of connecting grid blocks
6. Lower K-location of connecting grid blocks
7. Upper K-location of connecting grid blocks
8. Descriptor defining the face of the reservoir to which the rock connects (where `NDIVIX`, `NDIVIY` and `NDIVIZ` are specified in RUNSPEC keyword [DIMENS](#)):

I- or X- I or X = 1 face

I+ or X+ I or X = `NDIVIX` face

J- or Y- J or Y = 1 face

J+ or Y+ J or Y = `NDIVIY` face

K- or Z- K or Z = 1 face (top)

K+ or Z+ K or Z = `NDIVIZ` face (bottom)

9. The rock influx coefficient.

This is a transmissibility multiplier for the connection between the rock and grid.

DEFAULT: 1.0

The effect of the multiplier is cumulative. If the same block is specified twice with coefficients of 0.5, the final coefficient is 0.25.

The rock connections can be listed by specifying the ROCKCON mnemonic in the [RPTSOL](#) keyword.

An array with the name ROCKCONA is written to the [INIT](#) file to illustrate which cells are connected to each rock. If a cell is connected to rock N then the number  $2^{(N-1)}$  appears in the ROCKCONA array. If a cell is connected to multiple rocks then the appropriate output numbers are summed.

---

**Note:** Each unique rock can only be connected to one grid. In other words, a rock can only be connected to either the global grid or to a single local grid refinement.

---

See "[Thermal option](#)" in the *ECLIPSE Technical Description* for further information on this option.

## Example

Two rock types, connected to the top and bottom of a 10 x 10 x 2 grid, with no rock influx coefficient.

```
ROCKCON
1  1 10  1 10  1 1  'K-' /
2  1 10  1 10  2 2  'K+' /
/
```

## ROCKCONL Specifies local grid refinement connection data for cap and base rocks

x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can only be used with the THERMAL option (keyword [THERMAL](#) in the RUNSPEC section).

ROCKCONL connects cap and base rocks (declared using [ROCKPROP](#)) to one or more reservoir cells.

The connection to the reservoir is set up by an arbitrary box defined with lower and upper I, J and K indices within the local grid refinement (refer to items 3-8 below). For each active grid block within the box, a rock connection is made to the face specified in item 9 if either of the following conditions are met:

- The face is on the outside of the reservoir, or
- The face adjoins an inactive cell.

Any number of records may be entered, each terminated with a slash (/). The set of records must be terminated with a blank record containing just a slash (/).

The items in each record are:

1. Rock type identification number
 

This should be a number between 1 and the maximum number of rocks, entered using [ROCKDIMS](#) in the RUNSPEC section.
2. Local grid refinement name (up to 8 characters).
3. Lower I-location of connecting grid blocks.
4. Upper I-location of connecting grid blocks.
5. Lower J-location of connecting grid blocks.
6. Upper J-location of connecting grid blocks.
7. Lower K-location of connecting grid blocks.
8. Upper K-location of connecting grid blocks.
9. Descriptor defining the face of the reservoir to which the rock connects (where `NDIVIX`, `NDIVIY` and `NDIVIZ` are specified in RUNSPEC keyword [DIMENS](#)):
 

I- I = 1 of LGR face

I+ I = `NDIVIX` of LGR face

J- J = 1 of LGR face

J+ J = `NDIVIY` of LGR face

K- K = 1 of LGR face (top)

K+ K = `NDIVIZ` of LGR face (bottom)
10. The rock influx coefficient.
 

This is a transmissibility multiplier for the connection between the rock and grid.

DEFAULT: 1.0

The effect of the multiplier is cumulative. If the same block is specified twice with coefficients of 0.5, the final coefficient is 0.25.

The rock connections to local grid refinements can be listed by specifying the ROCKCON mnemonic in the RPTSOL keyword.

An array with the name ROCKCONA is written to the INIT file to illustrate which cells are connected to each rock. If a cell is connected to rock N then the number  $2^{(N-1)}$  appears in the ROCKCONA array. If a cell is connected to multiple rocks then the appropriate output numbers are summed.

---

**Note:** Each unique rock can only be connected to one grid. In other words, a rock can only be connected to either the global grid or to a single local grid refinement.

---

See "Thermal option" in the *ECLIPSE Technical Description* for further information on this option.

## Example

Two rock types, connected to the top and bottom of a 10 x 10 x 2 local grid refinement (called LGRROCK), with no rock influx coefficient.

```
ROCKCONL
1 LGRROCK 1 10 1 10 1 1 'K-' /
2 LGRROCK 1 10 1 10 2 2 'K+' /
/
```

## ROCKDEN **Rock density**

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword has three uses. It can be used with the Geomechanics option (keyword [GEOMECH](#)) for rock stress balance calculation, or with runs with solids (keyword [SOLID](#)) for adsorption calculations, or with runs with the coal bed methane option (keyword [COAL](#)) for specifying the coal density. If neither [GEOMECH](#), [SOLID](#) or [COAL](#) is specified in the [RUNSPEC](#) section this keyword has no effect.

The keyword should be followed by one non-negative real number for every grid block in the current input box, specifying the rock density. The data must be terminated by a slash (/).

UNITS: kg/m<sup>3</sup> ([METRIC](#)), lb/ft<sup>3</sup> ([FIELD](#)), gm/cc ([LAB](#)), kg/m<sup>3</sup> ([PVT-M](#))

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*208.4). Note that spaces may not be inserted on either side of the asterisk.

---

**Note:** The default for rock density is zero. If this keyword is not specified, the simulation proceeds but in the Geomechanics option the gravity body forces are zero.

---

### Example

```
ROCKDEN
324*128 /
```

## ROCKDIMS **Rock over and underburden dimensions**

	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can only be used with the THERMAL option (see "[Thermal option](#)" in the *ECLIPSE Technical Description*).

The data consists of the following items of data, describing the number of types of cap and base rock to be used in the run to model heat loss or gain from the reservoir.

1. The maximum number of rock types
2. Not used
3. The maximum number of lines of connection data

DEFAULT: The maximum number of rock types.

### Example

Two rock types, defined using two lines of [ROCKCON](#) and/or [ROCKCONL](#) data for each type.

```
ROCKDIMS
2 1* 4 /
```

## ROCKFRAC **Rock volume fraction**

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword is used to calculate the rock volumes. For each grid cell the rock volume is calculated as the bulk volume times the fractional value. The keyword is optional.

The keyword should be followed by one non-negative real number for every grid block in the current input box, specifying the fractional value. The data must be terminated by a slash (/).

This keyword will typically be useful in dual/multi-porosity runs with:

- The [THERMAL](#) option, where energy is stored in the rock
- The [COAL](#) option (shale gas) where the rock contains adsorbed gas.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0.9). Note that spaces may not be inserted on either side of the asterisk.

If the keyword is defaulted, the standard procedure for calculating rock volumes will be applied.

Keyword ROCKFRAC is not available in runs with the triple porosity ([TRPLPORO](#)) or discretized matrix ([NMATRIX](#)) options.

UNITS: dimensionless

### Example

This defines all cell values for a grid of size 10 x 10 x 10 (5 layers in each of 2 porosities). More rock is put into the matrix than into the fracture.

```
ROCKFRAC
500*0.8 500*0.1 /
```

*ECLIPSE 100 only*

## ROCKNUM **Rock compaction table region numbers**

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword should be followed by one integer for every grid block in the current input box, specifying the rock compaction table region to which it belongs. The region number should not be less than 1 or greater than NTROCC (see keyword [ROCKCOMP](#)). The data must be terminated by a slash (/).

The region number specifies which rock compaction table (input using [ROCKPAMA](#), [ROCKTAB](#), [ROCKTABH](#), [ROCKTABW](#) or [ROCK2D](#) and [ROCK2DTR](#) in the PROPS section) should be used to calculate the porosity and permeability multipliers for each grid block. The Rock Compaction option must be enabled using keyword [ROCKCOMP](#).

---

**Note:** ROCKNUM can also be used together with the [ROCK](#) keyword for specifying rock compressibility. See keywords [ROCK](#) and [ROCKOPTS](#).

---

If the keyword [ROCKTSIG](#) or [ROCKTHSG](#) is used to specify pressure tables of the sigma multiplier for matrix-fracture coupling in dual porosity runs, only the ROCKNUM numbers of the **matrix** cells are used to obtain the pressure tables. The ROCKNUM numbers of the fracture cells are ignored.

The rock compaction region numbers can be modified during the simulation by re-specifying the ROCKNUM keyword in the SCHEDULE section. This procedure should only be carried out with care and is **not** recommended in general. It cannot be used in a parallel run, and changes to ROCKNUM will not be honored in a restart run unless the re-specification is also included in the restart data file.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

See also keywords [ROCKWNOD](#), [ROCKOPTS](#) and [OVERBURD](#), and "[Rock compaction](#)" in the *ECLIPSE Technical Description*.

ECLIPSE 100

ECLIPSE 300

---

**Note:** If ROCKNUM is unspecified for a cell, the default value for ROCKNUM will be based on the ROCKOPTS keyword item 3. If item 3 is set to [PVTNUM](#), then the defaulted value will be based on PVTNUM; if item 3 is set to [SATNUM](#), then it will be based on SATNUM; and if item 3 is set to ROCKNUM, then the defaulted value of 1 will be used.

---

### Example

With NTROCC=4 specified in keyword [ROCKCOMP](#); NDIVIX=8, NDIVIY=6 and NDIVIZ=5 specified in RUNSPEC keyword [DIMENS](#); and no input BOX set:

```
ROCKNUM
8*1 16*2 8*3 16*4
8*1 16*2 8*3 16*4
8*1 16*2 8*3 16*4
8*1 16*2 8*3 16*4
8*1 16*2 8*3 16*4 /
```

## ROCKOPTS Options for rock compaction or rock compressibility

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The ROCKOPTS keyword is used to control options associated with the rock compaction and compressibility facilities. It should be followed by some or all of the following data items, terminated by a slash (/).

1. The method of application of **OVERBURD** to the tabulated pressures in the **ROCKTAB**, **ROCKTABH** keywords:

OPTIONS: **PRESSURE** or **STRESS**

If the overburden pressure supplied in the **OVERBURD** keyword is greater than the fluid pressure (which it often will be), the effective fluid pressure ( $P_{\text{eff fl}} = P_{\text{fluid}} - \text{Overburden}$ ) will be negative. In this case the rock compaction tables will have to be entered with negative pressure values. The tables can be input in a more intuitive manner by selecting the **STRESS** option before the tables are entered. In this case the pore volume and transmissibility multipliers will be tabulated against the effective overburden pressure,  $P_{\text{effov}} = \text{Overburden} - P_{\text{fluid}}$ , which will then be positive.

This item should be left defaulted if the **OVERBURD** keyword is not used.

DEFAULT: **PRESSURE**

2. The reference pressure option:

OPTIONS: **STORE** or **NOSTORE**

The **STORE** option copies the initial equilibrated pressure at the start of the run into the overburden array. This has the effect of referencing the pore volume (as a function of pressure) to the initial pressure rather than the reference pressure, that is, the pressure with a pore volume multiplier of 1.0 in the **ROCKTAB** or **ROCKTABH** tables. Thus the input pore volume for a cell is defined as the pore volume at initial conditions rather than the pore volume at the reference pressure.

Note that the **OVERBURD** keyword should **not** be used with the **STORE** option as the input **OVERBURD** data will be overwritten and ignored.

*ECLIPSE 300*

If the **STORE** option is used with the **ROCK** keyword for the elastic rock compressibility model, the input pore volume for a cell is similarly defined as the reservoir pore volume at initial conditions rather than the pore volume at the reference pressure.

DEFAULT: **NOSTORE**

3. Table region to be used:

Possible values are: **ROCKNUM**, **SATNUM** or **PVTNUM**

DEFAULT: **PVTNUM**

If **SATNUM** or **ROCKNUM** are not found in the **REGIONS** section, default **PVTNUM** values will be used. Note that the number of **ROCK** tables must be set with **TABDIMS** item 13.

4. Flag determining the initial conditions for the **HYSTER** and **BOBERG** options.

OPTIONS:

**DEFLATION** The reservoir rock is assumed to be fully compacted and initial pore volume and transmissibility multipliers are calculated from the deflation curve.

ELASTIC     The reservoir rock is assumed to lie on an elastic curve with pore volume multiplier equal to 1 at the cell pressure.

---

**Note:** The elastic curve will not be calculated if the initial pressure is below the minimum pressure in the table. If the initial pressure is below the minimum pressure in the table the deflation curve will be used and this could lead to unphysical values. It is recommend to ensure that the initial pressure is within the specified range of pressure in the table(s).

---

DEFAULT: DEFLATION

See also keywords [ROCKTAB](#), [ROCKTABH](#), [ROCK2D](#), [ROCK2DTR](#) and [OVERBURD](#), and "Rock compaction" in the *ECLIPSE Technical Description*.

ECLIPSE 300

---

**Note:** If [ROCKNUM](#) is unspecified for a cell, the default value for ROCKNUM will be based on the ROCKOPTS keyword item 3. If item 3 is set to [PVTNUM](#), then the defaulted value will be based on PVTNUM; if item 3 is set to [SATNUM](#), then it will be based on SATNUM; and if item 3 is set to ROCKNUM, then the defaulted value of 1 will be used.

---

## Example

```
ROCKOPTS
STRESS  NOSTORE/
```

## ROCKPAMA Palmer-Mansoori rock model data

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is only available in the coal bed methane option (see keyword [COAL](#) in the RUNSPEC section). It is used to specify data for the Palmer-Mansoori rock model ("[Palmer-Mansoori rock model](#)" in *ECLIPSE Technical Description*).

The data comprises NTROCC (see keyword [ROCKCOMP](#) in the RUNSPEC section) rows of Palmer-Mansoori rock model data, each terminated by a slash (/). If a row is left blank, then its values are copied from the previous row.

Each row consists of the following columns of data:

1. The bulk modulus,  $K$   
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)
2. The constrained axial modulus,  $M$   
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)
3. Grain compressibility,  $\gamma$   
UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB), 1/atm (PVT-M)  
DEFAULT: 0
4. Langmuir curve parameter,  $\beta$   
UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB), 1/atm (PVT-M)  
DEFAULT: 0
5. Langmuir curve parameter,  $\varepsilon_l$   
UNITS: dimensionless  
DEFAULT: 0
6. Fraction,  $f$ , between 0 and 1  
UNITS: dimensionless  
DEFAULT: 0.5
7. Exponent in the porosity-permeability relationship,  $n$   
UNITS: dimensionless  
DEFAULT: 3
8. Geometric factor,  $g$   
UNITS: dimensionless  
DEFAULT: 1.0
9. Langmuir solvent curve parameter,  $\beta_s$   
UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB), 1/atm (PVT-M)  
DEFAULT: Same as item 4,  $\beta$
10. Langmuir solvent curve parameter,  $\varepsilon_s$

UNITS: dimensionless

DEFAULT: Same as item 5,  $\varepsilon_l$

The Palmer-Mansoori model adjusts the pore volumes,  $V(P)$ , at the current pressure,  $P$ , using

$$V(P) = V(P_0) \left\{ 1 + \frac{c_m}{\varphi_0} (P - P_0) + \frac{1}{\varphi_0} \left( \frac{K}{M} - 1 \right) (\text{eps} - \text{eps}_0) \right\}$$

where

$\varphi_0$  is the initial porosity,

$V(P_0)$  is the pore volume at the initial pressure,  $P_0$ , and

$$c_m = \frac{g}{M} - \left[ \frac{K}{M} + f - 1 \right] \gamma.$$

Following Palmer-Mansoori, assuming that permeability varies with porosity as

$$\frac{k}{k_0} = \left( \frac{\varphi}{\varphi_0} \right)^n$$

then the transmissibility multiplier is given by  $\left\{ 1 + \frac{c_m}{\varphi_0} (P - P_0) + \frac{1}{\varphi_0} \left( \frac{K}{M} - 1 \right) (\text{eps} - \text{eps}_0) \right\}^n$

The calculation of the volumetric strain term due to gas adsorption or desorption (eps) depends on the setting of [CBMOPTS](#) item 5, where eps0 is the initial strain term.

PMSTD:

This is the standard form assuming instant adsorption

$$\text{eps}(P) = \frac{\varepsilon_l \beta P}{1 + \beta P}$$

The pre-2013.1 version used modifications of the derivative of the pore volume multiplier with respect to pressure, for negative derivatives. This is removed from the 2013.1 release and onwards. See [item 179](#) in [OPTIONS3](#) and [item 96](#) in [OPTIONS](#) for an explanation of the old behavior. The pre-2013.1 method can be activated by using [item 295](#) in [OPTIONS3](#) or [item 200](#) in [OPTIONS](#).

It is recommended that you investigate the other models described below if the standard model is not appropriate and the simulator is struggling. This will be the case if the pore volume is changing due to the volumetric strain term (eps) without a corresponding exchange of gas between the fracture pore volume and the coal matrix.

PMADTN or PMADIMP:

For cases where the diffusion process is much slower than the assumed instant adsorption of the standard method, these methods are preferred. For ECLIPSE 300 these methods require [TPAMEPS](#). The standard method would in these cases suffer from an incorrect strain term that does not correspond to the desorption/adsorption process. This could lead to a negative total compressibility and the reservoir equations could become unsolvable. To overcome this the strain term is formulated as:

ECLIPSE 100 only

$$\text{eps}(G_C, S_C) = \frac{\varepsilon_l \beta P_g + \varepsilon_s \beta_s P_s}{1 + \beta P_g + \beta_s P_s}$$

where

$P_g(G_C)$  is the inverse look-up of the equilibrium gas pressure, corresponding to the adsorbed gas  $G_C$  and

$P_s(S_C)$  is the equilibrium solvent pressure of the adsorbed solvent concentration  $S_C$

Here

$G_C$  is the bulk gas concentration in the coal matrix (surface volume / unit coal volume)

$S_C$  is the bulk solvent concentration in the coal matrix (surface volume / unit coal volume).

These matrix coal gas concentration quantities can be output by [RPTRST](#) using [COALGAS](#) or [RPTSCHED](#) using [GASCONC](#). Using the [LANGMUIR](#) and [LANGSOLV](#) input, the pressures  $P_g$  and  $P_s$  can be obtained from the corresponding pressure entry of the coal gas concentration within these tables. These pressures are the equilibrium pressure for the single component, gas or solvent, at the given bulk coal gas concentrations,  $G_C = \text{LANGMUIR}(P_g)$  and  $S_C = \text{LANGSOLV}(P_s)$ .

Note that using the different sorption models [COALADS](#) or [COALPP](#) also affects the computations of the eps term, since the adsorption models are different.

Alternatively the eps term can be looked up directly from the [TPAMEPS](#) and [TPAMEPSS](#) tables (ECLIPSE 100 and ECLIPSE 300)

$$\text{eps}(G_C, S_C) = T_{\text{PAMEPS}}(G_C) + T_{\text{PAMEPSS}}(S_C)$$

which enables the user to specify the sorption-induced strain term directly as a function of the adsorbed quantities. If [TPAMEPS](#) is used and the case includes [SOLVENT](#), [TPAMEPSS](#) should also be present, otherwise the solvent concentration is not accounted for ( $\epsilon_s$  is not used).

For ECLIPSE 300, [TPAMEPS](#) tabulates the eps term for each [NCOMPS](#) component, where the total volumetric strain is the sum over each component:

$$\text{eps}(Gc_1, \dots, Gc_{\text{NCOMPS}}) = \left( \sum_{i=1}^{\text{NCOMPS}} T_{\text{PAMEPS}}(Gc_i) \right)$$

The bulk coal gas concentration can be output by using [RPTRST](#) or [RPTSCHED](#) using [CGAS](#).

Using the [PMADIMP](#) method, the fracture pore volume derivatives with respect to the matrix simulation grid cells unknowns are included in the Jacobian matrix of the reservoir equations, but are ignored for the transmissibility multipliers. The [PMADTN](#) method uses the adsorbed gas in the matrix for the sorption-induced swelling/shrinkage strain at the current timestep, given by the Newton iterations. However, derivatives with respect to the gas concentrations are not included in the Jacobian matrix.

[PMADTT](#) This method is doing exactly the same as [PMADTN](#) but use the gas concentration and solvent concentrations at the previous timestep. For ECLIPSE 300 this method requires [TPAMEPS](#).

---

**Note:** The alternative methods will only equal the standard Palmer-Mansoori method ([PMSTD](#)) when an equilibrium is reached (and when used with a single component gas). If the diffusion process is slow so that the adsorption capacity and the adsorbed bulk gas concentration differ a lot, the transient response of the standard method will predict a sorption induced strain as a function of the fracture pressure only, and not

capture the time lag of the gas sorption process. It is recommended that you evaluate whether the diffusion process will have a significant impact on the rock modeling by comparing the PMSTD method with the alternative models before selecting the standard method for use.

---

**Note:** If the diffusion process is fast it is recommended that you do not use the PMADTT method because the approximation using the bulk gas concentration at the previous timestep could lead to inaccurate results.

---

With tabular input, it is important to include enough data points to achieve accurate modeling, but for many cases, the sorption induced strain term will be a linear function with respect to the adsorbed concentration. However, pay attention to the end points of the table as this will become the maximum value. The minimum value is given in the first row of the table and should usually be zero.

For ECLIPSE 100 cases, having a scaling of the adsorption capacities using [MLANG](#), [MLANGSLV](#) or [GASSATC](#), the corresponding strain terms  $\varepsilon_l$ ,  $\varepsilon_s$  are scaled with the same value as the [LANGMUIR](#) and [LANGSOLV](#) curves. This can be disabled using item 6 of [CBMOPTS](#).

In ECLIPSE 300 the [LANGMULT](#) and [GASSATC](#) values are used if present, otherwise an average of the [LANGMULC](#) or [GASADEC](#) component specific values are used. For the compositional case, it might be better to supply the strain by using TPAMEPS values, where the scaling is not required and the individual components strain term can be specified.

Summary output of the multiplier for a given grid block is available through the keywords BPORVMOD and BPERMMOD in the SUMMARY section. The output to restart can be obtained by using [RPTRST](#) with ROCKC.

## Notes

- The Palmer-Mansoori rock compaction model assumes that the input porosities are taken as the porosities at reservoir conditions.
- The rock model only applies to the pore-volume grid-cells ([COALNUM](#) =0).
- Only the first part of the equation, the compression term, is used if the pore volume is not connected to coal. See keyword [COALNUM](#).
- [CBMOPTS](#) item 4 can be used to activate monitoring of passes through the rebound region (when the pore volume pressure derivative changes sign). This enables the output of the number of passes through the rebound region using mnemonic [NPMREB](#) in [RPTSCHED](#) or [RPTRST](#).
- [CBMOPTS](#) item 5 can be used to set a different method from the standard Palmer-Mansoori method. This method captures the time dependence of the strain term when the sorption time is controlling the exchange of gas from the matrix.
- [CBMOPTS](#) item 6 can be used to deactivate scaling of the strain term.
- [CBMOPTS](#) item 7 can be used to select that the method only apply to the transmissibility or the pore volume, or to apply a compression term to the pore volume but use the multiplier for the transmissibility.
- [CBMOPTS](#) item 8 can be used to select pressure chop when passing through the rebound pressure (ECLIPSE 100)
- [CBMOPTS](#) item 9 can be used to set a minimum pore volume to be used if the pore volume multiplier results in a pore volume being below this value.

## Example

In FIELD units, and with NTROCC=3 specified in keyword [ROCKCOMP](#):

```
ROCKPAMA
450000 600000 0 0.0016 0.0128 /
500000 700000 0 0.0010 0.0080 /
450000 600000 /
```

## ROCKPAME Compositional coal swelling and shrinkage

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is only available in the coal bed methane option (see keyword [COAL](#) in the [RUNSPEC](#) section). It is used to specify data for a modified Palmer-Mansoori rock model. See also keyword [ROCKPAMA](#).

A similar approach is described in [\[Ref. 73\]](#). An important difference is that the model described here will not predict volume changes for undersaturated coal.

The data comprises NTCREG records of input data as specified by item 6 of [REGDIMS](#) in the [RUNSPEC](#) section and applies to the different coal region numbers as assigned by [COALNUM](#). Each record is terminated by a slash (/) and the keyword is terminated by a final slash (/).

The data follows the Palmer-Mansoori rock model data, except that each component are assigned Langmuir curve parameters. If a row is left blank, then its values are copied from the previous row.

Note that [CBMOPTS](#) items 4, 6, 7 and 9 apply to this keyword.

For cases where the instant adsorption assumption in this model is far from valid, the [ROCKPAMA](#) model together with [TPAMEPS](#) should be considered.

Each row consists of  $5 + 2 \cdot n_c$  columns of data, where  $n_c$  is the number of components as set by the keyword [NCOMPS](#).

Item 1	The bulk modulus, $K$ UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)
Item 2	The constrained axial modulus, $M$ UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)
Item 3	Grain compressibility, $\gamma$ UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB), 1/atm (PVT-M) DEFAULT: 0
Item 4	Fraction, $f$ , between 0 and 1 UNITS: dimensionless DEFAULT: 0.5
Item 5	Exponent in the porosity-permeability relationship, $n$ UNITS: dimensionless DEFAULT: 3
Item 6 (i=1), Item 7 (i=2), ..., Item $n_c+5$	Langmuir curve parameter, $\beta_i$ for component $i$ UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB), 1/atm (PVT-M) DEFAULT: 0
Item $n_c+6$ .... Item $2 \cdot n_c + 5$	Langmuir curve parameter, $\varepsilon_i$ for component $i$ . UNITS: dimensionless

DEFAULT: 0

The Palmer-Mansoori model adjusts the pore volumes,  $V(P, Y)$ , at the current pressure,  $P$  and gas phase composition  $Y = (y_1, y_2, \dots, y_{nc})$  using

$$V(P, Y) = V_0 \left\{ 1 + \frac{c_m}{\varphi_0} (P - P_0) + \frac{1}{\varphi_0} \left( \frac{K}{M} - 1 \right) (E - E_0) \right\}$$

where

$\varphi_0$  is the initial porosity,

$V_0$  is the pore volume at the initial pressure,  $P_0$ , and initial gas phase composition  $Y_0$ .

The term  $c_m$  is given as  $c_m = \frac{1}{M} - \left[ \frac{K}{M} + f - 1 \right] \gamma$ .

The strain for component  $k$  is computed from the input Langmuir parameters by  $e_k = \frac{\varepsilon_k \beta_k a_k P}{1 + \sum \beta_j a_j P}$

where  $a_k = L_k / (\sum L_j)$  represent the adsorbed mole fraction of component  $k$ . These are computed assuming instant adsorption from the gas phase mole fractions  $Y$  and pressure  $P$  using the Langmuir storage capacities  $L_k(Y, P)$  (see keyword [LANGMEXT](#) or [LANGMUIR](#)).

The total strain is computed as

$$E = \sum e_k$$

Following Palmer-Mansoori, assuming that permeability varies with porosity as

$$\frac{k}{k_0} = \left( \frac{\varphi}{\varphi_0} \right)^n$$

then the transmissibility multiplier is given by

$$\left\{ 1 + \frac{c_m}{\varphi_0} (P - P_0) + \frac{1}{\varphi_0} \left( \frac{K}{M} - 1 \right) (E - E_0) \right\}^n$$

It is possible to output a table of the pore volume and permeability multipliers to the PRT file by using the keyword [RPRKPAME](#) in the SCHEDULE section.

The pore volume multiplier is limited, so the resulting pore volume cannot become less than  $5 \times 10^{-6}$ , unless this value is altered in [CBMOPTS](#) item 9, while the permeability multiplier is allowed to go to zero.

## Notes

- The rock compaction model assumes that the input porosities are taken as the porosities at reservoir conditions. In areas with cells that are not connected to coal cells different rock compaction models can be used. Some care should be taken as the input porosities might be assumed to be given at a different reference pressure.
- The coal volume itself is kept constant, since usually this is large compared to the pore volumes. Changes due to compaction hence only marginally makes a difference on the overall composition of the adsorbed gas contents.

- For under saturated coal the desorption pressure and the equilibrium composition is used instead of the pressure in the pore space, thus honoring that the coal gas contents is not changing. Note also that the current model compute the strain as if the gas sorption is instant.
- [CBMOPTS](#) item 4 can be used to activate monitoring of passes through the rebound region (when the pore volume derivative changes sign). This enables the output of the number of passes through the rebound region using mnemonic [NPMREB](#) in [RPTSCHED](#) or [RPTRST](#).
- Unless [CBMOPTS](#) item 6 is set to [NOPMSCAL](#), the strain term (E) is scaled with the adsorption capacity multiplier.

## Example

In METRIC units, and with [NCOMPS](#)=2, and [NTCREG](#)=2 specified in keyword [REGDIMS](#):

/
```

## ROCKPMAT Thermal Palmer-Mansoori rock model data

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is only available in a THERMAL run. It is used to specify data for the Thermal Palmer-Mansoori rock model ([Ref. 78] in *ECLIPSE Technical Description*).

The data comprises NTROCC (see keyword [ROCKCOMP](#) in the RUNSPEC section) rows of Thermal Palmer-Mansoori rock model data, each terminated by a slash (/). If a row is left blank, then its values are copied from the previous row.

Each row consists of 9 columns of data:

1. The bulk modulus,  $K$   
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)
2. The constrained axial modulus,  $M$   
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)
3. Grain compressibility,  $\gamma$   
UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB), 1/atm (PVT-M)  
DEFAULT: 0
4. Langmuir curve parameter,  $\beta$   
UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB), 1/atm (PVT-M)  
DEFAULT: 0
5. Langmuir curve parameter,  $\varepsilon_l$   
UNITS: dimensionless  
DEFAULT: 0
6. Fraction,  $f$ , between 0 and 1  
UNITS: dimensionless  
DEFAULT: 0.5
7. Exponent in the porosity-permeability relationship,  $n$   
UNITS: dimensionless  
DEFAULT: 3
8. Grain thermal expansivity,  $\alpha$   
UNITS: 1/K (METRIC), 1/°R (FIELD), 1/K (LAB), 1/K (PVT-M)  
DEFAULT: 0.0
9. Grain thermal expansivity,  $c_v$   
UNITS: kJ/m<sup>3</sup>/K (METRIC), Btu/ft<sup>3</sup>/°R (FIELD), J/cc/K (LAB), kJ/m<sup>3</sup>/K (PVT-M)  
DEFAULT: 0.0

The Thermal Palmer-Mansoori model adjusts the change of pore volumes,  $\Delta V(P, T)$ , and total internal energy  $\Delta E^T(P, T)$ , at the current pressure,  $P$ , and temperature,  $T$ , using

$$\Delta V(P, T) = V(P_0, T_0) \left\{ \frac{c_m}{\phi_0} \Delta P + \frac{1}{\phi_0} \left( \frac{K}{M} - 1 \right) \alpha \Delta T \right\}$$

$$\Delta E^T = \Delta E^C - \frac{c_v}{\alpha} \left( \frac{\varepsilon_l \beta P}{1 + \beta P} \right)_p \Delta P$$

where

$\phi_0$  is the initial porosity,

$V(P_0, T_0)$  is the pore volume at the initial pressure,  $P_0$ , and temperature,  $T$ ,

$\Delta E^C$  is the conventional change of the internal energy,

$\Delta E^T$  is the total change of the internal energy and

$c_m = \frac{1}{M} \left[ \frac{K}{M} + f - 1 \right] \gamma$  is the bulk elastic compressibility

This follows the conventional Palmer-Mansoori model, assuming that permeability varies with porosity as

$$\frac{k}{k_0} = \left( \frac{\phi}{\phi_0} \right)^n$$

**Note:** The Thermal Palmer-Mansoori rock compaction model assumes that the input porosities are taken as the porosities at reservoir conditions.

## Example

In FIELD units, and with NTROCC=3:

```

ROCKPMAT
450000 600000 0 0.0016 0.0128 1* 1* 0.01 /
500000 700000 0 0.0010 0.0080 /
450000 600000 /
    
```

## ROCKPROP Property data for the base or cap rock

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can only be used with the THERMAL option (keyword [THERMAL](#) in the RUNSPEC section).

ROCKPROP specifies properties of the rock surrounding the reservoir. Rocks can be specified in any order, and in one or several keywords, but each rock should not be re-specified. The set of records must be terminated with a blank record containing just a slash (/).

Each record refers to a rock type and contains the following items of data:

- Rock type identification number  
This should be a number between 1 and the maximum number of rocks, entered using [ROCKDIMS](#) in the RUNSPEC section.
- Initial temperature  
UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)
- Rock conductivity  
UNITS: kJ/m/day/K (METRIC), Btu/ft/day/°R (FIELD), J/cm/hr/K (LAB), kJ/m/day/K (PVT-M)
- Volumetric heat capacity of the rock  
UNITS: kJ/m<sup>3</sup>/K (METRIC), Btu/ft<sup>3</sup>/°R (FIELD), J/cc/K (LAB), kJ/m<sup>3</sup>/K (PVT-M)
- Temperature-dependent part of the volumetric heat capacity of the rock  
UNITS: kJ/m<sup>3</sup>/K<sup>2</sup> (METRIC), Btu/ft<sup>3</sup>/°R<sup>2</sup> (FIELD), J/cc/K<sup>2</sup> (LAB), kJ/m<sup>3</sup>/K<sup>2</sup> (PVT-M)  
DEFAULT: 0.0.
- Calculation method for heat loss  
This has the value 'V' for Vinsome and Westerveld or 'N' for numerical.  
DEFAULT: Vinsome.
- Minimum temperature difference needed between block temperature and item 2 above to start the heat loss calculation in case of Vinsome and Westerveld model ('V' in item 6)  
The lower limit is 0; the upper limit is 10°C (18°F).  
UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)  
DEFAULT: 0 (all unit sets)

The [ROCKCON](#) keyword is used to define which cells on the edge of the reservoir connect to each rock type (which reference to the global grid), and the [ROCKCONL](#) keyword is used to specify the local grid refinement connection data for these cap and base rocks.

See "[Thermal option](#)" in the *ECLIPSE Technical Description* for further information on this option.

## ROCKSPLV Dual porosity rock volume partitioning for thermal calculations

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

If the dual porosity or dual permeability options and the thermal option are being used (by specifying the **THERMAL** or **TEMP** and **DUALPORO** or **DUALPERM** keywords in the **RUNSPEC** section), this keyword can be used to specify a multiplier which determines the proportion of total rock volume used in each porosity.

The rock volume partitioning using **ROCKSPLV** is calculated as follows. The set of cells belonging to a given spatial location (that is the same I and J, and all Ks differing by (grid height)/(number of porosities)) is defined to have a bulk volume which is the average bulk volume of the individual cells, and a pore volume which is the total of each of the cell pore volumes. The total rock volume  $R$  for the set is then the set bulk volume minus the set total pore volume. The **ROCKSPLV** values,  $r_i$  for each cell  $i$  in the set, are then used so that a rock volume of  $r_i R$  is assigned to cell  $i$ .

It is not required to have the proportions sum to unity, so that a multiplier effect can also be achieved. But the total rock volume must first have been calculated to have a positive value.

If this keyword is specified, then this proportionality factor must be defined for all cells in the grid. There is no default value.

If this keyword is not specified, then the rock proportions will be calculated as described for the thermal option in its section on "**Dual porosity**" in the *ECLIPSE Technical Description*.

UNITS: dimensionless

### Example

This defines all cell values for a grid of size 10 x 10 x 10 (5 layers in each of 2 porosities.) More rock is put into the matrix than into the fracture. For user-specified tuning purposes, only 90% of the rock volume is used, for example, for history matching.

```
ROCKSPLV
500*0.8 500*0.1 /
```

## ROCKTAB **Rock compaction data tables**

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTROCC (see keyword [ROCKCOMP](#) in the RUNSPEC section) tables of rock compaction data, each terminated by a slash (/).

Each table consists of at least 3 columns of data

If the [RKTRMDIR](#) keyword has been specified, each table consists of 5 columns of data.

Apart from the last or first rows, values in the second and third columns may be defaulted, and such values are linearly interpolated.

All values in the fourth and fifth columns can be defaulted, and if this is done the values from the third column are used. Defaulting all these values is equivalent to not specifying [RKTRMDIR](#).

1. The pressure.

Values should increase monotonically down the column, unless the 'STRESS' option has been used in the [ROCKOPTS](#) keyword, in which case the values should decrease monotonically down the column.

UNITS: barsa ([METRIC](#)), psia ([FIELD](#)), atma ([LAB](#)), atma ([PVT-M](#))

2. The corresponding pore volume multiplier.

Values should be level or increasing down the column.

3. The corresponding transmissibility multiplier.

Values should be level or increasing down the column. If [RKTRMDIR](#) has been specified, this column is the transmissibility multiplier in the x-direction.

4. If [RKTRMDIR](#) has been specified, this column is the transmissibility multiplier in the y-direction.

5. If [RKTRMDIR](#) has been specified, this column is the transmissibility multiplier in the z-direction.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than [NPPVT](#) (see keyword [TABDIMS](#)). The NTROCC records correspond to the rock compaction table region numbers, which are set using [ROCKNUM](#).

---

**Note:** In ECLIPSE 300, NTROCC can be set using the 13<sup>th</sup> item in the [TABDIMS](#) keyword; if the value is set in both places ([TABDIMS](#) and [ROCKCOMP](#)) the maximum is taken. See item 2 of keyword [ROCKCOMP](#).

---

If the Rock Compaction is specified by the keyword [ROCKCOMP](#) in the RUNSPEC section then one of the following keywords: [ROCKTAB](#), [ROCKTABH](#) or [ROCK2D](#) must be used.

The grid block pore volumes and transmissibilities are adjusted dynamically by multiplying the reference values (derived from the input data) by the corresponding factors in the table, interpolated at the instantaneous grid block pressures. If the [OVERBURD](#) keyword is present the cell overburden pressure is subtracted from the grid block pressure prior to interpolate the pore volume and transmissibility multipliers.

If the overburden pressure supplied in the [OVERBURD](#) keyword is greater than the fluid pressure (which it often will be), the effective fluid pressure ( $P_{\text{eff fl}} = P_{\text{fluid}} - \text{Overburden}$ ) is negative. In this case the [ROCKTAB](#) table has to be supplied with negative pressures in column 1. The [ROCKTAB](#) table can be input in a more intuitive manner by using the 'STRESS' option in the [ROCKOPTS](#) keyword before the [ROCKTAB](#) keyword. In this case the pore volume and transmissibility multipliers are tabulated against the effective overburden pressure,  $P_{\text{eff ov}} = \text{Overburden} - P_{\text{fluid}}$ , that are then positive.

If the rock compaction process is irreversible ('IRREVERS' specified in keyword [ROCKCOMP](#)), the table is interpolated at the minimum pressure reached in each grid block, to stop the pore space re-inflating if the pressure increases.

The transmissibility multipliers specified in the table are applied in a similar way to the static transmissibility multipliers entered using keywords [MULTX](#), [MULTY](#) and [MULTZ](#) for example. The multiplier associated with the block (I, J, K) is applied to the transmissibility between the block and its positive-direction neighbors (I+1, J, K), (I, J+1, K), and (I, J, K+1). The transmissibility multipliers are also applied to the well connection transmissibility factors, and to non-neighbor connections.

In the current version of ECLIPSE 100, the transmissibility multiplier is obtained using the explicit value of the grid block pressure (or the explicit minimum pressure if the process is irreversible).

For ECLIPSE 100, coal bed methane option. The monotonicity restriction for the multipliers can be relaxed by setting [item 89](#) of the [OPTIONS](#) keyword (coal bed methane runs only).

For ECLIPSE 300, Coal Bed Methane option. The monotonicity restriction for the multipliers can be relaxed by setting [item 98](#) of the [OPTIONS3](#) keyword (coal bed methane runs only).

See also keywords [ROCKTABH](#), [ROCK2D](#), [ROCK2DTR](#), [ROCKTABW](#), [ROCKTSIG](#), [OVERBURD](#) and [ROCKOPTS](#), and "[Rock compaction](#)" in the *ECLIPSE Technical Description*.

## Example

With [NTROCC](#)=2 and [NPPVT](#)≥4:

```

4000 1.02 1.01 /

```

## ROCKTABH Hysteretic rock compaction data tables

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTROCC (see keyword [ROCKCOMP](#) in the RUNSPEC section) tables of rock compaction data. A single table consists of at least 2 and up to NPPVT (see keyword [TABDIMS](#) in the RUNSPEC section) records, each terminated by a slash (/).

Each set of records gives curves of pore volume and transmissibility multipliers against pressure that define the elastic expansion and contraction of the rock. The elastic behavior is bounded at low pressure by the deflation curve, which is made up of the first points on each elastic curve. If the 'HYSTER' option is used (see below), the elastic curves are extrapolated to infinite pressure. If however the 'BOBERG' option is used, the elastic behavior is bounded at high pressure by the dilation curve, which is made up of the last points on each elastic curve. A table is terminated by a null record (that is a record with no data before the terminating slash).

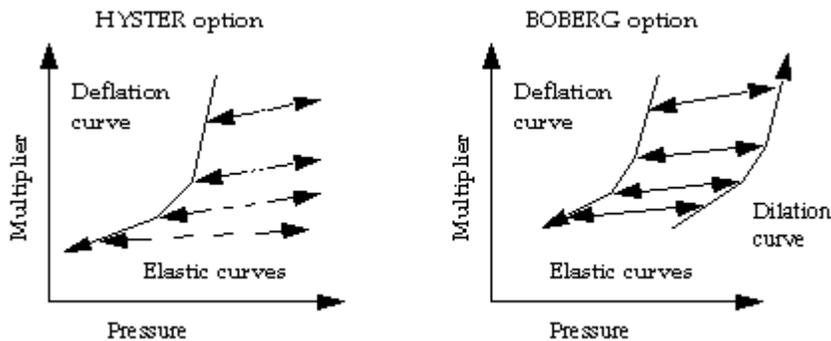

Figure 3.13. Hysteresis options

Each record consists of 3 columns of data and a terminating slash. However, if the [RKTRMDIR](#) keyword has been specified, each table consists of 5 columns of data.

All values in the fourth and fifth columns can be defaulted and, if this is done, the values from the third column are used. Defaulting these values is equivalent to not specifying [RKTRMDIR](#).

1. The pressure.

Values should increase monotonically down the column, unless the 'STRESS' option has been used in the [ROCKOPTS](#) keyword, in which case the values should decrease monotonically down the column.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

2. The corresponding pore volume multiplier.

Values should be level or increasing down the column.

3. The corresponding transmissibility multiplier.

Values should be level or increasing down the column.

If [RKTRMDIR](#) has been specified, this column is the transmissibility multiplier in the x-direction.

4. If [RKTRMDIR](#) has been specified, this column is the transmissibility multiplier in the y-direction.

5. If [RKTRMDIR](#) has been specified, this column is the transmissibility multiplier in the z-direction.

There should be the same number of entries in each column of a given record. This number should not be less than 2 or greater than NPPVT (see keyword [TABDIMS](#)).

The NTROCC records correspond to the rock compaction table region numbers, which are set using [ROCKNUM](#). Note that in ECLIPSE 300, NTROCC can be set using the 13<sup>th</sup> item in the TABDIMS keyword; if the value is set in both places the maximum is taken.

The ROCKTABH keyword must be used if the Hysteretic Rock Compaction option is selected ('HYSTER' or 'BOBERG' specified in keyword [ROCKCOMP](#) in the RUNSPEC section). The grid block pore volumes and transmissibilities are adjusted dynamically by multiplying the reference values (derived from the input data) by the corresponding factors in the table, interpolated at the instantaneous grid block pressures. If the [OVERBURD](#) keyword is present, the cell overburden pressure is subtracted from the grid block pressure prior to interpolating the pore volume and transmissibility multipliers.

---

**Note:** The curve to be used for both transmissibility and pore volume multipliers is determined by the pore volume multiplier data. The pore volume multiplier curves must therefore be distinct - it is not possible to have separate curves for the transmissibility multipliers but superposed curves for the pore volume multipliers.

---

If the overburden pressure supplied in the OVERBURD keyword is greater than the fluid pressure (which it often will be), the effective fluid pressure ( $P_{eff\ fl} = P_{fluid} - \text{Overburden}$ ) is negative. In this case the ROCKTABH table has to be supplied with negative pressures in column 1. The ROCKTABH table can be input in a more intuitive manner by using the 'STRESS' option in the [ROCKOPTS](#) keyword before the ROCKTABH keyword. In this case the pore volume and transmissibility multipliers will be tabulated against the effective overburden pressure, ( $P_{eff\ ov} = \text{Overburden} - P_{fluid}$ ), which is then positive.

The transmissibility multipliers specified in the table are applied in a similar way to the static transmissibility multipliers entered using keywords [MULTX](#), [MULTY](#) and [MULTZ](#) for example. The multiplier associated with the block (I, J, K) is applied to the transmissibility between the block and its positive-direction neighbors (I+1, J, K), (I, J+1, K), and (I, J, K+1). The transmissibility multipliers are also applied to the well connection transmissibility factors, and to non-neighbor connections.

#### ECLIPSE 100

In the current version of ECLIPSE 100, the transmissibility multiplier is obtained using the explicit value of the grid block pressure.

There is a potential problem when using transmissibility multipliers with the BOBERG hysteresis option. When the pressure exceeds the elastic limits, pore volume and transmissibility multipliers are taken either from the deflation curves or dilation curves. The elastic limits are determined by finding where the pore volume elastic curves intersect the pore volume deflation and dilation curves. Therefore, the transmissibility is discontinuous at the elastic limits if the transmissibility multipliers differ significantly from the pore volume multipliers. To ensure this problem does not arise, the transmissibility multipliers can be set equal to the pore volume multipliers, or not used, by setting them equal to 1.

See also keywords [ROCKTAB](#), [ROCK2D](#), [ROCK2DTR](#), [ROCKTABW](#), [ROCKTHSG](#), [OVERBURD](#) and [ROCKOPTS](#), and "[Rock compaction](#)" in the *ECLIPSE Technical Description*.

It is possible to define a minimum and maximum pore volume multiplier, for each table, in the BOBERG model using the keyword [RKPVMNMX](#). Given the pressure, if the calculated pore volume multiplier is less than the minimum value set using the RKPVMNMX keyword, then the multipliers are redefined on the elastic curve. Similarly, if the calculated multiplier is greater than the maximum value set using the RKPVMNMX keyword, then the multipliers are redefined on the elastic curve.

## Example

With NTROCC=2 and NPPVT≥4:

```

ROCKTABH
-- Table 1
1000 .96 .98
2000 .97 .985
3000 .98 .99
4000 .99 .995 /
2000 .99 .99
3000 .995 .995
4500 .998 .998 /
3000 1.0 1.0
5000 1.01 1.01 /
4000 1.01 1.01
5500 1.02 1.02 /
/
-- Table 2
1000 .94 .97
2700 .94 .97 /
2000 .98 .99
3500 .98 .99 /
3000 1.0 1.0
4300 1.0 1.0 /
4000 1.02 1.01
5000 1.02 1.01 /
/

```

In this example the deflation curve for Table 1 is:

```

1000 0.96 0.98
2000 0.99 0.99
3000 1.00 1.00
4000 1.01 1.01

```

and the dilation curve (if used) is:

```

4000 0.99 0.995
4500 0.998 0.998
5000 1.01 1.01
5500 1.02 1.02

```

## ROCKTABW Water induced compaction tables

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTROCC (see keyword [ROCKCOMP](#) in the RUNSPEC section) tables of water induced compaction data, each terminated by a slash (/).

Each table consists of 3 columns of data:

1. The water saturation increase from initial value.  
Values should increase monotonically down the column.
2. The corresponding pore volume multiplier.  
Values should be level or decreasing down the column.
3. The corresponding transmissibility multiplier.

There must be the same number of entries in each column of a given table. The number should not be less than 2 or greater than NSSFUN (see keyword [TABDIMS](#) in the RUNSPEC section).

The NTROCC records correspond to the rock compaction table region numbers, which are set using [ROCKNUM](#).

The ROCKTABW keyword should be used in conjunction with either the [ROCK](#), [ROCKTAB](#) or [ROCKTABH](#) keywords which specify the compaction as a function of pressure. The overall multipliers applied to the pore volume, and the transmissibility will be the product of the pressure induced compaction multipliers and the water induced compaction multipliers. Alternatively the overall compaction multipliers can be entered as a two-dimensional table in pressure and water saturation using the [ROCKWNOD](#), [ROCK2D](#) and [ROCK2DTR](#) keywords.

The water saturation used when looking up the table is the maximum attained water saturation for a grid block minus the water saturation at the start of the run. Thus the water induced compaction is assumed to be irreversible and is tabulated relative to the change in water saturation rather than the absolute saturation. See "[Rock compaction](#)" in the *ECLIPSE Technical Description* for details.

See also keywords [ROCKTAB](#), [ROCKTABH](#), [ROCK2D](#), [ROCK2DTR](#) and [ROCKWNOD](#).

### Example

With NTROCC=2 and NSSFUN≥4:

```

ROCKTABW
0.0 1.0 1.0
0.3 1.0 1.0
0.4 0.93 0.98
1.0 0.93 0.96 /
0.0 1.0 1.0
0.3 1.0 1.0
0.4 0.90 0.98
1.0 0.90 0.96 /

```

## ROCKTHSG Hysteretic rock compaction data tables in dual porosity runs

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

In addition to the [ROCKTABH](#) tables, dual porosity models can also contain pressure tables of the sigma multiplier modifying the matrix-fracture coupling as a result of rock compaction.

The data comprises NTROCC (see item 2 of keyword [ROCKCOMP](#) in the RUNSPEC section) tables of rock compaction data. A single table consists of at least 2 and up to NPPVT (see keyword [TABDIMS](#) in the RUNSPEC section) records, each terminated by a slash (/).

Each set of records gives curves of sigma multipliers against pressure that define the elastic expansion and contraction of the dual porosity rock. The elastic behavior is bounded at low pressure by the deflation curve, which is made up of the first points on each elastic curve. If the 'HYSTER' option is used (see below), the elastic curves are extrapolated to infinite pressure. If, however, the 'BOBERG' option is used, the elastic behavior is bounded at high pressure by the dilation curve, which is made up of the last points on each elastic curve. Each table is terminated by a null record (that is a record with no data before the terminating slash).

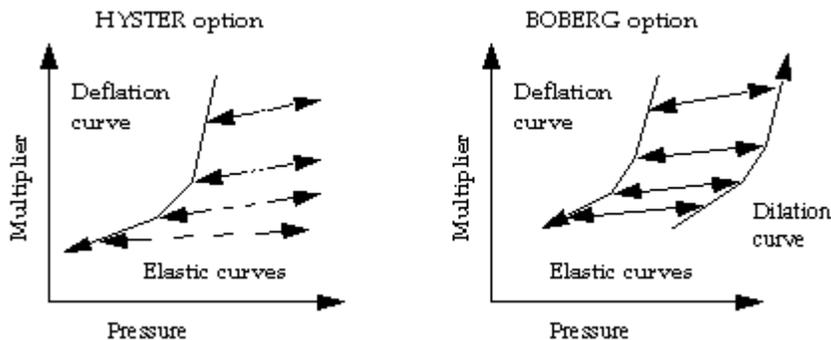

Figure 3.14. Hysteresis options

Each record consists of 2 columns of data and a terminating slash.

1. The pressure.

Values should increase monotonically down the column, unless the 'STRESS' option has been used in the [ROCKOPTS](#) keyword, in which case the values should decrease monotonically down the column.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

2. The corresponding sigma multiplier.

Values should be level or increasing down the column.

There must be the same number of entries in each column of a given record. This number should not be less than 2 or greater than NPPVT (see keyword [TABDIMS](#)). The NTROCC records correspond to the rock compaction table region numbers, which are set using [ROCKNUM](#).

ECLIPSE 300

**Note:** NTROCC can be set using the 13<sup>th</sup> item of the [TABDIMS](#) keyword; if the value is set in both places ([TABDIMS](#) and [ROCKCOMP](#)) the maximum is taken.

**Note:** Although ROCKNUM regions always cover the entire grid (even when defaulted), only the ROCKNUM numbers of the **matrix** cells are used to obtain the ROCKTHSG tables for the matrix-fracture coupling modification. ROCKNUM for fracture cells is ignored.

The ROCKTHSG keyword may be used only if the Hysteretic Rock Compaction option is selected ('HYSTER' or 'BOBERG' specified in keyword [ROCKCOMP](#) in the RUNSPEC section). The grid-block matrix-fracture coupling transmissibilities are adjusted dynamically by multiplying the reference values (derived from the input data) by the corresponding factors in the table, interpolated at the instantaneous grid block pressures. If the [OVERBURD](#) keyword is present, the cell overburden pressure is subtracted from the grid block pressure prior to interpolating the sigma multipliers.

If the overburden pressure supplied in the OVERBURD keyword is greater than the fluid pressure (which it often will be), the effective fluid pressure ( $P_{eff\ fl} = P_{fluid} - \text{Overburden}$ ) is negative. In this case the ROCKTHSG table has to be supplied with negative pressures in column 1. The ROCKTHSG table can be input in a more intuitive manner by using the 'STRESS' option in the [ROCKOPTS](#) keyword before the ROCKTHSG keyword. In this case the sigma multipliers will be tabulated against the effective overburden pressure, ( $P_{eff\ ov} = \text{Overburden} - P_{fluid}$ ), which is then positive.

ECLIPSE 100

**Note:** The implicit value of the grid block pressure is used for the calculations, as it is for ECLIPSE 300. This is different from the treatment of the transmissibility multipliers in the [ROCKTABH](#) keyword in ECLIPSE 100, where the pressure is explicit.

Either [DUALPORO](#) or [DUALPERM](#) keyword must be specified in the RUNSPEC section, and valid ROCKTABH data must be supplied, in order to enable ROCKTHSG input. The deflation pressures, as well as the dilation pressures in the BOBERG case, must be identical between the corresponding tables of ROCKTABH and ROCKTHSG. This is to ensure the same hysteretic behavior in both sets of tables. Note that the elastic curves may differ between the two sets.

See also keywords [ROCKTSIG](#), [RKPVMNMX](#), [OVERBURD](#) and [ROCKOPTS](#), and "[Rock compaction](#)" in the *ECLIPSE Technical Description*.

## Example

With NTROCC=2 specified keyword [ROCKCOMP](#) and NPPVT≥4 specified in keyword [TABDIMS](#):

```

ROCKTHSG
-- Table 1
1000 .98
2000 .985
3000 .99
4000 .995 /
2000 .99
3000 .995
4500 .998 /
3000 1.0
5000 1.01 /
4000 1.01
5500 1.02 /
/
-- Table 2
1000 .97
2700 .97 /
2000 .99
3500 .99 /
3000 1.0
4300 1.0 /

```

```
4000 1.01
5000 1.01 /
/
```

In this example the deflation curve for Table 1 is:

```
1000 0.98
2000 0.99
3000 1.00
4000 1.01
```

and the dilation curve (if used) is:

```
4000 0.995
4500 0.998
5000 1.01
5500 1.02
```

## ROCKTRMX Transmissibility variation parameters in X-direction

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword allows you to input transmissibility variation parameters for each grid cell in the X-direction.

Currently, ECLIPSE 300 allows the transmissibility to vary along with pore volume as a function of pressure (for instance, [ROCKTAB](#) and [ROCKTABH](#) keyword input). This approach is quite simplified as it does not take into account various important aspects:

- The transmissibility value in a cell which has a high porosity value would change differently to a cell which has a low porosity value.
- Some cells, around the well for instance, may require different modifications to be applied to them for history matching.

The information provided with this keyword will be used if you set [ROCKCOMP](#) keyword item 4 to [EXP](#), which will define the transmissibility as an exponential function of porosity, given by the following expression:

$$\frac{\kappa}{\kappa_0} = e^{\left[ \kappa_{\text{mult}} \left( \frac{\varphi - \varphi_0}{1 - \varphi_0} \right) \right]}$$

where

$\kappa_0$  is the initial transmissibility,

$\varphi_0$  is the initial porosity and

$\kappa_{\text{mult}}$  is the user-defined multiplier factor defined by the [ROCKTRMX](#) keyword.

Any transmissibility multiplier previously set using the [ROCKTAB](#) or [ROCKTABH](#) keywords will be ignored if the [ROCKTRMX](#) keyword is defined.

The transmissibility multipliers are also applied to the well connection factors and to non-neighbor connections.

This keyword is not compatible with the [NINEPOIN](#) and [MPFA](#) keywords.

Values entered using this keyword should range from 0 to 1E10. The default value will be set to 0 which corresponds to no transmissibility variation with fluid porosity.

The keyword should be followed by one real number for every grid block in the current input box, specifying the required water saturation. The data field should be terminated by a slash (/).

Grid blocks are ordered with the X-axis index cycling fastest (from 1 to [NDIVIX](#)), followed by the Y-axis index (from 1 to [NDIVIY](#)), and finally the Z-axis index (from 1 to [NDIVIZ](#)). [NDIVIX](#), [NDIVIY](#) and [NDIVIZ](#) are specified in [RUNSPEC](#) keyword [DIMENS](#).

Repeat counts may be used for repeated values (for example 115\*0.22). Note that spaces must not be inserted on either side of the asterisk (\*).

### Example

With [NDIVIX](#)=20, [NDIVIY](#)=6 and [NDIVIZ](#)=5 specified in [RUNSPEC](#) keyword [DIMENS](#):

```
ROCKTRMX  
120*0  
120*0.1  
120*0.5  
120*0.7  
120*1 /
```

## ROCKTRMY Transmissibility variation parameters in Y-direction

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword allows you to input transmissibility variation parameters for each grid cell in the Y-direction.

Currently, ECLIPSE 300 allows the transmissibility to vary along with pore volume as a function of pressure (for instance, [ROCKTAB](#) and [ROCKTABH](#) keyword input). This approach is quite simplified as it does not take into account various important aspects:

- The transmissibility value in a cell which has a high porosity value would change differently to a cell which has a low porosity value.
- Some cells, around the well for instance, may require different modifications to be applied to them for history matching.

The information provided with this keyword will be used if you set [ROCKCOMP](#) keyword item 4 to [EXP](#), which will define the transmissibility as an exponential function of porosity, given by the following expression:

$$\frac{\kappa}{\kappa_0} = e^{\left[ \kappa_{\text{mult}} \left( \frac{\varphi - \varphi_0}{1 - \varphi_0} \right) \right]}$$

where

$\kappa_0$  is the initial transmissibility,

$\varphi_0$  is the initial porosity and

$\kappa_{\text{mult}}$  is the user-defined multiplier

Any transmissibility multiplier previously set using the [ROCKTAB](#) or [ROCKTABH](#) keywords will be ignored if the [ROCKTRMY](#) keyword is defined.

The transmissibility multipliers are also applied to the well connection factors and to non-neighbor connections.

This keyword is not compatible with the [NINEPOIN](#) and [MPFA](#) keywords.

Values entered using this keyword should range from 0 to 1E10. The default value will be set to 0 which corresponds to no transmissibility variation with fluid porosity.

The keyword should be followed by one real number for every grid block in the current input box, specifying the required water saturation. The data field should be terminated by a slash (/).

Grid blocks are ordered with the X-axis index cycling fastest (from 1 to [NDIVIX](#)), followed by the Y-axis index (from 1 to [NDIVIY](#)), and finally the Z-axis index (from 1 to [NDIVIZ](#)). [NDIVIX](#), [NDIVIY](#) and [NDIVIZ](#) are specified in [RUNSPEC](#) keyword [DIMENS](#).

Repeat counts may be used for repeated values (for example 115\*0.22). Note that spaces must not be inserted on either side of the asterisk (\*).

### Example

With [NDIVIX](#)=20, [NDIVIY](#)=6 and [NDIVIZ](#)=5 specified in [RUNSPEC](#) keyword [DIMENS](#):

```
ROCKTRMY  
120*0  
120*0.1  
120*0.5  
120*0.7  
120*1 /
```

## ROCKTRMZ Transmissibility variation parameters in Z-direction

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword allows you to input transmissibility variation parameters for each grid cell in the Z-direction.

Currently, ECLIPSE 300 allows the transmissibility to vary along with pore volume as a function of pressure (for instance, [ROCKTAB](#) and [ROCKTABH](#) keyword input). This approach is quite simplified as it does not take into account various important aspects:

- The transmissibility value in a cell which has a high porosity value would change differently to a cell which has a low porosity value.
- Some cells, around the well for instance, may require different modifications to be applied to them for history matching.

The information provided with this keyword will be used if you set [ROCKCOMP](#) keyword item 4 to `EXP`, which will define the transmissibility as an exponential function of porosity, given by the following expression:

$$\frac{\kappa}{\kappa_0} = e^{\left[ \kappa_{\text{mult}} \left( \frac{\varphi - \varphi_0}{1 - \varphi_0} \right) \right]}$$

where

$\kappa_0$  is the initial transmissibility,

$\varphi_0$  is the initial porosity and

$\kappa_{\text{mult}}$  is the user-defined multiplier factor defined by the `ROCKTRMZ` keyword.

Any transmissibility multiplier previously set using the `ROCKTAB` or `ROCKTABH` keywords will be ignored if the `ROCKTRMZ` keyword is defined.

The transmissibility multipliers are also applied to the well connection factors and to non-neighbor connections.

This keyword is not compatible with the [NINEPOIN](#) and [MPFA](#) keywords.

Values entered using this keyword should range from 0 to 1E10. The default value will be set to 0 which corresponds to no transmissibility variation with fluid porosity.

The keyword should be followed by one real number for every grid block in the current input box, specifying the required water saturation. The data field should be terminated by a slash (/).

Grid blocks are ordered with the X-axis index cycling fastest (from 1 to `NDIVIX`), followed by the Y-axis index (from 1 to `NDIVIY`), and finally the Z-axis index (from 1 to `NDIVIZ`). `NDIVIX`, `NDIVIY` and `NDIVIZ` are specified in `RUNSPEC` keyword [DIMENS](#).

Repeat counts may be used for repeated values (for example `115*0.22`). Note that spaces must not be inserted on either side of the asterisk (\*).

### Example

With `NDIVIX=20`, `NDIVIY=6` and `NDIVIZ=5` specified in `RUNSPEC` keyword [DIMENS](#):

```
ROCKTRMZ  
120*0  
120*0.1  
120*0.5  
120*0.7  
120*1 /
```

## ROCKTSIG Rock compaction data tables in dual porosity runs

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

In addition to the [ROCKTAB](#) tables, dual porosity models can also contain pressure tables of the sigma multiplier modifying the matrix-fracture coupling as a result of rock compaction.

The data comprises NTROCC (see item 2 of keyword [ROCKCOMP](#) in the RUNSPEC section) tables of Rock Compaction data, each terminated by a slash (/).

Each table consists of 2 columns of data:

1. The pressure.

Values should increase monotonically down the column, unless the 'STRESS' option has been used in the [ROCKOPTS](#) keyword, in which case the values should decrease monotonically down the column.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

2. The corresponding sigma multiplier.

Values should be level or increasing down the column.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NPPVT (see keyword [TABDIMS](#)). The NTROCC records correspond to the rock compaction table region numbers, which are set using [ROCKNUM](#).

ECLIPSE 300

---

**Note:** NTROCC can be set using the 13<sup>th</sup> item of the TABDIMS keyword; if the value is set in both places (TABDIMS and ROCKCOMP) the maximum is taken.

---

**Note:** Although ROCKNUM regions always cover the entire grid (even when defaulted), only the ROCKNUM numbers of the **matrix** cells are used to obtain the ROCKTSIG tables for the matrix-fracture coupling modification. ROCKNUM for fracture cells is ignored.

---

The ROCKTSIG keyword may be used only if the reversible or irreversible rock compaction option is selected ('REVERS' or 'IRREVERS' specified in keyword [ROCKCOMP](#) in the RUNSPEC section). The grid block matrix-fracture coupling transmissibilities are adjusted dynamically by multiplying the reference values (derived from the input data) by the corresponding factors in the table, interpolated at the instantaneous grid block pressures. If the [OVERBURD](#) keyword is present, the cell overburden pressure is subtracted from the grid block pressure prior to interpolating the sigma multipliers.

If the overburden pressure supplied in the OVERBURD keyword is greater than the fluid pressure (which it often will be), the effective fluid pressure ( $P_{eff\ fl} = P_{fluid} - \text{Overburden}$ ) is negative. In this case the ROCKTSIG table has to be supplied with negative pressures in column 1. The ROCKTSIG table can be input in a more intuitive manner by using the 'STRESS' option in the [ROCKOPTS](#) keyword before the ROCKTSIG keyword. In this case the sigma multipliers will be tabulated against the effective overburden pressure, ( $P_{eff\ ov} = \text{Overburden} - P_{fluid}$ ), which is then positive.

If the rock compaction process is irreversible ('IRREVERS' specified in keyword [ROCKCOMP](#)), the table is interpolated at the minimum pressure reached in each grid block, in accordance with the [ROCKTAB](#) behavior which stops the pore space re-inflating if the pressure increases.

---

**Note:** The implicit value of the grid block pressure is used for the calculations, as it is for ECLIPSE 300. This is different from the treatment of the transmissibility multipliers in the `ROCKTAB` keyword in ECLIPSE 100, where the pressure is explicit.

---

Either `DUALPORO` or `DUALPERM` keyword must be specified in the RUNSPEC section, and valid ROCKTAB data must be supplied, in order to enable ROCKTSIG input.

See also keywords `ROCKTHSG`, `OVERBURD` and `ROCKOPTS`, and "Rock compaction" in the *ECLIPSE Technical Description*.

## Example

With `NTROCC=2` specified in keyword `ROCKCOMP` and `NPPVT ≥ 4` specified in keyword `TABDIMS`:

```
ROCKTSIG
1000 .98
2000 .99
3000 1.0
4000 1.0 /
1000 .97
2000 .99
3000 1.0
4000 1.01 /
```

## ROCKV

## Grid block rock volumes

## ROCKWNOD The water saturation node values for water-induced compaction tables

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTROCC (see keyword [ROCKCOMP](#) in the RUNSPEC section) tables of water saturation values, each terminated by a slash (/). The tables define the water saturation node values for the 2-D water induced compaction tables entered with keywords [ROCK2D](#) and [ROCK2DTR](#).

Each table consists of up to NSSFUN (see keyword [TABDIMS](#) in the RUNSPEC section) values of the water saturation increase, that is the current water saturation minus its initial value. Within each table the values should be positive and strictly increasing. The number of entries in each table must correspond to the number of pore volume and transmissibility multiplier entries in the corresponding ROCK2D and ROCK2DTR tables.

The NTROCC tables correspond to the rock compaction table region numbers, which are set using keyword [ROCKNUM](#).

The water saturation used when looking up the tables is the maximum attained water saturation for a grid block minus the water saturation at the start of the run. Thus the water induced compaction is assumed to be irreversible and is tabulated relative to the change in water saturation rather than the absolute saturation. See "[Rock compaction](#)" in the *ECLIPSE Technical Description* for details.

See also keywords [ROCK2D](#), [ROCK2DTR](#) and [ROCKTABW](#).

## Specifies cell residual oil composition

This keyword specifies the initial residual oil composition values for each cell. It can only be used with the [SOR](#) option. When flashed at the initial cell pressure the fluid must be a single phase oil.

The keyword should be followed by  $N_x \cdot N_y \cdot N_z \cdot N_c$  values in normal order, with the X index changing fastest.

### Example

```

ROMF
300*0.00
300*0.00
300*1.00
/

```

## RPRKPAME Output ROCKPAME table for a cell

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to output a table of pore volume and permeability multipliers versus pressure to the PRT file. The keyword is intended for validation of the input data in connection with the use of the [ROCKPAME](#) rock compaction model. A table is generated when the keyword is read in the SCHEDULE section. The keywords have the following items and are ended with a slash.

1. I - location of grid block  
No default
2. J - location of grid block  
No default
3. K - location of grid block  
No default
4. Lower pressure of table  
UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)  
DEFAULT: 1.0 barsa
5. Upper pressure of table  
UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)  
DEFAULT: 600.0 barsa
6. Number of pressure values in table  
DEFAULT: 20

The keyword can only be applied to global grid cells (not LGRs) and cannot be used in parallel mode.

**Note:** When using the time-dependent sorption model, a coal region number, [COALNUM](#), needs to be defined for the connecting dual/multi-porosity grid cell. When using the instant sorption model, a coal region number needs to be defined for the given grid cell.

### Example

```
RPRKPAME
1 1 2 100 200 50/
/
```

## RPTGRID

## Controls on output from GRID section

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by a string of mnemonics to request output of grid data to the print file. The appropriate keywords used to input grid data, such as DX and DY, may be used as mnemonics. Aliases may be used; for example DR may be used in place of DX and DTHETA may be used in place of DY. The data should be terminated by a slash (/).

Note the following for ECLIPSE 100:

- Older ECLIPSE 100 data sets may use integer controls, not mnemonics. The meaning of these is documented in "RPTGRID" in the *ECLIPSE Technical Description*.
- Entering the mnemonic NOTHING clears all the reporting flags.
- For additional control over the output, integer values greater than one may be assigned to selected mnemonics using the syntax:

```
mnemonic=integer
```

where there must be no spaces either side of the equals sign.

Output requested using the keyword RPTGRID applies only to the global grid. To request output for local grids, use [RPTGRIDL](#).

The following table lists the mnemonics available. Mnemonics available are identified by an x in the appropriate column.

Mnemonic	Output	E100	E300
ALLNNC	Output of all global-grid non-neighbor connections from all sources	x	x
AQUCON	Output of numerical aquifer connections	x	x
AQUNUM	Output of numerical aquifer definitions	x	x
COALNUM	Output of coal region numbers	x	x
COALV	Output of grid block coal volumes (Coal Bed Methane)	x	x
COLLAPSE	Output of VE compression flag	x	
COORD	Output of coordinate lines	x	
COORDSYS	Output of coordinate systems	x	
DEPTH	Output of grid block center depths	x	x
DIFFMMF	Output of Matrix/Fracture diffusivity multipliers	x	
DIFFMX	Output of X diffusivity multipliers	x	x
DIFFMY	Output of Y diffusivity multipliers	x	x
DIFFMZ	Output of Z diffusivity multipliers	x	x
DIFFX or DIFFTX	Output of X diffusivities	x	x
DIFFY or DIFFTY	Output of Y diffusivities	x	x
DIFFZ or DIFFTZ	Output of Z diffusivities	x	x

Mnemonic	Output	E100	E300
DOMAINS	Output of domains (Parallel Option). See also the <a href="#">DOMAINS</a> keyword. The output consists of: <ul style="list-style-type: none"> <li>The solver direction, which ECLIPSE calculates automatically but which may be modified by using the <a href="#">SOLVDIRS</a> keyword.</li> <li>The split of the outer solver dimension into domains.</li> </ul> The split can be entered using the <a href="#">DOMAINS</a> keyword, otherwise ECLIPSE will calculate it automatically.	x	
DPCON or SIGMA	Output of dual porosity connections	x	
DPNUM	Output of dual porosity/single porosity regions	x	x
DX	Output of X direction grid block sizes	x	x
DY	Output of Y direction grid block sizes	x	x
DZ	Output of Z direction grid block sizes	x	x
DZMTRXV	Output of $D_{z_{mtrx}}$ values	x	
DZNET	Output of net Z-direction grid block sizes		x
EXTHOST or EXTFIN	Output the host cell map for Pebi local grid refinements supplied using the <a href="#">EXTFIN</a> keyword	x	
FAULTS	Output of fault data	x	x
FLUXNUM	Output of flux region numbers	x	x
HEATTX	X thermal transmissibility		x
HEATTY	Y thermal transmissibility		x
HEATTZ	Z thermal transmissibility		x
HM****	Outputs multipliers for gradient parameters		x
IOCN	Output of active cell numbers	x	x
IONROCK	Rock ion exchange capacity	x	
ISOLNUM	Output of independent reservoir region numbers	x	
JFUNCR	Output of Leverett J-Function data specified using <a href="#">JFUNCR</a> keyword.	x	x
KOVERD	Output of K/D values (Surfactant Model)	x	
LIMITS	Outputs limits (max/min) of grid arrays		x
LX	Output of matrix block size, X-direction (Viscous Displacement Option)	x	
LY	Output of matrix block size Y-direction	x	
LZ	Output of matrix block size Z-direction	x	
MIDS	Output of cell mid-point depths		x
MINPV or MINPVV	Output of cells with pore volume less than the input minimum values	x	x

Mnemonic	Output	E100	E300
MPFANUM	Output the <a href="#">MPFANUM</a> data when using the multi-point flux approximation		x
MPFORTH	Output the multi-point flux k-orthogonality error		x
MPFTRAN	Output the multi-point flux forward transmissibilities		x
MPFTREV	Output the multi-point flux reverse transmissibilities		x
MULTNUM	Output of regions for inter-region transmissibility multipliers	x	x
MULTPV	Output of the pore volume multipliers	x	x
MULTREGP	Output region pore volume multipliers	x	x
MULTREGT	Output of multipliers between regions	x	x
MULTX	Output of X transmissibility multipliers	x	x
MULTY	Output of Y transmissibility multipliers	x	x
MULTZ	Output of Z transmissibility multipliers	x	x
NINENUM	Output the <a href="#">NINENUM</a> data when using the nine-point scheme	x	x
NNC	Output of non-neighbor connections	x	x
NTG	Output of grid block net-to-gross ratios	x	x
OPERNUM	Output of regions for use with <a href="#">OPERATER</a> keyword	x	x
PERMX	Output of X direction permeabilities	x	x
PERMY	Output of Y direction permeabilities	x	x
PERMZ	Output of Z direction permeabilities	x	x
PERMXY, PERMYZ or PERMZ	Output of all tensor permeability coefficients		x
PINCH or PINCHREG	Output of pinchout data	x	
PINCHNUM	Output of pinchout region numbers	x	
POLYMER or FOAM	Output of 1/(porosity*area) (Polymer and Foam Models)	x	
PORO	Output of grid block porosities	x	x
PORV	Output of grid block pore volumes	x	x
PORVF	Output of grid block fluid pore volumes (Coal Bed Methane option)	x	x
ROCKFRAC	Output of grid block rock volume fractions (Coal Bed Methane option)	x	x
ROCKVOL	Output of bulk (net and gross) rock volumes to the print file. In addition, if <a href="#">FIPNUM</a> regions are defined, the bulk rock volumes for each region will be output.	x	x
SIGMAGDV	Output of <a href="#">SIGMAGD</a> values (gravity drainage option)		x

Mnemonic	Output	E100	E300
SIGMAK	Output of the processed $\frac{f_x \cdot K_x}{l_x^2} + \frac{f_y \cdot K_y}{l_y^2} + \frac{f_z \cdot K_z}{l_z^2}$ term for the matrix-fracture transmissibility in dual porosity runs, if item 5 of the <a href="#">LTOSIGMA</a> keyword is set to ALL.	x	
SIGMAV	Output of Sigma values	x	x
SOLVMUM	Output the mapping between cells in the input order and the order used for the nested factorization solver when using Pebi grid data and supplied by the <a href="#">SOLVNUM</a> keyword.	x	x
THCAVE	Output of average thermal conductivities		x
THCGAS	Output of gas phase thermal conductivities		x
THCOIL	Output of oil phase thermal conductivities		x
THCONR	Output of thermal rock and fluid conductivities	x	x
THCROCK	Output of rock thermal conductivities		x
THCSOLID	Output of solid phase thermal conductivities		x
THCWATER	Output of water phase thermal conductivities		x
TOPS	Output of grid block top depths	x	x
TRANX	Output of X transmissibilities	x	x
TRANY	Output of Y transmissibilities	x	x
TRANZ	Output of Z transmissibilities	x	x
TRTHERM	Output of thermal transmissibilities	x	
VELFLO	Output of 1/(porosity*area)  Only allowed if velocity or flow output requested via summary mnemonics or restart output	x	
ZCORN	Output of cell corner depths	x	

Table 3.29: RPTGRID output controls

ECLIPSE 100

The coordinate line data ([COORD](#)) and the corner depth data ([ZCORN](#)) can be written out to the [DEBUG](#) file in keyword form, by setting the [COORD](#) and [ZCORN](#) controls greater than 1. This keyword data can be read directly into the program. When used in conjunction with the [BOUNDARY](#) keyword, a grid corresponding to a small portion of the field can easily be generated. Note that block centered grids input using the [DX](#), [DY](#), [DZ](#), [TOPS](#) keywords can also be output in corner point form.

Control	Setting	Definition
COORD control	0	No output
	1	Output to the PRINT file.
	2	COORD keyword written to the DEBUG file in floating point format (F12.2)
	3	COORD keyword written in exponent format (1PE12.6)
ZCORN control	0	No output
	1	Output to the PRINT file.

Control	Setting	Definition
	2	ZCORN keyword written to the DEBUG file in floating point format (F12.2)
	3	ZCORN keyword written in exponent format (1PE12.6)

Table 3.30: RPTGRID COORD and ZCORN control

ECLIPSE 100

Grid-valued output values in certain types of cell have the decimal point replaced with a special character for ease of identification.

Character replacing the decimal point	Meaning
C	Coarsened cell
T	Compressed vertical equilibrium — cell is the top (representative) cell in a column of merged cells
V	Compressed vertical equilibrium — cell is in a column of merged cells but not the top (representative) cell
R	Cell is refined (contains an LGR)
F	In a <a href="#">USEFLUX</a> run using pressure/saturation boundary conditions, flow is specified in this cell
*	Cell contains a well connection

Table 3.31: Output format conventions

## RPTGRIDL GRID section data output for local refined grids

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

RPTGRIDL is used to request output of GRID section data for local grids. The keyword data is the same as for the first 57 mnemonics described in the [RPTGRID](#) keyword, except for the following switches (see also section "RPTGRID - definition with integer controls" in the *ECLIPSE Technical Description*):

### Control/Mnemonic

24 ALLNNC Output of all non-neighbor connections:

1. The local grid non-neighbor connections, and connections between the global and local grids, are written to the Print file.
2. As 1, but the connections between the global and local grids are also written to the Debug file.
3. As 2, but the connections written to the Debug file have the local grids stacked in the z-direction so that they do not overlay one another.

The output to the Debug file is useful when converting an ECLIPSE 100 LGR to a traditional in place refinement.

57 EXTHOST Output host cells for unstructured (PEBI) LGRs.

#### ECLIPSE 300

---

**Note:** The GRID section data will only be output for local refined grids if it is possible to output similar data for global cells (refer to the E300 availability column in the RPTGRID keyword description). It is currently not possible to output GRID section information using this keyword for a parallel run.

---

#### ECLIPSE 100

---

**Note:** COALV and PORVF are not available in a [PARALLEL](#) run.

---

The data entered with keyword RPTGRIDL applies to **all** local grids. The keyword needs only to be specified once. If specified more than once, the last specification applies.

If RPTGRIDL is not used, there will be no GRID section data output for local grids.

Output requested using the keyword RPTGRID applies only to the global grid.

In ECLIPSE 100, grid-valued output values in certain types of cell have the decimal point replaced with a special character for ease of identification. See [3.31](#) for details.

# RPTHMD

## Controls on output to the HMD file

The keyword should be followed some or all of the following integer items, which control the amount of data written to the HMD file (see "Gradient Option" in the *ECLIPSE Technical Description*). Values greater than zero generally reduce the amount of output. The data should be terminated with a slash (/). Repeat counts (for example, 3\*0) can be used if required but with no spaces before or after the asterisk.

Item	Setting	Description
Item 1	If set = 0	Derivatives for all parameters are output.
	If set > 0	No derivatives are output and all derivative calculations are switched off (equivalent to <a href="#">NOHMD</a> ).
	DEFAULT: 0	
Item 2	If set = 0	Derivatives are output at each simulator timestep
	If set > 0	Derivatives will be output only at report times ( <a href="#">RPTONLY</a> )
	DEFAULT: 0	
Item 3	If set = 0	Derivatives will be output for all producers, injectors and any shut or stopped wells.
	If set > 0	Derivatives will only be output for active producers (a producer is active if it is open or stopped, but not shut.)
	DEFAULT: 0	
Item 4	If set = 0	The values of well rates, pressures and so on are written in addition to the derivatives
	If set > 0	The values of well rates, pressures and so on ('VALUES' record in the .HMD file) are not output.
	DEFAULT: 0	
Item 5	If set = 0	The 'VALUES ' and 'DERIVS' records in the .HMD file will be double precision.'
	If set > 0	The 'VALUES ' and 'DERIVS ' records in the .HMD file will be single precision.
	DEFAULT: 0	
Item 6	If set = 0	Group, field and cumulative production gradients may not be requested
	If set > 0	Cumulative gradients (WOPT, WWPT and WGPT for example) may be requested using the <a href="#">GRADWELL</a> keyword.  Group and field gradients (GOPR, GWPR and GGPR for example) may be requested using <a href="#">GRADGRUP</a> keyword.
	DEFAULT: 0	

Table 3.32: RPTHMD item settings

At a restart when [SKIPREST](#) has been read, RPTHMD is then processed while skipping any data up to the restart time, analogously to the [RPTSCHED](#) and [RPTRST](#) keywords.

### Example

Only output derivatives for production wells at report times

	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword can be used to switch on or off the output of gradient information to the HMD file for individual groups (see "Gradient Option" in the *ECLIPSE Technical Description*). This is normally used by the SimOpt program.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Group name.

A well name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record. Field quantities are obtained by specifying 'FIELD' as the group name.

2. Flag to switch the output for the specified group (or groups) on or off in the gradient HMD file.

ON Switch on the output of derivatives for this group if the output has previously been switched off.

OFF Switch off the output of derivatives for this group if the output was previously switched on.

DEFAULT: ON

In order to use any group quantities, the 6<sup>th</sup> switch of the RPTHMG keyword should be set positive.

When item 2 is set to ON, the group gradient quantities written to the HMD file are configured by the GRADGRUP keyword.

If the keyword is entered without any data records (that is followed only by blank record and terminated by a slash) then every group will be output until the flag is reset.

## Examples

## Example 1

```
RPTHMG
'TARBERT'    OFF /
'NESS'       ON  /
'FIELD'      ON  /
/
```

## Example 2

Switch on output for every group

## Configure output of derivatives for wells

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword can be used to switch on or off the output of gradient information to the HMD file for individual wells (see "[Gradient Option](#)" in the *ECLIPSE Technical Description*). This is normally used by the SimOpt program.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Flag to switch the output for the specified well (or wells) on or off in the gradient HMD file.

ON Switch on the output of derivatives for this well if the output has previously been switched off.

OFF Switch off the output of derivatives for this well if the output was previously switched on.

DEFAULT: ON

3. For ECLIPSE 100, this flag switches the RFT gradient output for the specified well (or wells) on or off in the RFT file.

ON Switch on the output of RFT derivatives for this well if the output has previously been switched off.

OFF Switch off the output of RFT derivatives for this well if the output was previously switched on.

DEFAULT: OFF

The third item requesting RFT gradients is not available in ECLIPSE 300.

Note that any actions specified in the [RPTHMD](#) keyword take priority over those specified using RPTHMW. Thus, for example, if output for injection wells is switched off by item 3 in RPTHMD, then any action in RPTHMW will be ignored for injection wells.

When item 2 is set to ON, the well gradient quantities written to the HMD file are configured by the [GRADWELL](#) keyword.

When item 3 is set to ON, the connection gradient quantities written to the RFT file are configured by the [GRADRFT](#) keyword.

If the keyword is entered without any data records (that is followed only by blank record and terminated by a slash) then every well will be output until the flag is reset.

## Examples

## Controls on output from GRID and EDIT sections to INIT file

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by a string of mnemonics to request output of GRID and EDIT data to the .INIT (or .FINIT) file. The appropriate keywords used to input some GRID and EDIT data, such as DX and DY, may be used as mnemonics. Aliases may be used; for example DR may be used in place of DX and DTHETA may be used in place of DY.

By default, some arrays will always be output depending on the model definition. For instance, to name a few examples, the minimum cell rock volume (MINRVV) will always be output for a [THERMAL](#) run; FLUXNUM, MULTNUM and OPERNUM will always be output if this information is present in the dataset.

The data should be terminated by a slash (/).

When the keyword is specified along with a series of mnemonics, only PORV and the mnemonics specified will be output to the .INIT or .FINIT file. This has been extended to include Cartesian LGRs, radial LGRs and nested LGRs.

The following table lists the mnemonics available. The mnemonics available for each simulator are identified by an x in the appropriate column.

Mnemonic	Output	E100	E300
AREAX	Output of X direction Area (Velocity dependent flow option; Velocity dependent relative permeabilities (E300))	x	x
AREAY	Output of Y direction Area (Velocity dependent flow option; Velocity dependent relative permeabilities (E300))	x	x
AREAZ	Output of Z direction Area (Velocity dependent flow option; Velocity dependent relative permeabilities (E300))	x	x
BTOBALFV	Output of Dual Porosity block-to-block matrix-fracture coupling multiplier	x	
COALV	Output of grid block coal volumes (Coal Bed Methane)	x	x
DEPTH	Output of grid block center depths	x	x
DIFFX	Output of X direction diffusivities	x	x
DIFFY	Output of Y direction diffusivities	x	x
DIFFZ	Output of Z direction diffusivities	x	x
DIFFMX	Output of X direction diffusivity multipliers	x	x
DIFFMY	Output of Y direction diffusivity multipliers	x	x
DIFFMZ	Output of Z direction diffusivity multipliers	x	x
DIFFMMF	Output of Matrix/Fracture diffusivity multipliers	x	
DIFFMX-	Output of X- direction diffusivity multipliers	x	x

Mnemonic	Output	E100	E300
DIFFMY-	Output of Y- direction diffusivity multipliers	x	x
DIFFMZ-	Output of Z- direction diffusivity multipliers	x	x
DR	Output of R direction grid block sizes	x	x
DTHETA	Output of THETA direction grid block sizes	x	x
DX	Output of X direction grid block sizes	x	x
DY	Output of Y direction grid block sizes	x	x
DZ	Output of Z direction grid block sizes	x	x
DZMTRXV DZMATRIX DZMTRXV	Output of $D_{zmtx}$ values	x	
DZNET	Output of net DZ values		x
FRACTURE	Output of fracture propagation data (fracture modeling only)	x	
HEATCR	Output of rock heat capacity		x
HEATCRT	Output of temperature dependence of the rock heat capacity		x
HEATTX	Output of X direction Thermal transmissibilities		x
HEATTY	Output of Y direction Thermal transmissibilities		x
HEATZ	Output of Z direction Thermal transmissibilities		x
IONROCK	Rock ion exchange capacity	x	
LX	Output of matrix block size in X direction (Viscous Displacement Option)	x	
LY	Output of matrix block size in Y direction (Viscous Displacement Option)	x	
LZ	Output of matrix block size in Z direction (Viscous Displacement Option)	x	
MIDS	Output of midpoint depths		x
MINPVV	Output of cells with pore volume less than the input minimum values	x	x
MULTPV	Output of the pore volume multipliers	x	x
MULTX	Output of X direction transmissibility multipliers	x	x
MULTY	Output of Y direction transmissibility multipliers	x	x
MULTZ	Output of Z direction transmissibility multipliers	x	x
MULTX-	Output of X- direction transmissibility multipliers	x	x
MULTY-	Output of Y- direction transmissibility multipliers	x	x
MULTZ-	Output of Z- direction transmissibility multipliers	x	x
NTG	Output of grid block net-to-gross ratios	x	x
PERMX	Output of X direction permeabilities	x	x
PERMY	Output of Y direction permeabilities	x	x

Mnemonic	Output	E100	E300
PERMZ	Output of Z direction permeabilities	x	x
PORO	Output of grid block porosities	x	x
PORV	Output of grid block pore volumes	x	x
PORVF	Output of grid block fluid pore volumes (Coal Bed Methane option)	x	x
ROCKFRAC	Output of grid block rock volume fractions (Coal Bed Methane option)	x	x
ROCKDEN	Output of rock density		x
ROCKV	Output of rock volumes		x
SIGMAGDV	Output of SIGMAGD values (gravity drainage option)	x	
SIGMAV	Output of Sigma values	x	
SIGMA*K	Output of the processed $\frac{f_x \cdot K_x}{l_x^2} + \frac{f_y \cdot K_y}{l_y^2} + \frac{f_z \cdot K_z}{l_z^2}$ term for the matrix-fracture transmissibility in dual porosity runs, if item 5 of the LTOSIGMA keyword is set to ALL.	x	
THCGAS	Output of Thermal conductivity for gas phase		x
THCOIL	Output of Thermal conductivity for oil phase		x
THCONR	Output of thermal rock and fluid conductivities (For ECLIPSE 300 only, this header will be renamed THCAVE, similar to RPTGRID keyword)	x	x
THCONSF	Output saturation dependence of conductivity		x
THCSOLID	Output of Thermal conductivity for solid phase		x
THCWATER	Output of Thermal conductivity for water phase		x
TOPS	Output of grid block top depths	x	x
TRANX	Output of X direction transmissibilities	x	x
TRANX	Output of Y direction transmissibilities	x	x
TRANZ	Output of Z direction transmissibilities	x	x

## RPTISOL

## Generates a grid array of isolated reservoir numbers

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword requests ECLIPSE to generate a grid array of isolated reservoir region numbers, which it outputs to the Debug file. The array can then be extracted and included in the input data file under the keyword `ISOLNUM`, to activate the efficient solution technique for independent reservoir regions (see "[Independent reservoir regions](#)" in the *ECLIPSE Technical Description*).

ECLIPSE determines the extent of each region of the reservoir (if any) that is isolated from the rest of the grid by examining the flow connections between grid blocks (normal transmissibility, non-neighbor connections, and multiply connected wells). If the model contains more than one independent reservoir region, it may be solved more efficiently by activating the Independent Reservoir Regions facility with the keyword `ISOLNUM`.

The RPTISOL keyword has no associated data.

### Example

```
RPTISOL
```

## RPTONLY

## Limits the frequency of summary output

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
x	SUMMARY
x	SCHEDULE

This keyword requests that summary data be written to the Summary file only at report times. The default, if the RPTONLY keyword is not present (and it was not requested in a restart file), is to write the summary information at every timestep.

As RPTONLY is available in the SCHEDULE section, the setting can change during the simulation. The setting from a base run will be preserved in a restart run. To change the setting in a restart run, the RPTONLY (or RPTONLYO) keyword must be specified at or after the restart time. Any RPTONLY (or RPTONLYO) keywords in the SUMMARY section, or in the SCHEDULE section before the restart time, will be ignored in a restart run.

This facility can be useful when the size of the Summary files is important, for example when ECLIPSE is run at a remote site and the Summary files are transferred via a slow line. This restriction on the output can be turned off by using the RPTONLYO keyword.

The RPTONLY keyword has no associated data.

## Example

```
RPTONLY
```

## RPTONLYO Turns off RPTONLY restricted summary output

	EDIT
	PROPS
	REGIONS
	SOLUTION
x	SUMMARY
x	SCHEDULE

This keyword requests that summary data be written to the Summary file at every timestep. This is the default situation unless overridden in a restart file. This keyword need, therefore, only be used when [RPTONLY](#) has previously been used and it is wished to turn off this behavior later in the run.

As RPTONLYO is available in the [SCHEDULE](#) section, the setting can change during the simulation. The setting from a base run will be preserved in a restart run. To change the setting in a restart run, the RPTONLYO (or RPTONLY) keyword must be specified at or after the restart time. Any RPTONLYO (or RPTONLY) keywords in the [SUMMARY](#) section, or in the [SCHEDULE](#) section before the restart time, will be ignored in a restart run.

This facility can be useful when the size of the Summary files is important but more detail is needed at certain times.

The RPTONLYO keyword has no associated data.

### Example

```
RPTONLYO
```

## RPTOPT

## Optimization reporting options

	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE
x	OPTIMIZE

This keyword is used to request the detail of reporting from the reservoir optimization option. The presence of this keyword is entirely optional.

The keyword is followed by a list of mnemonics terminated by a slash (/).

Available mnemonics are summarized in the table.

Mnemonic	Output
SEPARATE	Output separate summary and restart files for each optimization iteration. These have the form BASE_01.xxx, BASE_02.xxx, and so on where BASE.DATA is the base dataset, and _01,_02, ... label the optimization iteration.
CLRFILES	Removes SEPARATE results files from any previous optimization for this model <i>if necessary</i> (that is, if the current optimization is about to overwrite some or all of them).  The current optimization will be considered about to overwrite previous optimization results files if it produces separate results files (so the SEPARATE mnemonic must be currently selected) with a formatted and unified status that matches those of a previous optimization.  This removal is useful in the situation where the current optimization takes fewer iterations than the previous optimization, but the presence of the old additional iteration results files leads to misleading interpretations of the results (for example, when plotting all the iterations results in ECLIPSE Office).

Table 3.34: RPTOPT output controls

## Example

```
RPTOPT
-- Output separate summary and restart files for each
-- optimization iteration, and clear previous results files
'SEPARATE' 'CLRFILES' /
```

## RPTPRINT

## Control printed simulation reports

	ECLIPSE 100

	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword controls the output of printed reports. It has the following integer data items, each of which controls a printed report. It may be specified any number of times in the SCHEDULE section.

1. Report step summary.  
DEFAULT: 1
2. Report fluid in place for field.  
If this is set to 2 or greater, when used in combination with item 3 or 11 or 12, reports the values for the additional set of fluid-in-place regions apart from the standard set.  
DEFAULT: 1
3. Report fluid in place by region.  
If this is set to 2 or greater, the fluid in place by region will include a separate flash of reservoir oil and reservoir gas to stock tank conditions.  
To report values for additional set of fluid-in -place regions, item 2 of this keyword need to be set to 2 and the value of this item to be set to 1 or 2 as desired.  
DEFAULT: 1
4. Report status of groups.  
DEFAULT: 1
5. Not used at present
6. Report status of wells.  
DEFAULT: 1
7. Report status of well completions.  
DEFAULT: 1
8. Report solution data, as specified by mnemonics in [RPTSCHED](#).  
DEFAULT: 1
9. Report convergence of non-linear equations.  
DEFAULT: 0
10. Report well potentials.  
DEFAULT: 0
11. Report inter-region flows.  
To report values for additional set of fluid-in -place regions, item 2 of this keyword need to be set to 2 and value of this item to be set to 1.  
DEFAULT: 0
12. Report component flows.  
To report values for additional set of fluid-in -place regions, item 2 of this keyword need to be set to 2 and value of this item to be set to 1.

DEFAULT: 0

13. Report aquifer flows.

DEFAULT: 0

14. Report heater connections in the Thermal option.

DEFAULT: 0

15. Reserved for use by FrontSim.

16. Reserved for use by FrontSim.

17. Reserved for use by FrontSim.

18. Report status of network

DEFAULT: 1

Each item may be set to 0 (or a negative number), to turn off the appropriate type of report, or to 1 (or a positive number), to turn it on. RPTSCHED in ECLIPSE 300 is a method of specifying which solution arrays (PRESSURE, SWAT, SGAS and VOIL for example) are to be printed out under the control of the item in RPTPRINT.

## Example

Request step summary, fluid in place reports, region fluid in place reports, group and well reports, and output of the solution arrays specified by mnemonics with RPTSCHED. Well completion reports, convergence reports and well potentials turned off.

```
RPTPRINT  
1 1 1 1 0 1 0 1 0 0 /
```

## RPTPROPS Controls on output from PROPS section

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by a list of mnemonics which control the output of PROPS section data to the Print file.

The list should be terminated by a slash (/).

In ECLIPSE 100

- Entering the mnemonic NOTHING clears all the reporting flags.
- For additional control over the output, integer values greater than one may be assigned to selected mnemonics using the syntax:

mnemonic=integer

where there must be no spaces either side of the equals sign.

Older ECLIPSE 100 data sets may not use mnemonics but integer controls. The meaning of these is documented in "RPTPROPS" in the *ECLIPSE Technical Description*.

The following table lists the mnemonics available. Mnemonics available in each simulator are identified by an x in the respective column.

Mnemonic	Output	E100	E300
ALSURFST	Outputs table of water-oil surface tension multipliers as a function of alkaline concentration		x
AQUTAB	Outputs the Carter-Tracy influence tables	x	
DENSITY, GRAVITY, SDENSITY, BDENSITY	Output of surface densities/gravities	x x x	x x x
DIFFC or DIFFCOAL	Output of the diffusion data	x	
DIFFCBM	Output of diffusion data (Coal Bed Methane)		x
DETAILVD	Output of the DETAILVD tables		x
ENDPT	Output of endpoint scaling values	x	
ENDPTVD	Output of endpoint versus depth tables		x
EPSODD3P	Output of end-point scaling control table for the ODD3P option		x
ESPNOE	Output of effective salinity nodes for Polymer Flood Model		x
ESSNOE	Output of effective salinity nodes for Surfactant Model		x
FHERCHBL	Output of Herschel-Bulkley data (fracture modeling only)	x	
FOAM	Output of the foam properties	x	
FRACMOVE	Output of fracture propagation (fracture modeling only)	x	
GINODE	Output of Gi-model saturated fluid properties	x	
HSGRO	Output of hysteresis gas residual end-point saturation for gas-oil system for the ODD3P option		x

Mnemonic	Output	E100	E300
HSGRW	Output of hysteresis gas residual end-point saturation for gas-water system for the ODD3P option		x
HSORG	Output of hysteresis oil residual end-point saturation for oil-gas system for the ODD3P option		x
HSORW	Output of hysteresis oil residual end-point saturation for oil-water system for the ODD3P option		x
HSWRG	Output of hysteresis water residual end-point saturation for water-gas system for the ODD3P option		x
HSWRO	Output of hysteresis water residual end-point saturation for water-oil system for the ODD3P option		x
IKRWH	Output of water relative permeabilities at maximum water saturation for WAG hysteresis three-phase water relative permeabilities when end-point scaling has been specified.	x	x
IKRWRH	Output of water relative permeabilities at residual oil for WAG hysteresis three-phase water relative permeabilities when end-point scaling has been specified.	x	x
KRG	Output of maximum gas relative permeabilities	x	x
KRGR	Output of gas relative permeabilities at residual	x	x
KRO	Output of maximum oil relative permeability		x
KROR	Output of oil relative permeabilities at residual		x
KRW	Output of maximum water relative permeabilities	x	x
KRWH	Output of water relative permeabilities at maximum water saturation for WAG hysteresis two-phase water relative permeabilities when end-point scaling has been specified.	x	x
KRWR	Output of water relative permeabilities at residual	x	x
KRWRH	Output of water relative permeabilities at residual oil for WAG hysteresis two-phase water relative permeabilities when end-point scaling has been specified.	x	x
LANGMEXT	Output of the extended Langmuir Isotherms data		x
LANGMPL	Output of the pressure scaling factor for the adsorption capacity for each grid cell.	x	x
LANGMULT	Output of the Langmuir multipliers		x
LANGMUIR, LANGSOLV, COALADS	Output of the Langmuir Isotherms	x	
LEAKOFF	Output of fracture fluid loss (fracture modeling only)	x	
MLANG	Output of the maximum surface gas concentration	x	
MLANGSLV	Output of the maximum surface solvent concentration	x	
MISC, PMISC	Output of the miscibility function and the pressure miscibility function	x	
OVERBURD	Overburden pressure data		x

Mnemonic	Output	E100	E300
PCG	Output of scaled maximum gas capillary pressures (provided data is supplied via the <a href="#">PCG</a> keyword), or the scaling factor for the <a href="#">JFUNC</a> keyword	x	x
PCODD3P	Output of capillary pressure calculation selection tables for the ODD3P option		x
PCODD3PG	Output of capillary pressure calculation gas saturation function for the ODD3P option		x
PCODD3PW	Output of capillary pressure calculation water saturation function for the ODD3P option		x
PCW	Output of scaled maximum water capillary pressures (provided data is supplied via the <a href="#">PCW</a> keyword), or the scaling factor for the <a href="#">JFUNC</a> keyword	x	x
PLYADS, PLYMAX, PLYROCK, PLYSHEAR, PLYDHFLF, PLYVISC, PLYVISCs, PLYVISCT, PLYVSCST, SALTNODE, TEMPNODE, PLMIXPAR	Output of Polymer Flood Model properties.  If the control is set to 2 for a mnemonic starting PL, the output includes values for the grid-valued keywords <a href="#">PLYKRRF</a> , <a href="#">PLYRMDEN</a> and <a href="#">PLYCAMAX</a> .	x	
PLYVISC	Output of water phase viscosity multipliers supplied by the <a href="#">PLYVISC</a> keyword		x
PLYVISCs	Output of water phase viscosity multipliers supplied by the <a href="#">PLYVISCs</a> keyword		x
PSGRO	Output of primary gas residual end-point saturation for gas-oil system for the <a href="#">ODD3P</a> option		x
PSGRW	Output of primary gas residual end-point saturation for gas-water system for the <a href="#">ODD3P</a> option		x
PSORG	Output of primary oil residual end-point saturation for oil-gas system for the <a href="#">ODD3P</a> option		x
PSORW	Output of primary oil residual end-point saturation for oil-water system for the <a href="#">ODD3P</a> option		x
PSWRG	Output of primary water residual end-point saturation for water-gas system for the <a href="#">ODD3P</a> option		x
PSWRO	Output of primary water residual end-point saturation for water-oil system for the <a href="#">ODD3P</a> option		x
PVDG, PVTG	Output of gas PVT tables	x	
PVDO, PVTO	Output of oil PVT tables	x	x
PVDS	Output of Solvent PVT properties	x	

Mnemonic	Output	E100	E300
PVTW	Output of water PVT tables	x	x
PVTWSALT	Output of brine properties	x	x
ROCK	Output of rock properties	x	
ROCKTAB	Output of rock properties	x	x
ROCKTABH	Output of rock properties (Hysteretic option only)	x	x
SGCR	Output of scaled critical gas saturations	x	x
SGFN	Output of gas saturation tables	x	x
SGF3	Output of gas saturation tables for the <a href="#">IKU3P</a> and <a href="#">ODD3P</a> options. Output of three-phase gas relative permeability table for the <a href="#">IKU3P</a> option.		x
SGL	Output of scaled connate gas saturations	x	x
SGU	Output of scaled maximum gas saturations	x	x
SOF2, SOF3, TLMIXPAR, SORWMIS	Output of oil saturation tables, three-phase relative permeability tables, Todd-Longstaff mixing parameter, Miscible residual oil saturation tables.  If control is set = 2, the output includes a print of the residual oil saturation as a function of water and gas saturations.	x	x
SOGCR	Output of scaled critical oil-in-gas saturations	x	x
SOWCR	Output of scaled critical oil-in-water saturations	x	x
SOLU	Output of aqueous phase property data ( <a href="#">CO2SOL</a> and <a href="#">GASSOL</a> options)		x
SPECHEAT, VISCVT	Output of the temperature-dependent properties.	x	
SSFN	Output of Solvent/Gas relative permeabilities.	x	
STOG, STOW	Output of Surface Tension properties.	x	
STONE1EX	Output of Stone 1 exponent values.	x	x
SURF	Output of surfactant properties including: surfactant solution viscosities (SURFVISC), adsorption (SURFADS), water-oil surface tension (SURFST or SURFSTES), surfactant capillary de-saturation functions (SURFCAPD), adsorbed surfactant concentration vs fractional saturation functions (SURFADDW), surfactant rock properties (SURFROCK) and salinity nodes (ESSNODE).	x	
SURFSTES	Outputs table of water-oil surface tension as function of surfactant concentration and effective salinity		x
SWCR	Output of scaled critical water saturations.	x	x
SWFN	Output of water saturation tables.	x	x
SWF3	Output of water saturation tables for the <a href="#">IKU3P</a> and <a href="#">ODD3P</a> options. Output of three-phase water relative permeability table for the <a href="#">IKU3P</a> option.		x
SWL	Output of scaled connate water saturations.	x	x

Mnemonic	Output	E100	E300
SWU	Output of scaled maximum water saturation.	x	x
TRACER	Output of passive fluid tracer names.	x	
TRADS, TRDCY, TRROCK	Output of environmental tracer properties.	x	
VDKRG	Velocity dependent relative permeability data for gas.		x
VDKRO	Velocity dependent relative permeability data for oil.		x
VEFRACV, VEFRAC	Output of Vefrac values.	x	

Table 3.35: RPTPROPS output controls

- ECLIPSE 100** If a value equal to 5 is used for any (or all) of SOF3, SWFN or SGFN, the saturation tables are printed at saturation interval of 5 percent. These values are printed in addition to the user-specified values and are calculated using the user-specified values. Similarly, if a value equal to 5 is used for the fourth, the fifth and the sixth control, the PVT tables are printed at a pressure interval of 200 psi (FIELD), 10 bars (METRIC) or 10 atm (LAB). As before, these values are printed in addition to the user-specified values.
- ECLIPSE 100** If the PVTO table output option is specified, the interpolated versions of the tables will also be printed if API tracking has been selected.
- ECLIPSE 100** For models, for which end-point scaling has been specified, if the **LOWSALT** option has been specified, the low salinity (oil-wet) end-points, for example, **LSWL**, can selected for reporting. Similarly, if the **SURFACTW** option has been specified, the (high salinity) water-wet end-points, for example, **HWSWL**, can selected for reporting. If both of these options have been specified, the low salinity water-wet end-points, for example, **LWSWL** may also be selected for reporting.
- ECLIPSE 300** If directional end point scaling is active via the **DIRECT** and **IRREVERS** items of the **ENDSCALE** keyword, then each of the preceding set of mnemonics (except for the capillary pressure mnemonics **PCG** and **PCW**) can be followed by either X, Y or Z (for the **DIRECT** option) and X-, Y- or Z- (if the **IRREVERS** option is active), for example **KRGRZ-**.
- ECLIPSE 100** Grid-valued output values in certain types of cell have the decimal point replaced with a special character for ease of identification. See Table 3.31 for details.

## Examples

# RPTREGS Controls on output from REGIONS section

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by a list of mnemonics which control the output of REGIONS section data to the Print file.

The list should be terminated by a slash (/).

In ECLIPSE 100

- Entering the mnemonic NOTHING clears all the reporting flags.
- For additional control over the output, integer values greater than one may be assigned to selected mnemonics using the syntax:

mnemonic=integer

where there must be no spaces either side of the equals sign.

- Optionally, for back compatibility, a list of integers (terminated with a slash) may be used to indicate the required output. A value less than or equal to zero switches off the corresponding output. Values greater than zero switch the output on. Repeat counts (for example 3\*0) can be used if required (with no spaces before or after the asterisk). If fewer than 26 integers are read, the remainder are left unchanged. The integer list cannot be mixed with mnemonics.

The following table lists the mnemonics available, and also their equivalent integers for the ECLIPSE 100 integer lists. Mnemonics without an integer in the E100 column are not available in ECLIPSE 100. Mnemonics available in ECLIPSE 300 are identified by an x in the E300 column

The following table lists the mnemonics available, and also their equivalent integers for the ECLIPSE 100 integer lists. Mnemonics without an integer in the E100 column are not available in ECLIPSE 100. Mnemonics available in ECLIPSE 300 are identified by an x in the E300 column.

Mnemonic	Output	E100 Integer Control	E300
ALPHANUM	Output of ALPHA region numbers		x
DSTNUM	Output of tertiary hysteresis saturation region numbers for the <a href="#">ODD3P</a> option		x
ENDNUM	Output of endpoint v depth region numbers	19	x
EOSNUM	Output of equation of state region numbers		x
EQLNUM	Output of equilibration region numbers	3	x
FIPNUM	Output of fluid in place region numbers	4	x
FIPOWG	Output original oil, water and gas zones	28	
FRACNUM	Output of fracture region numbers (fracture modeling only)	31	
HMxxxxxx	Output of gradient parameter regions when the Gradient Option is in use.  (If set >1, the parameter regions will be written to the Initial file when the INIT keyword is specified, this only applies to ECLIPSE 100).	25	x
HWSNUM	Output of (high salinity) water-wet saturation region numbers when the <a href="#">SURFACTW</a> option has been specified. This keyword is an alias for the <a href="#">SURFNUM</a> keyword.	x	

Mnemonic	Output	E100 Integer Control	E300
IMBNUM	Output of imbibition region numbers	11	x
IMBNUMMF	Output of matrix/fracture imbibition regions	23	
IMBNUMX	Output of X direction imbibition region numbers	12	x
IMBNUMX-	Output of -X direction imbibition region numbers	13	x
IMBNUMY	Output of Y direction imbibition region numbers	14	x
IMBNUMY-	Output of -Y direction imbibition region numbers	15	x
IMBNUMZ	Output of Z direction imbibition region numbers	16	x
IMBNUMZ-	Output of -Z direction imbibition region numbers	17	x
ISTNUM	Output of secondary hysteresis saturation region numbers for the ODD3P option		
LSNUM	Output of low salinity (oil-wet) saturation region numbers when the LOWSALT option has been specified. This keyword is an alias for the LWSLTNUM keyword.	x	
LWSLTNUM	Output of low salinity (oil-wet) saturation region numbers when the LOWSALT option has been specified. This keyword is an alias for the LSNUM keyword.	x	
LWSNUM	Output of low salinity water-wet saturation region numbers when the SURFACTW and the LOWSALT options have been specified. This keyword is an alias for the LSLTWNUM keyword.	x	
LSLTWNUM	Output of low salinity water-wet saturation region numbers when the SURFACTW and the LOWSALT options have been specified. This keyword is an alias for the LWSNUM keyword.	x	
KRNUMMF	Output of matrix/fracture saturation regions	22	
KRNUMX	Output of X direction $K_r$ region numbers	5	x
KRNUMX-	Output of -X direction $K_r$ region numbers	6	x
KRNUMY	Output of Y direction $K_r$ region numbers	7	x
KRNUMY-	Output of -Y direction $K_r$ region numbers	8	x
KRNUMZ	Output of Z direction $K_r$ region numbers	9	x
KRNUMZ-	Output of -Z direction $K_r$ region numbers	10	x
MISCNUM	Output of miscibility region numbers	21	x
PMANUM	Pressure maintenance region numbers		x
PSTNUM	Output of primary saturation region numbers for the ODD3P option		x
PVTNUM	Output of PVT region numbers	1	x
RESIDNUM	Output of VE residual flow region numbers	26	
ROCKNUM	Output of Rock Compaction region numbers	18	x
SATNUM	Output of saturation region numbers	2	x

Mnemonic	Output	E100 Integer Control	E300
SDRGO	Output of gas phase saturation direction indicators for gas-oil system for the ODD3P option		x
SDRGW	Output of gas phase saturation direction indicators for gas-water system for the ODD3P option		x
SDROG	Output of oil phase saturation direction indicators for oil-gas system for the ODD3P option		x
SDROW	Output of oil phase saturation direction indicators for oil-water system for the ODD3P option		x
SDRWG	Output of water phase saturation direction indicators for water-gas system for the ODD3P option		x
SDRWO	Output of water phase saturation direction indicators for water-oil system for the ODD3P option		x
SURFNUM	Output of the surfactant saturation regions	24	
SURFWNUM	Output of (high salinity) water-wet saturation region numbers when the SURFACTW option has been specified. This keyword is an alias for the HWSNUM keyword.	27	
WH2NUM	Output of two-phase water relative permeability saturation region numbers for the WAGHYSTR option.	x	x
WH3NUM	Output of three-phase water relative permeability saturation region numbers for the WAGHYSTR option.	x	x
TNUM	Output of tracer versus depth region numbers	20	
TRACKREG	Output of enhanced TRACK region numbers		x

Table 3.36: RPTREGS output controls

**Note:** For ECLIPSE 100, LWSLTNUM and its alias LSNUM, SURFWNUM and its alias HWSNUM, and LSLTWNUM and its alias LWSNUM are interchangeable, with the latter having been introduced to provide a closer correspondence between the saturation region names and the associated end-point scaling array names. The title provided in the PRT file will correspond with whichever name is entered; if both names are entered, the title will be determined by the later of the two names in the list.

## Controls on output to the RESTART file

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword should be followed by a list of mnemonics which control the output of data to the Restart file. The list should be terminated by a slash (/). Note that no restart files will be written if no RPTRST input keywords or mnemonics are specified.

For additional control over the output, integer values greater than one may be assigned to selected mnemonics using the syntax:

mnemonic=integer

where there must be no spaces either side of the equals sign.

---

**Note:** Older ECLIPSE 100 data sets may not use mnemonics but integer controls. The meaning of these is documented in "RPTRST" in the *ECLIPSE Technical Description*.

---

---

**Note:** Cannot be used in the SOLUTION section for ECLIPSE 100 parallel fast restart runs. It must instead be placed at the start of the SCHEDULE section.

---

ECLIPSE 100

Output to the Restart file for ECLIPSE 100 may also be controlled by using the mnemonic RESTART in the RPTSCHED and RPTSOL keywords. However, RPTRST allows greater flexibility when specifying extra data to be written to the Restart file. If the BASIC mnemonic of RPTRST is set to 1 or 2, subsequent use of RPTSCHED overrides the output frequency. However, if BASIC is set to 3 or more, any value of the mnemonic RESTART in RPTSCHED is ignored.

ECLIPSE 300

The RESTART mnemonic writes a record from which ECLIPSE 300 can be restarted, using the RESTART keyword in the SOLUTION section.

ECLIPSE 300

For back compatibility with the old OUTSOL keyword if no BASIC or RESTART keyword is specified the input quantities are output at every report step until reset.

ECLIPSE 300

If this keyword is placed in the SOLUTION section of a flexible restart case, the first record (time=restart time) cannot be used to restart ECLIPSE 300. If a restart is required for this time a Restart file from the original base case should be used.

---

**Note:** Although the old OUTSOL keyword is superseded, it is still recognized for back compatibility. If a data set contains both OUTSOL and RPTRST, the later one will determine the output to the Restart file.

---

The following table lists the mnemonics available.

Mnemonic	Output	E100	E300
ACIP	Output pressure-wave impedance (Petro-elastic Model only): this produces an array with the name ACOUIMPP  If you request this item, you must also request the DEN item.  These values are only output on the global grid cells (that is, not on local grid refinement cells).	x	

Mnemonic	Output	E100	E300
ACIS	Output shear-wave impedance (Petro-elastic Model only): this produces an array with the name ACOUIMPS  If you request this item, you must also request the DEN item.  These values are only output on the global grid cells (that is, not on local grid refinement cells).	x	
AIM	Output AIM status array (1 for explicit cells; 2 for implicit cells)		x
ALSURF	Output alkaline concentration when surfactant and alkaline models are activated.		x
ALSTML	Output alkaline surface tension multiplier when surfactant and alkaline models are activated.		x
ALLPROPS	Requests output of the data required by some programs that can interface with ECLIPSE. The output includes fluid densities (OIL_DEN, GAS_DEN and WAT_DEN), viscosities (OIL_VISC, GAS_VISC and WAT_VISC), reciprocal formation volume factors (1OVERBO, 1OVERBG and 1OVERBW) and phase relative permeabilities (OILKR, GASKR and WATKR).  If set =2 the old output mnemonic names (for example 1 / FVFOIL instead of 1OVERBO) are used.	x	
AMF	Output of aqueous mole fractions (CO2SOL, GASSOL, THERMAL options KWTABTn / CO2STORE and the COMPW option)		x
AQSP	Output of aqueous speciation (CO2STORE option)		x
AQPH	Output of aqueous pH level (CO2STORE option)		x
AREAC	Asphaltene reaction rates		x
ASPADS	Asphaltene cumulative adsorption volume fraction (pre-2011.1 model only)		x
ASPDOT	Asphaltene net cumulative volume fraction deposit (pre-2011.1 model only)		x
ASPENT	Asphaltene instantaneous entrainment volume fraction (pre-2011.1 model only)		x
ASPFLO	Oil velocities (useful to check the asphaltene entrainment) (Asphaltene pre-2011.1 model only)		x
ASPFLT	Average oil flow rate at the previous timestep (Asphaltene 2011.1 model only)		x
ASPFRD	Asphaltene precipitate fraction dissolved		x
ASPKDM	Asphaltene permeability multiplier (damage) (Asphaltene pre-2011.1 model only)		x
ASPLIM	Asphaltene precipitate fraction limit		x
ASPLUG	Asphaltene instantaneous plugging volume fraction (Asphaltene pre-2011.1 model only)		x
ASPRET	Asphaltene precipitate fraction (including flocs)		x

Mnemonic	Output	E100	E300
ASPREW	Asphaltene precipitate fraction (no flocs)		x
ASPVEL	Average oil velocity at the previous timestep (Asphaltene 2011.1 model only)		x
ASPVOM	Asphaltene relative oil viscosity multiplier		x
BASIC	<p>Output of basic Restart files</p> <ul style="list-style-type: none"> <li>If set to 1, restart files are created at every report time, but if the files are not unified, only the last one in the run is kept (designed for fail-safe restarts).</li> <li>If set to 2, restart files are created at every report time until this switch is reset, and all are kept.</li> <li>If set to 3, restart files are created every <math>n^{\text{th}}</math> report time. The frequency of the restarts is governed by the mnemonic "FREQ=<math>n</math>".</li> <li>If set to 4, a Restart file is written at the first report step of each year. Optionally, if the mnemonic FREQ is set <math>&gt;1</math> the restart is written only every <math>n^{\text{th}}</math> year.</li> <li>If set to 5, a Restart file is written at the first report step of each month. Optionally, if the mnemonic FREQ is set <math>&gt;1</math> the restart is written only every <math>n^{\text{th}}</math> month.</li> <li>If set to 6, a Restart file is written at every timestep.</li> </ul> <p><b>Notes:</b></p> <p>If the BASIC=6 mnemonic is used in a base run to generate save or restart information, then it is the timestep number that needs to be specified in item 2 of the <b>LOAD</b> or <b>RESTART</b> keyword when specifying which report step should be restarted from in a fast or flexible restart run using that base run's restart information. This timestep number can be obtained from the print file of the base run.</p> <p>ECLIPSE 300 assumes the case 'BASIC = 2' if the keyword BASIC is used. To subsequently turn off Restarts, use 'BASIC=0'.</p> <p>Value 1 is not available with ECLIPSE 300.</p>	x	x
BFORO	<p>Output of oil Forchheimer B-Factor / phase potential difference (as described in <a href="#">Construction of flows</a> in the <i>ECLIPSE Technical Description</i>). This is only output if VDFLOW, VDFLOWR or VELDEP has been used to activate a non-Darcy flow model.</p> <p>Note that this is not the Forchheimer beta parameter.</p>		x
BG	Gas formation volume factor	x	x
BGAS	Output of gas reservoir molar densities		x
BIOTCTAB	Geomechanics: outputs Biot's constant multipliers (stress dependence)		x
BO	Oil formation volume factor	x	x
BOIL	Output of oil reservoir molar densities		x

Mnemonic	Output	E100	E300
BSOL	Output of solid reservoir molar densities ( <a href="#">SOLID</a> option)		x
BTFORG	Output gas Forchheimer beta parameter		x
BTFORO	Output oil Forchheimer beta parameter		x
BW	Water formation volume factor	x	x
BWAT	Output of water reservoir molar densities		x
CELLINDX	Output the cell indices corresponding to the other output properties. If any cells are missing due to inactivity this allows determination of which cells properties are actually present in the restart file without the need for information in the INIT file. <ul style="list-style-type: none"> <li>The numbering on the global grid is from 1 to NX*NY*NZ, with the numbering cycling fastest in the X, then Y, then Z directions.</li> <li>The numbering on each local grid is from 1 to LX*LY*LZ, with the numbering cycling fastest in the X, then Y, then Z directions.</li> </ul>	x	x
CFL	Outputs CFL numbers (see <a href="#">CFLLIMIT</a> keyword)		x
CGAS	Output of grid-block adsorbed gas concentration (for the Coal Bed Methane option)		x
COHESION	Geomechanics: outputs cohesion (plasticity)		x
COLR	Output color of sub-grids (see " <a href="#">The ECLIPSE 300 WARP linear solver</a> " in the of the <i>ECLIPSE Technical Description</i> )		x
COILR	Residual oil compressibility ( <a href="#">SOR</a> option)		x
COMPRESS	Requests output of the well connection data on a well by well basis to make the Restart file smaller. This can be useful when a model has large numbers of wells, with just a few wells having a large number of connections.	x	
CONV	Output of cells which are causing convergence problems. Setting CONV =n focuses on the n worst cells. By default, n=1 (E100) and n=10 (E300). <b>Note:</b> ECLIPSE 100 outputs various convergence problem indicators as described in " <a href="#">Output of cells with convergence problems</a> " in the <i>ECLIPSE Technical Description</i> . ECLIPSE 300 outputs various convergence problem indicators as described in " <a href="#">Output of cells with convergence problems</a> " in the <i>ECLIPSE Technical Description</i> .	x	x
DEN	Output of phase reservoir densities	x	
DENG	Output of gas mass densities at reservoir conditions		x
DENO	Output of oil mass densities at reservoir conditions		x
DENS	Output of solid mass densities ( <a href="#">SOLID</a> option) at reservoir conditions		x
DEFFSTRS	Delta effective stresses = change from initial conditions: this produces output with the names DEFFSTXX, DEFFSTXY, DEFFSTXZ, DEFFSTYY, DEFFSTYZ, DEFFSTZZ.		x

Mnemonic	Output	E100	E300
DENW	Output of water mass densities at reservoir conditions		x
DPRSTRES	Delta principal stresses = change from initial conditions; this produces output with the names DPRSTRS1, DPRSTRS2, DPRSTRS3 followed by their respective directions		x
DRAIN(AGE)	Output of the drainage regions as DRAINAGE.  If set >1, an additional array, DRAINMIN, is output marking the sinks (typically wells) in the drainage region calculation.  (These may also be output to the Debug file - See <a href="#">item 25</a> in the OPTIONS keyword.)	x	
DROCKDIS	Geomechanics: outputs Delta rock displacements = change from initial conditions: DROCKDIX, DROCKDIY, DROCKDIZ. These values are interpolated to the centers of the grid blocks.		x
DSTRAIN	Geomechanics: outputs Delta strain components = change from initial conditions: DSTRAINXX, DSTRAINXY, DSTRAINXZ, DSTRAINYY, DSTRAINYZ, DSTRAINZZ.		x
DTOTSTRS	Geomechanics: outputs Delta total stresses = change from initial conditions: DTOTSTXX, DTOTSTXY, DTOTSTXZ, DTOTSTYY, DTOTSTYZ, DTOTSTZZ.		x
DYNREG	Output of Dynamic Regions	x	x
EFFSTRES	Geomechanics: outputs rock stresses: EFFSTRXX, EFFSTRXY, EFFSTRXZ, EFFSTRYY, EFFSTRYZ, EFFSTRZZ.		x
ENERGY	Internal energy / bulk volume ( <a href="#">THERMAL</a> option)		x
ESALTS	Effective salinity for the Surfactant Model calculated as specified by the <a href="#">SALTEFF</a> keyword		x
ESALTP	Effective salinity for the Polymer Flood Model calculated as specified by the <a href="#">SALTEFF</a> keyword		x
FFACTG	$FFACTG = FACTLI \times T_{crit}^{mix} / T_{reservoir}$  where $T_{crit}^{mix}$ is defined in the FACTLI keyword,  $Z_j$ used in the FACTLI definition is the gas phase mole fraction		x
FFACTO	$FFACTO = FACTLI \times T_{crit}^{mix} / T_{reservoir}$  where $T_{crit}^{mix}$ is defined in the FACTLI keyword,  $Z_j$ used in the FACTLI definition is the oil phase mole fraction		x
FFORO	Forchheimer Non-Darcy flow Factor for Oil ( <a href="#">VELDEP</a> option)		x

Mnemonic	Output	E100	E300
FIP	Output of fluids-in-place at separator conditions for ECLIPSE 100, and at reservoir conditions for ECLIPSE 300. For ECLIPSE 100, a basic restart file includes global fluids-in-place only: this mnemonic also outputs local fluids-in-place.  Since FIP is simulator-specific it is recommended that the user uses RFIP or SFIP.	x	x
FLOCn	Output of inter-block component flows (for component n, where n is an integer)		x
FLOE	Output of inter-block energy flow (ECLIPSE 300 Thermal option)		x
FLOGAS	Output of inter-block gas flows		x
FLOOIL	Output of inter-block oil flows		x
FLOWAT	Output of inter-block water flows		x
FLWS	Output of interblock flows  (Includes non-neighbor connection flows and flows between global and local grids.)	x	
FLORES	Output of interblock flows at reservoir conditions. The volumetric flow rates for each phase are output with headers such as FLRWATI+, FLRWATJ+ and FLRWATK+.  Outputs non-neighbor connection flows and flows between global and local grids with headers such as FLRWATN+, FLRWATL+ and FLRWATA+.	x	x
FMISC	Output of relative permeability miscibility factor (Miscible option)		x
FOAM	Output of foam surfactant density		x
FOAMST	Output of oil-gas surface tension for the Foam Model		x
FOAMCNM	Output of capillary number for the Foam Model		x
FOAMMOB	Output of gas mobility multiplier for the Foam Model		x
FPC	Output of capillary pressure miscibility factor (Miscible option)		x
FREQ=n	Controls the frequency of the restart files if BASIC is set >2	x	x
FUGG	Output of component fugacities in gas (Activity Driven Diffusion)		x
FUGO	Output of component fugacities in oil (Activity Driven Diffusion)		x
GASPOT	Output of gas potentials (or “depth corrected pressures”)		x
GENPLSTN	Geomechanics: outputs generalized plastic strains		x
GENPSTRS	Geomechanics: outputs stiffness matrix multiplied by plastic strain.		x
GIMULT	Outputs RSGI, RVGI, BOGI and BGGI values	x	
GOSTRES	Geomechanics: outputs initial rock stresses induced by gravity and overburden: GOESTRXX, GOESTRXY, GOESTRZX, GOESTRYY, GOESTRZY.		x
HGAS	Output gas enthalpy values (ECLIPSE 300 Thermal)		x
HOIL	Output oil enthalpy values (ECLIPSE 300 Thermal)		x

Mnemonic	Output	E100	E300
HSOL	Output solid enthalpy values (ECLIPSE 300 Thermal and <a href="#">SOLID</a> option)		x
HWAT	Output water enthalpy values (ECLIPSE 300 Thermal)		x
HYDH	Output hydraulic head. (Reference data must be supplied in item 1 of the <a href="#">HYDRHEAD</a> keyword.)	x	
HYDHFV	Output freshwater hydraulic head. (Reference data must be supplied in items 1 and 2 of <a href="#">HYDRHEAD</a> keyword.)	x	
JV	Output of ln(K-Value) values		x
KRG	Output of gas relative permeabilities: outputs the array GASKR (E100) or KRG (E300)	x	x
KRO	Output of oil relative permeabilities: outputs the array OILKR (E100) or KRO (E300)	x	x
KRW	Output of water relative permeabilities: outputs the array WATKR (E100) or KRW (E300)	x	x
KRGDM	Output of gas relative permeability damage multiplier		x
KRODM	Output of oil relative permeability damage multiplier		x
KRWDM	Output of water relative permeability damage multiplier		x
LGLCn	Output of number of <a href="#">LAGTRAC</a> streamlines generated for component n to pass through a cell		x
LGLCWAT	Output of number of <a href="#">LAGTRAC</a> streamlines generated for water to pass through a cell		x
LGLCHC	Output of number of <a href="#">LAGTRAC</a> streamlines generated for hydrocarbons (that is to solve <a href="#">LUMPING</a> tracers) to pass through a cell		x
MLSC	Output of total molar density for hydrocarbon components (moles per reservoir volume)		x
MWAT	Output of total molar density for water components (moles per reservoir volume)		x
NCNG	Output of capillary numbers for gas ( <a href="#">VELDEP</a> option). The normalized capillary number is output when used with keyword <a href="#">VDKRG</a> .		x
NCNO	Output of capillary numbers for oil ( <a href="#">VELDEP</a> option). The normalized capillary number is output when used with keyword <a href="#">VDKRO</a> .		x
NOGRAD	Output of total derivatives for the Gradient option  If set > 0, extra information is not written to the Restart file for the Gradient option.	x	

Mnemonic	Output	E100	E300
NORST	<p>Requests a graphics only Restart file.</p> <ul style="list-style-type: none"> <li>If set to 1, the Restart file does not contain arrays required for restarting but not usually required for graphical output (for example hysteresis arrays).</li> <li>If set to 2, the well arrays are not included on the restart file. In a standard black oil case the restart file will contain header data and 4 arrays, PRESSURE, SWAT, SGAS and RS (and any other arrays requested by the other controls in this keyword).</li> </ul> <p>The restart files dumped while this control is set &gt; 0 cannot be used to restart the run. You could, however, opt to have the restart data written to the Save file (see the mnemonic SAVE, and keyword <a href="#">RESTART</a>).</p>	x	
NPMREB	<p>Output of the number of passes through the rebound region during the calculations of the pore volumes of the Palmer-Mansoori rock model (keyword <a href="#">ROCKPAMA</a> or <a href="#">ROCKPAME</a>). Also gives the sign of the derivatives during the last calculation (positive &gt;=0). Requires <a href="#">CBMOPTS</a> item 4 to be set to PMREB.</p>	x	x
OILPOT	Output of oil potentials (or “depth corrected pressures”)		x
PART	Output of domain partitions (Parallel option)		x
PBPD	Output of bubble point and dew point pressures	x	
PCGW	Output of gas-water capillary pressures ( <a href="#">GASWAT</a> cases)		x
PCOG	Output of gas-oil capillary pressures	x	x
PCOW	Output of oil-water capillary pressures	x	x
PERMSTAB	Geomechanics: outputs permeability multipliers (stress dependence)		x
PERM_MDX PERM_MDY PERM_MDZ	<p>Output directional permeability multipliers (Rock Compaction option) when <a href="#">RKTRMDIR</a> or <a href="#">ROCKTRMX</a>, <a href="#">ROCKTRMY</a> and <a href="#">ROCKTRMZ</a> are defined in ECLIPSE 300.</p> <p>This information can be output in ECLIPSE 100 via the <a href="#">ROCKC</a> mnemonic (described below).</p>		x
PERM_MOD	<p>Output permeability multipliers (Rock Compaction option).</p> <p>This information can be output in E100 via the <a href="#">ROCKC</a> mnemonic (described below).</p>		x
PGAS	Output of gas phase pressure		x
PGOSTRES	Geomechanics: outputs initial principal stresses induced by gravity and overburden: <a href="#">GVPRSTS1</a> , <a href="#">GVPRSTS2</a> , and <a href="#">GVPRSTS3</a> .		x
PKRG	Processed gas relative permeability ( <a href="#">ENKRVC</a> and <a href="#">ENKRVT</a> cases)		x
PKRGR	Output of the processed scaled gas relative permeability at the residual oil saturation for each cell if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENKRVC</a> or <a href="#">ENKRVT</a> keywords respectively.		x
PKRO	Processed oil relative permeability ( <a href="#">ENKRVC</a> and <a href="#">ENKRVT</a> cases)		x

Mnemonic	Output	E100	E300
PKRORG	Output of the processed scaled oil relative permeability at the residual gas saturation for each cell if composition or temperature-dependent end-point scaling is selected via the use of the ENKRVC and ENKRVT keywords respectively.		x
PKRORW	Output of the processed scaled oil relative permeability at the residual water saturation for each cell if composition or temperature-dependent end-point scaling is selected using the ENKRVC or ENKRVT keywords respectively.		x
PKRW	Processed water relative permeability (ENKRVC and ENKRVT cases)		x
PKRWR	Output of the processed scaled water relative permeability at the residual oil saturation for each cell if composition or temperature-dependent end-point scaling is selected using the ENKRVC or ENKRVT keywords respectively.		x
PLASDISP	Geomechanics: outputs plastic displacements		x
POIL	Output of oil phase pressure		x
POIS	Output Poisson's ratio (Petro-elastic Model only): this produces an array with the name POISSONR  If you request this item, you must also request the DEN item  These values are only output on the global grid cells (that is, not on local grid refinement cells).	x	
POLY	Output of polymer concentration (Polymer option)		x
POLYVM	Output of polymer viscosity multiplier (Polymer option)		x
PORO	Output of effective porosities (Gradient Option only)	x	
PORV	Output of reservoir pore volumes at reference conditions	x	x
POT	Output of phase potentials (or "depth corrected pressures"): this produces the arrays OIL_POTN, GAS_POTN and WAT_POTN.  (Including the initial contact corrected potential output to the array POT_CORR.)	x	
PORV_MOD	Output pore volume multipliers (Rock compaction option)  This information can be output in E100 via the ROCKC mnemonic (described below).		x
PPCG	Output of processed capillary pressure gas-oil end-points		x
PPCW	Output of processed capillary pressure oil-water end-points		x
PRES_EFF	Output of effective fluid pressures for rock compaction (when <a href="#">OVERBURD</a> and <a href="#">ROCKOPTS</a> are specified).		x
PRES	ECLIPSE 100 Output of water and gas phase pressures  ECLIPSE 300 Output of grid block pressures	x	x
PRESMIN	Output of minimum pressures (Irreversible rock compaction option)		x
PRESSURE	Output of grid block pressures (equivalent to PRES)		x

Mnemonic	Output	E100	E300
PRSTRESS	Geomechanics: outputs principal stresses: PRSTRES1, PRSTRES2, PRSTRES3 followed by their respective directions.		x
PSAT	Output of saturation pressures (Compositional mode).  Note: Saturation pressures (PSAT) are not normally used in ECLIPSE 300, and their calculation may involve significant extra CPU time. The value of PSAT depends on the cell hydrocarbon state: for single phase gas it will usually be the dew point pressure; for single phase oil it will usually be the bubble point pressure; for two phase cells it will be the cell pressure. In thermal simulations, the value of PSAT, for both rock-filled cells and for water-filled cells, is the water saturation pressure at the cell temperature.		x
PSGCR	Output of the processed scaled critical gas saturation end-points for each grid cell if composition or temperature-dependent end-point scaling selected via the use of the ENPTVC or ENPTVT keywords respectively or the mobile fluid correction options or TZONE are activated.		x
PSGL	Output of the processed scaled minimum gas saturation end-points for each grid cell if composition or temperature-dependent end-point scaling is selected using the ENPTVC or ENPTVT keywords respectively.		x
PSGU	Output of the processed scaled maximum gas saturation end-points for each grid cell if composition or temperature-dependent end-point scaling is selected using the ENPTVC or ENPTVT keywords respectively.		x
PSOGCR	Output of the processed scaled critical oil-in-gas saturations for each grid cell if composition or temperature-dependent end-point scaling is selected using the ENPTVC or ENPTVT keywords respectively or the mobile fluid correction options or TZONE are activated.		x
PSOWCR	Output of the processed scaled critical oil-in-water saturations for each grid cell if composition or temperature-dependent end-point scaling is selected using the ENPTVC or ENPTVT keywords respectively or the mobile fluid correction options or TZONE are activated.		x
PSWCR	Output of the processed scaled critical water saturation end-points for each grid cell if composition or temperature-dependent end-point scaling is selected using the ENPTVC or ENPTVT keywords respectively or the mobile fluid correction options or TZONE are activated.		x
PSWL	Output of the processed scaled minimum water saturation end-points for each grid cell if composition or temperature-dependent end-point scaling is selected using the ENPTVC or ENPTVT keywords respectively.		x
PSWU	Output of the processed scaled maximum water saturation end-points for each grid cell if composition or temperature-dependent end-point scaling is selected via the use of the ENPTVC or ENPTVT keywords respectively.		x
PTCSTRES	Geomechanics: outputs initial principal stresses induced by tectonic loadings: T CPRSTS1, T CPRSTS2 and T CPRSTS3.		x
PVDPH	Derivative of pore volume with respect to porosity		x
PWAT	Output of water phase pressure		x
RATP	Ratio of actual to target throughputs		x

Mnemonic	Output	E100	E300
RATS	Ratio of actual to target solution changes		x
RATT	Ratio of actual to target temperature changes (Thermal option only)		x
REAC	Chemical reaction rates (See " <a href="#">Chemical Reactions</a> " in the <i>ECLIPSE Technical Description</i> )		x
RESTART	Output of data required for flexible restart		x
RFIP	Output of fluids-in-place at reservoir conditions. In ECLIPSE 100 this is the product of pore volume at reservoir conditions with saturation. In ECLIPSE 300, this is a synonym for FIP.	x	x
RK or PERMREDN	Polymer Flood: Permeability reduction for the aqueous phase due to polymer retention in the rock.	x	
ROCKC	Output of pore volume and permeability modifiers for the Rock Compaction option.  In ECLIPSE 300, this is the same as individually specifying mnemonics PORV_MOD, PERM_MOD (or PERM_MDX, PERM_MDY and PERM_MDZ in the directional case) and optionally SIGM_MOD (in a dual porosity model).  In ECLIPSE 100, the values output (where relevant) are PRES_OVB, PRES_EFF, PEFF_MIN, PORV_MOD, PERM_MOD (or PERM_MDX, PERM_MDY and PERM_MDZ in the directional case).	x	x
ROCKDISP	Geomechanics: outputs rock displacements: ROCKDISX, ROCKDISY, ROCKDISZ. These values are interpolated to the centers of the grid blocks.		x
ROMLS	Residual oil composition (SOR option)		x
RPORV	Output of reservoir pore volumes at Reservoir conditions	x	x
RS	Output dissolved GOR ( $R_s$ ) (In compositional runs this is interpreted as the GOR at surface conditions of the liquid phase in the reservoir)		x
RSSAT	Output of saturated $R_s$ values (dissolved gas-oil ratio).  Only in Blackoil mode for ECLIPSE 300.	x	x
RSW	Output of the aqueous concentration of soluble components. Each component is distinguished, as with mnemonic AMF, by its associated index.		x
RV	Output vaporized OGR ( $R_v$ ) (In compositional runs this is interpreted as the OGR at surface conditions of what was the vapor phase in the reservoir.)		x
RVSAT	Output of saturated $R_v$ values (vaporized oil-gas ratio).  Only in Blackoil mode for ECLIPSE 300.	x	x

Mnemonic	Output	E100	E300
SAVE	<p>Requests a Restart file be written to the Save file. This item has a similar effect to item 1, the BASIC restart control, but governs the writing of time-dependent restart data to the Save file.</p> <ul style="list-style-type: none"> <li>If set to 1 or 2, restart data is written to the Save file every report time until this switch is reset.</li> <li>If set to 3, restart data is written every <math>n^{\text{th}}</math> report time. The frequency of the restarts is governed by the mnemonic.</li> <li>If set to 4, restart data is written at the first report step of each year. Optionally, if SFREQ is set <math>&gt;1</math> the restart is written only every <math>n^{\text{th}}</math> year.</li> <li>If set to 5, restart data is written at the first report step of each month. Optionally, if SFREQ is set <math>&gt;1</math> the restart is written only every <math>n^{\text{th}}</math> month.</li> <li>If set to 6, this setting is reserved for use by FrontSim.</li> </ul> <p>Note that the Save file <b>must</b> be requested either by using the <a href="#">SAVE</a> keyword in the RUNSPEC section or by requesting a Save file in the <a href="#">LOAD</a> keyword, otherwise no restart data is output to the Save file.</p>	x	
SDENO	Output of grid block oil surface densities (for API tracking)	x	
SFIP	Output of fluids-in-place at surface/separator conditions (see " <a href="#">Initial fluid in place</a> " and item 201 of <a href="#">OPTIONS3</a> )	x	x
SFIPGAS	Output of separator volumes for gas FIP data		x
SFIPOIL	Output of separator volumes for oil FIP data		x
SFIPWAT	Output of separator volumes for water FIP data (single component water only at present)		x
SFOIL	Output of grid block foamy oil saturation		x
SFREQ=n	Controls the frequency of the restart files written to the Save file if the mnemonic SAVE is set $>2$	x	
SFSOL	Output of grid block foamy solid saturation		x
SGAS	Output of grid block gas saturations		x
SGASMAX	Output of maximum gas saturation (Hysteresis option)		x
SGCRH	Output critical gas saturation (Hysteresis option)		x
SGTRH	Output the immobile gas saturation (Hysteresis option)		x
SGTRAP	Output of the trapped gas saturation $S_{\text{gtrap}}$ for the WAG hysteresis option	x	x
SIGM_MOD	Output dual porosity sigma multipliers (Rock Compaction option)	x	x
SMF	Output of solid component mole fractions ( <a href="#">CO2STORE</a> option only)		x
SMMULT	Output of solid mobility multiplier ( <a href="#">SOLID</a> option)		x
SOIL	Output of grid block oil saturations		x
SOILM	Mobile oil saturation ( <a href="#">SOR</a> option)		x

Mnemonic	Output	E100	E300
SOILMAX	Output of maximum oil saturation (Hysteresis option)		x
SOILR	Residual oil saturation (SOR option)		x
SOLADS	Adsorbed solid concentration (Solid option)		x
SOLADW	Adsorbed wetting-solid concentration (Solid option)		x
SOLWET	Solid wettability interpolation parameter (Solid option)		x
SSFRACT	Output of suspended solids fraction (Solid option)		x
SSOLID	Output of grid block solid saturations (Solid option)		x
STATE	Output of states present		x
STEN	Output of oil/gas surface tensions (Miscible option)		x
STRAIN	Geomechanics: outputs strain components: STRAINXX, STRAINXY, STRAINXZ, STRAINYY, STRAINYZ, STRAINZZ. Note that these do not form a tensor - see discussion on definition of strains in " <a href="#">Elastic Stress Equations</a> " of the <i>ECLIPSE Technical Description</i> .		x
STREAM=n	Reserved for use by FrontSim	x	
SUBG	Output the sub-grid (see " <a href="#">The ECLIPSE 300 WARP linear solver</a> " in the <i>ECLIPSE Technical Description</i> )		x
SURF	Surfactant concentration - Surfactant option		x
SURFBLK	When NORST mnemonic is activated, output of surfactant concentrations (SURFACT), maximum surfactant concentrations (SURFMAX), adsorption (SURFADS), log (capillary number) (SURFCNM) and water oil surface tension (SURFST or SURFSTES).  Surfactant option.	x	
SURFCNM	log (capillary number) - Surfactant option		x
SURFKR	Relative permeability interpolation parameter - Surfactant option		x
SURFCP	Capillary pressure multiplier - Surfactant option		x
SURFST	Oil-water surface tension - Surfactant option		x
SWAT	Output of grid block water saturations		x
SWATMIN	Output of minimum water saturation (Hysteresis option)		x
TCBULK	Output of the average thermal conductivity (using the mnemonic THCAVE specified in the <a href="#">RPTGRID</a> keyword) multiplied by saturation dependent thermal transmissibility multiplier $\lambda$ ( <a href="#">THERMAL</a> option)		x
TCMULT	Saturation dependent thermal transmissibility multiplier $\lambda$ ( <a href="#">THERMAL</a> option)		x
TCSTRES	Geomechanics: outputs initial rock stresses induced by tectonic loadings: TCESTRXX, TCESTRXY, TCESTRXZ, TCESTRYY, TCESTRYZ, TCESTRZZ		x
TEMP	Output of reservoir temperatures ( <a href="#">THERMAL</a> option)		x
TOTCOMP	Outputs total compressibility of the fluid system (excluding the rock compressibility)		x

Mnemonic	Output	E100	E300
TOTSTRES	Geomechanics: outputs total stresses: TOTSTRXX, TOTSTRXY, TOTSTRXZ, TOTSTRYY, TOTSTRYZ, TOTSTRZZ.		x
TRAS	Output the product of tracer concentration with the carrier saturation	x	
TREACM	Tracer dependent reaction rate multipliers (See " <a href="#">Chemical Reactions</a> " in the <i>ECLIPSE Technical Description</i> )		x
TRMFxxxx	Output the product of tracer concentration with the molar fraction of the carrier (molar fraction relative to all components, not just hydrocarbons). To output use TRMF followed by the tracer name.		x
TSUB	Output of the water saturation temperature minus the grid block temperature (THERMAL option)		x
VELGAS	Output of gas velocities  This gives phase velocity $u_p$ as defined in " <a href="#">ECLIPSE 100 Velocity calculations</a> " in the <i>ECLIPSE Technical Description</i> .	x	
VELOCITY	Output of all fluid velocities.  This gives phase velocity $u_p$ as defined in " <a href="#">ECLIPSE 100 Velocity calculations</a> " in the <i>ECLIPSE Technical Description</i> .  For polymer shear-thinning in the Polymer Flood Model, only water velocity is output.  For shear thinning in the Foam Model, only gas velocity is output.	x	
VELOIL	Output of oil velocities  This gives phase velocity $u_p$ as defined in " <a href="#">ECLIPSE 100 Velocity calculations</a> " in the <i>ECLIPSE Technical Description</i> .	x	
VELWAT	Output of water velocities  This gives phase velocity $u_p$ as defined in " <a href="#">ECLIPSE 100 Velocity calculations</a> " in the <i>ECLIPSE Technical Description</i> .	x	
VGAS	Output of gas viscosities		x

Mnemonic	Output	E100	E300
VISC	<p>Argument VISC allows to output extra viscosities when Polymer is active. You can obtain the following output:</p> <ul style="list-style-type: none"> <li>• EPVIS: effective polymer viscosity (Polymer option).</li> <li>• EMVIS: effective mixture (water/polymer) viscosity (Polymer option).</li> <li>• EWV_POL: effective water viscosity (Polymer option).</li> <li>• EWV_SAL: effective water viscosity due to salt concentration (Brine option).</li> <li>• PLADALK: polymer adsorption multiplier as a function of alkaline concentration.</li> <li>• SFIPPLY/SFIPPOL: polymer in place (mass)</li> <li>• RRFAC: residual resistance factor.</li> <li>• TRXBYRRF: I-direction transmissibility divided by the residual resistance factor.</li> <li>• TRYBYRRF: J-direction transmissibility divided by the residual resistance factor.</li> <li>• TRZBYRRF: K-direction transmissibility divided by the residual resistance factor.</li> <li>• SHWVISI, SHWVISJ, SHWVISK: shear viscosity of the water/polymer solution due to shear thinning/thickening in the positive I-, J- and K-directions, respectively (PLYSHEAR and PLYSHLOG keywords).</li> <li>• POLYMAX: maximum polymer concentration.</li> <li>• RRFTMAX: RRF maximum temperature.</li> <li>• POLYMER: polymer concentration.</li> </ul>	x	
VOIL	Output of oil viscosities		x
VMF	Output of vapor mole fractions (fraction of total hydrocarbon moles in gas)		x
VWAT	Output of water viscosities		x
WATPOT	Output of water potentials (or “depth corrected pressures”)		x
XFW	Output of liquid component mass fractions (weight fraction of each component in liquid)		x
XGAS	Output of gas fractional saturations (Sudation option)		x
XMF	Output of liquid component mole fractions (fraction of each component in liquid)		x
XWAT	Output of water fractional saturations (Sudation option)		x
YFW	Output of vapor component mass fractions (weight fraction of each component in gas)		x

Mnemonic	Output	E100	E300
YMF	Output of vapor component mole fractions (fraction of each component in gas)		x
ZMF	Output of total component mole fractions		x

Table 3.37: RPTRST output controls

The following table lists the deprecated mnemonics.

Mnemonic	Output	E100	E300
PKRGE	This has been superseded by the mnemonic PKRGR (ENKRVC and ENKRVT cases).		x
PKROGE	This has been superseded by the mnemonic PKRORG (ENKRVC and ENKRVT cases).		x
PKROWE	This has been superseded by the mnemonic PKRORW (ENKRVC and ENKRVT cases).		x
PKRWE	This has been superseded by the mnemonic PKRWR (ENKRVC and ENKRVT cases).		x
SGCR	This has been superseded by the mnemonic PSGCR (TZONE, mobile fluid correction options, ENKRVC and ENKRVT cases).		x
SGL	This has been superseded by the mnemonic PSGL (ENKRVC and ENKRVT cases).		x
SGU	This has been superseded by the mnemonic PSGU (ENKRVC and ENKRVT cases).		x
SOGCR	This has been superseded by the mnemonic PSOGCR (TZONE, mobile fluid correction options, ENKRVC and ENKRVT cases).		x
SOWCR	This has been superseded by the mnemonic PSOWCR (TZONE, mobile fluid correction options, ENKRVC and ENKRVT cases).		x
SWCR	This has been superseded by the mnemonic PSWCR (TZONE, mobile fluid correction options, ENKRVC and ENKRVT cases).		x
SWL	This has been superseded by the mnemonic PSWL (ENKRVC and ENKRVT cases).		x
SWU	This has been superseded by the mnemonic PSWU (ENKRVC and ENKRVT cases).		x
WMF	The mnemonic has been superseded by AMF.		x

Table 3.38: Deprecated RPTRST output controls

## XMF/YMF output

### ECLIPSE 300

If either [XMF](#) or [YMF](#) is requested, a set of values is written to the Restart file for each component. If for instance there are 5 components and the XMF mnemonic is used, then ECLIPSE 300 writes mnemonics XMF1, XMF2, XMF3, XMF4 and XMF5 to the restart file. These can be displayed in GRAF by asking for XMF1 and so on.

Saturation pressures are not normally used in ECLIPSE 300, and their calculation may involve significant extra CPU time.

## Tracer output

ECLIPSE 300

To output the distribution of a tracer, add the name of the tracer as one of the mnemonics.

ECLIPSE 100

ECLIPSE 100 always outputs the tracer distributions. This will be the tracer name followed by F (Free) and S (Solution) specifiers, or by the phase number # in the case of partitioned tracers, as appropriate.

## Output of flows

ECLIPSE 100

Under the FLOWS mnemonic, it is possible to output the interblock flows, including non-neighbor connection flows, and flows between global and local grids. For instance, the flow between neighbor cells in the water phase will be defined under the FLOWATI+, FLOWATJ+, FLOWATK+ headers for I, J, K positive directions. Flow between non-neighbor connections can be found under the FLOWATN+ header. The actual non-neighbor connections can be found in the grid file.

ECLIPSE 300

RPTRST/OUTSOL items exist that enable flows to be written to the Restart files. These may be used to produce arrow diagrams showing fluid movement. The mnemonics are FLOC1 for component 1, FLOC2 for component 2 and so on (as molar rates). FLOWAT outputs the water flow rate (as a surface rate). FLOOIL and FLOGAS output the surface flow rates of oil and gas, respectively. In thermal simulations, FLOE outputs the energy flow rate.

Where appropriate, interblock flows will be output to the restart files using a similar naming convention as for ECLIPSE 100, giving data with headers such as FLOC3I+ or FLOC1N+ in the restart file.

## Extra output for BASIC=2

ECLIPSE 100

When BASIC=2 is used in ECLIPSE 100, additional output is provided. For instance

BASIC=2	Additional Output
PRESSURE	Output of grid block pressures
RS	Output of dissolved GOR (Rs)
RV	Output of vaporized OGR (Rv)
SWAT	Output of grid block water saturations
SGAS	Output of grid block gas saturations
OILAPI	Output of grid block API values (for API tracking)

Table 3.39: Extra output for BASIC=2 in ECLIPSE 100

ECLIPSE 300

When BASIC=2 is used in ECLIPSE 300, additional output is provided. For instance,

	BASIC=2	Additional Output
Asphaltene 2011.1 model	ASPFLT	Average oil flow rate at the previous timestep
Asphaltene 2011.1 model	ASPVEL	Average oil velocity at the previous timestep
Residual oil model	COILR	Residual oil compressibility
Compositional models	LIFACT	Li Factors
	MLSC 1, 2, . . . , n	Hydrocarbon moles/reservoir volume for each component, 1,2,...,n (“total molar density”)
	MWAT	Water moles/reservoir volume for each water component (“total molar density of water”)

	<b>BASIC=2</b>	<b>Additional Output</b>
FREEZEPC or DPCDT options	PCOINIT	Initial oil capillary pressure
FREEZEPC or DPCDT options	PCWINIT	Initial water capillary pressure
FREEZEPC or DPCDT options	PCGINIT	Initial gas capillary pressure
Rock compaction options	PRESMIN	Minimum pressure
Rock compaction options	PRESMAX	Maximum pressure
Residual oil model	ROMOL	Residual oil moles
Sudation (GRAVDR) option	SGASINIT	Initial gas saturation
Hysteresis options (HYST)	SGASMAX	Maximum gas saturation
DPCDT option	SGT	Gas saturation at time t
HYST option	SOILMAX	Maximum oil saturation
HYST option	SOILMIN	Minimum oil saturation
Residual oil model	SOILRA	Initial residual oil saturation or residual oil volume, depending on which residual oil compressibility model is used
Asphaltene 2011.1 model	SOLIDT	Solid saturation at previous timestep
Sudation (GRAVDR) option	SWATINIT	Initial water saturation
Hysteresis options (HYST)	SWATMIN	Minimum water saturation
DPCDT option	SWT	Water saturation at time t

Table 3.40: Extra output for BASIC=2 in ECLIPSE 300

In addition, more well information is also provided, such as mixture data, completion data, separator data and group data.

Some data, such as SGT and SWT, are only output if the DPCDT option is on. Note that this can be on without explicitly having the keyword present.

#### ECLIPSE 300

When BASIC=2 is used in ECLIPSE 300 with the Thermal Option and in combination with ENDSCALE item 5 set to 1 or 2, the following set of reference grid-block end-points are output. These correspond to the grid-block end-points defined by the input end-point scaling arrays and are used in conjunction with the temperature-dependent tables to construct the temperature-dependent end-points.

<b>BASIC=2</b>	<b>Additional output</b>
RKRG	Reference scaled maximum gas relative permeability for each cell.
RKRGR	Reference scaled gas relative permeability at the residual oil saturation for each cell.
RKRO	Reference scaled maximum oil relative permeability for each cell.
RKRORG	Reference scaled oil relative permeability at the residual gas saturation for each cell.
RKRORW	Reference scaled oil relative permeability at the residual water saturation for each cell.
RKRW	Reference scaled maximum water relative permeability.
RKRWR	Reference scaled water relative permeability at the residual oil saturation for each cell.
RPCG	Reference scaled maximum gas-oil capillary pressure for each cell.
RPCW	Reference scaled maximum water-oil capillary pressure for each cell.

<b>BASIC=2</b>	<b>Additional output</b>
RSOGCR	Reference scaled critical oil-in-gas saturation for each grid cell.
RSOWCR	Reference scaled critical oil-in-water saturation for each grid cell.
RSGCR	Reference scaled critical gas saturation for each grid cell.
RSGL	Reference scaled minimum gas saturation for each grid cell.
RSGU	Reference scaled maximum gas saturation for each grid cell.
RSWCR	Reference scaled critical water saturation for each grid cell.
RSWL	Reference scaled minimum water saturation for each grid cell.
RSWU	Reference scaled maximum water saturation for each grid cell.

Table 3.41: Extra output for BASIC=2 in ECLIPSE 300 for processed end-points.

## Examples

### Example 1 (ECLIPSE 100)

```
RPTRST
BASIC=2 FLOWS POT PBPD /
```

### Example 2

In ECLIPSE 300 it is not possible to restart the simulator with this example but PRESSURE, SOIL and VGAS are output to every Restart file until reset.

```
RPTRST
PRESSURE SOIL VGAS /
```

## RPTRUNSP Controls output of RUNSPEC data

x	<b>ECLIPSE 100</b>
	<b>ECLIPSE 300</b>
	<b>SPECIAL</b>
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

If this keyword is specified in the RUNSPEC section, a listing of the parameters set in the RUNSPEC section will be written to the Print file. This output includes all variables set in the RUNSPEC section (both default and user defined values).

The keyword has no associated data.

## RPTSCHED Controls on output from SCHEDULE section

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword should be followed by a list of mnemonics which control the output of SCHEDULE section data to the Print file. Wherever possible, the mnemonics correspond to the related keywords. The list should be terminated by a slash (/).

The RPTSCHED keyword may be used to reset output controls for the SCHEDULE section as often as required.

Older ECLIPSE 100 data sets may not use mnemonics but integer controls. The meaning of these is documented in "RPTSCHED" in the *ECLIPSE Technical Description*.

---

**Note:** Do not use these integer controls in ECLIPSE 300.

---

In ECLIPSE 100

- Parallel runs will not output all requested quantities for performance reasons. The output can be enabled by setting item 8 of [PARAOPTS](#) to a value greater than zero.
- Entering the mnemonic NOTHING clears all the reporting flags.
- For additional control over the output, integer values greater than one may be assigned to selected mnemonics using the syntax:
 

```
mnemonic=integer
```

 where there must be no spaces either side of the equals sign.
- By default, the printed tables of values are rescaled so that the values printed are have significant figures within the decimal digits printed; however not all scalings are allowed and so not all significant digits may be printed. If insufficient digits are printed, then [OPTIONS](#) 235 may be set to 1. With this scaling option, the maximum value is always between 1 and 10 and all its significant digits will be printed; all possible scalings in the valid range for floating point variables are available.

The following table lists the mnemonics available. Mnemonics are identified by an x in the appropriate column.

Mnemonic	Output	E100	E300
AIM	Output of AIM status array (1 for implicit cells; 2 for explicit cells).		x
ALKALINE	Output of alkaline concentrations and alkaline adsorption when activated.	x	
ALSURF	Output alkaline concentration when surfactant and alkaline models are activated.		x
ALSTML	Output alkaline surface tension multiplier when surfactant and alkaline models are activated.		x
AMF	Output of aqueous mole fractions ( <a href="#">CO2SOL</a> , <a href="#">GASSOL</a> and <a href="#">THERMAL</a> options <a href="#">KWTABTn</a> / <a href="#">CO2STORE</a> and the <a href="#">COMPW</a> option).		x
ANIONS	Output of anion concentration.	x	
AQSP	Output of aqueous speciation ( <a href="#">CO2STORE</a> option).		x
AQPH	Output of aqueous pH level ( <a href="#">CO2STORE</a> option).		x

Mnemonic	Output	E100	E300
AQUCT or AQUFET or AQUFETP	Output of Fetkovich or Carter-Tracy aquifer status. Also outputs <a href="#">AQUCHWAT</a> , <a href="#">AQUCHGAS</a> and <a href="#">AQUFLUX</a> status.  Note: <a href="#">AQUFET</a> applies only for ECLIPSE 100.	x	x
AREAC	Asphaltene reaction rates.		x
ASPADS	Asphaltene cumulative adsorption volume fraction (pre-2011.1 model only).		x
ASPDOT	Asphaltene net cumulative volume fraction deposit (pre-2011.1 model only).		x
ASPENT	Asphaltene instantaneous entrainment volume fraction (pre-2011.1 model only).		x
ASPFLO	Oil velocities (useful to check the asphaltene entrainment) (pre-2011.1 model only).		x
ASPFLT	Average oil flow rate at the previous timestep (2011.1 model only).		x
ASPFRD	Asphaltene precipitate fraction dissolved.		x
ASPKDM	Asphaltene permeability multiplier (damage) (pre-2011.1 model only).		x
ASPLIM	Asphaltene precipitate fraction limit.		x
ASPLUG	Asphaltene instantaneous plugging volume fraction (pre-2011.1 model only).		x
ASPRET	Asphaltene precipitate fraction (including flocs).		x
ASPREW	Asphaltene precipitate fraction (no flocs).		x
ASPVEL	Average oil velocity at the previous timestep (2011.1 model only).		x
ASPVOM	Asphaltene relative oil viscosity multiplier.		x
BFORG	Output of gas Forchheimer B-Factor / phase potential difference (as described in <a href="#">Construction of flows</a> in the <i>ECLIPSE Technical Description</i> ). This is only output if <a href="#">VDFLOW</a> or <a href="#">VDFLOWR</a> (or <a href="#">VELDEP</a> in ECLIPSE 300) has been used to activate a non-Darcy flow model.  Note that this is not the Forchheimer beta parameter.	x	x
BFORO	Output of oil Forchheimer B-Factor / phase potential difference (as described in <a href="#">Construction of flows</a> in the <i>ECLIPSE Technical Description</i> ). This is only output if <a href="#">VDFLOW</a> , <a href="#">VDFLOWR</a> or <a href="#">VELDEP</a> has been used to activate a non-Darcy flow model.  Note that this is not the Forchheimer beta parameter.		x
BGAS	Output of gas reservoir molar densities.		x
BIOTCTAB	Geomechanics: outputs Biot's constant multipliers (stress dependence).		x
BOIL	Output of oil reservoir molar densities.		x
BSOL	Output of solid reservoir molar densities ( <a href="#">SOLID</a> option).		x
BTFORG	Output of gas Forchheimer beta parameter.		x
BTFORO	Output of oil Forchheimer beta parameter.		x
BWAT	Output of water reservoir molar densities.		x

Mnemonic	Output	E100	E300
CATIONS	Output of divalent cation concentration.	x	
CGAS	Output of grid-block adsorbed gas concentration (for the Coal Bed Methane option).		x
COHESION	Geomechanics: outputs cohesion (plasticity).		x
COILR	Residual oil compressibility (SOR option).		x
CPU	Output of breakdown of CPU and elapsed time for current run. <ol style="list-style-type: none"> <li>report is sent to Print file.</li> <li>in addition to being sent to the Print file, a copy of the report is sent to the short form output (terminal)</li> <li>report is sent to short form output only.</li> <li>as 2 but with actual cpu and elapsed times output in seconds.</li> </ol> <p>See "<a href="#">Timing Reports</a>" in the <i>ECLIPSE Technical Description</i> for an explanation of the outputs. Internal clocks within TS are not recorded during intermediate timesteps when set to 0.</p>	x	x
DENG	Output of grid block gas reservoir density.	x	x
DENO	Output of grid block oil reservoir density.	x	x
DENS	Output of grid block solid reservoir density (SOLID option).		x
DEFFSTRS	Delta effective stresses = change from initial conditions: this produces output with the names DEFFSTXX, DEFFSTXY, DEFFSTXZ, DEFFSTYY, DEFFSTYZ, DEFFSTZZ.		x
DENW	Output of grid block water reservoir density.	x	x
DPRSTRES	Delta principal stresses = change from initial conditions: this produces output with the names DPRSTRS1, DPRSTRS2, DPRSTRS3 followed by their respective directions.		x
DROCKDIS	Geomechanics: outputs Delta rock displacements = change from initial conditions: DROCKDIX, DROCKDIY, DROCKDIZ. These values are defined at the faces of the grids.		x
DSTRAIN	Geomechanics: outputs Delta strain components = change from initial conditions: DSTRANXX, DSTRANXY, DSTRANXZ, DSTRANYY, DSTRANYZ, DSTRANZZ.		x
DTOTSTRS	Geomechanics: outputs Delta total stresses = change from initial conditions: DTOTSTXX, DTOTSTXY, DTOTSTXZ, DTOTSTYY, DTOTSTYZ, DTOTSTZZ.		x
EFFSTRES	Geomechanics: outputs rock stresses: EFFSTRXX, EFFSTRXY, EFFSTRXZ, EFFSTRYY, EFFSTRYZ, EFFSTRZZ.		x
ENERGY	Output total energies/bulk volume (energy/(rock+pore volume)). ECLIPSE 300 Thermal.		x
ESALTP	Output of effective salinity for polymer properties.		x
ESALPLY	Output of effective salinity for polymer properties.	x	
ESALTS	Output of effective salinity for phase behavior and surfactant properties.		x

Mnemonic	Output	E100	E300
ESALSUR	Output of effective salinity for phase behavior and surfactant properties.	x	
FFORG	ECLIPSE 300: output of Forchheimer Non-Darcy flow factor for Gas (VELDEP option). ECLIPSE 100: Maximum deviation from Darcy Flow.	x	x
FFORO	Output of Forchheimer Non-Darcy flow factor for Oil (VELDEP option). ECLIPSE 100: not applicable yet.		x
FIP	Output of fluid in place and inter-region flow reports: 1. fluids in place are reported for the whole field. 2. in addition, a balance sheet is produced for each fluid in place region defined with the FIPNUM keyword. This shows current and initial fluids in place. ECLIPSE 100 only: output set to 2 shows cumulative flows to wells and other regions and material balance errors. 3. in addition, a balance sheet is produced for all sets of fluid-in-place regions defined with the FIP keyword.	x	x
FIPFOAM	Output of foam fluid in place reports (for the Foam Model): 1. gives a report for the whole field 2. in addition gives a report for each fluid in place region	x	
FIPRESV	Output of region reservoir volume reports.	x	
FIPSALT	Output of salt fluid in place reports (for the Brine option and salt-sensitive Polymer Flood option): 1. gives a report for the whole field 2. in addition gives a report for each fluid-in-place region	x	
FIPSOL	Output of the Solvent fluid in place reports: 1. gives a report for the whole field 2. gives a report for each fluid-in-place region	x	
FIPSURF	Output of surfactant fluid in place reports (for the Surfactant Model): 1. gives a report for the whole field 2. in addition gives a report for each fluid-in-place region	x	
FIPTEMP or FIPHEAT	Output of energy in place reports (for the Temperature option): 1. gives a report for the whole field 2. in addition gives a report for each fluid-in-place region	x	
FIPTR	Output of tracer fluid-in-place reports (for Tracer Tracking): 1. gives a report for the whole field 2. in addition gives a report for each fluid-in-place region	x	

Mnemonic	Output	E100	E300
FIPVE	Output of fluid in place in original oil, water and gas zones (for the <a href="#">VE</a> option).	x	
FLOCn	Output of inter-block component flows (for component n, where n is an integer).		x
FLOE	Output of inter-block energy flow (ECLIPSE 300 Thermal option).		x
FLOGAS	Output of inter-block gas flows: NNC flows are always given in ECLIPSE 300 =3 gives NNC flows in ECLIPSE 100	x	x
FLOOIL	Output of inter-block oil flows: NNC flows are always given in ECLIPSE 300 =3 gives NNC flows in ECLIPSE 100	x	x
FLOSOL	Output of inter-block solvent flows.	x	
FLOWAT	Output of inter-block water flows: NNC flows are always given in ECLIPSE 300 =3 gives NNC flows in ECLIPSE 100	x	x
FMISC	Output of relative permeability miscibility factor (Miscible option).		x
FOAM	Output of grid block foam surfactant concentration (for the Foam option).	x	x
FOAMADS	Output of grid block foam adsorption (for the Foam option).	x	
FOAMCNM	Output of logarithm base ten of grid block capillary number (for the Foam option).	x	x
FOAMDCY	Output of grid block foam decay (for the Foam option)	x	
FOAMMOB	Output of gas mobility factor due to foam (for the Foam option).	x	x
FOAMST	Output of oil-gas surface tension for foam.		x
FPC	Output of capillary pressure miscibility factor (Miscible option).		x
FUGG	Output of component fugacities in gas (Activity Driven Diffusion).		x
FUGO	Output of component fugacities in oil (Activity Driven Diffusion).		x
GASCONC	Output of grid-block adsorbed gas concentration (for the Coal Bed Methane option).	x	
GASPOT	Output of gas potentials		x
GASSATC	Output of matrix grid block initial gas saturated content (for the Coal Bed Methane option).	x	
GOWAT	Output of gas displaced into oil and water zones: (for the <a href="#">VE</a> option) 1= by regions and field >1 = by grid blocks	x	
GENPLSTN	Geomechanics: outputs generalized plastic strains.		x
GENPSTRS	Geomechanics: outputs plastic strain multiplied by stiffness matrix.		x

Mnemonic	Output	E100	E300
GI	Output of current GI value for GI Pseudo-compositional Model. Setting the value greater than 1 will also output the cell RSGI, RVGI, BOGI and BGGI multipliers.	x	
GMEG	Output gas phase energy mobility (ECLIPSE 300 Thermal).		x
GMEO	Output oil phase energy mobility (ECLIPSE 300 Thermal).		x
GMEW	Output water phase energy mobility (ECLIPSE 300 Thermal).		x
GOC	Output of current gas-oil contact (GOC) depths (for VE option): output is AAAAA if contact depth is above top of cell output is BBBBB if contact depth is below bottom of cell	x	
GOCDIFF	Output of current G.=OC depth - initial GOC depth (for VE option).	x	
GRAD	Summary of gradient calculations for the Gradient option.	x	
HGAS	Output gas enthalpies (ECLIPSE 300 Thermal).		x
HOIL	Output oil enthalpies (ECLIPSE 300 Thermal).		x
HSOL	Output solid enthalpies (ECLIPSE 300 Thermal and SOLID option).		x
HWAT	Output water enthalpies (ECLIPSE 300 Thermal).		x
JV	Output of ln(K-Value) values.		x
KRG	Output of grid block gas relative permeabilities.	x	x
KRN	Output of grid block solvent relative permeabilities (for the Solvent Model).	x	
KRO	Output of grid block oil relative permeabilities.	x	x
KRW	Output of grid block water relative permeabilities.	x	x
MLSC	Output of total molar density for hydrocarbon components (moles per reservoir volume).		x
MWAT	Output of total molar density for water components (moles per reservoir volume).		x
MULT	Output of grid block pore volumes and transmissibilities if they have been modified.	x	x
NCNG	Output of capillary numbers for gas (VELDEP option). The normalized capillary number is output when used with keyword VDKRG.		x
NCNO	Output of capillary numbers for oil (VELDEP option). The normalized capillary number is output when used with keyword VDKRO.		x
NEWTON	Output of a summary of the convergence of the Newton iteration: 1. report is sent to print file. 2. in addition, a copy of the report is sent to the short form output (terminal) 3. report is sent to short form output only.	x	

Mnemonic	Output	E100	E300
NPMREB	Output of the number of passes through the rebound region during the calculations of the pore volumes of the Palmer-Mansoori rock model (keyword <a href="#">ROCKPAMA</a> or <a href="#">ROCKPAME</a> ). Also gives the sign of the derivatives during the last calculation (positive $\geq 0$ ). Requires <a href="#">CBMOPTS</a> item 4 to be set to <code>PMREB</code> .	x	x
ODGAS	Output of oil displaced into gas zone (for VE option)  1 = by regions and field, >1 = by grid blocks	x	
ODWAT	Output of oil displaced into water zone (for VE option:  1 = by regions and field, >1 = by grid blocks	x	
OILAPI	Output of grid block oil API values (for API Tracking).	x	
OILPOT	Output of oil potentials.		x
PART	Output of domain partitions (Parallel option).		x
PB or PBUB RSSAT	Output of grid block bubble point pressures:  1. outputs bubble point pressures only 2. in addition, outputs the saturated dissolved gas-oil ratios	x	x
PBLK or POLYMER	Output of grid block polymer concentration values (for Polymer Flood option).	x	
PCOG	Output of gas-oil capillary pressures.		x
PCOW	Output of oil-water capillary pressures.		x
PCGW	Output of gas-water capillary pressures.		x
PD or PDEW RVSAT	Output of grid block dew point pressures:  1. outputs dew point pressures only 2. in addition, outputs the saturated vaporized oil-gas ratios	x	x
PERMSTAB	Geomechanics: outputs permeability multipliers (stress dependence).		x
PERM_MDX PERM_MDY PERM_MDZ	Output of directional permeability modifiers (Rock Compaction option) when <a href="#">RKTRMDIR</a> or <a href="#">ROCKTRMX</a> , <a href="#">ROCKTRMY</a> and <a href="#">ROCKTRMZ</a> are defined in ECLIPSE 300.  This information can be output in ECLIPSE 100 using the <a href="#">ROCKC</a> mnemonic (described below).		x
PERM_MOD	Output of permeability modifiers for Rock Compaction option ( <a href="#">ROCKCOMP</a> or <a href="#">ROCKPAME</a> ).  This information can be output in E100 via the <a href="#">ROCKC</a> mnemonic (described below).		x
PGAS	Output of grid block gas phase pressures	x	x

Mnemonic	Output	E100	E300
PGASD or POTG	Output of grid block gas phase pressures (corrected to datum depth). (See also the <a href="#">DATUM</a> keyword).	x	
PKRG	Output of the processed scaled gas relative permeabilities at maximum gas saturation for each cell if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENKRVC</a> or <a href="#">ENKRVT</a> keywords respectively.		x
PKRGR	Output of the processed scaled gas relative permeability at residual oil saturation for each cell if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENKRVC</a> or <a href="#">ENKRVT</a> keywords respectively.		x
PKRO	Output of the processed scaled oil relative permeability at maximum oil saturation for each cell if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENKRVC</a> or <a href="#">ENKRVT</a> keywords respectively.		x
PKRORG	Output of the processed scaled oil relative permeability at residual gas saturation for each cell if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENKRVC</a> or <a href="#">ENKRVT</a> keywords respectively.		x
PKRORW	Output of the processed scaled oil relative permeability at residual water saturation for each cell if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENKRVC</a> or <a href="#">ENKRVT</a> keywords respectively.		x
PKRW	Output of the processed scaled water relative permeability at maximum water saturation for each cell if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENKRVC</a> or <a href="#">ENKRVT</a> keywords respectively.		x
PKRWR	Output of the processed scaled water relative permeability at residual oil saturation for each cell if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENKRVC</a> or <a href="#">ENKRVT</a> keywords respectively.		x
PLASDISP	Geomechanics: outputs plastic displacements.		x
PLYADS	Polymer Flood: output of current adsorbed polymer concentration on the formation rock.	x	
POILD or POTO	Output of grid block oil phase pressures (corrected to datum depth).	x	
POLY	Output of polymer concentration (Polymer option)		x
POLYVM	Output of polymer viscosity multiplier (Polymer option)		x
PORV_MOD	Output of pore volume modifiers for rock compaction ( <a href="#">ROCKCOMP</a> case or <a href="#">ROCKPAME</a> ).  This information can be output in E100 via the <a href="#">ROCKC</a> mnemonic (described below).		x
POTC	Output of initial contact corrected potential.	x	

Mnemonic	Output	E100	E300
PPCG	Output of the processed maximum gas-oil capillary pressures if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENPCVC</a> or <a href="#">ENPCVT</a> keywords respectively.		x
PPCW	Output of the processed maximum oil-water capillary pressures if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENPCVC</a> or <a href="#">ENPCVT</a> keywords respectively.		x
PRES or POIL or PRESSURE	Output of grid block pressures.	x	x
PRESMIN	Output of minimum pressures (Irreversible rock compaction option).		x
PRSTRESS	Geomechanics: outputs principal stresses: PRSTRES1, PRSTRES2, PRSTRES3 followed by their respective directions.		x
PSAT	Output of saturation pressures (Compositional mode).  Note: Saturation pressures (PSAT) are not normally used in ECLIPSE 300, and their calculation may involve significant extra CPU time. The value of PSAT depends on the cell hydrocarbon state: for single phase gas it will usually be the dew point pressure; for single phase oil it will usually be the bubble point pressure; for two phase cells it will be the cell pressure. In thermal simulations the value of PSAT, for both rock filled cells and for water filled cells, is the water saturation pressure at the cell temperature.		x
PSGCR	Output of the processed scaled critical gas saturation end-points for each grid cell if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENPTVC</a> or <a href="#">ENPTVT</a> keywords respectively or the mobile fluid correction options or <a href="#">TZONE</a> are activated.		x
PSGL	Output of the processed scaled minimum gas saturation end-points for each grid cell if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENPTVC</a> or <a href="#">ENPTVT</a> keywords respectively.		x
PSGU	Output of the processed scaled maximum gas saturation end-points for each grid cell if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENPTVC</a> or <a href="#">ENPTVT</a> keywords respectively.		x
PSOGCR	Output of the critical oil-in-gas saturations for each grid cell if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENPTVC</a> or <a href="#">ENPTVT</a> keywords respectively or the mobile fluid correction options or <a href="#">TZONE</a> are activated.		x
PSOWCR	Output of the processed scaled critical oil-in-water saturations for each grid cell if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENPTVC</a> or <a href="#">ENPTVT</a> keywords respectively or the mobile fluid correction options or <a href="#">TZONE</a> are activated.		x
PSWCR	Output of the processed scaled critical water saturation end-points for each grid cell if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENPTVC</a> or <a href="#">ENPTVT</a> keywords respectively or the mobile fluid correction options or <a href="#">TZONE</a> are activated.		x

Mnemonic	Output	E100	E300
PSWL	Output of the processed scaled minimum water saturation end-points for each grid cell if composition or temperature-dependent end-point scaling is selected via the use of the ENPTVC or ENPTVT keywords respectively.		x
PSWU	Output of the processed scaled maximum water saturation end-points for each grid cell if composition or temperature-dependent end-point scaling is selected via the use of the ENPTVC or ENPTVT keywords respectively.		x
PWAT	Output of grid block water phase pressures.	x	
PWATD or POTW	Output of grid block water phase pressures (corrected to datum depth).	x	
REAC	Chemical reaction rates (See " <a href="#">Chemical reactions</a> " in the <i>ECLIPSE Technical Description</i> ).		x
RECOV	Output of recovery mechanisms (See " <a href="#">Recovery mechanisms</a> " in the <i>ECLIPSE Technical Description</i> ).	x	
RESTART	<p>Output of Restart files:</p> <p>If set = 1, Restart files are created at every report time, but if the files are not unified only the last one in the run is kept (designed for fail-safe restarts).</p> <p>If set &gt; 1, Restart files are created at every report time until this switch is reset, and all are kept.</p> <p>If set &gt; 2, the inter block flows of each phase are written to the Restart files.</p> <p>If set &gt; 3, the current fluids-in-place and phase potentials in each grid cell are written to the Restart files.</p> <p>If set = 6, Restart files are created at every timestep.</p> <p>See also the keywords <a href="#">RESTART</a>, <a href="#">RPTRST</a>, <a href="#">FMTOUT</a>, <a href="#">FMTIN</a>, <a href="#">UNIFIN</a> and <a href="#">UNIFOUT</a>. The value of this control will be ignored if the mnemonic BASIC in keyword <a href="#">RPTRST</a> has previously been set &gt; 2.</p> <p>Output of the initial Restart file (at 0.0 Days) is governed by the mnemonic RESTART in keyword <a href="#">RPTSOL</a>, but there must be at least one timestep.</p> <p>In ECLIPSE 300 the keyword <a href="#">RPTRST</a> controls output to the Restart file.</p>	x	
RK	Output of the permeability reduction factor currently being applied to water phase relative permeability (for Polymer Flood option).	x	

Mnemonic	Output	E100	E300
ROCKC	Output of pore volume and permeability modifiers for the Rock Compaction option.  In ECLIPSE 300, this is the same as individually specifying mnemonics PORV_MOD, PERM_MOD (or PERM_MDX, PERM_MDY and PERM_MDZ in the directional case) and optionally SIGM_MOD (in a dual porosity model).  In ECLIPSE 100, the values output (where relevant) are PRES_OVB, PRES_EFF, PEFF_MIN, PORV_MOD, PERM_MOD (or PERM_MDX, PERM_MDY and PERM_MDZ in the directional case).	x	x
ROCKDISP	Geomechanics: outputs rock displacements ROCKDISX, ROCKDISY, ROCKDISZ. These values are defined at the faces of the grids.		x
ROMLS	Residual oil composition (SOR option),		x
RPORV	Output of reservoir pore volumes,		x
PORV	Output of reservoir pore volumes at reference conditions,		x
RS	Output of grid block solution gas-oil ratios:  (In compositional runs this is interpreted as the GOR at surface conditions of the liquid phase in the reservoir.)	x	x
RSW	Output of the (grid block) aqueous concentration of soluble components. Each component is distinguished, as with mnemonic AMF, by its associated index.		x
RV	Output of grid block vapor oil-gas ratios.  (In compositional runs this is interpreted as the OGR at surface conditions of what was the vapor phase in the reservoir.)  If set >1: With the discretized matrix option active, the solution values into the matrix are also reported.	x	x
SALT	Output of grid block salt concentration values (for the Brine option and salt-sensitive Polymer Flood option).	x	x
SFOIL	Output of grid block foamy oil saturation.		x
SFSOL	Output of grid block foamy solid saturation.		x
SGAS	Output of grid block gas saturations.	x	x
SGCRH	Output critical gas saturation (Hysteresis option).		x
SGTRH	Output the immobile gas saturation (Hysteresis option).		x
SGTRAP	Trapped gas saturation and dynamic trapped gas saturation (for WAG Hysteresis model only).	x	x
SIGM_MOD	Output dual porosity sigma multipliers (Rock Compaction option)	x	x
SL	Output liquid mole fractions (ECLIPSE 300 Thermal).		x
SMF	Output of solid component mole fractions (CO2STORE option only).		x
SMMULT	Output of solid mobility multiplier (SOLID option).		x
SOIL	Output of grid block oil saturations.	x	x

Mnemonic	Output	E100	E300
SOILM	Mobile oil saturation (SOR option).		x
SOILR	Residual oil saturation (SOR option).		x
SOLADS	Adsorbed solid concentration (Solid option)		x
SOLADW	Adsorbed wetting-solid concentration (Solid option)		x
SOLWET	Solid wettability interpolation parameter (Solid option)		x
SPENGAS	Output gas internal energy (ECLIPSE 300 Thermal).		x
SPENOIL	Output oil internal energy (ECLIPSE 300 Thermal).		x
SPENWAT	Output water internal energy (ECLIPSE 300 Thermal).		x
SSFRAC	Output of suspended solids fraction (SOLID option).		x
SSOL	Output of the current Solvent saturation.	x	
SSOLID	Output of grid block solid saturations (SOLID option).		x
STATE	Output of states present.		x
STEN	Output of oil/gas surface tensions (Miscible option).		x
STRAIN	Geomechanics: outputs output of strain components: STRAINXX, STRAINXY, STRAINXZ, STRAINYY, STRAINYZ, STRAINZZ . Note that these do not form a tensor - see discussion on definition of strains in "Elastic stress equations" in the <i>ECLIPSE Technical Description</i> .		x
SUMMARY	Output of solution summary at end of each timestep:  If set to 1: report is sent to Print file.  If set to 2: in addition, a copy of the report is sent to the short form output (terminal).  If set to 3: report is sent to short form output only.  For runs using Local Grid Refinement, adding 4 to the above reports the fluid-in-place errors in global cells due to adjacent local grids.	x	
SURF	Surfactant concentration - Surfactant option.		x
SURFADS	Output of current adsorbed surfactant concentration on the formation rock (for the Surfactant Model).	x	
SURFBLK	Output of the surfactant concentrations, the SURFBLK capillary number (for the Surfactant Model) and water-oil surface tension (SURFST or SURFSTES).	x	
SURFCNM	log (capillary number) - Surfactant option.		x
SURFKR	Relative permeability interpolation parameter - Surfactant option.		x
SURFCP	Capillary pressure multiplier - Surfactant option.		x
SURFST	Oil-water surface tension - Surfactant option.		x
SV	Output vapor mole fractions (ECLIPSE 300 Thermal).		x
SW	Output water mole fractions (ECLIPSE 300 Thermal).		x
SWAT	Output of grid block water saturations.	x	x

Mnemonic	Output	E100	E300
T2	Output temperature at the two-phase to three-phase transition (ECLIPSE 300 Thermal).		x
T3	Output bubble point (ECLIPSE 300 Thermal).		x
TBLK or TRACER	Output of grid block tracer concentrations (for Tracer Tracking).	x	
TCMULT	Output saturation dependent thermal conductivity transmissibility multiplier (ECLIPSE 300 Thermal).		x
TEMP	Output of the grid block temperature (for the Temperature option or ECLIPSE 300 Thermal).	x	x
TET	Output temperatures at last time level (ECLIPSE 300 Thermal).		x
TO	Output temperature at which the oil phase leaves the system (ECLIPSE 300 Thermal).		x
TOTCOMP	Output the total compressibility of the fluid system (excluding the rock).		x
TOTSTRES	Geomechanics: outputs total stress tensor: TOTSTRXX , TOTSTRXY, TOTSTRXZ, TOTSTRYY, TOTSTRYZ , TOTSTRZZ.		x
TW	Output temperature at which the water phase leaves the system (ECLIPSE 300 Thermal).		x
TRADS or TRDCY	Output of tracer adsorption and decay (for Environmental Tracers).	x	
TREACM	Tracer-dependent reaction rate multipliers (See " <a href="#">Chemical Reactions</a> " in the <i>ECLIPSE Technical Description</i> ).		x
TSUB	Output the water saturation temperature minus the grid block temperature (THERMAL option).		x
TUNING	Output of simulator control parameters set by <a href="#">TUNING</a> keyword.	x	
UGAS	Output gas phase specific volumes (ECLIPSE 300 Thermal).		x
UOIL	Output oil phase specific volumes (ECLIPSE 300 Thermal).		x
UWAT	Output water phase specific volumes (ECLIPSE 300 Thermal).		x
V2	Output vapor mole fraction at the system two phase to three phase transition (ECLIPSE 300 Thermal).		x
VFPPROD	Output of vertical flow performance tables. (In order to obtain this, RPTSCHED must be placed before <a href="#">VFPPROD</a> and <a href="#">VFPINJ</a> .)  This also turns on network convergence messages in the Network option.  If set > 1: a table is also written comparing the maximum dimensions as defined in the <a href="#">VFPPDIMS</a> keyword with those observed in the input tables.  If set > 2: only the table comparing the maximum dimensions is written.	x	
VGAS	Output of grid block gas viscosity.	x	x
VMF	Output of vapor mole fractions (fraction of total hydrocarbon moles in gas).		x

Mnemonic	Output	E100	E300
VOIL	Output of grid block oil viscosity.	x	x
VWAT	Output of grid block water viscosity.	x	x
WATPOT	Output of water potentials.		x
WDOGAS	Output of water displaced into oil and gas zones: (for VE option) 1 = by regions and field, >1 = by grid blocks	x	
WELLS	Output of well reports with production and injection rates and totals: 1. gives a report of well flows 2. gives a report of well and connection flows 3. gives a report of layer totals 4. gives a report of layer totals and well flows 5. gives a report of layer totals, well and connection flows. In ECLIPSE 300, the keyword <code>RPTPRINT</code> controls well report output to the Print file.	x	
WELSPECS or WELSPECL	Output of connection, well and group keyword data from the SCHEDULE section.	x	
WOC	Output of current water-oil contact (WOC) depths (for VE option): output is AAAAA if contact depth is above top of cell output is BBBBB if contact depth is below bottom of cell	x	
WOCDIFF	Output of current WOC depth - initial WOC depth (for VE option).	x	
WOCGOC	Output of current WOC depth - current GOC depth (for VE option).	x	
XFW	Output of liquid component mass fractions (weight fraction of each component in liquid).		x
XGAS	Output of gas fractional saturations (Sudation option, switched on using GRAVDR or GRAVDRM keywords).		x
XMF	Output of liquid component mole fractions (fraction of each component in liquid).		x
XWAT	Output of water fractional saturations (Sudation option, switched on using GRAVDR or GRAVDRM keywords).		x
YFW	Output of gas component mass fractions (weight fraction of each component in vapor).		x
YMF	Output of gas component mole fractions (fraction of each component in vapor).		x
ZMF	Output of total component mole fractions (fraction of each component in liquid).		x

Table 3.42: RPTSCHED output controls

**Note:** In ECLIPSE 300, to output the distribution of a **tracer**, add the name of the tracer as one of the mnemonics.

The following table lists the additional mnemonics which are available when the **ODD3P** relative permeability and capillary pressure hysteresis model has been selected.

Mnemonic	Output	E100	E300
IFTGO	Output of gas-oil interfacial tension		x
IFTOW	Output of oil-water interfacial tension		x
IFTGW	Output of gas-water interfacial tension		x
KRGOE	Output of equivalent relative permeabilities to gas for gas-oil system		x
KRGWE	Output of equivalent relative permeabilities to gas for gas-water system		x
KROGE	Output of equivalent relative permeabilities to oil for oil-gas system		x
KROWE	Output of equivalent relative permeabilities to oil for oil-water system		x
KRWGE	Output of equivalent relative permeabilities to water for water-gas system		x
KRWOE	Output of equivalent relative permeabilities to water for water-oil system		x
KRGOH	Output of turning point relative permeabilities to gas for gas-oil system		x
KRGWH	Output of turning point relative permeabilities to gas for gas-water system		x
KROGH	Output of turning point relative permeabilities to oil for oil-gas system		x
KROWH	Output of turning point relative permeabilities to oil for oil-water system		x
KRWGH	Output of turning point relative permeabilities to water for water-gas system		x
KRWOH	Output of turning point relative permeabilities to water for water-oil system		x
KRGOR	Output of representative gas-oil relative permeabilities		x
KRGWR	Output of representative gas-water relative permeabilities		x
KROGR	Output of representative oil-gas relative permeabilities		x
KROWR	Output of representative oil-water relative permeabilities		x
KRWGR	Output of representative water-gas relative permeabilities		x
KRWOR	Output of representative water-oil relative permeabilities		x
KRGOT	Output of opposite saturation direction turning point relative permeabilities to gas for gas-oil system		x
KRGWT	Output of opposite saturation direction turning point relative permeabilities to gas for gas-water system		x
KROGT	Output of opposite saturation direction turning point relative permeabilities to oil for oil-gas system		x
KROWT	Output of opposite saturation direction turning point relative permeabilities to oil for oil-water system		x
KRWGT	Output of opposite saturation direction turning point relative permeabilities to water for water-gas system		x

<b>Mnemonic</b>	<b>Output</b>	<b>E100</b>	<b>E300</b>
KRWOT	Output of opposite saturation direction turning point relative permeabilities to water for water-oil system		x
PCOWR	Representative oil-water capillary pressure		x
PCWOR	Representative water-oil capillary pressure		x
PCOGR	Representative oil-gas capillary pressure		x
PCGOR	Representative gas-oil capillary pressure		x
PCGWR	Representative gas-water capillary pressure		x
PCWGR	Representative water-gas capillary pressure		x
SONRM	Output of normalized oil saturations		x
SGNRM	Output of normalized gas saturations		x
SWNRM	Output of normalized water saturations		x
SDRGO	Output of gas phase saturation direction indicators for gas-oil system		x
SDRGW	Output of gas phase saturation direction indicators for gas-water system		x
SDROG	Output of oil phase saturation direction indicators for oil-gas system		x
SDROW	Output of oil phase saturation direction indicators for oil-water system		x
SDRWG	Output of water phase saturation direction indicators for water-gas system		x
SDRWO	Output of water phase saturation direction indicators for water-oil system		x
SGONE	Output of normalized gas equivalent opposite direction saturations for gas-oil system		x
SGWNE	Output of normalized gas equivalent opposite direction saturations for gas-water system		x
SOGNE	Output of normalized oil equivalent opposite direction saturations for oil-gas system		x
SOWNE	Output of normalized oil equivalent opposite direction saturations for oil-water system		x
SWGNE	Output of normalized water equivalent opposite direction saturations for water-gas system		x
SWONE	Output of normalized water equivalent opposite direction saturations for water-oil system		x
SGONH	Output of normalized gas hysteresis saturations for gas-oil system		x
SGWNH	Output of normalized gas hysteresis saturations for gas-water system		x
SOGNH	Output of normalized oil hysteresis saturations for oil-gas system		x
SOWNH	Normalized oil hysteresis saturations for oil-water system		x
SWGNH	Output of normalized water hysteresis saturations for water-gas system		x
SWONH	Output of normalized oil hysteresis saturations for water-oil system		x
SGROB	Output of residual gas saturation in gas-oil system used to calculate normalized saturations		x
SGRWB	Output of residual gas saturation in gas-water system used to calculate normalized saturations		x

Mnemonic	Output	E100	E300
SORGB	Output of residual oil saturation in oil-gas system used to calculate normalized saturations		x
SORWB	Output of residual oil saturation in oil-water system used to calculate normalized saturations		x
SWRGB	Output of residual water saturation in water-gas system used to calculate normalized saturations		x
SWROB	Output of residual water saturation in water-oil system used to calculate normalized saturations		x
SGROP	Output of process dependent residual gas saturation in gas-oil system		x
SGRWP	Output of process dependent residual gas saturation in gas-water system		x
SORWP	Output of process dependent residual oil saturation in oil-water system		x
SORGP	Output of process dependent residual oil saturation in oil-gas system		x
SWRGP	Output of process dependent residual water saturation in water-gas system		x
SWROP	Output of process dependent residual water saturation in water-oil system		x
SGONT	Output of normalized gas turning point saturations for gas-oil system		x
SGWNT	Output of normalized gas turning point saturations for gas-water system		x
SOGNT	Output of normalized oil turning point saturations for oil-gas system		x
SOWNT	Output of normalized oil turning point saturations for oil-water system.		x
SWGNT	Output of normalized water turning point saturations for water-gas system		x
SWONT	Output of normalized water turning point saturations for water-oil system		x

Table 3.43: ODD3P RPTSCHED output controls

The following table lists the deprecated mnemonics.

Mnemonic	Output	E100	E300
SGCR	This mnemonic has been superseded by PSGCR (TZONE, mobile fluid correction options, ENKRVC and ENKRVT cases).		x
SGL	This mnemonic has been superseded by PSGL (ENKRVC and ENKRVT cases).		x
SGU	This mnemonic has been superseded by PSGU (ENKRVC and ENKRVT cases).		x
SOGCR	This mnemonic has been superseded by PSOGCR (TZONE, mobile fluid correction options, ENKRVC and ENKRVT cases).		x
SOWCR	This mnemonic has been superseded by PSOWCR (TZONE, mobile fluid correction options, ENKRVC and ENKRVT cases).		x
SWCR	This mnemonic has been superseded by PSWCR (TZONE, mobile fluid correction options, ENKRVC and ENKRVT cases).		x
SWL	This mnemonic has been superseded by PSWL (ENKRVC and ENKRVT cases).		x
SWU	This mnemonic has been superseded by PSWU (ENKRVC and ENKRVT cases).		x
WMF	The mnemonic has been superseded by AMF.		x

Table 3.44: Deprecated RPTSCHED output controls

ECLIPSE 100

Grid-valued output values in certain types of cell have the decimal point replaced with a special character for ease of identification. See [3.31](#) for details.

## Examples

### Example 1

ECLIPSE 100 example

```
RPTSCHED  
'OIL' 'SGAS' 'RS' 'RESTART' 'FIP=2' 'WELSPECS' 'WELLS=2'  
'SUMMARY=2' 'AQUCT' 'NEWTON' /
```

### Example 2

ECLIPSE 300 example

```
RPTSCHED  
PRES SWAT SOIL SGAS PSAT XMF YMF /
```

## RPTSLN

## Controls output to the SLN file

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword should be followed by a list of mnemonics which control the output of data to the streamline output files. This keyword will not cause streamlines to be traced by ECLIPSE; it will simply cause any streamlines generated for other purposes such as the Lagrangian Tracer Solver ([LAGTRAC](#)) to be output. The list should be terminated by a slash (/).

For additional control over the output, integer values greater than one may be assigned to selected mnemonics using the syntax:

mnemonic=integer

where there must be no spaces either side of the equals sign.

The following table lists the mnemonics available.

Mnemonic	Output
BASIC	If this mnemonic is set to 1 then the standard properties will be output for each streamline. If it is set to zero, no streamline data will be output. The standard properties are the start and end ID of the streamline, the time of flight to the start and end of the streamline, phase saturations on the streamline and the phase or component number of the streamline.
FLows	If this mnemonic is present then the FLOWRATE attribute will be output. This is the molar flow of the carrier component or phase attributed to each streamline segment.
LiNES	This mnemonic controls the number of lines output. If defaulted it will take the value 300. If set to a negative value then all lines traced will be output.
NOADDLiN	If this mnemonic is present then no lines traced to meet the minimum number of streamline segments requirement for any given cell will be output to the SLN files.
TRACERS	If this mnemonic is present then tracer concentration attributes will be output. These attributes will be named TRACXXXX where XXXX is the name of the tracer output. If a streamline is for a component or phase which does not carry a given tracer then that tracer will have a concentration of zero for that streamline

Table 3.45: RPTSLN output controls

**Note:** Separate SLN files for each report step will still be produced if [UNIFOUT](#) is specified.

## Example

```
RPTSLN
  BASIC=1 LINES=1500 FLOWS /
```

## RPTSMRY

**Controls on output from SUMMARY section**

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
x	SUMMARY
	SCHEDULE

The keyword should be followed by a single integer which determines whether or not ECLIPSE prints a table of the variables to be written to the Summary file during the current run.

A value of 0 switches the output off.

A value of 1 switches it on.

The data field should be terminated by a slash (/).

**Example**

```
RPTSMRY
 1 /
```

## RPTSOL

## Controls on output from SOLUTION section

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by a list of mnemonics which control the output of SOLUTION section data to the Print file. Wherever possible, the mnemonics correspond to the related keywords. The list should be terminated by a slash (/).

---

**Note:** Older ECLIPSE 100 data sets may not use mnemonics but integer controls. The meaning of these is documented in "RPTSOL" in the *ECLIPSE Technical Description*.

---

---

**Note:** In Parallel, ECLIPSE 100 will not output all requested quantities for performance reasons. Output can be enabled by setting item 8 of [PARAOPTS](#) to a value greater than zero.

---

In ECLIPSE 100

- Entering the mnemonic NOTHING clears all the reporting flags.
- For additional control over the output, integer values greater than one may be assigned to selected mnemonics using the syntax:

mnemonic=integer

where there must be no spaces either side of the equals sign.

---

**Note:** It is currently not possible to output SOLUTION section information for local grid cells using this keyword for an ECLIPSE 300 parallel run.

---

The following table lists the mnemonics available. Mnemonics available are identified by an x in the appropriate column.

Mnemonic	Output	E100	E300
AIM	Output AIM status array (1 for implicit cells; 2 for explicit cells).		x
ALSURF	Output alkaline concentration when surfactant and alkaline models are activated.		x
ALSTML	Output alkaline surface tension multiplier when surfactant and alkaline models are activated.		x
AMF	Output of aqueous mole fractions ( <a href="#">CO2SOL</a> , <a href="#">GASSOL</a> and <a href="#">THERMAL</a> , <a href="#">KWTABTn</a> / <a href="#">CO2STORE</a> and <a href="#">COMPW</a> options).		x
ANIONS	Output of anion concentration.	x	
APIVD	Output of tables of initial API versus depth.	x	

Mnemonic	Output	E100	E300
AQUFET or AQUFETP or AQUCT or AQUFLUX or AQUANCON	Output of analytic (Fetkovich, Carter-Tracy, Constant Flux or Constant Head) aquifer data (entered using <a href="#">AQUFET</a> , <a href="#">AQUFETP</a> , <a href="#">AQUCT</a> , <a href="#">AQUCHWAT</a> , <a href="#">AQUCHGAS</a> and <a href="#">AQUFLUX</a> ).  ECLIPSE 100: if set to 2: in addition, data for each aquifer-grid block connection will be printed (input using <a href="#">AQUANCON</a> ).  ECLIPSE 300: data for each aquifer-grid block connection will be printed (input using <a href="#">AQUANCON</a> ).  Note: <a href="#">AQUFET</a> applies only for ECLIPSE 100.	x	x
AQANCONL	Data for each aquifer-grid block connection within local grid refinements will be printed.		x
BFORG	Output of gas Forchheimer B-Factor / phase potential difference (as described in <a href="#">Construction of flows</a> in the <i>ECLIPSE Technical Description</i> ). This is only output if <a href="#">VDFLOW</a> or <a href="#">VDFLOWR</a> (or <a href="#">VELDEP</a> in ECLIPSE 300) has been used to activate a non-Darcy flow model.  Note that this is not the Forchheimer beta parameter.	x	x
BFORO	Output of oil Forchheimer B-Factor / phase potential difference (as described in <a href="#">Construction of flows</a> in the <i>ECLIPSE Technical Description</i> ). This is only output if <a href="#">VDFLOW</a> , <a href="#">VDFLOWR</a> or <a href="#">VELDEP</a> has been used to activate a non-Darcy flow model.  Note that this is not the Forchheimer beta parameter.		x
BGAS	Output of gas reservoir molar densities.		x
BIOTCTAB	Geomechanics: outputs Biot's constant multipliers (stress dependence).		x
BOIL	Output of oil reservoir molar densities.		x
BSOL	Output of solid reservoir molar densities ( <a href="#">SOLID</a> option).		x
BTFORG	Output of gas Forchheimer beta parameter.		x
BTFORO	Output of oil Forchheimer beta parameter.		x
BWAT	Output of water reservoir molar densities.		x
CATIONS	Output of divalent cation concentration.	x	
CGAS	Output of grid-block adsorbed gas concentration (for the Coal Bed Methane option).		x
COILR	Residual oil compressibility ( <a href="#">SOR</a> option).		x
DENG	Output of grid block gas reservoir density.	x	x
DENO	Output of grid block oil reservoir density.	x	x
DENS	Output of grid block solid reservoir density ( <a href="#">SOLID</a> option).		x
DENW	Output of grid block water reservoir density.	x	x
EFFSTRES	Geomechanics: outputs initial effective in-situ stress.		x
ENERGY	Internal energy / bulk volume ( <a href="#">THERMAL</a> option).		x
EQUIL	Output of equilibration data.	x	

Mnemonic	Output	E100	E300
ESALTP	Output of effective salinity for polymer properties.		x
ESALPLY	Output of effective salinity for polymer properties.	x	
ESALTS	Output of effective salinity for phase behavior and surfactant properties.		x
ESALSUR	Output of effective salinity for phase behavior and surfactant properties.	x	
FFORG	Forchheimer Non-Darcy flow factor for Gas ( <b>VELDEP</b> option). ECLIPSE 100: maximum deviation from Darcy Flow.	x	x
FFORO	Forchheimer Non-Darcy flow factor for Oil ( <b>VELDEP</b> option). ECLIPSE 100: not applicable in the current version.		x
FIP	Output of fluid in place reports:  If set to 1: initial fluids in place are reported for the whole field,  If set to 2: in addition, initial fluids in place are reported for each fluid in place region defined with the <b>FIPNUM</b> keyword,  If set to 3: in addition, initial fluids in place are reported for all sets of fluid in place regions defined with the <b>FIP</b> keyword.  ECLIPSE 300 only: FIP=1 or 2 produces no additional output as these reports are produced by default.	x	x
FIPFOAM	Output of foam fluid in place reports (for the Foam model):  1: gives a report for the whole field  2: in addition, gives a report for each fluid-in-place region	x	
FIPPLY	Output of polymer/salt fluid in place reports (for Brine option and salt-sensitive Polymer Flood Model):  1: gives a report for the whole field  2: in addition, gives a report for each fluid-in-place region	x	
FIPRESV	Output of region reservoir volume reports.	x	
FIPSOL	Output of the solvent fluid in place reports:  1: gives a report for the whole field  2: in addition, gives a report for each fluid-in-place region	x	
FIPSURF	Output of surfactant fluid in place reports (for the Surfactant Model):  1. gives a report for the whole field  2. in addition, gives a report for each fluid-in-place region	x	
FIPTEMP or FIPHEAT	Output of energy in place reports (for the Temperature option):  1. gives a report for the whole field  2. in addition, gives a report for each fluid-in-place region	x	

Mnemonic	Output	E100	E300
FIPTR	Output of tracer fluid in place reports (for Tracer Tracking): 1. gives a report for the whole field 2. in addition, gives a report for each fluid-in-place region	x	
FIPVE	Output of fluid in place in original oil, water and gas zones in the VE option.	x	
FLOCn	Output of inter-block component flows (for component n).		x
FLOE	Output of inter-block energy flow ( <a href="#">THERMAL</a> option only).		x
FLOGAS	Output of inter block gas flows.	x	x
FLOOIL	Output of inter block oil flows.	x	x
FLOSOL	Output of inter block solvent flows (for the Solvent Model).	x	
FLOWAT	Output of inter block water flows.	x	x
FMISC	Output of relative permeability miscibility factor (Miscible option).		x
FOAM	Output of grid block foam concentration (for the Foam option).	x	x
FOAMADS	Output of grid block foam adsorption (for the Foam option).	x	
FOAMCNM	Output of logarithm base ten of grid block capillary number (for the Foam option).	x	x
FOAMDCY	Output of grid block foam decay (for the Foam option).	x	
FOAMMOB	Output of gas mobility factor due to foam (for the Foam option).	x	x
FOAMST	Output of gas-water surface tension.		x
FPC	Output of capillary pressure miscibility factor (Miscible option).		x
FUGG	Output of component fugacities in gas (Activity Driven Diffusion).		x
FUGO	Output of component fugacities in oil (Activity Driven Diffusion).		x
GASCONC	Output of grid-block adsorbed gas concentration (for the Coal Bed Methane option).	x	
GASPOT	Output of gas potentials.		x
GASSATC	Output of matrix grid block initial gas saturated content (for the Coal Bed Methane option).	x	
GI	Output of initial GI value for condensate/volatile oil model.	x	
GOC	Output of initial gas-oil contact depths in the VE option: output is AAAAA for contact depth above top of cell output is BBBBB for contact depth below bottom of cell	x	
GOSTRES	Geomechanics: outputs initial gravity induced effective stress.		x
HGAS	Output gas enthalpy values (ECLIPSE 300 Thermal).		x
HOIL	Output oil enthalpy values (ECLIPSE 300 Thermal).		x
HSOL	Output solid enthalpy values (ECLIPSE 300 Thermal and <a href="#">SOLID</a> option).		x
HWAT	Output water enthalpy values (ECLIPSE 300 Thermal).		x

Mnemonic	Output	E100	E300
JV	Output of ln(K-Value) values (compositional cases only).		x
KRG	Output of grid block gas relative permeabilities.	x	x
KRN	Output of grid block solvent relative permeabilities (for the Solvent Model)	x	
KRO	Output of grid block oil relative permeabilities.	x	x
KRW	Output of grid block water relative permeabilities.	x	x
MLSC	Output of total molar density for hydrocarbon components (moles per reservoir volume).		x
MWAT	Output of total molar density for water components (moles per reservoir volume).		x
NCNG	Output of capillary numbers for gas ( <a href="#">VELDEP</a> option). The normalized capillary number is output when used with keyword <a href="#">VDKRG</a> .		x
NCNO	Output of capillary numbers for oil ( <a href="#">VELDEP</a> option). The normalized capillary number is output when used with keyword <a href="#">VDKRO</a> .		x
OILAPI	Output of initial grid block API values (for API tracking).	x	
OILPOT	Output of oil potentials.		x
PART	Output of all possible domain partitions for the Parallel option, that is the <a href="#">PSPLITX</a> and <a href="#">PSPLITY</a> keywords. This is always enabled in parallel.		x
PERM_MDX PERM_MDY PERM_MDZ	Output of directional permeability modifiers (Rock Compaction option) when <a href="#">RKTRMDIR</a> or <a href="#">ROCKTRMX</a> , <a href="#">ROCKTRMY</a> and <a href="#">ROCKTRMZ</a> are defined in ECLIPSE 300.  This information can be output in ECLIPSE 100 via the <a href="#">ROCKC</a> mnemonic (described below).		x
PERM_MOD	Output of permeability modifiers for Rock Compaction option ( <a href="#">ROCKCOMP</a> or <a href="#">ROCKPAME</a> ).  This information can be output in ECLIPSE 100 via the <a href="#">ROCKC</a> mnemonic (described below).		x
PORV_MOD	Output of pore volume modifiers for rock compaction ( <a href="#">ROCKCOMP</a> case or <a href="#">ROCKPAME</a> ).  This information can be output in ECLIPSE 100 via the <a href="#">ROCKC</a> mnemonic (described below).		x
PB or PBUB RSSAT	Output of grid block bubble point pressures:  1: outputs bubble point pressures only  2: in addition, outputs the saturated dissolved gas-oil ratios	x	x
PBLK or POLYMER	Output of initial grid block polymer concentration values (for Polymer Flood Model).	x	
PCGW	Output of gas-water capillary pressures ( <a href="#">GASWAT</a> cases).		x
PCOG	Output of gas-oil capillary pressures.		x

Mnemonic	Output	E100	E300
PCOW	Output of oil-water capillary pressures.		x
PD or PDEW RVSAT	Output of grid block dew point pressures: 1: outputs dew point pressures only 2: in addition, outputs the saturated vaporized oil-gas ratios	x	
PERMSTAB	Geomechanics: outputs permeability multipliers (stress dependence).		x
PGAS	Output of initial grid block gas phase pressures.	x	
PGASD or POTG	Output of initial grid block gas phase pressures corrected to datum depth) (See also the <a href="#">DATUM</a> keyword).	x	
PGOSTRES	Geomechanics: outputs initial gravity induced principal stress.		x
PKRG	Output of processed max. oil relative permeability and the gas relative permeability at residual oil if the end point scaling is activated.	x	
PKRO	Output of processed max. oil relative permeability and the oil relative permeability at residual gas and water if end-point scaling is activated.	x	
PKRW	Output of processed max. water relative permeability and the water relative permeability at residual oil if the end-point scaling is activated.	x	
PKRG	Output of the processed scaled gas relative permeabilities at maximum gas saturation for each cell if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENKRVC</a> or <a href="#">ENKRVT</a> keywords respectively.		x
PKRGR	Output of the processed scaled gas relative permeability at the residual oil saturation for each cell if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENKRVC</a> or <a href="#">ENKRVT</a> keywords respectively.		x
PKRO	Output of the processed scaled oil relative permeability at the maximum oil saturation for each cell if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENKRVC</a> or <a href="#">ENKRVT</a> keywords respectively.		x
PKRORG	Output of the processed scaled oil relative permeability at the residual gas saturation for each cell if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENKRVC</a> or <a href="#">ENKRVT</a> keywords respectively.		x
PKRORW	Output of the processed scaled oil relative permeability at the residual water saturation for each cell if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENKRVC</a> or <a href="#">ENKRVT</a> keywords respectively.		x
PKRW	Output of the processed scaled water relative permeability at the maximum water saturation for each cell if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENKRVC</a> or <a href="#">ENKRVT</a> keywords respectively.		x
PKRWR	Output of the processed scaled water relative permeability at the residual oil saturation for each cell if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENKRVC</a> or <a href="#">ENKRVT</a> keywords respectively.		x

Mnemonic	Output	E100	E300
PLYADS	Output of polymer concentration currently adsorbed by the rock formation (for Polymer Flood Model).	x	
POIL	Output of initial grid block pressures.	x	x
POILD or POTO	Output of initial grid block oil phase pressures (corrected to datum depth).	x	
POLY	Output of polymer concentration (Polymer option)		x
POLYVM	Output of polymer viscosity multiplier (Polymer option)		x
POTC	Output of initial contact corrected potential.	x	
PPCG	Output of the processed maximum gas-oil capillary pressures (End-Point Scaling).	x	
PPCW	Output of the processed maximum oil-water capillary pressures (End-Point Scaling).	x	
PPCG	Output of the processed maximum gas-oil capillary pressures if composition or temperature-dependent end-point scaling selected via the use of the <a href="#">ENPCVC</a> or <a href="#">ENPCVT</a> keywords respectively.		x
PPCW	Output of the processed maximum oil-water capillary pressures if composition or temperature-dependent end-point scaling selected via the use of the <a href="#">ENPCVC</a> or <a href="#">ENPCVT</a> keywords respectively.		x
PRES or PRESSURE	Output of initial oil pressures.	x	x
PRESMIN	Output of minimum pressures (irreversible Rock Compaction option).		x
PRSTRESS	Geomechanics: outputs initial principal in-situ stress.		x
PSAT	Output of saturation pressures (Compositional mode).  Note: The value of PSAT depends on the cell hydrocarbon state: for single phase gas it will usually be the dew point pressure; for single phase oil it will usually be the bubble point pressure; for two phase cells it will be the cell pressure. In thermal simulations the value of PSAT, for both rock filled cells and for water filled cells, is the water saturation pressure at the cell temperature.		x
PSGCR	Output of the processed scaled critical gas saturation end-points for each grid cell if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENPTVC</a> or <a href="#">ENPTVT</a> keywords respectively or the mobile fluid correction options or <a href="#">TZONE</a> are activated.		x
PSGL	Output of the processed scaled minimum gas saturation end-points for each grid cell if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENPTVC</a> or <a href="#">ENPTVT</a> keywords respectively.		x
PSGU	Output of the processed scaled maximum gas saturation end-points for each grid cell if composition or temperature-dependent end-point scaling is selected via the use of the <a href="#">ENPTVT</a> or <a href="#">ENPTVT</a> keywords respectively.		x

Mnemonic	Output	E100	E300
PSOGCR	Output of the processed scaled critical oil-in-gas saturations for each grid cell if composition or temperature-dependent end-point scaling is selected via the use of the ENPTVT or ENPTVT keywords respectively or the mobile fluid correction options or TZONE are activated.		x
PSOWCR	Output of the processed scaled critical oil-in-water saturations for each grid cell if composition or temperature-dependent end-point scaling is selected via the use of the ENPTVC or ENPTVT keywords respectively or the mobile fluid correction options or TZONE are activated.		x
PSWCR	Output of the processed scaled critical water saturation end-points for each grid cell if composition or temperature-dependent end-point scaling is selected via the use of the ENPTVC or ENPTVT keywords respectively or the mobile fluid correction options or TZONE are activated.		x
PSWL	Output of the processed minimum water saturation end-points for each grid cell if composition or temperature-dependent end-point scaling is selected via the use of the ENPTVC or ENPTVT keywords respectively.		x
PSWU	Output of the processed maximum water saturation end-points for each grid cell if composition or temperature-dependent end-point scaling is selected via the use of the ENPTVC or ENPTVT keywords respectively.		x
PTCSTRES	Geomechanics: outputs initial tectonic induced principal stress.		x
PTHSTRES	Geomechanics: outputs initial thermal induced principal stress.		x
PVDPH	Derivative of pore volume with respect to porosity.		x
PWAT	Output of initial grid block water phase pressures.	x	
PWATD or POTW	Output of initial grid block water phase pressures (corrected to datum depth).	x	
QUIESC	Output phase pressure modifications.	x	
RECOV	Output of recovery mechanisms.	x	
RESTART	Output of Restart files:  If set > 1: an initial Restart file is created.  If set > 2: the inter block flows of each phase are written to the Restart files.  If set > 3: the current fluids in place and phase potentials in each grid cell are written to the Restart files.  (There must be at least one <a href="#">TIME</a> , <a href="#">TSTEP</a> or <a href="#">DATES</a> keyword if an initial Restart file is required; but the simulation mode can be turned off by the keyword <a href="#">NOSIM</a> in the RUNSPEC section)  In ECLIPSE 300 the keyword <a href="#">RPTRST</a> controls output to the Restart file.	x	
RK	Output of permeability reduction factor currently being applied to the water phase (for Polymer Flood Model).	x	

Mnemonic	Output	E100	E300
ROCKC	Output of pore volume and permeability modifiers for the Rock Compaction option.  In ECLIPSE 300, this is the same as individually specifying mnemonics PORV_MOD, PERM_MOD (or PERM_MDX, PERM_MDY and PERM_MDZ in the directional case) and SIGM_MOD (in a dual porosity model).  In ECLIPSE 100, the values output (where relevant) are PRES_OVB, PRES_EFF, PEFF_MIN, PORV_MOD, PERM_MOD (or PERM_MDX, PERM_MDY and PERM_MDZ in the directional case).	x	x
ROCKCON	Output of rock connections to the local grid refinements and to the global grid ( <b>THERMAL</b> option only).		x
ROCKMASS	Output rock mass (Polymer, Surfactant and Environmental Tracer options).	x	
ROMLS	Residual oil composition ( <b>SOR</b> option).		x
RPORV	Output of reservoir pore volumes.		x
PORV	Output of reservoir pore volumes at reference pressure.		x
RS	Output of initial grid block solution gas-oil ratios.  In compositional runs this is interpreted as the GOR at surface conditions of the liquid phase in the reservoir.	x	x
RSVD or PBVD	Output of tables of either initial $R_s$ versus depth or initial $P_b$ versus depth.	x	
RSW	Output of the initial aqueous concentration of soluble components. Note that this is after the initial flash calculation. Each component is distinguished, as with mnemonic AMF, by its associated index.		x
RV	Output of initial grid block vapor oil-gas ratios.  In compositional runs this is interpreted as the OGR at surface conditions of what was the vapor phase in the reservoir.	x	x
RVVD	Output of tables of initial $R_v$ versus depth.	x	
SALT	Output of initial grid block salt concentration values (for Brine option and salt-sensitive Polymer Flood Model).	x	x
SALTVD	Output of tables of initial salt concentration versus depth (entered using <b>SALTVD</b> keyword)  For the Multi-component Brine Model (ECLIPSE 100 only) SALTVD outputs tables of initial anion and divalent cation equivalent molar concentrations versus depth.	x	x
SFOIL	Output of initial grid block foamy oil saturation.		x
SFSOL	Output of initial grid block foamy solid saturation.		x
SGAS	Output of initial grid block gas saturations.	x	x

Mnemonic	Output	E100	E300
SGCO or SGCR or SGL or SGU	Output of the connate, critical and maximum gas saturations for each grid cell if the end-point scaling or the mobile fluid correction option is activated. The output is headed by mnemonic PSGCO or PSGCR or PSGL or PSGU.	x	
SIGM_MOD	Output of dual porosity sigma multipliers (Rock Compaction option)	x	x
SMMULT	Output of solid mobility multiplier ( <b>SOLID</b> option).		x
SOCRS	Output of critical oil saturations following a surfactant flood (Surfactant option with end point scaling active).	x	
SOGCR	Output of the critical oil-in-gas saturations for each direction for each grid cell if the end point scaling or the mobile fluid correction is activated. The output is headed by mnemonic PSOGCR.	x	
SOIL	Output of initial grid block oil saturations.	x	x
SOILM	Mobile oil saturation ( <b>SOR</b> option).		x
SOILR	Residual oil saturation ( <b>SOR</b> option).		x
SOLADS	Adsorbed solid concentration ( <b>Solid</b> option).		x
SOLADW	Adsorbed wetting-solid concentration ( <b>Solid</b> option).		x
SOLVD	Composition with depth.		x
SOLWET	Solid wettability interpolation parameter ( <b>Solid</b> option).		x
SOWCR	Output of the critical oil-in-water saturations for each direction for each grid cell if the end point scaling or the mobile fluid correction is activated. The output is headed by mnemonic PSOWCR.	x	
SSFRAC	Output of suspended solids fraction ( <b>SOLID</b> option).		
SSOL	Output of the initial solvent saturation.	x	
SSOLID	Output of initial grid block solid saturations ( <b>SOLID</b> option).		x
STATE	Output states present.		x
STEN	Output of oil/gas surface tensions ( <b>Miscible</b> option).		x
SURF	Surfactant concentration - Surfactant option.		x
SURFADS	Output of current adsorbed surfactant concentration on the formation rock (for the Surfactant Model).	x	
SURFBLK	Output of the Surfactant concentrations (for the Surfactant Model) and water-oil surface tensions.	x	
SURFCNM	log (capillary number) - Surfactant option.		x
SURFKR	Relative permeability interpolation parameter - Surfactant option.		x
SURFCP	Capillary pressure multiplier - Surfactant option.		x
SURFST	Oil-water surface tension - Surfactant option.		x
SWAT	Output of grid block water saturations.	x	x
SWATINIT	Output of scaled maximum water-oil capillary pressures generated from initial water distribution entered with keyword <b>SWATINIT</b> .	x	

Mnemonic	Output	E100	E300
SWCO or SWL	Output of the connate water saturation if the end point scaling or the mobile fluid correction option is activated. The output is headed by mnemonic P <sub>SWL</sub> .	x	
SWCR	Output of critical water saturation for each grid cell if the end point scaling or the mobile fluid correction option is activated. The output is headed by mnemonic P <sub>SWCR</sub> .	x	
SWU	Output of the maximum water saturation for each grid cell if the end point scaling or the mobile fluid correction option is activated. The output is headed by mnemonic P <sub>SWU</sub> .	x	
TBLK or TRACER	Output of initial grid block tracer concentrations (for Tracer Tracking).	x	
TCMULT	Saturation dependent thermal transmissibility multiplier $\lambda$ ( <a href="#">THERMAL</a> option).		x
TCSTRES	Geomechanics: outputs initial tectonic induced effective stress.		x
TEMP	Output of the grid block temperature (for the Temperature option in ECLIPSE 100 or the <a href="#">THERMAL</a> option in ECLIPSE 300).	x	x
THPRES	Output of threshold pressures (see keywords <a href="#">EQLOPTS</a> and <a href="#">THPRES</a> )	x	x
THSTRES	Geomechanics: outputs initial thermal induced effective stress.		x
TRADS or TRDCY	Output of tracer adsorption and decay (for Environmental Tracers).	x	
TVDP	Output of initial tracer concentration versus depth tables for the Tracer Tracking option (input using <a href="#">TVDP</a> ).	x	
VGAS	Output of grid block gas viscosity.	x	x
VMF	Output of vapor mole fractions (fraction of total hydrocarbon moles in gas).		x
VOIL	Output of grid block oil viscosity.	x	x
VWAT	Output of grid block water viscosity.	x	x
WATPOT	Output of water potentials		x
WOC	Output of initial water-oil contact depths in the VE option: output is AAAAA for contact depth above top of cell output is BBBBB for contact depth below bottom of cell	x	
XFW	Output of liquid component mass fractions (weight fraction of each component in liquid).		x
XGAS	Output of gas fractional saturations (Sudation option).		x
XMF	Output of liquid component mole fractions (fraction of each component in liquid).		x
XWAT	Output of water fractional saturations (Sudation option).		x
YFW	Output of vapor component mass fractions (weight fraction of each component in gas).		x

Mnemonic	Output	E100	E300
YMF	Output of vapor component mole fractions (fraction of each component in gas).		x
SOLVD	Output of initial solution versus depth tables.		x
ZMF	Output of total component mole fractions.		x

Table 3.46: RPTSOL output controls

The following table lists the additional mnemonics which are available when the `ODD3P` relative permeability and capillary pressure hysteresis model has been selected.

Mnemonic	Output	E100	E300
I'FTGO	Output of gas-oil interfacial tension		x
I'FTOW	Output of oil-water interfacial tension		x
I'FTGW	Output of gas-water interfacial tension		x
KRGOE	Output of equivalent relative permeabilities to gas for gas-oil system		x
KRGWE	Output of equivalent relative permeabilities to gas for gas-water system		x
KROGE	Output of equivalent relative permeabilities to oil for oil-gas system		x
KROWE	Output of equivalent relative permeabilities to oil for oil-water system		x
KRWGE	Output of equivalent relative permeabilities to water for water-gas system		x
KRWOE	Output of equivalent relative permeabilities to water for water-oil system		x
KRGOH	Output of turning point relative permeabilities to gas for gas-oil system		x
KRGWH	Output of turning point relative permeabilities to gas for gas-water system		x
KROGH	Output of turning point relative permeabilities to oil for oil-gas system		x
KROWH	Output of turning point relative permeabilities to oil for oil-water system		x
KRWGH	Output of turning point relative permeabilities to water for water-gas system		x
KRWOH	Output of turning point relative permeabilities to water for water-oil system		x
KRGOR	Output of representative gas-oil relative permeabilities		x
KRGWR	Output of representative gas-water relative permeabilities		x
KROGR	Output of representative oil-gas relative permeabilities		x
KROWR	Output of representative oil-water relative permeabilities		x
KRWGR	Output of representative water-gas relative permeabilities		x
KRWOR	Output of representative water-oil relative permeabilities		x
KRGOT	Output of opposite saturation direction turning point relative permeabilities to gas for gas-oil system		x
KRGWT	Output of opposite saturation direction turning point relative permeabilities to gas for gas-water system		x
KROGT	Output of opposite saturation direction turning point relative permeabilities to oil for oil-gas system		x
KROWT	Output of opposite saturation direction turning point relative permeabilities to oil for oil-water system		x

<b>Mnemonic</b>	<b>Output</b>	<b>E100</b>	<b>E300</b>
KRWGT	Output of opposite saturation direction turning point relative permeabilities to water for water-gas system		x
KRWOT	Output of opposite saturation direction turning point relative permeabilities to water for water-oil system		x
PCOWR	Representative oil-water capillary pressure		x
PCWOR	Representative water-oil capillary pressure		x
PCOGR	Representative oil-gas capillary pressure		x
PCGOR	Representative gas-oil capillary pressure		x
PCGWR	Representative gas-water capillary pressure		x
PCWGR	Representative water-gas capillary pressure		x
SONRM	Output of normalized oil saturations		x
SGNRM	Output of normalized gas saturations		x
SWNRM	Output of normalized water saturations		x
SDRGO	Output of gas phase saturation direction indicators for gas-oil system		x
SDRGW	Output of gas phase saturation direction indicators for gas-water system		x
SDROG	Output of oil phase saturation direction indicators for oil-gas system		x
SDROW	Output of oil phase saturation direction indicators for oil-water system		x
SDRWG	Output of water phase saturation direction indicators for water-gas system		x
SDRWO	Output of water phase saturation direction indicators for water-oil system		x
SGONE	Output of normalized gas equivalent opposite direction saturations for gas-oil system		x
SGWNE	Output of normalized gas equivalent opposite direction saturations for gas-water system		x
SOGNE	Output of normalized oil equivalent opposite direction saturations for oil-gas system		x
SOWNE	Output of normalized oil equivalent opposite direction saturations for oil-water system		x
SWGNE	Output of normalized water equivalent opposite direction saturations for water-gas system		x
SWONE	Output of normalized water equivalent opposite direction saturations for water-oil system		x
SGONH	Output of normalized gas hysteresis saturations for gas-oil system		x
SGWNH	Output of normalized gas hysteresis saturations for gas-water system		x
SOGNH	Output of normalized oil hysteresis saturations for oil-gas system		x
SOWNH	Normalized oil hysteresis saturations for oil-water system		x
SWGNH	Output of normalized water hysteresis saturations for water-gas system		x
SWONH	Output of normalized oil hysteresis saturations for water-oil system		x
SGROB	Output of residual gas saturation in gas-oil system used to calculate normalized saturations		x

Mnemonic	Output	E100	E300
SGRWB	Output of residual gas saturation in gas-water system used to calculate normalized saturations		x
SORGB	Output of residual oil saturation in oil-gas system used to calculate normalized saturations		x
SORWB	Output of residual oil saturation in oil-water system used to calculate normalized saturations		x
SWRGB	Output of residual water saturation in water-gas system used to calculate normalized saturations		x
SWROB	Output of residual water saturation in water-oil system used to calculate normalized saturations		x
SGROP	Output of process dependent residual gas saturation in gas-oil system		x
SGRWP	Output of process dependent residual gas saturation in gas-water system		x
SORGP	Output of process dependent residual oil saturation in oil-gas system		x
SORWP	Output of process dependent residual oil saturation in oil-water system		x
SWRGP	Output of process dependent residual water saturation in water-gas system		x
SWROP	Output of process dependent residual water saturation in water-oil system		x
SGONT	Output of normalized gas turning point saturations for gas-oil system		x
SGWNT	Output of normalized gas turning point saturations for gas-water system		x
SOGNT	Output of normalized oil turning point saturations for oil-gas system		x
SOWNT	Output of normalized oil turning point saturations for oil-water system.		x
SWGNT	Output of normalized water turning point saturations for water-gas system		x
SWONT	Output of normalized water turning point saturations for water-oil system		x

Table 3.47: ODD3P RPTSOL output controls

The following table lists the deprecated mnemonics.

Mnemonic	Output	E100	E300
SGCR	This mnemonic has been superseded by PSGCR (TZONE, mobile fluid correction options, ENKRVC and ENKRVT cases).		x
SGL	This mnemonic has been superseded by PSGL (ENKRVC and ENKRVT cases).		x
SGU	This mnemonic has been superseded by PSGU (ENKRVC and ENKRVT cases).		x
SOGCR	This mnemonic has been superseded by PSOGCR (TZONE, mobile fluid correction options, ENKRVC and ENKRVT cases).		x
SOWCR	This mnemonic has been superseded by PSOWCR (TZONE, mobile fluid correction options, ENKRVC and ENKRVT cases).		x
SWCR	This mnemonic has been superseded by PSWCR (TZONE, mobile fluid correction options, ENKRVC and ENKRVT cases).		x
SWL	This mnemonic has been superseded by PSWL (ENKRVC and ENKRVT cases).		x
SWU	This mnemonic has been superseded by PSWU (ENKRVC and ENKRVT cases).		x

Mnemonic	Output	E100	E300
WMF	The mnemonic has been superseded by AMF.		x

Table 3.48: Deprecated RPTSOL output controls

**Note:** For ECLIPSE 100 gas-water models in which end-point scaling is used, if [SCALECRS](#) is specified with item 1 set to YES and one or more of the mnemonics [SGCO](#), [SGCR](#), [SGL](#), [SGU](#), [SGMAX](#), [PSCGO](#), [PSGCR](#), [PSGL](#), [PSGU](#) or [PPCG](#) have been specified, the gas-water scaling limit will also be output. For a given grid block, this is the maximum of the end-point value specified via [SGCR](#) and the scaling limit specified using [SCALELIM](#). If the [SCALELIM](#) keyword has not been specified, the gas-water scaling limit will correspond to the end-point value specified via [SGCR](#). The gas-water scaling limit is identified by the heading G-W SLIM in the output file.

## ECLIPSE 100

Grid-valued output values in certain types of cell have the decimal point replaced with a special character for ease of identification. See [Table 3.31](#) for details.

## Examples

### Example 1 (ECLIPSE 100)

```
RPTSOL
RESTART=2 SOIL SWAT SGAS /
```

### Example 2 (ECLIPSE 300)

```
RPTSOL
PRESSURE SWAT SOIL SGAS PSAT XMF YMF /
```

## RS

## Initial solution gas-oil ratios

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by one real number for every grid block, specifying the initial solution gas-oil ratio. The data field should be terminated by a slash (/).

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), Mscf/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

Grid blocks are ordered with the X axis index cycling fastest (from 1 to NDIVIX), followed by the Y axis index (from 1 to NDIVIY), and finally the Z axis index (from 1 to NDIVIZ). NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword [DIMENS](#). Repeat counts may be used for repeated values (for example 115\*2.893). Note that spaces must not be inserted on either side of the asterisk (\*).

This keyword is an alternative to the [PBUB](#) keyword for defining the initial dissolved gas distribution in runs with enumerated initial conditions.

See also the keywords [PRESSURE](#), [PRVD](#), [RV](#), [PDEW](#), [SWAT](#) and [SGAS](#) in the SOLUTION section.

## Example

With NDIVIX=8, NDIVIY=6 and NDIVIZ=5 specified in RUNSPEC keyword [DIMENS](#):

```
RS
48*1.29      192*1.42      /
```

## RSCONST Sets a constant $R_s$ value for dead oil

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword is used to declare that dead oil contains a constant and uniform concentration of dissolved gas. This provides a more efficient way of modeling black oil systems in which there is no free gas and the pressure never falls below the bubble point. The flags for gas and dissolved gas in the RUNSPEC section should not be switched on (keywords [GAS](#) and [DISGAS](#)), so that gas is not treated in the model as an active phase. The system therefore becomes a two-phase or single-phase model, depending on whether or not water is present as well as the oil. The oil should be treated as dead oil (using keyword [PVDO](#) to supply its PVT properties).

The keyword should be followed by a line containing two items of data, terminated by a slash (/):

1. The dissolved gas concentration ( $R_s$ ).

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), Mscf/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

2. The bubble point pressure.

The run will terminate if the pressure in any grid block falls below this value.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

The keyword causes the oil density to be modified to include the dissolved gas, and causes the gas flow rates to be set equal to  $R_s$  \* the oil flow rate.

See also keyword [RSCONSTT](#).

### Example

```
RSCONST
0.37 1015 /
```

## RSCONSTT Sets a constant $R_s$ value for each dead oil PVT table

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword is used to declare that the dead oil associated with each individual PVT table region contains a constant and uniform concentration of dissolved gas. This provides a more efficient way of modeling black oil systems in which there is no free gas and the pressure never falls below the bubble point.

The difference between this keyword and [RSCONST](#) is that [RSCONSTT](#) allows the oil in different PVT table regions to have different  $R_s$  values. There must be no transmissibility between PVT table regions with different  $R_s$  values, to prevent oils with different  $R_s$  values from mixing. (If oil is allowed to flow between the regions, their  $R_s$  values will change with time, and the reservoir must be modeled as live oil system with gas as an active phase.) Similarly, no well can be completed in two or more PVT table regions having different  $R_s$  values.

The flags for gas and dissolved gas should not be switched on (keywords [GAS](#) and [DISGAS](#) in the [RUNSPEC](#) section), so that gas is not treated in the model as an active phase. The system therefore becomes a two-phase or single-phase model, depending on whether or not water is present as well as the oil. The oil should be treated as dead oil (using keyword [PVDO](#) to supply its PVT properties). PVT table regions are defined using keyword [PVTNUM](#).

The keyword should be followed by [NTPVT](#) (see keyword [TABDIMS](#) in the [RUNSPEC](#) section) lines, one for each PVT table region.

Each line contains two items of data, terminated by a slash (/):

1. The dissolved gas concentration ( $R_s$ ).

UNITS:  $\text{sm}^3/\text{sm}^3$  ([METRIC](#)),  $\text{Mscf}/\text{stb}$  ([FIELD](#)),  $\text{scc}/\text{scc}$  ([LAB](#)),  $\text{sm}^3/\text{sm}^3$  ([PVT-M](#))

The run will terminate if the pressure in any grid block in the PVT region falls below this value.

UNITS: barsa ([METRIC](#)), psia ([FIELD](#)), atma ([LAB](#)), atma ([PVT-M](#))

2. The bubble point pressure.

The keyword causes the oil density of each PVT region to be modified to include the dissolved gas, and causes the gas flow rate from each well to be set equal to its oil flow rate multiplied by the  $R_s$  value associated with the region in which it is completed. The group and field gas flows are obtained by summing the well gas flows.

### Example

With [NTPVT](#)=2:

```
RSCONSTT
 0.37 1015 /
 0.47 1030 /
```

## RSGI

## Variation of saturated GOR with pressure and Gi

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTPVT (item 2 in keyword [TABDIMS](#)) tables of saturated oil gas-oil ratio multiplier functions, each terminated by a slash (/), describing the variation of the maximum possible GOR of oil with pressure and Gi values. Each table consists of up to NPPVT sets of data records. Each set of records within a table consists of up to NPPVT records of data items to allow the specification of a two-dimensional (P, Gi) function which multiplies the saturated GOR value at (P, Gi=0) to give the true saturated GOR at (P, Gi). The saturated GOR value at (P, Gi=0) is obtained from the corresponding PVTO table.

The first record of each elementary set of records contains the following items of data:

1. The oil pressure value.

The values should increase monotonically down the column.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB)

2. The factor by which the saturated oil GOR calculated from the PVTO keyword at a pressure corresponding to item 1 has to be multiplied to give the true saturated oil GOR at a pressure corresponding to item 1 and a Gi value given by item 1 in the corresponding GINODE table.

For record 2 and all subsequent records up to a maximum of NPPVT, there should be only 1 data item in the record. This item defines the corresponding factor by which the saturated oil GOR at (P, Gi=0) (computed from the PVTO data) has to be multiplied to give the true saturated oil GOR at a pressure value given in item 1 above and whose Gi value is specified in the corresponding record in the [GINODE](#) keyword.

See "[Gi pseudo-compositional model](#)" in the *ECLIPSE Technical Description* for further information.

### Example

With NTPVT=1 and NPPVT=2

```
RSGI
100.0  1.0
        0.9  /
200.0  1.0
        0.85 /
/
```

## Rs versus depth tables for equilibration

The data comprises NTEQUL (see keyword [EQLDIMS](#)) tables of dissolved gas-oil ratio versus depth, one for each equilibration region. Each table consists of 2 columns of data, and must be terminated by a slash (/).

1. Depth values.

The values should increase monotonically down the column.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

2. The corresponding values of  $R_s$ , the dissolved gas-oil ratio.

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), Mscf/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NDRXVD (see keyword [EQLDIMS](#)).

The entire table may be defaulted provided the table is not the first. Defaulted tables are replaced with a copy of the previous table.

This keyword is an alternative to the [PBVD](#) keyword, in which the bubble point pressure is tabulated against depth for each equilibration region. See also the keyword [EQUIL](#).

ECLIPSE 100

In API tracking runs, however, the PBVD keyword cannot be used, and thus the RSVD keyword should be used.

ECLIPSE 300

The RSVD keyword may also be used in the PROPS section, but is active only for Black-Oil cases. For compositional runs please refer to alternative ways for initialization such as [ZMFVD](#).

---

**Note:** It is possible to specify a negative depth value.

---

See "[Initializing the study](#)" in the *ECLIPSE Technical Description* for further information

### Example

With NTEQUL=1 and NDRXVD  $\geq$ 2:

```

RSVD
7000 1.4
8000 1.4 /

```

## Initial aqueous concentration of dissolved gases

This keyword should be used in `CO2SOL` and/or `H2SSOL`, or `GASSOL` cases where the initial solution is given by enumeration.

The keyword should be followed by up to `NCMPHW` real numbers for every grid block, specifying the initial concentration of dissolved gases (for example,  $\text{CO}_2$  and/or  $\text{H}_2\text{S}$ ) in the aqueous phase. This is expressed as the volume of dissolved gases (for example,  $\text{CO}_2$  or  $\text{H}_2\text{S}$ ) at surface conditions per volume of water at surface conditions. If `H2SSOL` is used the grid values correspond to the  $\text{H}_2\text{S}$  component. If both `CO2SOL` and `H2SSOL` are present all grid values for  $\text{CO}_2$  are entered first followed by the values for  $\text{H}_2\text{S}$ . If `GASSOL` is used the grid values correspond to the `NCMPHW` components.

The data field should be terminated by a slash (/).

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), Mscf/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

Grid blocks are ordered with the X axis index cycling fastest (from 1 to `NDIVIX`), followed by the Y axis index (from 1 to `NDIVIY`), and finally the Z axis index (from 1 to `NDIVIZ`). `DIVIX`, `NDIVIY` and `NDIVIZ` are specified in `RUNSPEC` keyword `DIMENS`. Repeat counts may be used for repeated values (for example `115*2.893`). Note that spaces must not be inserted on either side of the asterisk (\*).

See also the `RSWVD` keyword and "[CO2/H2S solution in the aqueous phase](#)" and "[GASSOL solution in the aqueous phase](#)" in the *ECLIPSE Technical Description*.

## RSWVD

## Aqueous concentration of dissolved gases versus depth

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises a table of concentrations of dissolved gases (for example, CO<sub>2</sub> and or H<sub>2</sub>S) versus depth. Each table consists of number columns of data (for example, 2 columns for CO<sub>2</sub>SOL or H<sub>2</sub>SSOL, 3 columns for CO<sub>2</sub>SOL and H<sub>2</sub>SSOL, and NCMPHW +1 columns for the GASSOL case), and must be terminated by a slash (/).

Column:

- Depth values.  
Should increase monotonically down column.  
UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)
- Concentration of first dissolved gas (for example, CO<sub>2</sub> in the CO<sub>2</sub>SOL case or the concentration of H<sub>2</sub>S for the H<sub>2</sub>SSOL case) in the aqueous phase.  
UNITS: sm<sup>3</sup>/sm<sup>3</sup> (METRIC), Mscf/stb (FIELD), scc/scc (LAB), sm<sup>3</sup>/sm<sup>3</sup> (PVT-M)
- Concentration of second dissolved gas (for example, H<sub>2</sub>S if both CO<sub>2</sub>SOL and H<sub>2</sub>SSOL are present) in the aqueous phase.  
UNITS: sm<sup>3</sup>/sm<sup>3</sup> (METRIC), Mscf/stb (FIELD), scc/scc (LAB), sm<sup>3</sup>/sm<sup>3</sup> (PVT-M)
- to NCMPHW+1.  
Concentration of last dissolved gas, for example concentration of dissolved gas number NCMPHW specified by the GASSOL keyword.  
UNITS: sm<sup>3</sup>/sm<sup>3</sup> (METRIC), Mscf/stb (FIELD), scc/scc (LAB), sm<sup>3</sup>/sm<sup>3</sup> (PVT-M)

There must be the same number of entries in each column of a given table. This number should not be greater than the maximum number of entries in a quantity versus depth table (EQLDIMS item 3).

If RSWVD is not used in equilibrated cases (EQUIL keyword present) then the initial concentration of dissolved gases (for example, for CO<sub>2</sub> and or H<sub>2</sub>S) is taken to be zero.

The initial aqueous concentration will be set from this keyword, unless the concentration exceeds the saturated value in which case the saturated value will be taken. Note, however, that the aqueous concentration may not be in equilibrium with the gaseous concentration (for example, for CO<sub>2</sub> or H<sub>2</sub>S) and hydrocarbon liquid. The concentration reported at initialization is the concentration after flashing the system, and hence dissolved gases (for example, CO<sub>2</sub> or H<sub>2</sub>S) may be redistributed between the phases in each grid block.

See also "CO<sub>2</sub>/H<sub>2</sub>S solution in the aqueous phase" and "GASSOL solution in the aqueous phase" in the *ECLIPSE Technical Description*.

## Specifies a constant reservoir temperature

When an equation of state (EoS) is being used, the reservoir temperature must be specified. This is then used to calculate reduced temperatures according to the formula  $T_r = T_{res}/T_c$ , where  $T_c$  is the critical temperature. In Thermal simulations this keyword can be used to set the initial temperature in the reservoir.

A variable temperature profile with depth can be specified with the [TEMPVD](#) keyword. If an explicit initialization is used, the [TEMPI](#) keyword can also be used.

---

**Note:** The keyword [RTEMPA](#) is accepted as an alias for RTEMP.

---

In ECLIPSE 100, the RTEMP keyword is used to specify the initial reservoir temperature in runs where the Temperature option is active (keyword [TEMP](#) in the [RUNSPEC](#) section). See also keywords [RTEMPVD](#), [SPECHEAT](#), [SPECROCK](#) and [WTEMP](#), and "Temperature option" in the *ECLIPSE Technical Description*.

In ECLIPSE 100, the RTEMP keyword is accepted in the PROPS section only if the [EQUIL](#) keyword is defined in the SOLUTION section. Non-equilibrium initialization requires the RTEMP keyword to appear in the SOLUTION section.

Except in the following scenario, the keyword is followed by a single item of data, the reservoir temperature, terminated with a slash (/).

In ECLIPSE 300, if multiple EoS regions are used, the temperature value in the SOLUTION section must be entered for each such region. The number of reservoir EoS regions is specified by the 9<sup>th</sup> parameter of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "Equations of State Regions" in the *ECLIPSE Technical Description*.

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

DEFAULT: 60 °F (ECLIPSE 100), 100 °C (ECLIPSE 300)

### Example

```
RTEMP
200 /
```

## RTEMPA

## RTEMPVD

## Initial reservoir temperature versus depth tables

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

The RTEMPVD keyword is used to specify the initial reservoir temperature as a function of depth, in runs where the Temperature option is active (see keyword [TEMP](#) in the RUNSPEC section).

The data comprises NTEQUL (see keyword [EQLDIMS](#)) tables of temperature versus depth, one for each equilibration region. Each table consists of 2 columns of data, and must be terminated by a slash (/).

1. Depth values.

The values should increase monotonically down the column.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

2. The corresponding values of reservoir temperature.

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NDRXVD (see keyword [EQLDIMS](#)).

The entire table may be defaulted provided that the table is not the first. Defaulted tables are replaced with a copy of the previous table.

Note that this keyword sets up the initial temperature distribution, but as there are no heat sources/sinks at the top and bottom of the reservoir this thermal gradient will not be in equilibrium. Over a long time period the reservoir equilibrates to a constant temperature. However, as this equilibration process is usually very slow it may often be ignored in many reservoir applications.

See also keywords [RTEMPA](#), [SPECHEAT](#), [SPECROCK](#) and [WTEMP](#), and the "Temperature option" in the *ECLIPSE Technical Description*.

ECLIPSE 300

The RTEMPVD keyword is an alias for the [TEMPVD](#) keyword.

The keyword should be followed by one real number for every grid block, specifying the initial vapor oil-gas ratio. The data field should be terminated by a slash (/).

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/Mscf (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

Grid blocks are ordered with the X axis index cycling fastest (from 1 to NDIVIX), followed by the Y axis index (from 1 to NDIVIY), and finally the Z axis index (from 1 to NDIVIZ). DIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword [DIMENS](#). Repeat counts may be used for repeated values (for example 115\*0.00377). Note that spaces must not be inserted on either side of the asterisk (\*).

This keyword is an alternative to the [PDEW](#) keyword for defining the initial vaporized oil distribution in runs with enumerated initial conditions.

See also the keywords [PRESSURE](#), [PRVD](#), [RS](#), [PBUB](#), [SWAT](#) and [SGAS](#) in the SOLUTION section.

## Example

With NDIVIX=8, NDIVIY=6 and NDIVIZ=5 specified in RUNSPEC keyword [DIMENS](#):

```
RV
48*0.00725 48*0.00326 144*0 /
```

## RVCONST Sets a constant $R_v$ value for dry gas

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword is used to declare that dry gas contains a constant and uniform concentration of vaporized oil. This provides a more efficient way of modeling gas condensate systems in which there is no free oil and the pressure never falls below the dew point. The flags for oil and vaporized oil should not be switched on (keywords [OIL](#) and [VAPOIL](#) in the RUNSPEC section), so that oil is not treated in the model as an active phase. The system therefore becomes a two-phase or single-phase model, depending on whether or not water is present as well as the gas. The gas should be treated as dry gas (using keyword [PVDG](#) to supply its PVT properties).

The keyword should be followed by a line containing two items of data, terminated by a slash (/):

1. The vaporized oil concentration ( $R_v$ ).

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/Mscf (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

2. The dew point pressure.

DEFAULT: 0.0

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

The run terminates if the pressure in any grid block falls below this value.

The keyword causes the gas density to be modified to include the vaporized oil, and causes the oil flow rates to be set equal to  $R_v$  \* the gas flow rate.

See also keyword [RVCONSTT](#).

### Example

```
RVCONST
0.00047 330 /
```

## RVCONSTT Sets a constant $R_v$ value for each dry gas PVT table

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword is used to declare that the dry gas associated with each individual PVT table region contains a constant and uniform concentration of vaporized oil. This provides a more efficient way of modeling gas condensate systems in which there is no free oil and the pressure never falls below the dew point.

The difference between this keyword and [RVCONST](#) is that [RVCONSTT](#) allows the gas in different PVT table regions to have different  $R_v$  values. There must be no transmissibility between PVT table regions with different  $R_v$  values, to prevent gases with different  $R_v$  values from mixing. (If gas is allowed to flow between the regions, their  $R_v$  values will change with time, and the reservoir must be modeled as wet gas system with oil as an active phase.) Similarly, no well can be completed in two or more PVT table regions having different  $R_v$  values.

The flags for oil and vaporized oil should not be switched on (keywords [OIL](#) and [VAPOIL](#) in the [RUNSPEC](#) section), so that oil is not treated in the model as an active phase. The system therefore becomes a two-phase or single-phase model, depending on whether or not water is present as well as the gas. The gas should be treated as dry gas (using keyword [PVDG](#) to supply its PVT properties). PVT table regions are defined using keyword [PVTNUM](#).

The keyword should be followed by [NTPVT](#) (see item 2 of keyword [TABDIMS](#) in the [RUNSPEC](#) section) lines, one for each PVT table region.

Each line contains two items of data, terminated by a slash (/):

1. The vaporized oil concentration ( $R_v$ ).

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/Mscf (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

2. The dew point pressure.

DEFAULT: 0.0

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

The run will terminate if the pressure in any grid block in the PVT region falls below this value.

The keyword causes the gas density of each PVT region to be modified to include the vaporized oil, and causes the oil flow rate from each well to be set equal to its gas flow rate multiplied by the  $R_v$  value associated with the region in which it is completed. The group and field oil flows are obtained by summing the well oil flows.

### Example

With [NTPVT](#)=2:

```
RVCONSTT
0.00047 330 /
0.00057 350 /
```

## RVGI

## Variation of saturated OGR with pressure and Gi

	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTPVT (item 2 in keyword [TABDIMS](#)) tables of saturated gas oil-gas ratio multiplier functions, each terminated by a slash (/), describing the variation of the maximum possible OGR of gas with pressure and Gi values. Each table consists of up to NPPVT sets of data records. Each set of records within a table consists of up to NPPVT records of data items to allow the specification of a two-dimensional (P, Gi) function which multiplies the saturated OGR value at (P, Gi=0) to give the true saturated OGR at (P, Gi). The saturated OGR value at (P, Gi=0) is obtained from the corresponding PVTG table.

The first record of each elementary set of records contains the following items of data:

1. The gas pressure value.  
The values should increase monotonically down the column.  
UNITS: barsa (METRIC), psia (FIELD), atma (LAB)
2. The factor by which the saturated OGR calculated from the PVTG keyword at a pressure corresponding to item 1 has to be multiplied to give the true saturated OGR at a pressure corresponding to item 1 and a Gi value given by item 1 in the corresponding GINODE table.

For record 2 and all subsequent records up to a maximum of NPPVT, there should be only 1 data item in the record. This item defines the corresponding factor by which the saturated OGR at (P, Gi=0) (computed from the PVTG data) has to be multiplied to give the true saturated OGR for gas at a pressure value given in item 1 above and whose Gi value is specified in the corresponding record in the [GINODE](#) keyword.

See "[Gi pseudo-compositional model](#)" in the *ECLIPSE Technical Description* for further information.

## Example

With NTPVT=1 and NPPVT=2

```
RVGI
100.0  1.0
        0.75 /
200.0  1.0
        0.72 /
/
```

## Rv versus depth tables for equilibration

The data comprises NTEQUL (see keyword [EQLDIMS](#)) tables of vaporized oil-gas ratio versus depth, one for each equilibration region.

Each table consists of 2 columns of data, and must be terminated by a slash (/).

1. Depth values.

The values should increase monotonically down the column.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

2. The corresponding values of Rv, the vaporized oil-gas ratio.

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/Mscf (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NDRXVD (see item 3 of keyword [EQLDIMS](#)).

The entire table may be defaulted provided the table is not the first. Defaulted tables are replaced with a copy of the previous table.

This keyword is an alternative to the [PDVD](#) keyword, in which the dew point pressure is tabulated against depth for each equilibration region. See also the keyword [EQUIL](#).

The RVVD keyword may also be used in the PROPS section.

---

**Note:** It is possible to specify a negative depth value.

---

See "[Initializing the study](#)" in the *ECLIPSE Technical Description* for further information.

### Example

With NTEQUL=1 and NDRXVD  $\geq$ 2:

```
RVVD
7000 0.00725
8000 0.00725 /
```

## **S**

This section contains an alphabetic listing of keywords starting with the letter S.

## SALINTR

This keyword is an extension of the [SALINITY](#) keyword and can be used to specify a salinity value **region-by-region**. The regions are the regions defined for the EoS (Equation Of State) using [EOSNUM](#) and their number is specified in item 9 of [TABDIMS](#) keyword.

The salinity is used in the modified Peng-Robinson equation of state in [GASWAT](#) cases and in the default CO<sub>2</sub> solubility data in [CO2SOL](#) cases. The units are molality (gm-M/kg).

UNITS: 10<sup>-3</sup> kg-M/kg (METRIC), 10<sup>-3</sup> lb-M/lb (FIELD), 10<sup>-3</sup> gm-M/gm (LAB), 10<sup>-3</sup> kg-M/kg (PVT-M)

The relationship to the alternative definition in terms of parts per million by mass is described in "[GASWAT option](#)" in the *ECLIPSE Technical Description*.

## Example

Example with item 9 of TABDIMS equal to 2.

```
SALINTR
0.51 /
0.30 /
```

## SALINITY

## Reservoir salinity

	SUMMARY
	SCHEDULE

This keyword can be used to define the salinity used in the modified Peng-Robinson equation of state in [GASWAT](#) cases and in the default CO<sub>2</sub> solubility data in [CO2SOL](#) cases.

The units are molality (gm-M/kg).

UNITS: 10<sup>-3</sup> kg-M/kg (METRIC), 10<sup>-3</sup> lb-M/lb (FIELD), 10<sup>-3</sup> gm-M/gm (LAB), 10<sup>-3</sup> kg-M/kg (PVT-M)

In CO2SOL cases, this keyword corrects the solubility table and does not have any impact on the surface water density. [DENSITY](#) or [GRAVITY](#) can be used to that effect.

The relationship to the alternative definition in terms of parts per million by mass is described in "[GASWAT option](#)" in the *ECLIPSE Technical Description*.

## Example

```
SALINITY
0.51 /
```

# SALT

## Initial salt concentrations

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by one real number for every grid block specifying the initial salt concentration. The data field should be terminated by a slash (/).

The brine option must be activated (keyword [BRINE](#)).

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB), kg/sm<sup>3</sup> (PVT-M)

Grid blocks are ordered with the X axis index cycling fastest (from 1 to NDIVIX), followed by the Y axis index (from 1 to NDIVIY), and finally the Z axis index (from 1 to NDIVIZ). NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword [DIMENS](#). Repeat counts may be used for repeated values (for example 115\*0.22). Note that spaces must not be inserted on either side of the asterisk (\*).

This keyword should be used when the initial state has been set by enumeration (see keywords [PRESSURE](#), [RS](#), [RV](#), [SGAS](#) and [SWAT](#) in the SOLUTION section). For a run initialized by equilibration ([EQUIL](#) keyword), the [SALTVTD](#) keyword should be used instead of SALT.

When the multi-component brine model (keyword [BRINE](#) in conjunction with keyword [ECLMC](#)) is active the SALT keyword specifies the initial mass concentration of every salt in the model as specified by the [BRINE](#) keyword. In this case the keyword should be followed by one record of data for every salt, each record containing one real number for every grid block specifying the initial salt concentration. The whole data field should be terminated by a single slash (/).

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB)

### Examples

#### Example 1

With NDIVIX =8, NDIVIY =6 and NDIVIZ =5 specified in RUNSPEC keyword [DIMENS](#):

```
SALT

## SALTEFF

## Effective salinity coefficients for surfactant and polymer models

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword may only be used when salinity dependent surfactant and/or polymer models are active (when keywords `SURFSTES` with `ESSNODE` or `PLYVISCS` with `ESPNOE` are specified in the `PROPS` section).

The `SALTEFF` keyword determines the effective salinity calculations of the water phase.

The data comprises NTPVT records of data (see item 2 of keyword `TABDIMS`). In a run with  $N_w$  water components (see keyword `COMPW`), each record requires  $2 + 2(N_w + 1)$  items:

1. This item specifies the model for which effective salinity must be calculated. This item should be entered as characters `SURF` or `POLY` to indicate if the calculations are for Surfactant or Polymer models respectively.
2. The expression to be used for effective salinity calculation. The item should be entered as an integer number: 1 or 2.

- If this item is set to 1, the effective salinity  $E_s$  is calculated using:

$$E_s = \frac{a_0 + \sum_{i=1}^{N_w} a_i C_i}{b_0 + \sum_{i=1}^{N_w} b_i C_i}$$

- If this item is set to 2, the effective salinity  $E_s$  is calculated using:

$$E_s = \frac{a_0 + \sum_{i=1}^{N_w} a_i C_i}{b_0 + \frac{1}{C_s} \sum_{i=1}^{N_w} b_i C_i}$$

where the coefficients  $a_0$ ,  $a_i$ ,  $b_0$  and  $b_i$  are input with subsequent items of this keyword,  $C_i$  is the concentration of water component  $i$  and  $C_s$  stands for the concentration of surfactant.

Formula 2 is only valid for the Surfactant model. If formula 2 is used for Polymer model, a warning message will be displayed and the item 2 of `SALTEFF` will be defaulted to 1.

3. The coefficient  $a_0$ .

4. The coefficient  $a_1$

...

...

- $N_w + 3$ . The coefficient  $a_{N_w}$

$N_w + 4$ . The coefficient  $b_0$

...

...

$2(N_w + 1) + 2$ . The coefficient  $b_{N_w}$

items other than the first two might be defaulted to 0.0 using 1\*.

The set of coefficients input with this formula are meant to allow the user flexibility when defining the calculation of effective salinity as a function of the concentration of salts in the model. It might be noted, for instance that the expression for effective salinity input with the ECLIPSE 100 keyword [PLYESAL](#) can be recovered with Formula 1 above. Similarly, the expression for effective salinity input with the ECLIPSE 100 keyword [SURFESAL](#) can be recovered with Formula 2 above.

There are currently no restrictions on the choice of coefficients  $a_i$  and  $b_i$ ,  $i = 1, \dots, N_w$ . However, if item 2 is set to 2, it is not recommended to choose coefficients  $a_i$  and  $b_i$ ,  $i = 0, \dots, N_w$  in such a way that the resulting expression only depends on surfactant concentration.

If the Surfactant and Polymer models are used in the same run, this keyword may be used twice; one instance of the keyword to input data for each model.

For further information on effective salinity calculations, see "[Effective salinity calculations](#)" in the *ECLIPSE Technical Description* and Chapter 3 "Salinity Effect and Ion Exchange" in [\[Ref. 137\]](#).

## Example

With  $N_w = 3$  and NTPVT=1:

```

SALTEFF
-- model    effective      a_0   a_1   a_2   a_3   b_0   b_1   b_2   b_3
-- type     salinity type
  POLY      1              0.0   1.1   0.0   0.1   1.0   0.6   1.0   0.3 /

SALTEFF
--model     effective      a_0   a_1   a_2   a_3   b_0   b_1   b_2   b_3
-- type     salinity type
  SURF      2              0.0   2.1   1.4   0.0   0.1   2.1   0.8   0.0 /
    
```

## SALTNODE Salt concentration nodes for polymer solution viscosity

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTPVT (see RUNSPEC keyword [TABDIMS](#)) tables of salt concentration values, each terminated by a slash (/), describing the nodal values for salt concentration to be used in the calculation of the polymer solution viscosity.

Note that this differs from the [ADSALNOD](#) keyword in being specified by PVT region rather than by saturation function.

Each table consists of up to NPPVT (see RUNSPEC keyword [TABDIMS](#)) values of the salt concentration. Within each table the values should be positive and strictly increasing.

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB)

The number of entries in each table must correspond to the number of polymer solution viscosity entries used in the [PLYVISC](#) keyword.

Note that if keyword [ECLMC](#) is selected, the [BRINE](#) keyword activates the Multi-Component Brine Model (ECLIPSE 100 only) and functionality such as the polymer salt-sensitivity option (keywords [POLYMER](#), [BRINE](#), [SALTNODE](#) and [ADSALNOD](#)) cannot be used.

### Example

With NTPVT=2 and NPPVT ≥4

```
SALTNODE
  1.0
  5.0
 10.0
 30.0 /
  5.0
 30.0 /
```

## SALTVD

## Salt concentration versus depth for equilibration

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTEQUL (see keyword [EQLDIMS](#)) tables of salt concentration versus depth, one for each equilibration region. The Brine option must be activated (keyword [BRINE](#)).

Each table consists of the following columns of data, and must be terminated by a slash (/).

Column:

1. Depth values.

The values should increase monotonically down the column.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

2. to [N+1] The corresponding values of salt concentration.

The standard Brine Model has a single salt component. In this case, column 2 of this keyword contains a single value which is the concentration of this salt at each depth.

When the Multi-Component Brine model (keyword [BRINE](#) with keyword [ECLMC](#)) is active, the [BRINE](#) keyword has N entries which specify the brine's salt components. In this case, columns 2 to [N+1] of the [SALTVD](#) keyword contain tables of salt concentration versus depth, one for each salt in the model as specified by the [BRINE](#) keyword.

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB), kg/sm<sup>3</sup> (PVT-M)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than [NDRXVD](#) (see keyword [EQLDIMS](#)).

See also keyword [EQUIL](#).

## Examples

### Example 1

With NTEQUL=1 and NDRXVD ≥2:

```
SALTVD
7000 1.4
8000 1.4 /
```

### Example 2

Multi-component brine model with two salts specified in the [BRINE](#) keyword and with NTEQUL=2 and NDRXVD ≥2:

```
SALTVD
-- Region 1
-- Depth Salt1 Salt2
7000 1.4 0.02
8000 1.4 0.03/
-- Region 2
-- Depth Salt1 Salt2
7000 1.2 0.01
8000 1.3 0.02/

	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

ECLIPSE 300 only. This is an optional keyword which specifies that the underlying linear systems should be solved using the algebraic multigrid solver SAMG, and controls its behavior. SAMG is currently a suitable choice in combination with the [IMPES](#) or [GEOMECH](#) keywords, but not in general for other types of simulation. Some additional SAMG control parameters are included under the [CVCRIT](#) keyword.

ECLIPSE 100 only. This keyword is only available to Schlumberger engineers and can only be accessed if the Water Services license is obtained. It is only used to replace the linear solver when using the standard solution method for a single phase tracer. It should not generally be used as it will slow down most runs. It does offer a huge benefit, though, when hydraulic dispersion, [HDISP](#) keyword, is being used. It does not work when parallel is being used.

The keyword may be followed by up to 2 items, terminated by a slash (/).

### 1. EPS

This defines the tolerance used in the stopping criterion. Positive values define the required relative residual norm reduction. Negative values define the required absolute residual norm. A zero value indicates no stopping requirement.

DEFAULT:1.0E-4

### 2. REUSE

Specifies whether to reuse the coarse grid and smoothing operators from a previous call to SAMG.

0 do not reuse operators

1 reuse operators throughout timestep

DEFAULT:1

## Example

```
SAMG
1.0E-6 /
```

## SATNUM

## Saturation function region numbers

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by one integer for every grid block in the current input box specifying the saturation function region to which it belongs. The region number should not be less than 1 or greater than NTSFUN (see keyword [TABDIMS](#)). The data must be terminated by a slash (/).

The saturation function region number specifies which set of saturation functions (input using [SGFN](#), [SOF3](#) and related keywords in the PROPS section) should be used to calculate relative permeabilities and capillary pressures in each grid block.

---

**Note:** The saturation function region numbers can be modified during the simulation by re-specifying the SATNUM keyword in the SCHEDULE section. This procedure should only be carried out with care and is **not** recommended in general. In particular this will **not** work with the parallel option.

---

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

ECLIPSE 300

If the [ODD3P](#) relative permeability and capillary pressure hysteresis model has been selected, the SATNUM keyword should not be used. Instead, the primary, secondary hysteresis and tertiary hysteresis saturation region numbers should be specified using the [PSTNUM](#), [ISTNUM](#) and [DSTNUM](#) keywords respectively.

For more information, see the saturation function keywords [SGFN](#), [SWFN](#), [SOF2](#), [SOF3](#), [SOF32D](#), [SGOF](#), [SLGOF](#) and [SWOF](#) in the PROPS section.

### Example

With NTSFUN=2 specified in keyword [TABDIMS](#); NDIVIX=8, NDIVIY=6 and NDIVIZ=5 specified in RUNSPEC keyword [DIMENS](#); and no input BOX set:

```
SATNUM
144*1 96*2 /
```

## SATOPTS

## Options for directional and hysteretic relative permeabilities

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword enables the use of a directional, irreversible or hysteretic relative permeability model and an option to allow capillary pressures to depend on surface tensions. The keyword should be followed by some or all of the following options. The default is for all these options to be switched off.

The data should be terminated by a slash (/).

**DIRECT** Directional relative permeability tables are to be used. Different saturation tables will be used for flows in the I, J and K directions. The table numbers should be entered using [KRUNUMX](#), [KRUNUMY](#) and [KRUNUMZ](#) in the **REGIONS** section. If the flow is reversible (that is the **IRREVERS** option is not specified), then the same table is used whether the flow is from I to I-1 or from I to I+1.

**IRREVERS** This specifies that directional relative permeabilities are irreversible, so that different saturation tables are used depending on whether the flow is from I to I-1 or from I to I+1. The **DIRECT** option must also be specified here. Six sets of directional relative permeability table numbers must be defined using [KRUNUMX](#), [KRUNUMX-](#), [KRUNUMY](#), [KRUNUMY-](#), [KRUNUMZ](#) and [KRUNUMZ-](#) in the **REGIONS** section.

If **DIRECT** is specified but **IRREVERS** is not, then only 3 sets of tables are needed ([KRUNUMX](#), [KRUNUMY](#) and [KRUNUMZ](#)). In this case, the same table is used whether the flow is from I to I-1 or from I to I+1.

**HYSTER** This indicates that the hysteresis option is required (see "[Hysteresis](#)" in the *ECLIPSE Technical Description*). Separate saturation function tables are used for drainage and imbibition. The imbibition table numbers should be identified using [IMBNUM](#) in the **REGIONS** section. If directional relative permeability tables are also specified (**DIRECT**), then imbibition tables for each of the I, J and K directions should be identified using the keywords [IMBNUMX](#), [IMBNUMY](#) and [IMBNUMZ](#). If in addition irreversible relative permeabilities are required (**IRREVERS**), then additional imbibition tables for the opposite directions should also be identified using [IMBNUMX-](#), [IMBNUMY-](#) and [IMBNUMZ-](#).

*ECLIPSE 100 only*

**SURFTENS** This specifies that the oil-gas or oil-water capillary pressures vary with surface tension, so allowing a pressure-dependent adjustment to the oil-gas or oil-water capillary pressures. Tables of surface tension versus pressure should be entered using the [STOG](#) and [STOW](#) keywords in the **PROPS** section.

*ECLIPSE 300*

If the [ODD3P](#) relative permeability and capillary pressure hysteresis model has been selected, the **DIRECT** and **IRREVERS** options are not available and should not be specified. However, the **SATOPTS** keyword with **HYSTER** option must be specified in order to define the model as hysteretic.

---

**Note:** When directional forms of the keywords are used, the isotropic form is still required for use in equilibration and well block flows.

---

## Example

Relative permeabilities are directional and irreversible:

DIRECT IRREVERS /

## SAVE

## Requests output of SAVE file for fast restarts

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The SAVE keyword in the RUNSPEC section is used to write a SAVE file containing the initial non-recurrent data. In ECLIPSE 300, SAVE file output can be controlled using the [MULTSAVE](#) keyword.

The SAVE keyword can be used in the SCHEDULE section of either simulator to write the current solution to the SAVE file.

The SAVE file contains the data entered in the RUNSPEC, GRID, EDIT, PROPS and REGIONS sections, in a processed form so that, for example, the grid block transmissibilities do not have to be recalculated. This data is read in a fast restart. A fast restart cannot be performed without a SAVE file.

In addition for ECLIPSE 100, the time-dependent data (for example grid block solution variables and the status of wells) can optionally be written to the SAVE file instead of the Restart file, leaving the latter free for graphics output. (Use the SAVE keyword in the SCHEDULE section or the SAVE mnemonic in keyword [RPTRST](#) to control data written to the SAVE file.) The SAVE keyword must be present in the RUNSPEC section if you wish to do this, irrespective of whether you will be performing Fast Restarts or Flexible Restarts.

The SAVE keyword is required either if you subsequently want to perform a fast restart on the run, or if you wish to write the time-dependent data to the SAVE file instead of the Restart file. A SAVE file is not required for flexible restarts when the time-dependent data is written to the Restart file.

### ECLIPSE 300

ECLIPSE 300 does not allow a SAVE file to be written during a parallel run. Fast restarts are not supported for parallel runs.

### ECLIPSE 300

In ECLIPSE 300 the current solution can only be written to the SAVE file by using the SAVE keyword in the SCHEDULE section.

### ECLIPSE 100

The SAVE keyword in the RUNSPEC section is followed by one record of data, terminated with a slash (/). The record contains a single word (in quotes):

either FORMATTED or UNFORMATTED

which sets the formatted/unformatted status of the SAVE file, irrespective of whether formatted output is specified using keyword [FMTOUT](#) in the RUNSPEC section. The default status is UNFORMATTED. The word may be shortened to F or U. The use of multiple Save files is not supported in ECLIPSE 100.

### ECLIPSE 300

In ECLIPSE 300 the formatted/unformatted and multiple/unified attributes of the SAVE files are controlled by the [FMPSAVE](#) and [UNIFSAVE](#) /[MULTSAVE](#) keywords.

The SAVE keyword in the SCHEDULE section contains **no** items.

## Examples

### Example 1

Produces an unformatted SAVE file

```

-- ECLIPSE 100
RUNSPEC
SAVE
/

```

## Example 2

Produces a formatted SAVE file

```
-- ECLIPSE 100
RUNSPEC
SAVE
  FORMATTED /
```

## Example 3

Save the current solution after 1 year

```
-- ECLIPSE 100 or ECLIPSE 300
SCHEDULE
TSTEP
365 /
SAVE
TSTEP
365 /
```

## SAVEEND

### Write SAVE file at end of run

This keyword requests that a SAVE file record is always written at the end of the run, irrespective of the reason for ending.

The SAVEEND keyword contains no items.

## SCALECRS Controls the end point scaling method

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The SCALECRS keyword is optional in runs with the end-point scaling option active (keyword [ENDSCALE](#) in the RUNSPEC section). It is used to control the scaling method.

The keyword should be followed by one item of data, indicating whether the alternative scaling method is required, terminated with a slash (/):

either YES or NO

DEFAULT: NO

The word may be shortened to Y or N.

In the default case, the scaling process preserves relative permeabilities at two saturation nodes. The following end-points are assumed for each phase relative permeability:

$K_{rw}$ , [SWCR](#) and [SWU](#)

$K_{rg}$ , [SGCR](#) and [SGU](#)

$K_{row}$ , [SOWCR](#) and (1.0- [SWL](#) - [SGL](#))

$K_{rog}$ , [SOGCR](#) and (1.0-SWL-SGL)

The alternative form of scaling (if YES is specified) preserves the relative permeabilities at three saturation nodes. In three-phase, oil-water or oil-gas runs, or runs that use the miscible flood option, the following end-points are used:

$K_{rw}$ , [SWCR](#), (1.0-SOWCR-SGL) and [SWU](#)

$K_{rg}$ , [SGCR](#), (1.0-SOGCR-SWL) and [SGU](#)

$K_{row}$ , [SOWCR](#), (1.0-SWCR-SGL) and (1.0-SWL-SGL)

$K_{rog}$ , [SOGCR](#), (1.0-SGCR-SWL) and (1.0-SWL-SGL)

In gas-water runs, the following end points are used if the second form of relative permeability scaling is selected:

$K_{rw}$ , [SWCR](#), (1.0-SGCR) and [SWU](#)

$K_{rg}$ , [SGCR](#), (1.0-SWCR) and [SGU](#)

---

### Note:

If the input tables are pure normalized curves (for example if 1.0-SOWCR-SGL equals SWU in the water case), the action of SCALECRS can affect the behavior of the vertical scaling keywords ([KRW](#) and [KRWR](#) in the water case). If the default scaling is used the two end-points (1.0-SOWCR-SGL) and SWU is the same and in this case the [KRWR](#) keyword is ignored. The alternative scaling is likely to split the two end-points and hence both [KRW](#) and [KRWR](#) are honored.

---

ECLIPSE 300

If the [ODD3P](#) relative permeability and capillary pressure hysteresis model has been selected, the alternative scaling method is not available and will be ignored if specified.

See "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for further details.

## Example

```
SCALECRS

```

## SCALELIM Sets saturation table scaling limits

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTENDP (see item 3 of keyword [ENDSCALE](#) in the RUNSPEC section) records of saturation scaling limits to be used in the end point versus depth table method of defining saturation table end point scaling data. Each record consists of at most one real number terminated by a slash (/).

The limiting saturation scaling values must lie between 0.0 and 1.0. A default value of 0.0 is assumed for records where no scaling limit entry is specified.

SCALELIM is only applied to the water phase and can only be used in two-phase runs or runs using the Miscible Flood option.

See the keywords [ENDNUM](#) (REGIONS section) and [ENPTVD](#) (PROPS section).

See "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for further details.

### Example

With NTENDP =6:

```
SCALELIM
0.23 /
0.16 /
0.11 /
0.10 /

## SCDATAB Scale damage tables

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword may be used to input tables which give the reduction factor for the PI of each connection in a well as a function of the current amount of scale deposited per unit length of perforated interval. The tables defined here are allocated to individual wells with the [WSCTAB](#) keyword. The rate of scale deposition around the well connections per unit water flow rate should be defined as a function of the sea water fraction in scale deposition tables supplied by the [SCDPTAB](#) keyword.

The keyword is followed by NTSCDA tables **exactly**, each containing two columns and no more than NPSCDA rows of data. The dimensions NTSCDA and NPSCDA are entered in the RUNSPEC section keyword [SCDPDIMS](#). Each table should be terminated with a slash (/).

1. The current amount of scale deposited per unit length of perforated interval in a well connection.

The values should increase monotonically down the column.

UNITS: gm/m (METRIC), lb/ft (FIELD), gm/cm (LAB), gm/m (PVT-M)

2. The corresponding reduction factor for the PI of the connection.

The effect of the scale damage is to multiply the original connection transmissibility factor by this amount.

Empty tables (containing just their terminating slash) default to a copy of the previous table. Extrapolation outside the range of a table will return the value of the nearest point in the table.

---

**Note:** The scale damage tables are **not** written to the Restart files. Accordingly they must be present in any restarted data set. Thus it is also possible to change the tables at a restart.

---

The calculation for the effect of scale damage on a well is performed explicitly. Thus, at the end of each timestep the mass of scale deposited around each connection will be incremented according to the flow of water during the timestep and the current sea water concentration. This is translated into a PI reduction factor for each connection, which will be used during the following timestep.

The current amount of scale deposited around a connection (calculated using the scale deposition tables) is converted to the current amount of scale deposited per unit length of perforation (for use in these tables) by dividing by the connection length. For multisegment and friction wells, this length is taken directly from associated keyword data. For all other wells, this length is obtained by dividing the effective Kh value by the permeability perpendicular to the direction of penetration (see [COMPDAT](#) keyword).

### Example

With NTSCDA=1. NPSCDA must have been set  $\geq 5$ :

```

SCDATAB
-- scale      PI
-- deposit    mult
   0.0        1.0
   10.0       0.95
   20.0       0.85
   40.0       0.55
   90.0       0.43 /

```

## SCDATABG Scale damage tables for proppant flowback

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword may be used to input tables which give the reduction factor for the productivity index of each connection in a well, as a function of the current amount of proppant or scale deposited per unit length of perforated interval. The tables defined here are allocated to individual wells with the [WSCTAB](#) keyword. This keyword must be used together with the [PROPFLOW](#) and [GEOMECH](#) keywords.

The keyword is followed by exactly NTSCDG tables, each containing two columns and no more than NPSCDG rows of data. The dimensions NTSCDG and NPSCDG are entered in the RUNSPEC section keyword [SCDPDIMS](#). Each table should be terminated with a slash (/).

1. The current amount of scale deposited per unit length of perforated interval in a well connection.

The values should increase monotonically down the column.

UNITS: gm/m (METRIC), lb/ft (FIELD), gm/cm (LAB), gm/m (PVT-M)

2. The corresponding reduction factor for the PI of the connection.

The effect of the scale damage is to multiply the original connection transmissibility factor by this amount.

Empty tables (containing just their terminating slash) default to a copy of the previous table. Extrapolation outside the range of a table will return the value of the nearest point in the table.

The current amount of proppant that is deposited at each completion is calculated by accumulating the total weight of released or flowing proppant over all fracture blocks, which is then divided by the total completed length of the well. The well associated with this fracture is specified in item 12 of the [PROPFLOW](#) keyword. For multisegment and friction wells, this length is taken directly from associated keyword data. For all other wells, this length is obtained by dividing the effective Kh value by the permeability perpendicular to the direction of penetration (see [COMPDAT](#) keyword).

The calculation for the effect of scale damage on a well is performed explicitly. At the end of each timestep or report step, the mass of proppant deposited around each connection will be incremented according to the amount of proppant that is released. The resulting PI reduction factor is applied to all completion connection factors during the following timestep. When the reduction in PI is calculated for the well, the connection factors of all connections are immediately multiplied by the specified reduction factor.

### Example

With NTSCDA=1, NPSCDA must have been set  $\geq 5$ :

```
SCDATABG
-- scale      PI
-- deposit    mult
   0.0        1.0
  10.0        0.95
  20.0        0.85
  40.0        0.55
  90.0        0.43 /
```

	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword may be used to define tables for karst aquifer conduit pipe system, laminar and turbulent salt dissolution and transport parameters.

The SCDETAB keyword is followed by NTSCDE records, each record containing the following data items and each terminated with a slash (/). The dimension NTSCDE is entered in item 7 of keyword [SCDPDIMS](#).

The set of records must be followed by a blank record, containing only a slash.

- Kinetic first order rate constant for laminar flow

UNITS: kg/m<sup>2</sup>/day (METRIC), lb/ft<sup>2</sup>/day (FIELD), gm/cm<sup>2</sup>/hr (LAB)

A value of 0, or a negative value, means dissolution turned off for laminar flow

DEFAULT: 0
- Kinetic first order rate constant for turbulent flow

UNITS: kg/m<sup>2</sup>/day (METRIC), lb/ft<sup>2</sup>/day (FIELD), gm/cm<sup>2</sup>/hr (LAB)

A value of 0, or a negative value, means dissolution turned off for turbulent flow

DEFAULT: 0
- Kinetic fourth order rate constant

UNITS: kg/m<sup>2</sup>/day (METRIC), lb/ft<sup>2</sup>/day (FIELD), gm/cm<sup>2</sup>/hr (LAB)

A value of 0, or a negative value, means dissolution turned off for turbulent flow

DEFAULT: 0
- Diffusion coefficient of calcite in conduit water flow

UNITS: m<sup>2</sup>/day (METRIC), ft<sup>2</sup>/day (FIELD), cm<sup>2</sup>/hr (LAB)

This input cannot be defaulted to zero, rather a positive small value should be given.

DEFAULT: 0.00001 (all unit sets)
- Equilibrium concentration beyond which dissolution of karst conduit will stop.

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB)

DEFAULT: no default
- Relative equilibrium concentration fraction threshold beyond which dissolution kinetics changes from first order to higher order

UNITS: dimensionless

DEFAULT: 1.0
- Maximum diameter size beyond which dissolution stops.

UNITS: m (METRIC), ft (FIELD), cm (LAB)

DEFAULT: no default

8. Density of carbonate rock

UNITS: kg/m<sup>3</sup> (METRIC), lb/ft<sup>3</sup> (FIELD), gm/cc (LAB)

DEFAULT: default to values in the ROCKDEN keyword.

## Example

With NTSCDE=2 specified in keyword `SCDPDIMS`:

```
SCDETAB
1.2e-6 6.94e-9 1.38e-9 3.33e9 2.77e-9 2e-6 0.9 1*/
1.3e-6 6.94e-9 1.38e-9 3.33e9 2.77e-9 2e-6 0.9 1*/
```

x	SCHEDULE

This keyword is used to nominate the tracer whose concentration represents the fraction of sea water present in the water flowing into a well. In conjunction with scale deposition tables (see keyword [SCDPTAB](#)), this tracer is used to calculate the current amount of scale deposited around well connections. The tracer must be already defined as a water phase passive tracer (keyword [TRACER](#) in the PROPS section), with water injectors given a tracer value of 1.0 (keyword [WTRACER](#)), while the tracer value of the water initially in the reservoir is set to 0.0. (See "[Tracer tracking](#)" in the *ECLIPSE Technical Description* for an account of how to define tracers.)

The keyword is followed by a single record, terminated with a slash (/).

1. Name of the tracer

(ECLIPSE 100: Up to 3 characters, ECLIPSE 300: Up to 4 characters)

End data record with a slash (/).

### Example

```
SCDPTRAC
SWA /
```

## SCONINJE Control data for secondary injection wells

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The records may be terminated early with a slash (/), the remaining items taking default values. Default values can be specified before the slash by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records must end with a blank record, containing only a slash (/).

1. Secondary well name or secondary well name template.

A template enclosed in quotes can be used to refer to multiple wells. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. The secondary well name must have been previously associated with a well segment of an existing multisegment well using the [WSEGWELL](#) keyword.

2. Injector type.

WATER Water injector.

STREAM Hydrocarbon stream injector. The molar composition of the injected fluid is defined using the [WELLSTRE](#) keyword. The name of the stream must be entered in item 9.

3. Open/shut flag for the well.

OPEN Well open for injection.

SHUT Well shut for injection.

DEFAULT: OPEN.

4. Control mode.

RATE Controlled by surface flow rate target (item 6).

5. Reserved for future use.

6. Surface flow rate target or upper limit.

UNITS: sm<sup>3</sup>/day (METRIC), stb/day for oil or water (FIELD), Mscf/day for gas (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: No target or limit.

7. Reserved for future use.

8. Segment pressure upper limit.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: No upper limit.

If the secondary well (segment) pressure rises above this value, the secondary well will be shut.

9. Well stream for hydrocarbon injection.

If injection using a hydrocarbon stream is specified in item 2, this item is required to define the name of the stream. The molar composition of the injected fluid is defined using the [WELLSTRE](#) keyword.

Thermal

10. Temperature of injected fluid.

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

This item is required for the Thermal option; otherwise it should be defaulted.

Thermal

11. Quality of imported water.

If the injected fluid is water, the water quality may be specified.

UNITS: dimensionless

DEFAULT: 1.0.

12. The maximum injection rate per unit pressure difference between the current segment pressure and the upper pressure limit defined by item 8.

UNITS:  $\text{sm}^3/\text{day}/\text{bars}$  (METRIC),  $\text{stb}/\text{day}/\text{psi}$  or  $\text{Mscf}/\text{day}/\text{psi}$  (FIELD),  $\text{scc}/\text{hr}/\text{atm}$  (LAB),  $\text{sm}^3/\text{day}/\text{atm}$  (PVT-M)

DEFAULT: No upper limit.

13. An alternative segment designated for maximum pressure control. In some circumstances it may be desirable to control the fluid injection according to a limiting maximum pressure in a segment other than that being used as the secondary well. If this item is specified, the injection rate will be constrained additionally according to the maximum pressure specified in item 14.

DEFAULT: No maximum pressure control applied to an alternative segment.

14. The maximum pressure limit to be applied to the alternative segment number designated for maximum pressure control.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: No upper limit.

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

## Example

```

WSEGWELL
  INJ7 17  INJ7-S17  /
/
...

## SCONPROD Control data for secondary production wells

	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The records may be terminated early with a slash (/). The remaining items will assume their default values. Default values can be specified before the slash by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records must end with a blank record, containing only a slash (/).

1. Secondary well name or secondary well name template.

A template enclosed in quotes can be used to refer to multiple wells. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. The secondary well name must have been previously associated with a well segment of an existing multisegment well using the [WSEGWELL](#) keyword.

2. Open/shut flag for the well.

OPEN Well open for production.

SHUT Well shut for production.

DEFAULT: OPEN.

3. Control mode.

ORAT Controlled by oil rate target (item 5).

WRAT Controlled by water rate target (item 6).

GRAT Controlled by gas rate target (item 7).

LRAT Controlled by liquid rate target (item 8).

RESV Controlled by reservoir fluid volume rate target (item 9).

DEFAULT: ''

The control mode need not be specified if the secondary well is defined to be shut.

4. Fractional rate of primary well.

If a value is specified for this item, the fluid rate specified in item 3 will be produced at the fractional rate of the primary well, providing that the primary well is also a producer. The target specified by the control mode in item 3 is then treated as an additional limit. If this value is defaulted or if the primary well is not a producer, this item will be ignored and the well will be operated according to the target defined by item 3.

5. Oil rate target or upper limit.

UNITS: sm<sup>3</sup>/day (METRIC), stb/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: No target or limit.

6. Water rate target or upper limit.

UNITS: sm<sup>3</sup>/day (METRIC), stb/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: No target or limit.

7. Gas rate target or upper limit.

In compositional mode, the gas rate of a well is defined by passing the produced well hydrocarbon through a copy of the separator to which the well is assigned, or by a flash to standard conditions if no separator has been defined.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC),  $\text{Mscf}/\text{day}$  (FIELD),  $\text{scc}/\text{hr}$  (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

DEFAULT: No target or limit.

8. Liquid rate target or upper limit.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC),  $\text{stb}/\text{day}$  (FIELD),  $\text{scc}/\text{hr}$  (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

DEFAULT: No target or limit.

9. Reservoir fluid volume rate target or upper limit.

The reservoir fluid volume rate is the volume of the fluids produced when measured at the average hydrocarbon pressure in the field.

UNITS:  $\text{rm}^3/\text{day}$  (METRIC),  $\text{rb}/\text{day}$  (FIELD),  $\text{rcc}/\text{hr}$  (LAB),  $\text{rm}^3/\text{day}$  (PVT-M)

DEFAULT: No target or limit.

10. Segment pressure lower limit.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: Atmospheric pressure.

If the secondary well (segment) pressure falls below this value, the secondary well will be shut.

11. The maximum production rate per unit pressure difference between the current segment pressure and the lower pressure limit defined by item 10.

UNITS:  $\text{sm}^3/\text{day}/\text{bars}$  (METRIC),  $\text{stb}/\text{day}/\text{psi}$  or  $\text{Mscf}/\text{day}/\text{psi}$  (FIELD),  $\text{scc}/\text{hr}/\text{atm}$  (LAB),  $\text{sm}^3/\text{day}/\text{atm}$  (PVT-M)

DEFAULT: No upper limit.

12. An alternative segment designated for minimum pressure control. In some circumstances it may be desirable to control the fluid production according to a limiting minimum pressure in a segment other than that being used as the secondary well. If this item is specified, the production rate will be constrained according to the minimum pressure specified in item 13. The pressure difference between the minimum pressure limit defined by item 10 and the secondary well segment pressure is used in the flow rate calculations. In some cases, as the segment pressure approaches this limit, fluctuations in the flow rate can occur. If the alternative segment number is set equal to the secondary well segment number, item 13 can be used to define a higher cut-off pressure thereby avoiding these fluctuations.

DEFAULT: No minimum pressure control applied to an alternative segment.

13. The minimum pressure limit to be applied to the alternative segment number designated for minimum pressure control.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: Atmospheric pressure.

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

See also keyword [WELTARG](#), which can be used to reset selected control quantities individually.

## Example

```

/
...
SCONPROD
  PROD3-S14 OPEN ORAT 1* 1000 4* 50 /
/
```

## SCREF

## Solid component compressibility

In a run with  $N_c$  components this keyword specifies the solid compressibilities at the reference pressures and temperatures. The keyword can be used in runs with solids (keyword [SOLID](#) in the RUNSPEC section).

The expression used to calculate component solid densities is the following:

$$\rho_c = \frac{\rho_{ref,c}}{\left[1 - c_{P_c}(P - P_{ref,c})\right] \left[1 + c_{T1_c}(T - T_{ref,c})\right]} \quad \text{Eq. 3.166}$$

where

$\rho_{ref,c}$  is the reference density, specified with keyword [SDREF](#)

$c_{P_c}$  is the component solid compressibility, specified with this keyword

$P_{ref,c}$  is the reference pressure, specified with keyword [SPREF](#)

$T_{ref,c}$  is the reference temperature, specified with keyword [STREF](#)

$c_{T1_c}$  is the thermal expansion coefficient, specified with keyword [STHERMX1](#).

There should be one value for each component:

UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB), 1/atm (PVT-M)

DEFAULT: 0.0

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

## Example

For 3 components

```
SCREF
--Compressibility
 5.0E-06  5.2E-6  5.4E-6  /
```

## Initial coal solvent concentration versus depth tables

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTEQUL (see keyword [EQLDIMS](#) in the RUNSPEC section) tables of initial solvent concentration versus depth, one for each equilibration region. The keyword should only be used when the Coal Bed Methane option is active (keyword [COAL](#) in RUNSPEC section). Each table consists of 2 columns of data, and must be terminated by a slash (/).

1. Depth values.

The values should increase monotonically down the column.

UNITS: m (METRIC), ft (FIELD), cm (LAB)

2. The corresponding values of solvent concentration in the coal.

UNITS:  $\text{sm}^3/\text{m}^3$  (METRIC),  $\text{Mscf}/\text{ft}^3$  (FIELD),  $\text{scc}/\text{cc}$  (LAB)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NDRXVD (see keyword [EQLDIMS](#) in the RUNSPEC section).

Both [SOLVCONC](#) and SCVD are entirely optional. If neither of these keywords is present, the coal solvent concentration will be taken as the equilibrium concentration for the corresponding fracture pressure.

The initial coal solvent concentration should not be set above the initial equilibrium value; ECLIPSE issues a warning if it is. If the coal solvent concentration is below the equilibrium value, the non-reversible diffusion model is recommended (set item 2 in keyword [DIFFCOAL](#) to 0.0).

See also the [SOLVCONC](#) and [GCVD](#) keywords.

### Example

With NTEQUL=1 and NDRXVD  $\geq$  2

```
SCVD
 7000 94.0
10000 94.0 /
```

## SDENSITY

## Miscible gas density at surface conditions

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTPVT (see keyword [TABDIMS](#)) records, each terminated by a slash (/). Each record consists of a single item of data, defining the surface density of the miscible injection gas.

UNITS: kg/m<sup>3</sup> (METRIC), lb/ft<sup>3</sup> (FIELD), gm/cc (LAB)

The SDENSITY keyword is used to specify the surface density of miscible injection gas in miscible cases (see keyword [MISCIBLE](#)) and the Solvent surface density in a Solvent case (see keyword [SOLVENT](#)) or Coal Bed Methane case (see keyword [COAL](#)). SDENSITY is an obligatory keyword in miscible flood or solvent simulations.

For the Miscible Flood Model, the gas surface density values entered under the SDENSITY keyword are used in the calculation of the effective oil and gas densities in each grid cell. The miscible gas surface density within each cell is determined by the PVT region number of the cell (see keyword [PVTNUM](#)) and not by its miscibility region number (see keyword [MISCNUM](#)).

The surface density of the solution gas is entered using either the [DENSITY](#) or [GRAVITY](#) keyword in the normal way.

---

**Note:** There is no facility for specifying the surface gravity (with respect to air) of the miscible gas.

---

### Example

With NTPVT=3:

```
SDENSITY
.07020 /
.06950 /
.06820 /
```

## Reference densities for solid phase

In a run with  $N_c$  components, this keyword specifies the solid density for each component at the reference pressure and temperature. This keyword is only applicable in runs that include a solid phase (see keyword [SOLID](#) in the [RUNSPEC](#) section). The keyword [SDREF](#) should be followed by  $N_c$  real numbers, that is, a reference solid density is required for each component present in the run.

In a live-oil thermal run, the component reference solid densities are used to compute the corresponding solid densities using

$$\rho_c = \frac{\rho_{ref_c}}{\left[1 - c_{P_c}(P - P_{ref_c})\right] \left[1 + c_{T1_c}(T - T_{ref_c})\right]} \quad \text{Eq. 3.167}$$

where:

$\rho_{ref,c}$  is the component reference solid density, specified with keyword [SDREF](#)

$c_{P_c}$  is the component solid compressibility, specified with keyword [SCREF](#)

$P_{ref_c}$  is the component reference pressure, specified with keyword [SPREF](#)

$T_{ref_c}$  is the component reference temperature, specified with keyword [STREF](#)

$c_{T1_c}$  is the component thermal expansion coefficient, specified with keyword [STHERMX1](#).

Regarding the reference densities specified using [SDREF](#):

UNITS: kg/m<sup>3</sup> (METRIC), lb/ft<sup>3</sup> (FIELD), gm/cc (LAB), kg/m<sup>3</sup> (PVT-M)

DEFAULT: 799.2112 kg/m<sup>3</sup> (METRIC) for each component, except for the [CO2STORE](#) options where components NaCl, CaCl<sub>2</sub> and CaCO<sub>3</sub> are assigned default values of 2170 kg/m<sup>3</sup>, 2150 kg/m<sup>3</sup> and 2709.89 kg/m<sup>3</sup>, respectively (METRIC).

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 in keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "Equations of state regions" in the *ECLIPSE Technical Description*.

## Examples

## Example 1

For a run containing 5 components:

```
SDREF
2* 43.887 2* /
```

## Example 2

For a Blackoil model with oil, gas and one solid component:

SDREF  
2\* 43.887 /

## SECTBC

## Sector boundary conditions

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is used to specify or create the boundary conditions for a [SECTOR](#) run. A sector model can be run with either no-flow boundary conditions or with flux boundary conditions. Flux boundary conditions can be created from existing full field simulation output files.

The keyword contains the following items of data, terminated with a slash (/):

1. The type of boundary conditions

NOFLOW No flow on the sector boundaries.

DUMPFLUX Generate the fluxes which are stored in a FLUX file.

USEFLUX Use fluxes from an existing FLUX file on the sector boundaries.

DEFAULT: NOFLOW

2. The name of the full field run. This information is not required if the first item is NOFLOW.

The no-flow boundary condition can be applied without any extra data.

For flux boundary conditions, a flux file must first be generated from an existing full field run. This step is performed by running a sector model with the DUMPFLUX boundary condition. The flux file is generated from the full field RESTART files. (A GRID or EGRID file of the full field simulation is also required.) This intermediate step is relatively quick, since no simulation is performed.

To perform a sector run with flux boundaries, the USEFLUX boundary condition should be used. Data from the flux file previously created by the DUMPFLUX run is read in and interpolated between report steps.

Running a sector model with flux boundary conditions is similar to the approach using [FLUXNUM](#) regions, described in "[Flux boundary conditions](#)" in the *ECLIPSE Technical Description*. There are, however, two important differences:

- A sector can be specified after a full field simulation has been run. Flux files can be generated from a full field run for any number of sectors. On the other hand, when flux boundary conditions are generated for FLUXNUM regions, the regions must be specified before the full field run is performed.
- The sector flux file only contains data at the report steps of the full field run. This is then interpolated during the sector runs. Flux files that are created during a full field run for FLUXNUM regions contain data for each timestep.

These differences mean the sector model is a more flexible method than using FLUXNUM regions, but slightly less accurate.

---

**Note:** The sector flux boundary condition cannot be used together with FLUXNUM.

---

---

**Note:** The sector boundary should not cross LGRs, when the FLUX boundary option is used.

---

### Example with NOFLOW

To perform a simulation on an 11 x 11 x 30 sector of a full field model, the following keywords can be added to the RUNSPEC section of the data set:

```

-- Specify sector
SECTOR
  30 40 30 40 1 30 /
-- No flow boundary conditions
SECTBC
  NOFLOW /

```

## Example creating the FLUX file

If a full field model (BASE.DATA) has been run, a flux file can be generated for a sector of the full field. A copy of the full field data file is made, with the following keywords added to the RUNSPEC section:

```

-- Specify sector
SECTOR
  30 40 30 40 1 30 /
-- Generate flux file for sector from the full field run
SECTBC
  DUMPFLUX BASE /

```

When ECLIPSE 300 is run with this data file a simulation is not performed. Instead it uses the RESTART files and the GRID or EGRID file from the BASE run to produce a flux file:

BASE30-40X30-40Y.FLUX (or FFLUX if using formatted output).

If the output from the full field run is in a different directory, then the path should be specified with the file name, for example:

```

-- Specify sector
SECTOR
  30 40 30 40 1 30 /
-- Generate flux file for sector from the full field run
SECTBC
  DUMPFLUX '../BASE' /

```

A flux file will then be generated in the same directory as the full field output:

../BASE30-40X30-40Y.FLUX (or FFLUX if using formatted output).

---

**Note:** The sector size is part of the flux file name, so several flux files for different sectors can be present.

---

## Example using the FLUX file

To run a sector model with flux boundary conditions a copy of the full field data file is made, with the following keywords added to the RUNSPEC section:

```

-- Specify sector
SECTOR
  30 40 30 40 1 30 /
-- Use the fluxes on file as boundary conditions for sector
SECTBC
  USEFLUX BASE/

```

This will take the fluxes from the file

BASE30-40X30-40Y.FLUX (or FFLUX if using formatted input).

## SECTOR

## Sector model

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies a sector of the full field model. Simulation is only performed on the sector. This allows the user to perform quick simulations on small areas of the full field model, with smaller memory requirements and without the need to rewrite the data set.

Boundary conditions for the sector model are given by the [SECTBC](#) keyword.

The keyword contains the following items of data:

1. First block on X axis of the new input box (IX1)
2. Last block on X axis of the new input box (IX2)
3. First block on Y axis of the new input box (JY1)
4. Last block on Y axis of the new input box (JY2)
5. First block on Z axis of the new input box (KZ1)
6. Last block on Z axis of the new input box (KZ2)

The data must satisfy:

$$1 \leq IX1 \leq IX2 \leq \text{NDIVIX}$$

$$1 \leq JY1 \leq JY2 \leq \text{NDIVIY} \text{ (where NDIVIX and NDIVIY are specified in RUNSPEC keyword [DIMENS](#))}$$

The data should be terminated with a slash (/).

See also the keywords [GDFILE](#) and [IMPFIL](#) for fast initialization of the grid and grid arrays by binary read from the full field case.

---

**Note:** All layers in the Z-direction must be included.

---

## Example

```

RUNSPEC
-- IX1-IX2 JY1-JY2 KZ1-KZ2
SECTOR

	REGIONS
	SOLUTION
x	SUMMARY
	SCHEDULE

This keyword requests that the run summary output, generated by using the [RUNSUM](#) keyword, should be written to a separate file, rather than be appended to the end of the Print file. The separate run Summary file name is the root with the extension RSM.

It is possible to output the run summaries in a format suitable to be imported into a spreadsheet program such as Lotus 1-2-3 or Excel, by using the [LOTUS](#) or [EXCEL](#) keyword.

The `SEPARATE` keyword has no associated data.

See also keyword [NARROW](#).

### Example

```
SEPARATE
```

## SEPCOND Introduces a new separator condition stage

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword introduces or modifies a specified separator condition. These separator conditions may then be associated with a well, using keyword [WSEPCOND](#). The separator conditions are used to define oil, gas and liquid rates for a well, by flashing the produced hydrocarbons through the specified separation process.

Each line of SEPCOND data introduces a new stage, specifies the name of the separator condition, and sets the temperature and pressure. Several lines may be used to build up a multi-stage separator condition.

SEPCOND must be used to define a separator condition before it is used by a well, or is given a target.

A separator stage may be re-specified, or the whole separator condition re-specified. The separator stages must, however, be introduced in increasing order, in order to prevent missing stages when the simulation starts.

The default limit on the number of stages per separator is 5. This may be increased using item 5 in the [WELLDIMS](#) keyword. The default limit on the number of separators (including the [FIELDSEP](#) separator) is 4. This may be increased using item 8 in the [WELLDIMS](#) keyword.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. The separator name  
(up to 8 characters).
2. The name of the group for which this separator acts as a default.

This separator is automatically assigned as the default separator to all wells that can trace their parentage to this group. If a well belonging to this group has a separator explicitly assigned to it using either [WSEPCOND](#) or [WELLSPEC](#), it takes precedence over a default separator defined here. If this group contains subgroups, which also have default separators set, then wells belonging to the subgroups take their separator from their parent subgroup and not from this group.

For a multistage separator, the group name may be entered at any stage; it applies to the whole separator and not just that stage. To avoid confusion, it is best to enter the group name for the first stage only, or for all stages.

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to assign this separator as the default separator to several groups in one record.

If this item is defaulted or set to a blank (' '), the separator is not assigned as a default separator to any group.

3. The stage index.

DEFAULT: 1

4. The separator stage temperature.

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

DEFAULT: 15.56 °C (METRIC, LAB and PVT-M), 60 °F (FIELD)

5. The separator stage pressure.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: 1.01325 barsa (METRIC), 14.6959 psia (FIELD), 1 atma (LAB and PVT-M)

6. This defines the destination of the liquid output from the separator.

For all but the last stage in a separator, this is to a later stage, usually the next stage. The default destination is 0, which implies the next stage for all except the last stage, and the stock tank for the last stage.

---

**Note:** If -1 is specified for a stage before the last, this volume is added to the stock tank oil. Care must be taken, as this may result in the accumulation of oil volumes at different pressures or temperatures.

---

7. This defines the destination stage of the vapor output from the field separator. This is usually accumulated with the stock tank or field separator vapor, the volume rate being taken by conversion to a volume at standard conditions. This is done when the destination stage is set to 0, which is the default.

In the unusual case in which the vapor output from the field separator is fed to a subsequent stage, a non-default value of the destination stage may be entered. Note that, in this case, if intermediate stage separator gas is used as a source of reinjection gas, ECLIPSE 300 will calculate and report export oil rates. This export rate will be less than the produced oil rate which is the 'formation' oil rate prior to any reinjection work. The difference then between the formation oil and export oil is the oil vapor that is contained in the reinjected gas, that would otherwise have been separated in the subsequent separator stage. See also the discussion under "[Export tables](#)" in the *ECLIPSE Technical Description*.

8. The K-value table number.

This is required if a K-value table rather than an equation of state is being used for the separator. The default value is 0, indicating no K-value table, and implying an equation of state calculation.

9. The gas plant table number.

This is required if a gas plant table rather than an equation of state is being used for the separator. The default value is 0, indicating no gas plant table, and implying an equation of state calculation.

10. The surface equation of state number.

This should only be specified if multiple equations of state are used. When this option is employed, it may still be defaulted, in which case the fluid from a well is flashed using the equation of state for the cells in which the well is completed. If an equation of state index is specified, this forces the use of a given surface equation of state. The value must lie between 1 and the maximum number of equations of state for surface conditions, [TABDIMS](#) item 10. See also the discussion under "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

11. Temperature for NGL density evaluation.

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

12. Pressure for NGL density evaluation.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

**Note:** If both items 11 and 12 are specified, an equation of state NGL density calculation is performed, rather than using Amagat's law.

For the usual case, in which a separator chain is connected such that the liquid output from each stage feeds the next, the default values of the destination stages may be used.

## Related keywords

For well production, surface volumes are calculated using a well separator, defined by the [WSEPCOND](#) keyword. If a well separator is not defined, the group separator defined by this keyword [SEPCOND](#) is used. If the group separator is not defined, the field separator defined by the [FIELDSEP](#) keyword is used. If the field separator is not defined, a single flash to standard conditions given by [STCOND](#) is used.

## Examples

### Example 1

To obtain a three stage separator, the third stage representing the stock tank as shown in figure 3.15:

```
SEPCOND
SEP ' ' 1  80 815 /
SEP ' ' 2  80 65  /
SEP ' ' 3  60 14.7 /
/
```

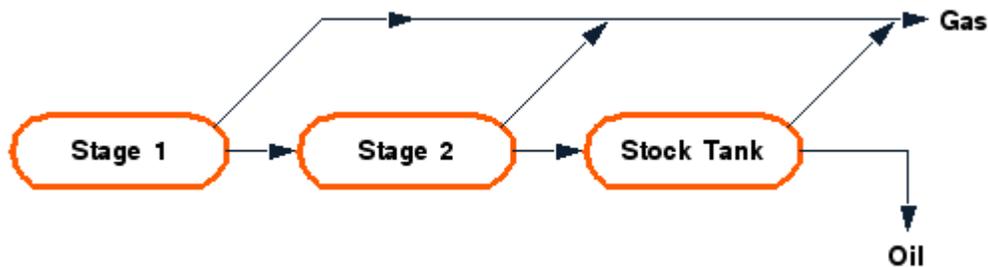

Figure 3.15. A three stage separator, with the stock tank as the third stage

### Example 2

Use gas plant number 1 to dry all the gas from stages 1, 2 and 3. Liquid from stage 3 is directed to the stock tank oil stream, bypassing the gas plant. The oil rate is the sum of the oil from stages 3 and 4. This separator acts as a default for all wells belonging to group GR1.

```
SEPCOND
SEP GR1 1  85 904  2 4 /
SEP ' ' 2  75 102  3 4 /
SEP ' ' 3  60 14.7 -1 4 /
SEP ' ' 4  60 14.7  0 0 1* 1 /
/
```

	SUMMARY
x	SCHEDULE

This keyword is used firstly to define the initial separator conditions in ECLIPSE 100, and subsequently to change them at any time in the simulation. It is required if you wish to model the effects of changing separator conditions in ECLIPSE 100 runs. The first entry of the keyword sets the initial separator conditions. The first entry must be followed by the keyword [GSEPCOND](#), which allocates groups to separators. Subsequent entries of [SEPVALS](#) can be used to change the conditions of one or more separators. When the separator conditions have been changed, ECLIPSE transforms the oil and gas flow rates of the wells and groups that feed into the separator. The transformed flow rates are used for reporting and the application of controls and limits.

The keyword can only be used in black oil runs, that is oil must contain dissolved gas, but gas must not contain vaporized oil. There must be at least one [TIME](#), [TSTEP](#) or [DATES](#) keyword between successive entries of [SEPVALS](#), in order to register the change in conditions.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/). The set of records must end with a blank record, containing only a slash (/).

1. Name of the separator

Up to 8 characters.

There can be up to [NGMAXZ](#) separators, where [NGMAXZ](#) is the maximum number of groups, entered using keyword [WELLDIMS](#) in [RUNSPEC](#).

The separator must be allocated to a group with keyword [GSEPCOND](#).

Separator name roots are not allowed. An error message is issued if the name contains an asterisk (\*).

2. Formation volume factor ( $B_{ob}$ ) of bubble point oil, when flashed from reservoir conditions ( $P_{bub}$ ,  $T_{res}$ ) to stock tank conditions through the separator system.

UNITS:  $rm^3/sm^3$  ([METRIC](#)),  $rb/stb$  ([FIELD](#)),  $rcc/scc$  ([LAB](#)),  $rm^3/sm^3$  ([PVT-M](#))

3. Solution gas-oil ratio ( $R_{si}$ ) of bubble point oil, when flashed from reservoir conditions ( $P_{bub}$ ,  $T_{re}$ ) to stock tank conditions through the separator system.

UNITS:  $sm^3/sm^3$  ([METRIC](#)),  $Mscf/stb$  ([FIELD](#)),  $scc/scc$  ([LAB](#)),  $sm^3/sm^3$  ([PVT-M](#))

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

See also keywords [GSEPCOND](#) and [COMPFLSH](#).

## Example

Set initial separator conditions:

```
SEPVALS
-- separator name   Bob      Rsi
   SEP1             1.251    0.510 /
   SEP2             1.261    0.515 /
/
```

Assign separators to groups:

```
GSEPCOND
-- group name      separator name
```

```

    PLAT-A      SEP1      /
    PLAT-B      SEP2      /
  /

```

Simulate:

```

TIME or TSTEP or DATES
.
.

```

Change conditions of SEP1:

```

SEPVALS
-- separator name  Bob    Rsi
   SEP1           1.276  0.526  /
/

```

Continue simulation:

```

TIME or TSTEP or DATES
.
.

```

## Separator tests

PVT analysis of a sample of reservoir fluid normally consists of three parts:

- A determination of the bubble point pressure,  $P_{bub}$ .
- A differential liberation, to determine the change in fluid properties and the amount of gas liberated as the reservoir pressure declines from  $P_{bub}$ .
- A separator test, in which the fluid sample is flashed from bubble point conditions ( $P_{bub}$ ,  $T_{res}$ ) to stock tank conditions through the separator system, at particular sets of separator conditions.

The separator test yields the two items required in this keyword. The formation volume factor ( $B_{ob}$ ) from the test is the ratio of the volume of oil at bubble point conditions to the volume of oil that comes through to the stock tank. (Its reciprocal is called the shrinkage factor.) The solution gas-oil ratio ( $R_{si}$ ) is the volume of gas, at standard conditions, that was removed by the separator system from a unit volume of oil in the stock tank.

The data entered in the [PVTO](#) keyword is prepared by a combined PVT analysis of the differential liberation and separator test results. Thus the values in the PVTO tables are specific to a particular set of separator conditions. ECLIPSE assumes that the PVTO tables were prepared using the original separator conditions, and it is up to you to ensure that the first entry of SEPVALS contains the values of  $B_{ob}$  and  $R_{si}$  from the separator test that were used to prepare the tables.

## How ECLIPSE 100 handles a change of separator conditions

A change in separator conditions alters the relationship between fluid volumes at reservoir conditions and stock tank conditions. The differential liberation data (which governs the shape of the PVTO table) will of course remain the same. The effect of a separator change is to multiply the oil formation volume factors by a constant factor, and to change the  $R_s$  values by a certain amount.

In fact, ECLIPSE does not transform the PVTO tables. All calculations of fluid flow and material balance within the reservoir are performed using the PVTO tables as input by the engineer. However, the oil and gas flows through the wells are transformed to reflect the change in separator conditions.

Let the original separator test results be  $B_{ob}$  and  $R_{si}$ , and the test results using the new separator conditions be  $B_{ob}^*$  and  $R_{si}^*$ . If  $Q_o$  and  $Q_g$  are the oil and gas flow rates at the original separator conditions (that is using the PVTO tables as input), then the oil and gas flow rates at the new separator conditions will be:

$$Q_o^* = T_{oil-oil} Q_o \quad \text{Eq. 3.168}$$

$$Q_g^* = T_{gas-oil} Q_o + Q_g \quad \text{Eq. 3.169}$$

Where the transformation coefficients are:

$$T_{oil-oil} = \frac{B_{ob}}{B_{ob}^*} \quad \text{Eq. 3.170}$$

$$T_{gas-oil} = T_{oil-oil} R_{si}^* - R_{si} \quad \text{Eq. 3.171}$$

After a change in separator conditions, the transformation coefficients is printed in a table of separator data if you request output of the well scheduling data (`RPTSCHEd` mnemonic `WELSPECS` or switch 14 > 0).

The well and group flow rates are transformed for output. Well and group flow targets and limits, and economic limits, are applied to the transformed rates. The fluids-in-place reports and inter-region flows, however, will still be reported at the original separator conditions.

In tubing head pressure calculations, the flow rates used to look up the VFP tables are not transformed to the new separator conditions. Thus if the VFP tables were prepared using PVT data at the original separator conditions, you will not have to recalculate them after a change in separator conditions. As a consequence, however, the pressure drops will no longer match the reported flows, since the reported flows are transformed to the new separator conditions. A similar policy is applied to pipeline pressure drops when using the Network option. In any pipeline subordinate to a separator with changed conditions, the flows are back-transformed to the original conditions for the pressure drop calculation.

## Initial foam concentrations

This keyword sets the initial foam concentration in runs where the initial conditions are specified by enumeration.

The keyword should be followed by one real number for every grid block specifying the initial foam concentration. The data field should be terminated by a slash (/).

If item 1 of [FOAMOPTS](#) is set to 'GAS':

UNITS: kg/sm<sup>3</sup> (METRIC), lb/Mscf (FIELD), gm/scc (LAB)

If item 1 of [FOAMOPTS](#) is set to 'WATER':

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB)

Grid blocks are ordered with the X axis index cycling fastest (from 1 to [NDIVIX](#)), followed by the Y axis index (from 1 to [NDIVY](#)), and finally the Z axis index (from 1 to [NDIVZ](#)). [NDIVIX](#), [NDIVY](#) and [NDIVZ](#) are specified in [RUNSPEC](#) keyword [DIMENS](#). Repeat counts may be used for repeated values (for example 115\*0.18). Note that spaces must not be inserted on either side of the asterisk (\*).

See also the keywords [PRESSURE](#), [SGAS](#), [RS](#), [PBUB](#), [RV](#), [PDEW](#) and [SWAT](#) in the [SOLUTION](#) section.

Refer to "[Foam model](#)" in the *ECLIPSE Technical Description* for further information.

---

**Note:** When adsorption is active, the concentration specified here will be honored and extra adsorped foam is added to the rock so that it is in equilibrium with the input fluid concentration.

---

---

**Note:** If a non-zero concentration is specified in cells containing none of the host phase, the concentration will be automatically reset to zero. This behavior can be turned off using [item 165](#) in [OPTIONS](#).

---

## Example

With [NDIVIX](#)=10, [NDIVY](#)=1 and [NDIVZ](#)=2 specified in [RUNSPEC](#) keyword [DIMENS](#)

```
SFOAM
 10*0.0
  9*0.0 0.5 /
```

## SGAS

## Initial gas saturations

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by one real number for every grid block specifying the initial gas saturation. The data field should be terminated by a slash (/).

This keyword may be used to specify the initial solution explicitly, as an alternative to equilibration using [EQUIL](#). It is expected if the [PRESSURE](#) keyword is present, indicating explicit initialization.

Grid blocks are ordered with the X axis index cycling fastest (from 1 to NDIVIX), followed by the Y axis index (from 1 to NDIVIY), and finally the Z axis index (from 1 to NDIVIZ). NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword [DIMENS](#). Repeat counts may be used for repeated values (for example 115\*0.18). Note that spaces must not be inserted on either side of the asterisk (\*).

See also the keywords [PRVD](#), [RS](#), [PBUB](#), [RV](#), [PDEW](#) and [SWAT](#) in the SOLUTION section.

In ECLIPSE 300, the same information may be obtained from a restart file using the [GETSOL](#) keyword.

For the ECLIPSE Thermal model using the mixed hydrostatic equilibration option, the initial saturations should be specified together with items 1 and 2 of the [EQUIL](#) keyword and the [NEI](#) keyword. For more information, refer to "[Initializing the study](#)" in the *ECLIPSE Technical Description*.

When using explicit initialization, you must ensure that the initial solution is stable and physically reasonable.

### Example

With NDIVIX=8, NDIVIY=6 and NDIVIZ=5 specified in RUNSPEC keyword [DIMENS](#):

```

SGAS
48*0.4
48*0.04
48*0
48*0
48*0 /

```

## SGCR

## Scaled critical gas saturations

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The SGCR and ISGCR keywords specify the critical gas saturation (that is the largest gas saturation for which the gas relative permeability is zero) within each grid cell. The free gas flow across each grid face is calculated from a transformed gas relative permeability curve obtained by linearly scaling the tabulated relative permeability data between the new critical gas saturation defined using an SGCR keyword, and the new maximum gas saturation (see under keyword [SGU](#) in the PROPS section). The SGCR keyword also permits scaling of the relative permeability table used in computing the flow of free gas between grid cells and well connections.

Seven keywords are provided to allow the critical gas saturation for each grid cell to be scaled independently.

These keywords are:

SGCR Critical gas saturation for the non-directional saturation function tables

SGCRX Critical gas saturation for the +X face of each grid cell

SGCRX- Critical gas saturation for the -X face of each grid cell

SGCRY Critical gas saturation for the +Y face of each grid cell

SGCRY- Critical gas saturation for the -Y face of each grid cell

SGCRZ Critical gas saturation for the +Z face of each grid cell

SGCRZ- Critical gas saturation for the -Z face of each grid cell

In radial grids the same directional keywords should be used to represent the critical gas saturations for flows in the +R,-R,+T,-T,+Z,-Z directions respectively.

None of the SGCR keywords should be used if gas is not present in the model. The keyword [ENDSCALE](#) should be specified in the RUNSPEC section.

If both directional and irreversible end point scaling is requested, using switches 'DIRECT' and 'IRREVERS' in the ENDSALE keyword in RUNSPEC, then the critical gas saturations for gas flow across the +X and -X faces of a grid cell are set using the keywords SGCRX, SGCRX-. Similarly SGCRY, SGCRY- are used for the +Y,-Y faces and the keywords SGCRZ, SGCRZ- for the +Z,-Z faces. Scaling of the well connection relative permeability tables for any well connections in the grid cell are performed using the SGCR keyword.

When the end point scaling is requested to be directional and reversible, using the switch 'DIRECT' but not 'IRREVERS' in ENDSALE, the keyword SGCRX defines the critical gas saturations for the +X and -X faces of each grid cell. Keywords SGCRY, SGCRZ are used for both the +Y, -Y faces and the +Z, -Z faces of each grid cell respectively. Scaling of well connection relative permeability tables uses data entered under the SGCR keyword.

If ENDSALE is specified in RUNSPEC without the switch 'DIRECT', then none of the directional forms of the SGCR keyword are allowed. The SGCR keyword then defines the new critical gas saturation for flow out of each face of the grid cell and for gas flows between the grid cell and well connections.

Each SGCR keyword should be followed by one real number for each grid block in the current input box specifying the critical gas saturation within the grid block. The saturation should be in the range 0.0 to 1.0 inclusive. The data must be terminated by a slash(/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If any of the keywords SGCR, SGCRX, SGCRX-, SGCRY, SGCRY-, SGCRZ, SGCRZ- are omitted in a model where they could be accepted then the critical gas saturation for a gas relative permeability calculation defaults to the value used in the appropriate relative permeability table.

If the Hysteresis model (switch 'HYSTER' in keyword SATOPTS) is active then the SGCR data will scale the drainage curve. The imbibition curve can be scaled by using the equivalent ISGCR (ISGCRX, ISGCRX-, ...) keyword.

ECLIPSE 300

If the ODD3P relative permeability and capillary pressure hysteresis model has been selected, the primary end-point scaling is specified using the PSORG, PSGRO, PSORW, PSWRO, PSGRW and PSWRG keywords and the hysteresis end-point scaling is specified using the HSORG, HSGRO, HSORW, HSWRO, HSGRW and HSWRG keywords

See also keywords SGU, SGL, ENPTVD in the PROPS section.

For details of the end point rescaling procedure, refer to "Saturation table scaling" in the *ECLIPSE Technical Description*.

## SGCWMIS

**Miscible critical gas saturation tables**

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTMISC (item 1 in keyword [MISCIBLE](#)) tables of miscible critical gas saturation versus water saturation, each terminated by a slash. See "[Miscible flood modeling](#)" in the *ECLIPSE Technical Description* for details of how the effective critical gas saturation tables are used in the calculation of the gas and oil relative permeabilities and PVT properties. See also "[Solvent model](#)" in the *ECLIPSE Technical Description* for further information on when the four-component solvent model is employed.

The SGCWMIS keyword can only be used in runs which use the miscible flood option (see keyword [MISCIBLE](#)) and where oil, water and gas are all present. For miscible flood simulations involving the water phase the SGCWMIS keyword may be omitted, in which case the program assumes a miscible critical gas saturation of zero.

Each table consists of 2 columns of data:

1. The water saturation.  
Values should be between 0 and 1 and should increase monotonically down the column.
2. The corresponding miscible critical gas saturation.  
Values should be between 0 and 1 and should be level or increasing down the column.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSMISC (item 2 in keyword [MISCIBLE](#)).

**Example**

With NTMISC=2 and NSMISC ≥3

```
SGCWMIS
 .00 .00
 1.00 .00 /
 .00 .00
 .25 .05
 1.00 .05 /
```

## SGF3

## Three-phase gas saturation functions

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword should only be used when the IKU three-phase relative permeability model has been requested using the [IKU3P](#) keyword or when the ODD3P three-phase relative permeability and capillary pressure hysteresis model has been requested using the [ODD3P](#) keyword or when the gas BAKER three-phase relative permeability and capillary pressure hysteresis model has been requested using the [BAKER1](#) or [BAKER2](#) keywords in the PROPS section.

The data specified consists of tables of two-phase gas saturation functions, each terminated by a slash. Each table consists of 4 columns of data:

Column:

1. The gas saturation.

Values should be between 0 and 1 and should increase monotonically down the column.

2. The corresponding gas in oil relative permeability measured in the absence of water.

Values should be between 0 and 1 and should be level or increasing down the column. The first value in the column must be 0.

3. The corresponding gas in water relative permeability measured in the absence of oil.

Values should be between 0 and 1 and should be level or increasing down the column. The first value in the column must be 0.

For the ODD3P option the relative permeability values between the critical and maximum saturations are not used and may be defaulted.

4. The corresponding oil-gas capillary pressure.

Values should be level or increasing down the column.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

The number of tables supplied should be equal to the number of saturation tables in the run, specified in item 1 of keyword [TABDIMS](#) in the RUNSPEC section.

The number of rows should be less than or equal to the maximum number of rows of saturation data specified in item 3 of [TABDIMS](#).

See also "[Saturation functions](#)" in the *ECLIPSE Technical Description*.

**Note:** The critical saturation for each relative permeability function is established by determining the highest saturation in the table for which the relative permeability is notionally zero, that is, less than a small threshold value. Relative permeability values which are lower than this threshold value will be treated as zero. For ECLIPSE 100 and ECLIPSE 300 the default threshold values are  $1.0 \times 10^{-6}$  and  $1.0 \times 10^{-20}$  respectively. These values may be modified using the [TOLCRIT](#) keyword.

## Example

```

SGF3
.00 .00 .00 .0
.04 .00 .00 .2
.10 .00 .022 .5
.20 .05 .10 1.0
.40 .15 .34 2.0

## SGF32D

## 2D table of gas relative permeability

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is an alternative to keyword [SGFN](#), allowing the three-phase relative permeability of gas to be input directly as a function of oil and water saturations in a two-dimensional table.

The data comprises NTSFUN (see item 1 of keyword [TABDIMS](#) in the RUNSPEC section) tables of gas relative permeability, tabulated against both oil and water saturations, each terminated by a slash (/).

Each table consists of a number of records:

Record 1: The oil saturation values

Values should be between 0 and 1 and should increase monotonically. The number of oil saturation values should not exceed NSSFUN (see item 3 of keyword [TABDIMS](#)).

Subsequent records (a maximum of NSSFUN records):

The water saturation.

Followed by the gas relative permeability values for this water saturation at all the corresponding oil saturations entered in Record 1.

The gas relative permeabilities should be monotonically decreasing, with a final value of zero. The number of gas relative permeability values should not exceed the number of oil saturation values entered in Record 1. The record may be truncated at any point provided that the last relative permeability value is zero.

The columns of data must also comply with the following constraints:

- The water saturation (the first item in the second and subsequent records) should increase monotonically down the column. The gas relative permeability for each oil saturation should decrease monotonically down the column and should end in a zero value.
- The relative permeability must also be zero for any point on the table in which  $S_{oil} + S_{wat} \geq 1.0$ .
- Default values may not be placed within the table.

The entire table may be defaulted provided that the table is not the first. Defaulted tables are replaced with a copy of the previous table.

ECLIPSE 100

The gas/oil capillary pressure must be provided using the [PCG32D](#) keyword.

ECLIPSE 300

The gas/oil capillary pressure can be provided using the [SGFN](#) keyword. The relative permeability data entered with the [SGFN](#) keyword will be ignored.

The keyword cannot be used with the end-point scaling, hysteresis and miscible options.

## Example

With NTSFUN=1 and NSSFUN ≥ 11:

```

## SGFN

## Gas saturation functions

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTSFUN (see item 1 of keyword [TABDIMS](#) in the RUNSPEC section) tables of gas saturation functions, each terminated by a slash (/).

Each table consists of 3 columns of data:

1. The gas saturation.  
Values should be between 0 and 1 and should increase monotonically down the column.
2. The corresponding gas relative permeability.  
Values should be between 0 and 1 and should be level or increasing down the column. The first value in the column must be 0.
3. The corresponding oil-gas capillary pressure.  
Values should be level or increasing down the column.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

In gas-water systems (that is no active oil phase), the gas-water capillary pressure is entered in the SWFN keyword. The oil-gas capillary pressure in SGFN should be set to zero.

Default values (represented by 1\*) may be inserted as required in columns 2 and 3. When the table is read in, defaults are replaced by values computed by linear interpolation.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (see item 3 of keyword [TABDIMS](#)).

The entire table may be defaulted provided the table is not the first. Defaulted tables are replaced with a copy of the previous table.

The keyword families:

(i) [SWOF](#), [SGOF](#), [SLGOF](#)

(ii) [SWFN](#), [SGFN](#), [SGWFN](#), [SOF2](#), [SOF3](#), [SOF32D](#)

provide two alternative formats for inputting the saturation functions. Do not mix keywords from the two families in the same run. In gas-water runs, or if you are using the ECLIPSE 100 miscible flood or solvent options, the saturation functions must be input with keywords from family (ii).

ECLIPSE 100

In gas-water runs the gas and water saturation functions may be input together using the SGWFN keyword as an alternative to using both SGFN and SWFN.

ECLIPSE 300

Any non-zero connate gas saturation entered with this keyword will be ignored, that is reset to zero.

---

**Note:** The critical saturation for each relative permeability function is established by determining the highest saturation in the table for which the relative permeability is notionally zero, that is, less than a small threshold value. Relative permeability values which are lower than this threshold value will be treated as zero. For ECLIPSE 100 and ECLIPSE 300 the default threshold values are  $1.0 \times 10^{-6}$  and  $1.0 \times 10^{-20}$  respectively. These values may be modified using the [TOLCRIT](#) keyword.

---

## Example

## SGL,ISGL Scaled connate gas saturations

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The different forms of this keyword specify the connate gas saturation (that is the smallest gas saturation in a gas saturation function table) within each grid cell. The gas-oil capillary pressure for gas flow across each grid face is calculated from a transformed gas-oil capillary pressure curve obtained by linearly scaling the tabulated capillary pressure data between the new connate gas saturation defined using an SGL keyword, and the new maximum gas saturation (see under the keyword [SGU](#) in the PROPS section). The SGL keyword also permits scaling of the gas-oil capillary pressure table used in computing the initial gas saturations.

Seven keywords are provided to allow the connate gas saturation for each grid cell to be scaled independently. These keywords are:

**SGL** Connate gas saturation for the non-directional saturation function tables

**SGLX** Connate gas saturation for the +X face of each grid cell

**SGLX-** Connate gas saturation for the -X face of each grid cell

**SGLY** Connate gas saturation for the +Y face of each grid cell

**SGLY-** Connate gas saturation for the -Y face of each grid cell

**SGLZ** Connate gas saturation for the +Z face of each grid cell

**SGLZ-** Connate gas saturation for the -Z face of each grid cell

In radial grids the same directional keywords should be used to represent the connate gas saturations for flows in the +R,-R,+T,-T,+Z,-Z directions respectively.

None of the SGL keywords should be used if gas is not present in the model. The keyword [ENDSCALE](#) should be specified in the RUNSPEC section.

If both directional and irreversible end point scaling is requested, using switches 'DIRECT' and 'IRREVERS' in the ENDSCALE keyword in RUNSPEC, then the connate gas saturations for gas flow across the +X and -X faces of a grid cell are set using the keywords SGLX, SGLX-. Similarly SGLY, SGLY- are used for the +Y,-Y faces and the keywords SGLZ, SGLZ- for the +Z,-Z faces. Scaling of the gas-oil capillary pressure tables used in the equilibration algorithm are performed with the SGL keyword.

When the end point scaling is requested to be directional and reversible, using the switch 'DIRECT' but not 'IRREVERS' in ENDSCALE, the keyword SGLX defines the connate gas saturations for the +X and -X faces of each grid cell. Keywords SGLY, SGLZ are used for both the +Y, -Y faces and the +Z,-Z faces of each grid cell respectively. Scaling of gas-oil capillary pressure data for the equilibration algorithm is done with the SGL keyword.

If ENDSCALE is specified in RUNSPEC without the switch 'DIRECT', then none of the directional forms of the SGL keyword are allowed. The SGL keyword then defines the new connate gas saturation for scaling the gas flow out of each grid cell face and for calculating the transformed capillary pressure table used in the equilibration procedure.

Each SGL keyword should be followed by one real number for each grid block in the current input box specifying the connate gas saturation within the grid block. The saturation should be in the range 0.0 to 1.0 inclusive. The data must be terminated by a slash(/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If any of the keywords SGL, SGLX, SGLX-, SGLY, SGLY-, SGLZ, SGLZ- are omitted in a model where they could be accepted then the connate gas saturation for a gas-oil capillary pressure calculation defaults to the value used in the appropriate gas saturation function table.

If a connate gas saturation is entered using the SGLPC keyword then this saturation will be used when scaling the capillary pressure curves. The connate gas saturation entered using SGL will only be used to scale the oil relative permeability curves.

If the Hysteresis Model (switch 'HYSTER' in keyword SATOPTS) is active then the SGL data will scale the drainage curve. The imbibition curve can be scaled by using the equivalent ISGL (ISGLX, ISGLX-, ...) keyword.

---

**Note:** In some cases, where messages relating to end-point scaling are emitted, for example, when checking that the scaled end-points are consistent, reference is made to SGCO as an alternative to SGL.

---

#### ECLIPSE 100

In ECLIPSE 100 the connate gas saturation is not included in the two-point end-point scaling of oil relative permeability to gas and water by default. In order to include connate gas in the maximum attainable gas saturation calculation, [item 205](#) in the OPTIONS keyword should be set to 1.

#### ECLIPSE 300

In ECLIPSE 300 the unscaled connate gas saturation is set to zero by default and this overrides any non-zero values in the input saturation tables. However, non-zero unscaled connate gas saturations can be modeled by setting [item 103](#) of the OPTIONS3 keyword to 1. Non-zero scaled connate gas saturations may be specified by the SGL keyword.

See also keywords SGLPC, SGU and ENPTVD in the PROPS section.

See "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for further details.

## Example

```

----RUNSPEC section

```

## SGLPC

## Scaled connate gas saturations, for Pc curves only

x	ECLIPSE 100
	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The SGLPC and ISGLPC keywords scales the connate gas end point of the gas-oil capillary pressure curves without scaling the corresponding oil relative permeability curves.

The SGLPC keyword should not be used unless gas is present in the model (keyword [GAS](#) in the RUNSPEC section). The keyword [ENDSCALE](#) should be specified in the RUNSPEC section.

The SGLPC keyword should be followed by one real number for each grid block in the current input box, specifying the connate gas saturation within the grid block. The saturation should be in the range 0.0 to 1.0 inclusive. The data must be terminated by a slash (/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If SGLPC is not specified, the gas-oil capillary pressure scaling is performed using the connate gas saturation specified with the [SGL](#) family of keywords (SGL, SGLX, SGLX-, SGLY, SGLY-, SGLZ, SGLZ-). If in turn any of the keywords SGL, SGLX, SGLX-, SGLY, SGLY-, SGLZ, SGLZ- are omitted, then the connate gas saturation for a gas-oil capillary pressure calculation defaults to the value used in the appropriate gas saturation function table.

If the hysteresis model (switch 'HYSTER' in keyword [SATOPTS](#)) is active then the SGLPC data will scale the drainage curve. The imbibition curve can be scaled by using the equivalent [ISGLPC](#) keyword.

See also keywords [SGL](#) and [ENPTVD](#) in the PROPS section.

### Example

With [ENDSCALE](#) in RUNSPEC; and [NDIVIX](#)=1, [NDIVIY](#)=7 and [NDIVIZ](#)=3 specified in RUNSPEC keyword [DIMENS](#):

```
SGLPC
7*0.0 7*0.02 7*0.0 /
```

## SGOF

## Gas/oil saturation functions versus gas saturation

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The SGOF keyword may be used in runs containing both oil and gas as active phases, to input tables of gas relative permeability, oil-in-gas relative permeability and oil-gas capillary pressure as functions of the gas saturation. If water is also an active phase in the run, the water/oil saturation functions must be input with keyword SWOF.

The data comprises NTSFUN (see item 1 of keyword TABDIMS in the RUNSPEC section) tables of gas/oil saturation functions, each terminated by a slash (/).

Each table consists of 4 columns of data:

1. The gas saturation.

Values should be between 0 and 1 and should increase monotonically down the column. The first value in the column must be zero.

2. The corresponding gas relative permeability.

Values should be between 0 and 1 and should be level or increasing down the column. The first value in the column must be zero.

3. The corresponding oil relative permeability when oil, gas and connate water are present.

Values should be between 0 and 1 and should be level or decreasing down the column. If water is present in the run, the first value in the column ( $k_{rog}$  at  $S_g = 0$ ) must be the same as the first value in the  $k_{row}$  column in keyword SWOF (that is  $k_{row}$  at  $S_o = 1 - S_{wco}$ ). The last value in the column must be zero.

4. The corresponding oil-gas capillary pressure.

Values should be level or increasing down the column.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

Default values (represented by 1\*) may be inserted as required in columns 2, 3 and 4. When the table is read in, defaults are replaced by values computed by linear interpolation.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (see item 3 of keyword TABDIMS).

The entire table may be defaulted provided the table is not the first. Defaulted tables are replaced with a copy of the previous table.

The keyword families

(i) SWOF, SGOF, SLGOF

(ii) SWFN, SGFN, SGWFN, SOF2 and SOF3

provide two alternative formats for inputting the saturation functions. Do not mix keywords from the two families in the same run. In gas-water runs, or if you are using the ECLIPSE 100 miscible flood or solvent options, the saturation functions must be input with keywords from family (ii).

For two dimensional tables the following keywords can also be used: SOF32D, SGF32D and SWF32D.

**Note:** The critical saturation for each relative permeability function is established by determining the highest saturation in the table for which the relative permeability is notionally zero, that is, less than a small threshold value. Relative permeability values which are lower than this threshold value will be treated as zero. For ECLIPSE 100 and ECLIPSE 300 the default threshold values are  $1.0 \times 10^{-6}$  and  $1.0 \times 10^{-20}$  respectively. These values may be modified using the `TOLCRIT` keyword.

See "[Saturation functions](#)" in the *ECLIPSE Technical Description* for more information, and a description of the methods used to compute three-phase relative permeabilities.

## Example

With `NTSFUN=2` and `NSSFUN ≥ 10`:

```

SGOF
-- Sg      Krg      Krog      Pcog
.0000      .0000      1.00      .0000

```

## SGU,ISGU

**Scaled saturation table maximum gas saturations**

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The different forms of this keyword specify the maximum gas saturation (that is the largest gas saturation in a gas saturation function table) within each grid cell. The scaled maximum gas saturation is used to determine the scaled forms for the gas-oil capillary pressure curves and the gas relative permeability curves. The scaled form of the capillary pressure curves is obtained by linearly scaling the tabulated capillary pressure data between the new connate gas saturation (see keyword [SGL](#) in the PROPS section) and the new maximum gas saturation defined using an SGU keyword. A similar linear transformation is used to produce the scaled gas relative permeability curves using the new critical gas saturation (see keyword [SGCR](#) in the PROPS section) and the new maximum gas saturation defined using an SGU keyword. The scaled capillary pressure and relative permeability curves are then used to compute the free gas flow out of each grid cell face, the free gas flow between grid cells and well connections and in the equilibration algorithm.

Seven keywords are provided to allow the maximum gas saturation for each grid cell to be scaled independently. These keywords are:

SGU Maximum gas saturation for the non-directional saturation function tables

SGUX Maximum gas saturation for the +X face of each grid cell

SGUX- Maximum gas saturation for the -X face of each grid cell

SGUY Maximum gas saturation for the +Y face of each grid cell

SGUY- Maximum gas saturation for the -Y face of each grid cell

SGUZ Maximum gas saturation for the +Z face of each grid cell

SGUZ- Maximum gas saturation for the -Z face of each grid cell

In radial grids the same directional keywords should be used to represent the maximum gas saturations for flows in the +R,-R,+T,-T,+Z,-Z directions respectively.

None of the SGU keywords should be used if gas is not present in the model. The keyword [ENDSCALE](#) should be specified in the RUNSPEC section.

If both directional and irreversible end-point scaling is requested, using switches 'DIRECT' and 'IRREVERS' in the ENDSCALE keyword, then the maximum gas saturations for computing the gas flow across the +X and -X faces of a grid cell are set using the keywords SGUX, SGUX-. Similarly SGUY, SGUY- are used for the +Y, -Y faces and the keywords SGUZ, SGUZ- for the +Z, -Z faces. Scaling of the gas-oil capillary pressure tables in the equilibration algorithm and scaling of the relative permeability curves to compute free gas flows between grid cells and well connections are performed using the SGU keyword.

When the end-point scaling is requested to be directional and reversible, using the switch 'DIRECT' but not 'IRREVERS' in ENDSCALE, the keyword >SGUX defines the maximum gas saturations for the +X and -X faces of each grid cell. Keywords SGUY, SGUZ are used for both the +Y,-Y faces and the +Z, -Z faces of each grid cell respectively. The maximum gas saturation values for use in the equilibration procedure and for computing the well connection flows are entered using the SGU keyword.

If ENDSCALE is specified in RUNSPEC without the switch 'DIRECT', then none of the directional forms of the SGU keyword are allowed. The SGU keyword then defines the new maximum gas saturation for

computing the gas flows between adjacent grid cells, well connection flows and in the equilibration algorithm.

Each SGU keyword should be followed by one real number for each grid block in the current input box specifying the maximum gas saturation within the grid cell. The saturation should be in the range 0.0 to 1.0 inclusive. The data must be terminated by a slash (/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If any of the keywords SGU, SGUX, SGUX-, SGUY, SGUY-, SGUZ, SGUZ- are omitted in a model where they could be accepted then the maximum gas saturation for capillary pressure and relative permeability calculations defaults to the value used in the appropriate gas saturation function table.

If the hysteresis model (switch 'HYSTER' in keyword SATOPTS) is active then the SGU data will scale the drainage curve. The imbibition curve can be scaled by using the equivalent ISGU (ISGUX, ISGUX-,...) keyword.

See also keywords SGL, SGCR, ENPTVD in the PROPS section.

## SGWCR

## Scaled critical gas saturations in water

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies the critical gas saturation in water within each grid cell. This is available when the [IKU3P](#), [BAKER1](#) or [BAKER2](#) three-phase relative permeability model is being used and the two-phase gas-water relative permeabilities are specified using the [SGF3](#) keyword. The critical gas saturation in oil is obtained from [SGCR](#).

Seven keywords are provided to allow the critical gas saturation in water for each grid cell to be scaled independently. These keywords are:

**SGWCR** Critical gas saturation in water for the non-directional saturation function tables

**SGWCRX** Critical gas saturation in water for the +X face of each grid cell

**SGWCRX-** Critical gas saturation in water for the -X face of each grid cell

**SGWCY** Critical gas saturation in water for the +Y face of each grid cell

**SGWCY-** Critical gas saturation in water for the -Y face of each grid cell

**SGWCRZ** Critical gas saturation in water for the +Z face of each grid cell

**SGWCRZ-** Critical gas saturation in water for the -Z face of each grid cell

In radial grids the same directional keywords should be used to represent the critical gas saturations in water for flows in the +R, -R, +T, -T, +Z and -Z directions respectively.

None of the SGWCR keywords should be used if water is not present in the model. The keyword [ENDSCALE](#) should be specified in the RUNSPEC section.

If both directional and irreversible end-point scaling are requested, using switches 'DIRECT' and 'IRREVERS' in the ENDSCALE keyword in RUNSPEC, the critical gas saturations in water for flow across the +X and -X faces of a grid cell are set using the keywords SGWCRX and SGWCRX-. Similarly the keywords SGWCY and SGWCY- are used for the +Y and -Y faces and the keywords SGWCRZ and SGWCRZ- for the +Z and -Z faces respectively. Scaling of the well connection relative permeability tables for any well connections in the grid cell is performed using the values specified via the SGWCR keyword.

When the end-point scaling is requested to be directional and reversible, using the switch 'DIRECT' but not 'IRREVERS' in ENDSCALE, the keyword SGWCRX defines the critical gas saturations in water for the +X and -X faces of each grid cell. Keywords SGWCY and SGWCRZ are used for both the +Y and -Y faces and the +Z and -Z faces of each grid cell respectively. Scaling of the well connection relative permeability tables for any well connections in the grid cell is performed using the values specified via the SGWCR keyword.

If ENDSCALE is specified in RUNSPEC without the switch 'DIRECT', none of the directional forms of the SGWCR keyword are allowed. The SGWCR keyword then defines the critical gas saturation in water for flow out of each face of the grid cell and for flows between the grid cell and well connections.

Each SGWCR keyword should be followed by one real number for each grid block in the current input box specifying the critical gas saturation in water within the grid block. The saturation should be in the range 0.0 to 1.0 inclusive. The data must be terminated by a slash(/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If any of the keywords SGWCR, SGWCRX, SGWCRX-, SGWCRY, SGWCRY-, SGWCRZ or SGWCRZ- are omitted in a model where they could be accepted, the critical gas saturation in water for a gas relative permeability calculation defaults to the value specified in the appropriate relative permeability table.

If the hysteresis model (switch 'HYSTER' in keyword SATOPTS) is active, the SGWCR data scales the drainage curve. The imbibition curve can be scaled by using the corresponding ISGWCR (ISGWCRX, ISGWCRX-, ...) keywords. (The IKU3P three phase relative permeability model does not support hysteresis.)

See "Saturation table scaling" in the *ECLIPSE Technical Description* for details of the end-point scaling procedure.

```

## SGWFN

## Gas-water saturation functions

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTSFUN (see item 1 of keyword [TABDIMS](#) in the RUNSPEC section) tables of gas-water saturation functions, each terminated by a slash (/).

The keyword may be used in gas-water systems (when no oil is present) as a convenient way of providing saturation function data for both gas and water, as an alternative to using the [SGFN](#) and [SWFN](#) keywords.

Each table consists of 4 columns of data:

1. The gas saturation.  
Values should be between 0 and 1 and should increase monotonically down the column.
2. The corresponding gas relative permeability.  
Values should be between 0 and 1 and should be level or increasing down the column.  
The first value in the column must be 0.
3. The corresponding water relative permeability (at  $S_w = 1 - S_g$ ).  
Values should be between 0 and 1 and should be level or decreasing down the column.  
The last value in the column must be 0.
4. The corresponding gas-water capillary pressure.  
Values should be level or increasing down the column.  
UNITS: bars (METRIC), psi (FIELD), atm (LAB)

Default values (represented by 1\*) may be inserted as required in columns 2, 3 and 4. When the table is read in, defaults are replaced by values computed by linear interpolation.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (see item 3 of keyword [TABDIMS](#)).

The entire table may be defaulted provided the table is not the first. Defaulted tables are replaced with a copy of the previous table.

The keyword families

- (i) [SWOF](#), [SGOF](#), [SLGOF](#)
- (ii) [SWFN](#), [SGFN](#), [SGWFN](#), [SOF2](#), [SOF3](#), [SOF32D](#)

provide two alternative formats for inputting the saturation functions. Do not mix keywords from the two families in the same run. In gas-water runs, or if you are using the Miscible Flood or Solvent options, the saturation functions must be input with keywords from family (ii).

---

**Note:** The critical saturation for each relative permeability function is established by determining the highest saturation in the table for which the relative permeability is notionally zero, that is, less than a small threshold value. Relative permeability values which are lower than this threshold value will be treated as zero. For ECLIPSE 100 and ECLIPSE 300 the default threshold values are  $1.0 \times 10^{-6}$  and  $1.0 \times 10^{-20}$  respectively. These values may be modified using the [TOLCRIT](#) keyword.

---

## Example

With NTSFUN=2 and NSSFUN ≥9:

```
SGWFN
.0000 .0000 1.0000 .0000
.0400 .0000 0.9000 .2000
.1000 .0220 0.8000 .5000
.2000 .1000 0.5000 1.0000
.3000 .2400 1* 1*
.5000 .4200 1* 1*
.6000 .5000 0.1125 3.0000
.7000 .8125 0.0000 3.5000
.7800 1.0000 0.0000 3.9000
/
.00 .0000 1.0 0
.12 .0220 0.85 0
.22 .1000 0.6 0
.32 .2400 0.45 0
.52 .4200 0.25 0
.62 .5000 0.05 0
.72 .8125 0.0 0
.80 1.0000 0.0 0
/
```

**Note:** Slow run times may result if the relative permeability changes abruptly over a small saturation interval, especially if IMPES is used. ECLIPSE honors the data input and does not attempt to overcome convergence problems by retabulating over equally spaced saturation intervals.

If chopped relative permeability data is used to minimize dispersion, ECLIPSE performs best in fully-implicit mode if the relative permeability rises steeply from zero (immobility) rather than from a small value.

## SHRATE

## Activate shear rate form of the polymer shear thinning/thickening logarithmic model

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used to activate the shear rate form of the alternative (natural logarithm-based) polymer shear thinning/thickening option and to supply the required shear rate constant. This keyword can only be used in conjunction with keyword [PLYSHLOG](#).

The data comprises NTPVT (see item 2 in RUNSPEC keyword [TABDIMS](#)) values that correspond to the shear rate constant in each PVT region, each terminated by a slash (/). The shear rate constants must be positive.

UNITS: Dimensionless.

DEFAULT: 4.8.

The default value given above is based upon the following expression for the shear rate constant:

$$C_\gamma = C \left( \frac{3n+1}{4n} \right)^{\frac{n}{n-1}}$$

This expression is derived using the capillary bundle approach to relating the apparent viscosity of a power-law fluid in porous media to the Darcy velocity. The constant  $C$  can be obtained by comparing viscometer measurements with the apparent viscosities in porous media, and is typically equal to 6.0. Log-log plots of viscosity versus shear rate (or velocity), suggesting that the apparent viscosity is proportional to the Darcy velocity raised to the power  $(n-1)$ , generate a value of  $n$  that is approximately 0.5. Substituting these values of  $C$  and  $n$  into the expression above provides the default shear rate constant used.

See the "[Polymer flood model](#)" in the *ECLIPSE Technical Description* for further information.

### Example

With NTPVT=1 specified using keyword [TABDIMS](#):

```
SHRATE
 4.8 /
```

ECLIPSE 100

ECLIPSE 100

## Dual porosity matrix-fracture coupling

If the dual porosity or dual permeability options are being used (by specifying the [DUALPORO](#) or [DUALPERM](#) keyword in the RUNSPEC section), this keyword can be used to specify a multiplier to be used in the construction of the matrix-fracture coupling transmissibilities.

If this keyword is used, the sigma factor is applied to the entire grid.

This 'sigma factor' may be related to the matrix block size by the expression:

$$\sigma = 4 \left( \frac{1}{l_x^2} + \frac{1}{l_y^2} + \frac{1}{l_z^2} \right) \quad \text{Eq. 3.172}$$

where  $l_x$ ,  $l_y$  and  $l_z$  are typical X, Y and Z dimensions of the matrix blocks.

The relationship was proposed by Kazemi (1976) [[Ref. 61](#)].

The dimensions of the matrix blocks used above are not the dimensions of the simulation grid, but of the elements of matrix material in the reservoir.

UNITS: m<sup>-2</sup> (METRIC), ft<sup>-2</sup> (FIELD), cm<sup>-2</sup> (LAB), m<sup>-2</sup> (PVT-M)

Alternatively, sigma may be treated as a simple history matching factor.

If neither SIGMA nor [SIGMAV](#) are specified then the default sigma factor is 0.0 throughout the grid, unless [LTOSIGMA](#) is specified in runs using the viscous displacement option.

The dual porosity and dual permeability options are discussed in more detail in "[Dual porosity](#)" in the *ECLIPSE Technical Description*.

### Example

```
SIGMA
0.12 /
```

Using Kazemi's expression, in FIELD units, a value of 0.12 would correspond to 10 ft. matrix blocks.

## SIGMAGD

## Matrix-fracture coupling for oil-gas gravity drainage

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used to specify an alternative matrix-fracture coupling for matrix cells in which the production mechanism is gravity drainage due to the presence of gas in the fractures.

If this keyword is used, the sigmagd factor is applied to the entire grid.

Different sigmagd values can be specified on a cell by cell basis using the [SIGMAGDV](#) keyword.

The particular formula used to prescribe the alternative is different between ECLIPSE 100 and ECLIPSE 300. In ECLIPSE 100 this keyword is used to provide a different sigma factor for regions swept by gas, while the standard sigma factor is used for regions swept by water. In ECLIPSE 300 however, the keyword is used to provide an alternative sigma factor value when the gravity drainage potential is the dominant pressure term, while allowing smooth variation of sigma as the pressure increases. The next paragraphs provide details on these two formulas.

In ECLIPSE 100 the matrix-fracture transmissibility based on SIGMAGD will be used to calculate the oil flow when the following conditions are satisfied:

- The gravity drainage model is active.
- Oil flow is from the matrix to the fracture.
- The gravity drainage head associated with gas in the fracture is greater than the head associated with water.

Hence regions in which the fractures are swept by gas drain through a transmissibility based on SIGMAGD, and regions swept by water will be produced through a transmissibility based on [SIGMA](#).

The SIGMAGD keyword is only available in three-phase dual porosity runs (keyword [DUALPORO](#) in the RUNSPEC section).

This sigma factor may be related to the matrix block size by the expression:

$$\Sigma = 4 \left( \frac{1}{l_x^2} + \frac{1}{l_y^2} + \frac{1}{l_z^2} \right) \quad \text{Eq. 3.173}$$

where  $l_x$ ,  $l_y$  and  $l_z$  are typical X, Y and Z dimensions of the matrix blocks.

The relationship was proposed by Kazemi (1976) [[Ref. 61](#)].

The dimensions of the matrix blocks used above are not the dimensions of the simulation grid, but of the elements of matrix material in the reservoir.

Alternatively sigma may be treated as a simple history matching factor.

When calculating the matrix-fracture transmissibility for gravity drainage, the matrix Z-permeabilities are used by default, rather than the X-permeabilities. The pre-99A treatment (using the X-permeabilities) may be restored using [item 70](#) in the OPTIONS keyword.

In ECLIPSE 300, if SIGMA and SIGMAGD are both entered, the program uses an interpolated value, depending on the relative sizes of the capillary pressure and gravity drainage pressure terms. Thus if capillary pressures dominates, SIGMA values are used, whilst if gravity drainage dominates SIGMAGD values are used.

If neither SIGMAGD nor SIGMAGDV are specified, the transmissibilities are based on the sigma value supplied by the SIGMA or [SIGMAV](#) keywords, unless [LTOSIGMA](#) is specified.

Refer to "[Gravity imbibition/drainage](#)" in the *ECLIPSE Technical Description* for more details.

## Examples

### Example 1

```
SIGMA  
0.12 /
```

Using Kazemi's expression, in FIELD units, a value of 0.12 would correspond to 10 ft matrix blocks.

### Example 2

Smaller SIGMAGD as the gravity drainage is assumed to be dominated by flow only in the z-direction.

```
SIGMAGD  
0.02 /
```

## SIGMAGDV Matrix-fracture coupling for oil-gas gravity drainage

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used to specify an alternative matrix-fracture coupling for matrix cells in which the production mechanism is gravity drainage due to the presence of gas in the fractures.

The keyword should be followed by one positive real number for every grid block in the current box within the top NDIVIZ /2 layers of the grid (that is, the matrix cells). Any values input in the bottom half of the grid (the lower NDIVIZ /2 layers) will be ignored.

The particular formula used to prescribe the alternative is different between ECLIPSE 100 and ECLIPSE 300. In ECLIPSE 100 this keyword is used to provide a different sigma factor for regions swept by gas, while the standard sigma factor is used for regions swept by water. In ECLIPSE 300 however, the keyword is used to provide an alternative sigma factor value when the gravity drainage potential is the dominant pressure term, while allowing smooth variation of sigma as the pressure increases. The next paragraphs provide details on these two formulas.

In ECLIPSE 100, the matrix-fracture transmissibility based on [SIGMAGD](#) will be used to calculate the oil flow when the following conditions are satisfied:

- The Gravity Drainage Model is active.
- Oil flow is from the matrix to the fracture.
- The gravity drainage head associated with gas in the fracture is greater than the head associated with water.

Hence regions in which the fractures are swept by gas will drain through a transmissibility based on [SIGMAGD](#) and regions swept by water will be produced through a transmissibility based on [SIGMA](#).

The [SIGMAGDV](#) keyword is only available in three-phase dual porosity runs (keyword [DUALPORO](#) in the RUNSPEC section).

This sigma factor may be related to the matrix block size by the expression:

$$\Sigma = 4 \left( \frac{1}{l_x^2} + \frac{1}{l_y^2} + \frac{1}{l_z^2} \right) \quad \text{Eq. 3.174}$$

where  $l_x$ ,  $l_y$  and  $l_z$  are typical X, Y and Z dimensions of the matrix blocks.

The relationship was proposed by Kazemi (1976) [[Ref. 61](#)].

The dimensions of the matrix blocks used above are not the dimensions of the simulation grid.

UNITS: m<sup>-2</sup> (METRIC), ft<sup>-2</sup> (FIELD), cm<sup>-2</sup> (LAB), m<sup>-2</sup> (PVT-M)

Alternatively sigma may be treated as a simple history matching factor.

When calculating the matrix-fracture transmissibility for gravity drainage, the matrix Z-permeabilities are used by default, rather than the X-permeabilities. The pre-99A treatment (using the X-permeabilities) may be restored using [switch 70](#) in the [OPTIONS](#) keyword.

In ECLIPSE 300, if [SIGMA](#) and [SIGMAGD](#) are both entered, the program uses an interpolated value, depending on the relative sizes of the capillary pressure and gravity drainage pressure terms. Thus if capillary pressures dominates, [SIGMA](#) values are used, whilst if gravity drainage dominates [SIGMAGD](#) values are used.

If neither `SIGMAGD` nor `SIGMAGDV` are specified, the transmissibilities will be based on the sigma value supplied by the `SIGMA` or `SIGMAV` keywords, unless `LTOSIGMA` is specified.

When the `SIGMAGD` values are output (mnemonic `SIGMAGDV` in the `RPTGRID` keyword) the first `NDIVIZ / 2` layers are copied into the lower half of the grid.

Refer to "Gravity imbibition/drainage" in the *ECLIPSE Technical Description* for more details.

This keyword can only be used with the THERMAL option (keyword [THERMAL](#) in the RUNSPEC section).

If the dual porosity or dual permeability options are being used (keyword [DUALPORO](#) or [DUALPERM](#) in the RUNSPEC section), this keyword can specify an overall multiplier to be used in the construction of the matrix-fracture thermal conductivity coupling transmissibilities.

The SIGMATH keyword is followed by a value for each matrix cell. Thus  $(N_x N_y N_z) / 2$  values are required in all, in normal grid order with the X-index changing fastest.

The dual porosity and dual permeability options are discussed in more detail in "[Dual porosity](#)" in the *ECLIPSE Technical Description*.

The Thermal option is described in "[Thermal option](#)" in the *ECLIPSE Technical Description*.

### Example

```
SIGMATH
350*0.12 /
```

## Dual porosity matrix-fracture coupling

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

If the dual porosity option is being used (keyword [DUALPORO](#) in the RUNSPEC section), this keyword can be used to specify a multiplier to be applied in the construction of the matrix-fracture coupling transmissibilities.

The keyword should be followed by one positive real number for every grid block in the current box within the top  $NDIVIZ / 2$  layers of the grid (that is, the matrix cells). Any values input in the bottom half of the grid (the lower  $NDIVIZ / 2$  layers) will be ignored.

This sigma factor may be related to the matrix block size by the expression:

$$\Sigma = 4 \left( \frac{1}{l_x^2} + \frac{1}{l_y^2} + \frac{1}{l_z^2} \right) \tag{Eq. 3.175}$$

where  $l_x, l_y$  and  $l_z$  are typical X, Y and Z dimensions of the matrix blocks.

The relationship was proposed by Kazemi (1976) [Ref. 61].

The dimensions of the matrix blocks used above are not the dimensions of the simulation grid.

UNITS: m<sup>-2</sup> (METRIC), ft<sup>-2</sup> (FIELD), cm<sup>-2</sup> (LAB), m<sup>-2</sup> (PVT-M)

### ECLIPSE 100

Alternatively sigma may be treated as a simple history matching factor.

If neither [SIGMA](#) nor SIGMAV are specified then the default sigma factor is 0.0 throughout the grid, unless [LTOSIGMA](#) is specified in runs using the Viscous Displacement option.

When the SIGMA values are output (mnemonic SIGMAV in the [RPTGRID](#) keyword) the first  $NDIVIZ / 2$  layers are copied into the lower half of the grid.

### ECLIPSE 300

When the multi-porosity option is in use ([NMATRIX](#) > 1) and the grid properties for each porosity are specified separately ([NMATOPTS](#) is not used), then each porosity in the grid now has  $NDIVIZ / (NMATRIX + 1)$  layers. Most of the properties entering the multi-porosity transmissibility or diffusivity between porosities are associated with the corresponding inner matrix layer. However, for SIGMAV this is only true for the matrix-fracture connection as in dual porosity. For multi-porosity connections between matrix cells, the SIGMAV value of the *outer* matrix is used (see "[Matrix-matrix transmissibility and diffusivity](#)" in the *ECLIPSE Technical Description*). This forces SIGMAV to have NMATRIX contiguous porosities of data, leaving the last porosity unused and preventing the need to fill a porosity with unused default values, as the last porosity can be defaulted by omission.

### Example

```

----- IX1-IX2 JY1-JY2 KZ1-KZ2
BOX
      1  8  1  1  1  2  /
SIGMAV
0.12 0.12 0.12 0.12 0.12 0.12 0.12 0.12
1.0  1.0  1.0  1.0  1.0  1.0  1.0  1.0  /
    
```

Using Kazemi's expression, in FIELD units, a value of 0.12 would correspond to 10 ft matrix blocks.

## SKIPREST Skip subsequent keywords until the restart time

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The SKIPREST keyword has no associated data. It instructs ECLIPSE to skip the subsequent keywords in the SCHEDULE section of a restart run until the restart time has been reached. This saves you from having to delete the keywords yourself. It should normally be placed at the very start of the SCHEDULE section - in ECLIPSE 100 parallel runs it is strongly recommended that the keyword is the first one in the SCHEDULE section.

The keyword has no effect in the base run (starting from time zero), but in a restart run it causes ECLIPSE to reset the simulation time to zero and skip the subsequent keywords until a timestepping keyword (for example, [TIME](#), [TSTEP](#), [DATES](#) or [GASYEAR](#)) advances the simulation time to the restart time. Thereafter the keywords are read in as normal.

Not all keywords are skipped. Some keywords supply data that is not carried over on the restart file, such as

- VFP tables  
(Keywords [VFPPROD](#), [VFPINJ](#))
- Reporting instructions  
(Keywords [RPTSCHED](#), [RPTRST](#) or [RPTPRINT](#))
- The “global keywords” that can be entered in any section  
(for ECLIPSE 100 [COLUMNS](#), [DEBUG](#), [ECHO](#), [EXTRAPMS](#), [FORMFEED](#), [INCLUDE](#), [MESSAGES](#), [NOECHO](#), [NOWARN](#) and [OPTIONS](#)) or  
(for ECLIPSE 300 [DEBUG3](#), [ECHO](#), [INCLUDE](#), [MESSAGES](#), [NOECHO](#) and [OPTIONS3](#))
- Annual scheduling files in the Gas Field Operations Model (keywords [GASBEGIN](#), [GASEND](#) and any keywords in between)
- The keywords [SLAVES](#), [DUMPCUPL](#) and [USECUPL](#) in the Reservoir Coupling Facility.
- Well PI Scaling tables (keyword [PIMULTAB](#)).
- Scale damage and scale deposition tables (keywords [SCDATAB](#) and [SCDPTAB](#)).
- The drift flux inclination factor table for multisegment wells (keyword [WSEGDFIN](#)).
- Polymer flood model tables (keywords [PLYSHEAR](#), [PLYROCKM](#), [PLYDHFLF](#), [PLYMAX](#), [PLYADS](#) and [PLYSHLOG](#)).
- The structure of the standard production and injection networks (keywords [GRUPNET](#) and [GRUPINJE](#)).
- Gas plan tables: keywords [GPTABLE](#), [GPTABLEN](#) and [GPTABLE3](#).
- The [TUNING](#) keyword.

These keywords must be present in the SCHEDULE section of the restart run, if they are needed in the run. Accordingly, ECLIPSE will read and process these keywords in the usual way, even if they occur between the SKIPREST keyword and the restart time. VFP tables should be entered before the first timestepping keyword (it is best to place them at the start of the SCHEDULE section).

If the SKIPREST keyword is present in a restart run, take care to ensure that it is followed by the timestepping keywords necessary to advance the simulation time from zero to the restart time. There **must** be a report step corresponding to the restart time, at which ECLIPSE stops skipping keywords and begins

simulating normally. Thus, if the DATES keyword is used to advance the simulation, there **must** be a DATES record with a date identical to the restart date.

---

**Note:** If TSTEP, GASYEAR or GASPERIO keywords are used to advance the simulation, and some have been deleted in the restart run, the remaining keywords do not advance the simulation time to reach the restart time at the correct place in the Schedule data. Advancing the simulation with the DATES or TIME keyword is safer in this respect, as these keywords advance the simulation **to** a given time rather than **by** a given time interval.

---

## SLAVES

## Starts the slave reservoir simulation runs

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used in a reservoir coupling master run to identify the slave reservoir data files, and to indicate where they are located. ECLIPSE starts their simulation processes, which waits for further instructions from the master run. (See "Reservoir coupling" in the *ECLIPSE Technical Description*.)

The keyword is followed by a data record for each active slave reservoir. Each record contains the following items of data, and should be terminated with a slash (/). The set of records must end with a blank record, containing only a slash (/).

1. Name of the slave reservoir  
(This should be up to 8 characters long)  
The slave reservoir name is used to identify the slave reservoir in keyword [GRUPMAST](#).
2. The root name of the slave reservoir's ECLIPSE data file  
(This should be up to 72 characters long)
3. This item should just be '\*' in almost all cases; this allows the system to pick which hosts to put the slaves on, depending on the host file supplied. In very specific cases this item should be the host name of the machine on which the slave process is to be run. If a host name has to be specified the following caveats apply:  
(If specified the host name can be up to 32 characters long)  
Enter the master's host name here, if the slave resides on the same machine as the master run.
4. The path-name of the directory in which the data file is located, from the root directory of the host machine  
(This should be up to 72 characters long)
5. Number of processors the slave is to be run on. If the slave is to be run in parallel this should be an integer corresponding to the first item in the [PARALLEL](#) keyword in the slave data set. This value should be set to 1 for runs in serial mode.  
DEFAULT: 1

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

### Notes

- The SLAVES keyword can only be entered once in a run, so all slave processes must be started together. If at a later date you wish to add another slave reservoir, this may be done in a restart run, adding the new slave reservoir to the others in the SLAVES keyword.
- The SLAVES keyword data is **not** carried over on the restart file. In restart runs the keyword must be entered again, naming all the slave processes to be activated during the run.
- Up to 20 slave reservoirs are allowed. ECLIPSE must be re-dimensioned if more are required.
- If a slave reservoir is removed in a restart run (by not specifying it again in the SLAVES keyword), any master groups that were originally associated with it will automatically be flagged to read their flows from the Reservoir Coupling file instead. Alternatively, if the slave reservoir is actually no longer producing, you could redefine the master groups as satellite groups with keywords [GSATPROD](#) and [GSATINJE](#), giving them zero production and injection rates.

- After reading the SLAVES keyword data, ECLIPSE starts the slave simulation processes. If a particular slave process cannot be started, the master run will print an error message and terminate the other processes. If a slave's host machine has insufficient free memory to run the process, the operating system may kill the process after MPI has started it. To prevent this situation from hanging the other coupled processes, the master run waits up to 30 seconds for each slave process to send its initial communication. If no response is received within 30 seconds of starting a slave process, the master run prints an error message and terminates the other processes.
- The master run may not include the [PARALLEL](#) keyword, so no dataset should contain both the PARALLEL keyword and the SLAVES keyword. Slave simulations may be parallel, but the master must run in serial mode.

## Example

```
SLAVES
--  slave  datafile  machine  directory
--  name   root      hostname  of data file
--
--  'upper' 'base'   '*'      '/usr/models/upper' /
--  'lower' 'base'   '*'      '/usr/models/lower' /
/
```

## SLGOF

## Gas/oil saturation functions versus liquid saturation

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The SLGOF keyword may be used in runs containing both oil and gas as active phases, to input tables of gas relative permeability, oil-in-gas relative permeability and oil-gas capillary pressure as functions of the liquid saturation. If water is also an active phase in the run, the water/oil saturation functions must be input with keyword [SWOF](#).

The data comprises NTSFUN (see item 1 in keyword [TABDIMS](#) in the RUNSPEC section) tables of gas/oil saturation functions, each terminated by a slash (/). Each table consists of 4 columns of data:

1. The liquid saturation.

Values should be between 0 and 1 and should increase monotonically down the column. The first value in the column is interpreted as  $S_1 = S_{wco} + S_{or}$  ( $S_{wco}$  is the connate water saturation, the first saturation value in the SWOF keyword, or zero if there is no water in the run). The last value must be 1.0, which corresponds to a gas saturation of zero.

2. The corresponding gas relative permeability.

Values should be between 0 and 1 and should be level or decreasing down the column. The last value in the column must be zero.

3. The corresponding oil relative permeability when oil, gas and connate water are present.

Values should be between 0 and 1 and should be level or increasing down the column. If water is present in the run, the last value in the column ( $k_{rog}$  at  $S_g=0$ ) must be the same as the first value in the  $k_{row}$  column in keyword SWOF (that is  $k_{row}$  at  $S_o = 1 - S_{wco}$ ). The first value in the column must be zero.

4. The corresponding oil-gas capillary pressure.

Values should be level or decreasing down the column.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

Default values (represented by 1\*) may be inserted as required in columns 2, 3 and 4. When the table is read in, defaults are replaced by values computed by linear interpolation.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (see item 3 in keyword [TABDIMS](#)).

The entire table may be defaulted provided the table is not the first. Defaulted tables are replaced with a copy of the previous table.

The keyword families

(i) [SWOF](#), [SGOF](#) and [SLGOF](#)

(ii) [SWFN](#), [SGFN](#), [SGWFN](#), [SOF2](#) and [SOF3](#)

provide two alternative formats for inputting the saturation functions. Do not mix keywords from the two families in the same run. In gas-water runs, or if you are using the ECLIPSE 100 Miscible Flood or Solvent options, the saturation functions must be input with keywords from family (ii).

For two dimensional tables the following keywords can also be used: [SOF32D](#), [SGF32D](#) and [SWF32D](#).

See "[Saturation Functions](#)" in the *ECLIPSE Technical Description* for more information, and a description of the methods used to compute three phase relative permeabilities.

**Note:** The critical saturation for each relative permeability function is established by determining the highest saturation in the table for which the relative permeability is notionally zero, that is, less than a small threshold value. Relative permeability values which are lower than this threshold value will be treated as zero. For ECLIPSE 100 and ECLIPSE 300 the default threshold values are  $1.0 \times 10^{-6}$  and  $1.0 \times 10^{-20}$  respectively. These values may be modified using the [TOLCRIT](#) keyword.

## Example

With NTSFUN=2 and NSSFUN ≥ 10:

```

SLGOF

	SCHEDULE

The SMULTX, SMULTY and SMULTZ keywords specify transmissibility multipliers for auto-refined grids which apply only between cells in the auto-refined grid that lie on an interface between cells in the base grid.

Thus a value of SMULTX for block (IB,JB,KB) in the base grid multiplies the transmissibility between all cells (IA,JA,KA) and (IA+1,JA,KA) in the auto-refined grid which lie on the X+ direction interface between cells (IB,JB,KB) and (IB+1,JB,KB) in the base grid. (That is, auto-refined cell (IA,JA,KA) is contained within the base grid cell (IB,JB,KB), and auto-refined cell (IA+1,JA,KA) is contained within the base grid cell (IB+1,JB,KB).) The behavior of SMULTY and SMULTZ is analogous.

By default, any data for **MULTX** for example, is inherited from the host cells in the base grid, so that **MULTX** for cell (IB,JB,KB) applies to all auto-refined cells (IA,JA,KA) contained within the base grid cell (IB,JB,KB).

The SMULT keywords can only be used if item 4 of the **AUTOREF** keyword in the RUNSPEC section is set to 2. In this case, both **MULTX** and **SMULTX** for example can be used together and **MULTX** will assume the default behavior.

If item 4 of **AUTOREF** is set to 1, then any **MULTX** multipliers in the base dataset are treated the same as **SMULTX** multipliers. The same is true for **MULTY** and **MULTZ** multipliers.

The keyword should be followed by one non-negative real number for every grid block in the current input box, and the data must be terminated by a slash (/).

### Example

```

----- IX1-IX2 JY1-JY2 KZ1-KZ2
BOX      5   5   3   8   4   6   /
SMULTX
 18*0.5 /

```

## SOCRS

## Scaled critical oil-in-water saturations at miscible conditions

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword allows input of the critical oil-in-water saturation within each cell for the Surfactant Model (see "Surfactant model" in the *ECLIPSE Technical Description*). In the same way that the [SOWCR](#) keyword scales the immiscible saturation ([SATNUM](#)) tables, the [SOCRS](#) keyword scales the [SURFNUM](#) tables.

This keyword can only be used when the End Point Scaling option is active (keyword [ENDSCALE](#) in the [RUNSPEC](#) section). No directional forms of the keyword are available, and thus if directional scaling is active the [SOCRS](#) value will be taken for all directions.

The [SOCRS](#) keyword should be followed by one real number for each grid block in the current input box, specifying the critical oil-water saturation within the grid block at miscible conditions. The saturation should be in the range 0.0 to 1.0 inclusive. The data must be terminated by a slash(/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

See also keywords [SOWCR](#) and [SOGCR](#) in the [PROPS](#) section.

## SOF2

## Oil saturation functions (two-phase)

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The SOF2 table has two uses:

- to specify the relative permeability of oil in two-phase models (oil-gas or oil-water)
- to specify the relative permeability of miscible hydrocarbon in solvent models.

SOF2 should not be used to specify the oil's relative permeability in three-phase systems.

The data comprises NTSFUN (see item 1 of keyword [TABDIMS](#) in the RUNSPEC section) tables of oil saturation functions, each terminated by a slash (/).

Each table consists of 2 columns of data:

1. The saturation  $S_p$ .

Values should be between 0 and 1 and should increase monotonically down the column.

2. The corresponding relative permeability  $k_{rp}$ .

Values should be between 0 and 1 and should be level or increasing down the column. The first value in the column must be 0.

When the keyword is used in two-phase models, column 1 is the saturation of the oil phase  $S_p = S_o$  and column 2 is the relative permeability of the oil phase  $k_{rp} = k_{ro}$ . When the keyword is used in solvent models, column 1 is the total hydrocarbon saturation (including solvent)  $S_p = S_n = S_o + S_g + S_s$  and column 2 is the relative permeability of the miscible hydrocarbon with respect to water  $k_{rp} = k_m$ .

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (see item 3 of keyword [TABDIMS](#)).

The entire table may be defaulted provided the table is not the first. Defaulted tables are replaced with a copy of the previous table.

The keyword families

- (i) [SWOF](#), [SGOF](#), [SLGOF](#)
- (ii) [SWFN](#), [SGFN](#), [SGWFN](#), [SOF2](#), [SOF3](#), [SOF32D](#)

provide two alternative formats for inputting the saturation functions. Do not mix keywords from the two families in the same run. SOF2 must be input with keywords from family (ii).

For more information, refer to "[Saturation functions](#)" and "[Solvent model](#)" in the *ECLIPSE Technical Description*.

---

**Note:** The critical saturation for each relative permeability function is established by determining the highest saturation in the table for which the relative permeability is notionally zero, that is, less than a small threshold value. Relative permeability values which are lower than this threshold value will be treated as zero. For ECLIPSE 100 and ECLIPSE 300 the default threshold values are  $1.0 \times 10^{-6}$  and  $1.0 \times 10^{-20}$  respectively. These values may be modified using the [TOLCRIT](#) keyword.

---

## Example

With NTSFUN=2 and NSSFUN ≥12:

```
SOF2
0      0

.4000  .0048
.4800  .0529
.5000  .0649
.5800  .1130
.6000  .1250
.6800  .3450
.7000  .4000
.7400  .7000
.7800  1.0000 /
```

## SOF3

## Oil saturation functions (three-phase)

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTSFUN (see item 1 of keyword [TABDIMS](#) in the RUNSPEC section) tables of oil saturation functions, each terminated by a slash (/).

Each table consists of 3 columns of data:

- The oil saturation.  
Values should be between 0 and 1 and should increase monotonically down the column. The maximum oil saturation should be equal to  $1 - S_{wco}$ , where  $S_{wco}$  is the connate water saturation.
- The corresponding oil relative permeability for regions where only oil and water are present.  
Values should be between 0 and 1 and should be level or increasing down the column. The first value in the column must be 0.
- The corresponding oil relative permeability for regions where only oil, gas and connate water are present.  
Values should be between 0 and 1 and should be level or increasing down the column. The first value in the column must be 0.

Default values (represented by 1\*) may be inserted as required in columns 2 and 3. When the table is read in, defaults are replaced by values computed by linear interpolation. Thus, in the table

```
SOF3
0      0      0
0.2    0      1*
1      1      0.6 /
```

the default value (the second entry in column 3) is converted to 0.12.

The entire table may be defaulted provided the table is not the first. Defaulted tables are replaced with a copy of the previous table.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (see item 3 of keyword [TABDIMS](#)).

The maximum values in columns 2 and 3 both represent the oil relative permeability at maximum oil saturation ( $S_o = 1 - S_{wco}$ ) and should therefore have the same value.

The keyword families

- (i) [SWOF](#), [SGOF](#), [SLGOF](#)
- (ii) [SWFN](#), [SGFN](#), [SGWFN](#), [SOF2](#), [SOF3](#), [SOF32D](#)  
[SWF3](#), [SGF3](#), [SOF3](#) ([IKU3P](#) and [ODD3P](#) options)

provide two alternative formats for inputting the saturation functions. Do not mix keywords from the two families in the same run. In gas-water runs, or if you are using the ECLIPSE 100 miscible flood or solvent options, the saturation functions must be input with keywords from family (ii).

See "[Saturation functions](#)" in the *ECLIPSE Technical Description* for a description of the method used to compute the oil relative permeability in blocks where all three phases are present.

See also keywords [BAKER1](#), [BAKER2](#), [STONE1](#), [STONE2](#), [IKU3P](#) and [ODD3P](#).

Note that SOF3 should be used only in three phase cases. In oil/gas and oil/water cases use SOF2.

The keyword SOF32D may be used in place of SOF3 to specify the three-phase oil relative permeabilities directly as a function of water and gas saturations in a two dimensional table.

ECLIPSE 300

If the IKU3P or the ODD3P option is selected, column 3 should correspond to the oil relative permeability in the presence of gas only; that is, in the absence of connate water.

**Note:** The critical saturation for each relative permeability function is established by determining the highest saturation in the table for which the relative permeability is notionally zero, that is, less than a small threshold value. Relative permeability values which are lower than this threshold value will be treated as zero. For ECLIPSE 100 and ECLIPSE 300 the default threshold values are  $1.0 \times 10^{-6}$  and  $1.0 \times 10^{-20}$  respectively. These values may be modified using the TOLCRIT keyword.

## Example

With NTSFUN=1 and NSSFUN ≥12:

```

SOF3
.0000 .0000 .0000
.2000 .0000 .0000
.3800 1* .0000
.4000 .0048 1*
.4800 1* .0200
.5000 .0649 1*
.5800 1* .1000
.6000 .1250 1*
.6800 1* .3300
.7000 .4000 1*
.7400 1* .6000
.7800 1.0000 1.0000 /

```

## SOF32D

## 2D table of oil relative permeability

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is an alternative to the [SOF3](#) keyword, allowing the three-phase relative permeability of oil to be input directly as a function of water and gas saturations in a two dimensional table.

The data comprises NTSFUN (see item 1 of keyword [TABDIMS](#) in the RUNSPEC section) tables of oil relative permeability, tabulated against both water and gas saturations, each terminated by a slash (/).

Each table consists of a number of records:

Record 1 The water saturation values

Values should be between 0 and 1 and should increase monotonically. The number of water saturation values should not exceed NSSFUN (see item 3 of keyword [TABDIMS](#)). The minimum water saturation should be set to  $S_{wco}$ , the connate water saturation.

Subsequent records (a maximum of NSSFUN records):

The gas saturation.

Followed by the oil relative permeability values for this gas saturation at all the corresponding water saturations entered in Record 1.

The oil relative permeabilities should be monotonically decreasing, with a final value of zero. The number of oil relative permeability values should not exceed the number of water saturation values entered in Record 1. The record may be truncated at any point provided that the last relative permeability value is zero.

The columns of data must also comply with the following constraints:

- The gas saturation (the first item in the second and subsequent records) should increase monotonically down the column. The oil relative permeability for each water saturation should decrease monotonically down the column and should end in a zero value.
- The relative permeability must also be zero for any point on the table in which  $S_{wat} + S_{gas} \geq 1.0$ .
- Default values may not be placed within the table.

The entire table may be defaulted provided that the table is not the first. Defaulted tables are replaced with a copy of the previous table.

Since the three-phase oil relative permeabilities are specified directly by this keyword, any keywords controlling the three-phase relative permeability model ([STONE1](#), [STONE2](#)) will be ignored.

The keyword cannot at present be used with the end-point scaling, hysteresis and miscible options.

## Example

With NTSFUN=1 and >NSSFUN ≥11:

## SOGCR

## Scaled critical oil-in-gas saturations

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The SOGCR and ISOGCR keywords specify the critical oil-in-gas saturation (that is the largest oil saturation for which the oil relative permeability is zero in an oil-gas-connate water system) within each grid cell. The oil flow across each grid face in an oil-gas-connate water system is calculated from a transformed oil-gas relative permeability curve obtained by linearly scaling the tabulated oil-gas relative permeability data between the new critical oil-in-gas saturation defined using an SOGCR keyword, and the new maximum oil saturation (see under the keywords [SWL](#), [SGL](#) in the PROPS section). The SOGCR keyword also permits scaling of the oil-gas relative permeability table used in computing the flow of oil between grid blocks and well connections.

Seven keywords are provided to allow the critical oil-in-gas saturation for each grid cell to be scaled independently.

These keywords are:

SOGCR Critical oil-gas saturation for the non-directional saturation function tables

SOGCRX Critical oil-gas saturation for the +X face of each grid cell

SOGCRX- Critical oil-gas saturation for the -X face of each grid cell

SOGCRY Critical oil-gas saturation for the +Y face of each grid cell

SOGCRY- Critical oil-gas saturation for the -Y face of each grid cell

SOGCRZ Critical oil-gas saturation for the +Z face of each grid cell

SOGCRZ- Critical oil-gas saturation for the -Z face of each grid cell

In radial grids the same directional keywords should be used to represent the critical oil-in-gas saturations for flows in the +R,-R,+T,-T,+Z,-Z directions respectively.

None of the SOGCR keywords should be used if either oil or gas is absent from the model. The keyword [ENDSCALE](#) must be specified in RUNSPEC.

If both directional and irreversible end-point scaling is requested, using switches 'DIRECT' and 'IRREVERS' in the ENDSALE keyword in RUNSPEC, then the critical oil-gas saturations for oil flow across the +X and -X faces of a grid cell are set using the keywords SOGCRX, SOGCRX-. Similarly SOGCRY, SOGCRY- are used for the +Y, -Y faces and the keywords SOGCRZ, SOGCRZ- for the +Z, -Z faces. Scaling of the well connection relative permeability tables for any well connections in the grid cell are performed using the SOGCR keyword.

When the end-point scaling is requested to be directional and reversible, using the switch 'DIRECT' but not 'IRREVERS' in ENDSALE, the keyword SOGCRX defines the critical oil-gas saturations for the +X and -X faces of each grid cell. Keyword SOGCRY is used for both the +Y,-Y faces and the keyword SOGCRZ, for both the +Z, -Z faces of each grid cell. Scaling of well connection relative permeability tables uses data entered under the SOGCR keyword.

If ENDSALE is specified in RUNSPEC without the switch 'DIRECT', then none of the directional forms of the SOGCR keyword are allowed. The SOGCR keyword then defines the new critical oil-gas saturation for oil flow out of each face of the grid cell and for oil flows between the grid cell and well connections.

Each SOGCR keyword should be followed by one real number for each grid block in the current input box specifying the critical oil-gas saturation within the grid block. The saturation should be in the range 0.0 to 1.0 inclusive. The data must be terminated by a slash(/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If any of the keywords SOGCR, SOGCRX, SOGCRX-, SOGCRY, SOGCRY-, SOGCRZ, SOGCRZ- are omitted in a model where they could be accepted then the critical oil-in-gas saturation for an oil relative permeability calculation defaults to the value used in the appropriate relative permeability table.

ECLIPSE 100

If the hysteresis model (switch 'HYSTER' in keyword SATOPTS) is active then the SOGCR data scales the drainage curve. The imbibition curve can be scaled by using the equivalent ISOGCR (ISOGCRX, ISOGCRX-, ...) keyword.

ECLIPSE 300

If the ODD3P relative permeability and capillary pressure hysteresis model has been selected, the primary end-point scaling is specified using the PSORG, PSGRO, PSORW, PSWRO, PSGRW and PSWRG keywords and the hysteresis end-point scaling is specified using the HSORG, HSGRO, HSORW, HSWRO, HSGRW and HSWRG keywords

See also keywords SGL, SWL, ENPTVD in the PROPS section.

See "Saturation table scaling" in the *ECLIPSE Technical Description* for further details.

**Note:** When consistency warning messages involving SOGCR are reported by ECLIPSE, in some cases this may be referred to using the alternative name SOCRG. (It should be noted that this is not accepted as an alternative keyword name.)

x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by one real number for each grid block in the current input box, terminated with a slash (/).

This keyword specifies the initial oil saturation values for each cell.

This keyword may be used to specify the initial solution explicitly, as an alternative to equilibration using [EQUIL](#). It is expected if the [PRESSURE](#) keyword is present, indicating explicit initialization, and if an oil phase is present. The same information may be obtained from a Restart file using the [GETSOL](#) keyword.

A sufficient set of the [SOIL](#), [SWAT](#) and [SGAS](#) keywords should be entered. For example, for a three phase run any pair may be used; for a two-phase oil/gas run use either [SOIL](#) or [SGAS](#).

For the mixed hydrostatic equilibration option, initial saturations should be specified together with items 1 and 2 of the [EQUIL](#) keyword and the [NEI](#) keyword. For more information, refer to "[Initializing the study](#)" in the *ECLIPSE Technical Description*.

When using explicit initialization, you must ensure that the initial solution is stable and physically reasonable.

	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTSFUN (see keyword [TABDIMS](#)) tables of solid adsorption functions describing the adsorption of solid by the rock formation. See "[Solid phase](#)" in the *ECLIPSE Technical Description* for further information.

Each table consists of 2 columns of data and is terminated by a slash (/):

1. The local solid concentration in the solution surrounding the rock.

The values should increase monotonically down the column.

UNITS: kg/m<sup>3</sup> (METRIC), lb/ft<sup>3</sup> (FIELD), gm/cc (LAB), kg/m<sup>3</sup> (PVT-M)

2. The corresponding concentration of solid adsorbed by the rock formation.

These values should not decrease down the column.

UNITS: kg/kg (METRIC), lb/lb (FIELD), gm/gm (LAB), kg/kg (PVT-M)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (see keyword [TABDIMS](#)).

The adsorbed concentration is measured as weight of solids per weight of rock. The rock density can be set with the [ROCKDEN](#) keyword.

If this keyword is not used then it is assumed that all solids are adsorbed to the rock. If this keyword is used, but the rock density is set to zero (or not set) then it is assumed that no solids are adsorbed to the rock.

### Example

With NTSFUN=2 and NSSFUN ≥6

```

	SUMMARY
	SCHEDULE

This keyword enables the default aqueous phase property data to be overwritten for the [GASSOL](#) option. The data for each soluble component consists of two records. The first record is the component index. It is followed by a table consisting of 2 columns of data. Each record is terminated by a slash. A null record, that is a record with no data before the terminating slash, must end this keyword.

Note that the solubility data may be defaulted for any given soluble component. In such a case, a default set of pressures and corresponding solubilities is generated. If the solubilities for all soluble components are defaulted, then each table comprises twenty rows of data. If the solubilities for some (but not all) soluble components are defaulted, then the number of rows in the defaulted solubility table(s) equals the maximum number of rows from the remaining input solubility tables. Since the default solubilities depend strongly on the data entered in the `PROPS` section, this may lead to unrealistic values if the component data is not accurate enough. Henceforth, you are strongly encouraged to enter your own values for the solubility data. Some recommended data, for CO<sub>2</sub>, is included at the end of this section. For further details concerning the calculation of default solubilities, see "[GASSOL solution in the aqueous phase](#)" in the *ECLIPSE Technical Description*.

### Record 1

One item of data:

1. The component index defined by the [CNAMEs](#) keyword.

### Record 2

A table consisting of 2 columns of data.

1. Pressure.

Values should increase monotonically down the column.

UNITS: barsa (`METRIC`), psia (`FIELD`), atma (`LAB`), atma (`PVT-M`)

2. The dissolved gas solution ratio at the specified pressure.

This is expressed as the volume of gas component at surface conditions per volume of water at surface conditions for a saturated solution.

UNITS: sm<sup>3</sup>/sm<sup>3</sup> (`METRIC`), Mscf/stb (`FIELD`), scc/scc (`LAB`), sm<sup>3</sup>/sm<sup>3</sup> (`PVT-M`)

See also "[GASSOL solution in the aqueous phase](#)" in the *ECLIPSE Technical Description*.

This table may be omitted if the solubility data is to be defaulted.

## SOLUBILI

## Specify properties of water-gas system

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword enables the default aqueous phase property data to be overwritten. The data consists of a **single** solubility table composed of a series of records terminated with a slash (/).

The dissolved gas can either be CO<sub>2</sub> ([CO2SOL](#)) or H<sub>2</sub>S ([H2SSOL](#))

The first line of the table should represent water at standard conditions when dissolved gas is at its minimum. The simulator does not assume that the minimum gas in water is zero; if you want to specify that the amount of gas in water is zero at standard conditions, you should set item 2 to zero in the first line of the table.

The contents of each column are as follows:

1. Pressure.  
UNITS: barsa ([METRIC](#)), psia ([FIELD](#)), atma ([LAB](#)), atma ([PVT-M](#))
2. The dissolved gas solution ratio at the specified pressure.  
This is expressed as the volume of gas at surface conditions per volume of water at surface conditions.  
UNITS: sm<sup>3</sup>/sm<sup>3</sup> ([METRIC](#)), Mscf/stb ([FIELD](#)), scc/scc ([LAB](#)), sm<sup>3</sup>/sm<sup>3</sup> ([PVT-M](#))
3. The formation volume of water saturated with gas at the specified pressure.  
UNITS: rm<sup>3</sup>/sm<sup>3</sup> ([METRIC](#)), rb/stb ([FIELD](#)), rcc/scc ([LAB](#)), rm<sup>3</sup>/sm<sup>3</sup> ([PVT-M](#))
4. The viscosity of water saturated with gas at the specified pressure.  
UNITS: cP ([METRIC](#)), cP ([FIELD](#)), cP ([LAB](#)), cP ([PVT-M](#))
5. The compressibility of water saturated with gas at the specified pressure.  
UNITS: 1/bars ([METRIC](#)), 1/psi ([FIELD](#)), 1/atm ([LAB](#)), 1/atm ([PVT-M](#))

---

**Note:** Default values are only generated for CO<sub>2</sub>

---

**Note:** Default values (represented by 1\*) may be inserted as required in columns 2 to 5. If all values in a given column are defaulted, they are replaced by values calculated using the rules used when the keyword is omitted as stated below. Otherwise, they are replaced by values computed by linear interpolation.

---

If this keyword is omitted, a default table is generated. The values for item 2 are calculated from the correlations given by Chang, Coats and Nolen [[Ref. 18](#)]. For the values of item 3, we first compute the density of pure water [[Ref. 62](#)], then we use Ezrokhi's method to calculate the effect of salt and CO<sub>2</sub>, [[Ref. 133](#)]. When setting item 115 of [OPTIONS3](#), the values for item 3 are calculated using the correlation given by [[Ref. 18](#)]. The value for items 4 and 5 are taken from the [PVTW](#) data.

The salinity values for the correlations used in items 2 and 3 can be input using either the [SALINITY](#) or [SALINITR](#) keyword, defaulting to zero.

See also "[CO<sub>2</sub>/H<sub>2</sub>S solution in the aqueous phase](#)" in the *ECLIPSE Technical Description*.

## SOLUBILS

Specify properties of water-CO<sub>2</sub> system with salt dependencies

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword enables the default aqueous phase property data to be overwritten. The data consists of a solubility table composed of a series of 2 records, each terminated by a slash. A null record, that is a record with no data before the terminating slash, must end this keyword.

The first line of record 2 should represent water at standard conditions when dissolved CO<sub>2</sub> is at its minimum for a given salinity. The simulator does not assume that the minimum CO<sub>2</sub> in water is zero; if you want to specify that the amount of CO<sub>2</sub> in water is zero at standard conditions then you should set item 2 to zero in each record 2 of the table.

If the brine option is active (keyword [BRINE](#)), the salinity values used to interpolate in this table are taken from the brine tracer. Otherwise, they are assumed to be zero.

If the brine option is active, the keywords [PVTWSALT](#) and [BDENSITY](#) are not allowed as the keyword SOLUBILS performs their function.

## Record 1

Three items of data:

1. The salt concentration.

Values should increase monotonically down the column.

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB), kg/sm<sup>3</sup> (PVT-M)

2. Brine surface density.

UNITS: kg/m<sup>3</sup> (METRIC), lb/ft<sup>3</sup> (FIELD), gm/cc (LAB), kg/m<sup>3</sup> (PVT-M)

DEFAULT: the brine takes the surface density of water, as specified in the [DENSITY](#) (or [GRAVITY](#)) keyword.

3. The reference salt concentration for stock tank water,  $c_{s\ ref}$ .

This item is only read in the first record of the table.

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB), kg/sm<sup>3</sup> (PVT-M)

DEFAULT: Salt concentration specified in item 1 of the first record of the table (typically zero).

## Record 2

A table consisting of 5 columns of data.

1. Pressure

Values should increase monotonically down the column.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

2. The dissolved CO<sub>2</sub> solution ratio at the specified pressure and salt concentration.

This is expressed as the volume of CO<sub>2</sub> at surface conditions per volume of water at surface conditions for a salt-saturated solution.

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), Mscf/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

- The formation volume factor of water saturated with  $\text{CO}_2$  at the specified pressure and salt concentration.

UNITS:  $\text{rm}^3/\text{sm}^3$  (METRIC), rb/stb (FIELD), rcc/scc (LAB),  $\text{rm}^3/\text{sm}^3$  (PVT-M)

- The viscosity of water saturated with  $\text{CO}_2$  at the specified pressure and salt concentration.

UNITS: cP (METRIC), cP (FIELD), cP (LAB), cP (PVT-M)

- The compressibility of water saturated with  $\text{CO}_2$  at the specified pressure and salt concentration.

UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB), 1/atm (PVT-M)

See also "[CO<sub>2</sub>/H<sub>2</sub>S solution in the aqueous phase](#)" in the *ECLIPSE Technical Description*.

This keyword enables the default aqueous phase property data to be overwritten. The data consists of a solubility table composed of a series of 2 records, each terminated by a slash. A null record, that is a record with no data before the terminating slash, must end this keyword.

The first line of record 2 should represent water at standard conditions when dissolved CO<sub>2</sub> is at its minimum for a given temperature. The simulator does not assume that the minimum CO<sub>2</sub> in water is zero; if you want to specify that the amount of CO<sub>2</sub> in water is zero at standard conditions then you should set item 2 to zero in each record 2 of the table.

If the [TEMPVD](#) keyword is used to specify a variable temperature profile with depth, this is used as temperature values to interpolate in this table. Otherwise, the values specified in [RTEMP](#) are used.

The salinity values for the correlations used in items 2 and 3 of record 2 can be input using either the [SALINITY](#) or [SALINITR](#) keyword, defaulting to zero.

### Record 1

One item of data:

1. The temperature

Values should increase monotonically down the column.

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

### Record 2

A table consisting of 5 columns of data.

1. Pressure

Values should increase monotonically down the column.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

2. The dissolved CO<sub>2</sub> solution ratio at the specified pressure and temperature.

This is expressed as the volume of CO<sub>2</sub> at surface conditions per volume of water at surface conditions.

UNITS: sm<sup>3</sup>/sm<sup>3</sup> (METRIC), Mscf/stb (FIELD), scc/scc (LAB), sm<sup>3</sup>/sm<sup>3</sup> (PVT-M)

3. The formation volume factor of water saturated with CO<sub>2</sub> at the specified pressure and temperature.

UNITS: rm<sup>3</sup>/sm<sup>3</sup> (METRIC), rb/stb (FIELD), rcc/scc (LAB), rm<sup>3</sup>/sm<sup>3</sup> (PVT-M)

4. The viscosity of water saturated with CO<sub>2</sub> at the specified pressure and temperature.

UNITS: cP (METRIC), cP (FIELD), cP (LAB), cP (PVT-M)

5. The compressibility of water saturated with CO<sub>2</sub> at the specified pressure and temperature.

UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB), 1/atm (PVT-M)

## SOLVCONC Initial coal solvent concentration

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword may be used with the coal bed methane model (see "[Coal bed methane model](#)" in the *ECLIPSE Technical Description*).

The keyword should be followed by one real number for every matrix grid block, specifying the initial solvent concentration in the coal. The data field should be terminated by a slash (/).

UNITS:  $\text{sm}^3/\text{m}^3$  (METRIC),  $\text{Mscf}/\text{ft}^3$  (FIELD),  $\text{scc}/\text{cc}$  (LAB),  $\text{sm}^3/\text{m}^3$  (PVT-M)

Grid blocks are ordered with the X axis index cycling fastest (from 1 to NDIVIX), followed by the Y axis index (from 1 to NDIVIY), and finally the Z axis index (from 1 to NDIVIZ). NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword [DIMENS](#). Repeat counts may be used for repeated values (for example  $115 * 0.22$ ). Note that spaces must not be inserted on either side of the asterisk (\*). Data need only be supplied for the matrix cells, that is, the upper half of the grid.

Both SOLVCONC and [SCVD](#) are entirely optional. If neither of these keywords is present, the coal solvent concentration is taken as the equilibrium concentration for the corresponding fracture pressure and solvent fraction.

The initial coal solvent concentration should not be set above the initial equilibrium value; ECLIPSE issues a warning if it is. If the coal solvent concentration is below the equilibrium value, the non-reversible diffusion model is recommended (set item 2 in keyword [DIFFCOAL](#) to 0.0).

See also the [GASCONC](#) and [SCVD](#) keywords.

### Example

With NDIVIX=8, NDIVIY=6 and NDIVIZ=10 specified in RUNSPEC keyword [DIMENS](#)

```
SOLVCONC
48*79.1
48*77.3
48*75.1
48*75.0
48*75.0 /
```

## SOLVDIMS

## Set dimensions for nested factorization solver for Pebi grids

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword instructs ECLIPSE that the solver operates on a given Cartesian box, but the data input is just for a list of active cells (supplied as a one dimensional list with all connections replaced by non-neighbor connections). The data is supplied by the FloGrid program.

The grid arrays need only be dimensioned according to the values in the [DIMENS](#) keyword. The SOLVDIMS keyword is only used for efficiency when the Nested Factorization solver is used, and is optional.

The number of cells  $NX \times NY \times NZ$  specified in the [DIMENS](#) keyword must equal the number of nonzero items in the  $NSOLX \times NSOLY \times NSOLZ$  array specified in the SOLVDIMS keyword.  $NX$  should be the number of active cells, and  $NY$  and  $NZ$  should then both equal one. Typically  $NSOLX \times NSOLY \times NSOLZ \ll NX \times NY \times NZ$ .

The [SOLVNUM](#) array should be used to map from the input to solver order within ECLIPSE.

In a local grid, SOLVDIMS should be specified in the GRID section between the [EXTFIN](#) and [ENDFIN](#) keywords which define the local grid. For a global unstructured grid, SOLVDIMS should be specified in the RUNSPEC section.

The number of cells  $NX \times NY \times NZ$  specified in the [EXTFIN](#) keyword must equal  $NSOLX \times NSOLY \times NSOLZ$  specified in the SOLVDIMS keyword.

### Example

```

RUNSPEC

DIMENS
 1000 1 1 /

SOLVDIMS
 10 10 10 /...

GRID

SOLVNUM

```

## SOLVDIRS Overrides the solver principal directions

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword overrides the default directions for the linear solver. By default ECLIPSE chooses the principal direction to correspond to the direction of highest transmissibility. However, if there are persistent linear convergence problems it may be useful to try alternative principal directions.

The data consists of a two-character string, enclosed in quotes, terminated with a slash (/).

The options are:

XY X principal Y second and Z outer

XZ X principal Z second and Y outer

YX Y principal X second and Z outer

YZ Y principal Z second and X outer

ZX Z principal X second and Y outer

ZY Z principal Y second and X outer

ECLIPSE 100

To fix only the outer dimension (for matrix diskling or the ECLIPSE 100 Parallel Option) set '-X' for the X direction, '-Y' for the Y direction or '-Z' for the Z direction. '-Z' is not permitted in parallel. To check the direction sequence set by the simulator, set [DEBUG](#) keyword item 4 to 1.

ECLIPSE 100

The SOLVDIRS keyword replaces [item 3](#) of [OPTIONS](#) keyword that was used in pre-97A releases. But for back-compatibility with old datasets the [OPTIONS](#) switch still functions (in local grid refinement runs it overrides the solver directions for the global and all local grids).

When the local grid refinement option is used, the solver directions can be set independently for each local grid by including the SOLVDIRS keyword between the [CARFIN](#) / [RADFIN](#) / [RADFIN4](#) / [REFINE](#) and [ENDFIN](#) pair. By default, the solver directions will be determined by ECLIPSE for each local grid unless set explicitly.

See "[Solution of the linear equations](#)" in the *ECLIPSE Technical Description* for further details.

### Example

```
SOLVDIRS
'XZ' /

This keyword may be used with the coal bed methane model (see "[Coal bed methane model](#)" in the *ECLIPSE Technical Description*).

This keyword can be used to specify the initial solvent fraction in the gas phase, in runs in which the initial conditions are calculated by equilibration.

The keyword should be followed by one real number for every grid block, specifying the initial solvent fraction in the gas. The data field should be terminated by a slash (/).

Grid blocks are ordered with the X axis index cycling fastest (from 1 to NDIVIX), followed by the Y axis index (from 1 to NDIVIY ), and finally the Z axis index (from 1 to NDIVIZ). NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword [DIMENS](#). Repeat counts may be used for repeated values (for example 115\*0.18). Note that spaces must not be inserted on either side of the asterisk (\*).

Data needs to be provided for the entire grid. However, the solvent fraction only applies to the cells in the fracture system. The equilibrium solvent concentration in the coal is calculated from the [LANGSOLV](#) / [COALADS](#) isotherm data and the prevailing fracture conditions.

See also the keyword [EQUIL](#) in the SOLUTION section.

### Example

With NDIVIX=10, NDIVIY=1 and NDIVIZ=2 specified in RUNSPEC keyword [DIMENS](#)

```
SOLVFRAC
20*0.05 /
```

## SOLVNUM

## Set map from user to solver order for Pebi grids

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

When the grid is supplied as a one-dimensional list of cells together with a collection of NNCs or MPFNNCs for an unstructured grid, the SOLVNUM array defines the mapping to solver order. The SOLVDIMS keyword should also be specified to inform ECLIPSE of the solver dimensions used when mapping to a Cartesian structured grid for the Nested Factorization linear solver. The data is supplied by the FloGrid program.

SOLVNUM should be followed by one integer for each grid cell in the current input box. For example, with SOLVDIMS of  $NSOLX \times NSOLY \times NSOLZ$ :

$$SOLVNUM(IX, IY, IZ) = ISX + (ISY - 1) \times NSOLX + (ISZ - 1) \times NSOLX \times NSOLY$$

where  $(ISX, ISY, ISZ)$  is the solver position in the box  $[1, NSOLX]$  by  $[1, NSOLY]$  by  $[1, NSOLZ]$ .

In a local grid, the DIMENS data is supplied by the EXTFIN keyword which defines the extent of the unstructured local grid. The SOLVDIMS keyword should be specified between the EXTFIN and ENDFIN keywords. Then SOLVNUM should be specified between the EXTFIN and ENDFIN pair or a matching REFINE and ENDFIN pair.

ECLIPSE 300

**Note:** The MPFA option is currently not available for use with this keyword. As a consequence, ECLIPSE 300 will ignore any MPFNNC read in.

## Examples

## Example 1

There are 1000 x 1 x 1 cells, mapped to an array of dimension 10 x 10 x 10 in the solver. Gaps are filled by inactive cells.

This keyword specifies the saturation table numbers used in the [SOLID](#) model to calculate the relative permeabilities and capillary pressures when the adsorbed solid concentration is high. Alternatively, the [SATNUM](#) keyword is used for the saturation functions when the adsorbed solid concentration is low. The [SOLWTAB](#) keyword determines the interpolation factor between these extremes.

The keyword should be followed by one integer for every grid block in the current input box, specifying the saturation function region numbers for the areas of high concentration of adsorbed solid. The region number should not be less than 1 or greater than NTSFUN (see RUNSPEC section keyword [TABDIMS](#)). The data must be terminated by a slash (/).

The saturation functions are specified using the [SWFN](#), [SOF2](#), [SOF3](#) or [SWOF](#) keywords.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

---

**Note:** If end-point scaling has been specified via the [ENDSCALE](#) option, both the high and low adsorbed concentration tables (specified via SOLWNUM and [SATNUM](#) respectively) will use the same set of end-points, for example, [SWL](#), [SWCR](#), [SWU](#) and related end-points .

---

### Example

With NTSFUN=4 specified in keyword [TABDIMS](#); NDIVIX=10, NDIVIY=10 and NDIVIZ=1 specified in RUNSPEC keyword [DIMENS](#); and no input [BOX](#) set

```
SATNUM
 50*1 50*2 /
SOLWNUM
 50*3 50*4 /

## SOLWTAB Solid wettability table

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTSFUN (item 1 of keyword [TABDIMS](#)) tables that define an interpolation parameter as a function of the adsorbed solid concentration. The parameter is used to interpolate between two sets of saturation functions, representing two different wettability conditions, defined by [SATNUM](#) and [SOLWNUM](#). Oil and water relative permeability and capillary pressure saturation functions are interpolated. The gas saturation functions are not affected by solid wettability and only the SATNUM tables are used for gas permeability and capillary pressure.

Each table consists of 2 columns of data and should be terminated by a slash (/):

1. Concentration of adsorbed solid

The values should increase monotonically down the column.

UNITS: kg/kg (METRIC), lb/lb (FIELD), gm/gm (LAB), kg/kg (PVT-M)

2. Interpolation parameter

The value should not be greater than 1.0 or less than 0.0. A value of 0 means the SATNUM saturation functions and a value of 1 means the SOLWNUM saturation functions will be used.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (item 3 of keyword [TABDIMS](#)).

---

**Note:** NTSFUN tables must be supplied. However only SOLWTAB tables referenced by SATNUM are used. If any table after the first is defaulted, then that table is copied from the previous table.

---

The keyword can only be used with the [SOLID](#) model. The [ROCKDEN](#) keyword must be supplied, to allow the adsorbed solid concentration to be determined. The keyword can be used with standard saturation functions and can also be used with the oil-water miscibility model which is described in the "[Surfactant model](#)" in the *ECLIPSE Technical Description*. However, it cannot be used with other saturation function options, such as hysteresis, [ODD3P](#) and [IKU3P](#).

### Example

With NTSFUN=4 and NSSFUN ≥ 4

```
SOLWTAB
0 0.0
20 0.2
600 0.3
1800 0.6/
/ default second table to the first table
0 0.0
2 0.0 / dummy table corresponding to a SATNUM table value
/ default the fourth table to the third table
```

## SOLWW

## Solid wettability weighting factor

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used with the [SOLID](#) model to specify a weighting factor for use in the solid wettability calculation. By default, the component molecular weight [MW](#) is used to calculate the adsorbed solid concentration, which can then be used with the [SOLWTAB](#) keyword to determine wettability effects. When there is more than one solid component, this keyword can be used to multiply the molecular weight, allowing different components to contribute differently to the wettability.

The keyword should be followed by  $N_c$  values, one for each hydrocarbon component. However, only values for solid components are significant.

- UNITS: kg/kg-M (METRIC), lb/lb-M (FIELD), gm/gm-M (LAB), kg/kg-M (PVT-M)
- DEFAULT: 1.

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

## Example

In a run with three solid components, the full weight of the first two solid components will be included in the wetting-solid concentration, while the third solid component will have no effect on the wettability:

```

CVTYPE
1* 1* 1* SOL SOL SOL /
MW
18.0 32.0 45.6 78.0 88.0 98.0 /
SOLWW
1* 1* 1* 1* 1.0 0.0 /

```

## Minimum oil saturation for the STONE I model

This keyword is optional, and specifies the minimum oil saturation used in the STONE I three-phase relative permeability model, as a function of the gas saturation. The data will be ignored if the [STONE1](#) keyword has not been used.

The data comprises NTSFUN (see item 1 of keyword [TABDIMS](#) in the RUNSPEC section) tables of minimum oil saturation. Each table consists of two columns of data, terminated by a slash (/):

1. The gas saturation.

Values should increase down the column.

The first gas saturation should equal the connate gas saturation in the corresponding [SGFN](#) table (which is usually zero).

The last gas saturation in the table should equal  $1 - S_{wco} - S_{ogcr}$ , where  $S_{wco}$  is the connate water saturation and is the residual oil-to-gas saturation, in the corresponding saturation tables. ( $S_{wco}$  is the lowest saturation in the [SWFN](#) table and  $S_{ogcr}$  is the largest oil saturation with  $k_{rog}$  of zero, in column 3 of the [SOF3](#) keyword.)

2. The corresponding minimum oil saturation.

The minimum oil saturation at connate gas (first point) should not exceed  $S_{owcr}$ , the residual oil-to-water saturation in the corresponding [SOF3](#) table. ( $S_{owcr}$  is the largest oil saturation with  $k_{row}$  of zero, in column 2 of the [SOF3](#) keyword.)

The minimum oil saturation at  $1 - S_{wco} - S_{ogcr}$  (last point) should not exceed  $S_{ogcr}$ , the residual oil-to-gas saturation in the corresponding [SOF3](#) table.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (see item 3 of keyword [TABDIMS](#)).

The entire table may be defaulted, provided the table is not the first. Defaulted tables are replaced with a copy of the previous table.

An alternative keyword [SOMWAT](#) can be used to input the minimum oil saturation; [SOMWAT](#) tabulates the minimum oil saturation against the water saturation rather than the gas saturation. Either keyword can be used to describe the same minimum oil isoperm. However, the actions of the two keywords are slightly different at oil saturations above the minimum. Using the [SOMGAS](#) keyword implies that the [SOM](#) is looked up at the prevailing gas saturation. Both keywords cannot be used in the same run.

The alternative family of saturation keywords ([SWOF](#), [SGOF](#), [SLGOF](#)) can be used to input the relative permeability data. In this case the connate water saturation  $S_{wco}$  and the residual oil-to-water saturation  $S_{owcr}$  are determined from the [SWOF](#) table and the residual oil-to-gas saturation  $S_{ogcr}$  is determined from the [SGOF](#) or [SLGOF](#) table.

---

**Note:** The consistency requirements described above refer to the table end-points irrespective of whether or not end-point scaling has been specified.

---

Refer to "[Saturation functions](#)" in the *ECLIPSE Technical Description* for more information.

## Minimum oil saturation for the STONE I model

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is optional, specifies the minimum oil saturation used in the STONE I three-phase relative permeability model, as a function of the water saturation. The data will be ignored if the [STONE1](#) keyword has not been used.

The data comprises NTSFUN (see item 1 of keyword [TABDIMS](#) in the RUNSPEC section) tables of minimum oil saturation. Each table consists of two columns of data, and is terminated by a slash (/).

1. The water saturation.

Values should increase down the column.

The first water saturation should equal the connate water saturation in the corresponding [SWFN](#) table. (The connate water saturation is the lowest saturation in the [SWFN](#) table.)

The last water saturation in the table should equal to  $1 - S_{gco} - S_{owcr}$  where:

$S_{gco}$  is the connate gas saturation

$S_{owcr}$  is the residual oil-to-water saturation in the corresponding [SOF3](#) table.

( $S_{owcr}$  is the largest oil saturation with  $k_{row}$  of zero, in column 2 of the [SOF3](#) keyword.)

2. The corresponding minimum oil saturation.

The minimum oil saturation at connate water (first point) should not exceed  $S_{ogcr}$ , the residual oil-to-gas saturation in the corresponding [SOF3](#) table. ( $S_{ogcr}$  is the largest oil saturation with  $k_{rog}$  of zero, in column 3 of the [SOF3](#) keyword.)

The minimum oil saturation at  $1 - S_{gco} - S_{owcr}$  (last point) should not exceed  $S_{owcr}$ , the residual oil-to-water saturation in the corresponding [SOF3](#) table.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (see item 3 in keyword [TABDIMS](#)).

The entire table may be defaulted, provided the table is not the first. Defaulted tables are replaced with a copy of the previous table.

An alternative keyword [SOMGAS](#) can be used to input the minimum oil saturation; [SOMGAS](#) tabulates the minimum oil saturation against the gas saturation rather than the water saturation. Either keyword can be used to describe the same minimum oil isoperm. However, the actions of the two keywords are slightly different at oil saturations above the minimum. Using the [SOMWAT](#) keyword implies that the [SOM](#) is looked up at the prevailing water saturation. Both keywords cannot be used in the same run.

The alternative family of saturation keywords ([SWOF](#), [SGOF](#), [SLGOF](#)) can be used to input the relative permeability data. In this case the connate water saturation  $S_{wco}$  and the residual oil-to-water saturation  $S_{owcr}$  are determined from the [SWOF](#) table and the residual oil-to-gas saturation  $S_{ogcr}$  is determined from the [SGOF](#) or [SLGOF](#) table.

---

**Note:** The consistency requirements described above refer to the table end-points irrespective of whether or not end-point scaling has been specified.

---

See "[Saturation functions](#)" in the *ECLIPSE Technical Description* for more information.

## Residual oil saturation

This keyword should be used in conjunction with [EOS](#) compositional simulations. It specifies a residual oil saturation that does not vaporize. Residual oil could be modeled in a number of ways: by using heavy oil components that do not vaporize (though these would be mobile); by using critical oil saturations (though the oil would be volatile); by using [SOLID](#) components; or by using dual porosity ([DUALPORO](#)). The SOR model is intended as a simple alternative to these.

SOR is a replacement for [SORMW1](#) and works in a different way. In the SOR model, the hydrocarbons are divided into two: residual oil and mobile hydrocarbons. The residual oil composition remains fixed throughout the simulation. It is treated as a separate phase that does not flow and does not contribute to the flash. It does contribute to the cell oil saturation and calculations of saturation functions such as relative permeabilities. The residual oil phase can be thought of as being trapped in pores, separate from the mobile hydrocarbon in the cell. The residual oil has only two properties: compressibility and saturation.

In the residual oil model, the oil saturation is divided into two parts, the mobile oil saturation and the residual oil saturation:

$$SOIL = SOILM + SOILR$$

The residual oil saturation given by this keyword is the fraction of the pore volume that is residual oil. It is not the fraction of the hydrocarbon volume (as used by some other authors).

### Related keywords

Three optional keywords can be used with SOR.

[SOILR](#) By default the residual oil saturation is set by the SOR keyword, with the same value for all cells in each saturation region. However, the SOILR keyword can be used to override the SOR values and specify the residual oil saturation on a cell-by-cell basis.

[ROMF](#) By default the residual oil composition is set equal to the initial oil composition in each cell, but the ROMF keyword can be used to specify the composition directly.

[SOROPTS](#) By default the residual oil saturation in a cell remains constant throughout the simulation. However a more physically realistic compressibility model can be set using the SOROPTS keyword.

### Initialization

The way the initial residual oil is calculated varies, depending on whether the [ROMF](#) keyword is used.

If the ROMF keyword is used to set the residual oil composition, then the mobile oil composition is set equal to the original cell composition, and mixed with the residual oil in proportion  $1 - SOILR_o : SOILR_o$ , where  $SOILR_o$  is the initial residual oil saturation, equal to the SOR or [SOILR](#) value.

If the ROMF keyword is not used, the oil in the cell is partitioned into residual oil and mobile oil. If there is not enough oil in the cell, the initial residual oil saturation is reduced to the initial oil saturation  $SOILR_o < SOIL_o$ . The residual oil composition will be equal to the initial oil composition.

### Simulation

The number of residual oil moles in a cell stays constant throughout the simulation, which means the concentration will change as the pressure changes.

The mobile hydrocarbons are flashed in the usual way to determine the phase split and phase properties (such as density and viscosity). The phase saturations are then modified to include the residual oil. Therefore relative permeabilities and capillary pressures will be based on the total oil saturation in the cell. It is recommended that the oil relative permeability is set to zero for oil saturations below the residual oil saturation.

## Output

Reported oil saturations `SOIL` represent the total oil saturation, including both residual and mobile oil. Other fluid properties (such as oil phase density, viscosity, `XMF`) are for the mobile hydrocarbon only. In the case where there is no mobile oil, the cell hydrocarbon state will be single phase gas, although the cell may contain residual oil and water. Apart from saturation, the oil phase properties for cells with no mobile hydrocarbon are meaningless; this is also true of oil phase properties for gas-filled cells in normal simulations, but may seem surprising since these cells can have a non-zero (residual) oil saturation.

Fluid in place calculations are performed using both the residual oil and the mobile hydrocarbons.

The composition of the residual oil and the saturations of residual and mobile oil can be output to the print file `RPTSOL`, `RPTSCHED`, the restart file `RPTRST`, and the summary file, using the following mnemonics and keywords:

	RPTSOL/RPTSCHED/RPTRST	SUMMARY vector
Residual oil composition	ROMLS	BROMLS
Residual oil saturation	SOILR	BSOILR
Residual oil compressibility (see <code>SOROPTS</code> )	COILR	BCOILR
Mobile oil saturation	SOILM	BSOILM

Table 3.49: Residual and mobile oil output keywords

## Keyword data

The data comprises `NTSFUN` (see item 1 of keyword `TABDIMS` in the `RUNSPEC` section) values, each terminated by a slash. Each value represents the residual oil saturation in each saturation region and should be between 0 and 1. Values close to 1 may cause convergence issues, since the effective pore volume (that is that available to flow) is proportional to  $1 - SOILR$ .

## Example

With `NTSFUN=2`

```
SOR
.1 /
.15 /

This keyword may be used with the coal bed methane model (see "[Coal bed methane model](#)" in the *ECLIPSE Technical Description*).

This keyword can be used to specify that only a fraction of the calculated equilibrium gas contents is actually present in the coal matrix.

---

**Note:** The same fraction is applied to all components.

---

The keyword should be followed by one real number for every grid block, specifying the fraction used. The data field should be terminated by a slash (/).

Grid blocks are ordered with the X axis index cycling fastest (from 1 to NDIVIX), followed by the Y axis index (from 1 to NDIVIY ), and finally the Z axis index (from 1 to NDIVIZ). NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword [DIMENS](#). Repeat counts may be used for repeated values (for example 115\*0.18). Note that spaces must not be inserted on either side of the asterisk (\*).

Only the values given for the matrix cells are used, so it is sufficient to supply NDIVIX \* NDIVIY \* NDIVIZ /2 values. The molar densities in the coal is calculated from the [LANGMEXT](#) isotherm data and the prevailing matrix conditions and then multiplied with the scaling fraction.

The keyword is entirely optional, if not specified, or defaulted values are used, the value of unity is assumed.

DEFAULT: 1.0

Values should be in the range [0,1] but values larger than unity are not flagged as an error, but a message is given. Values larger than unity means that the initial coal gas contents are not in equilibrium (unless the sorption pressure is sufficiently low).

See also the keyword [EQUIL](#) in the SOLUTION section.

### Example

With NDIVIX=10, NDIVIY=1 and NDIVIZ=2 specified in RUNSPEC keyword [DIMENS](#):

```
SORBFRAC
5* 5*0.95 /
```

The first 5 cells are defaulted to 100%, while for the 5 next cells 95% of the adsorption capacity as given by the Langmuir isotherm is initialized in the coal matrix.

## SORBPRES Initial adsorption pressure

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword may be used with the coal bed methane model (see "[Coal bed methane model](#)" in the *ECLIPSE Technical Description*).

The keyword specifies the initial sorption pressure. The sorption pressure overwrites the computed matrix pressure, as given by equilibration, and is then used to set the initial coal gas contents.

The keyword should be followed by one real number for every grid block, specifying the pressure for each cell in the matrix. The data field should be terminated by a slash (/).

Grid blocks are ordered with the X axis index cycling fastest (from 1 to NDIVIX), followed by the Y axis index (from 1 to NDIVIY), and finally the Z axis index (from 1 to NDIVIZ). NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword [DIMENS](#). Repeat counts may be used for repeated values (for example 115\*1009). Note that spaces must not be inserted on either side of the asterisk (\*).

Only the values given for the matrix cells are used, so it is sufficient to supply NDIVIX \* NDIVIY \* NDIVIZ / 2 values.

The molar densities of the coal are calculated from the [LANGMEXT](#) isotherm data, the input gas mole fractions and the sorption pressure.

The keyword is entirely optional and if not specified, or defaulted values are used, the computed value from equilibration or the explicitly set pressure value is used.

See also the keyword [EQUIL](#) in the SOLUTION section.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

### Example

With NDIVIX=10, NDIVIY=1 and NDIVIZ=2 specified in RUNSPEC keyword [DIMENS](#):

```
SORBPRES
5* 5*1009.0 /
```

The first 5 cells are unaltered, while the 5 next cells are set to a sorption pressure of 1009.0. This is used when computing the adsorption capacity as given by the Langmuir isotherm.

## SORMW1

## Residual oil saturation for compositional

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword has been replaced by the [SOR](#) keyword.

This keyword should be used in conjunction with the [ENDSCALE](#) keyword. It allows the user to set a residual oil saturation that does not vaporize due for example to continuous gas injection.

The data comprises NTSFUN (see item 1 of keyword [TABDIMS](#) in the RUNSPEC section) values, each terminated by a slash. Each value represents the residual oil saturation in each saturation region.

The residual oil saturation should not be higher than the critical oil in gas saturation ([SOGCR](#)). If it is the case, then the residual oil saturation is reset to [SOGCR](#).

### Example

With NTSFUN=2

```
SORMW1
.1 /
.15 /
```

**Note:** The composition of the residual oil is set as a fraction of the initial oil composition after equilibration. This fraction is not flashed, and is used later on to calculate the oil molar as a function of pressure. In this version of ECLIPSE the composition of the residual oil does not change with time. Note that in some cases tuning may be needed (for example reducing the maximum timestep using the [TSCRIT](#) keyword) to adjust the timestep for a better performance. [ENDSCALE](#)

## SOROPTS Residual oil model options

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies options for the residual oil model. See the [SOR](#) keyword. Only one option is currently available: the compressibility model for the residual oil.

The residual oil saturation is the ratio of the residual oil volume in a cell to the pore volume:

$$SOILR = \frac{VOILR}{PORV}$$

Since the residual oil composition remains constant, the volume of residual oil depends only on pressure. The residual oil saturation therefore depends only on pressure, given by:

$$\frac{1}{SOILR} \cdot \frac{dSOILR}{dP} = -COILR - \frac{1}{PORV} \cdot \frac{dPORV}{dP}$$

where  $COILR$  is the residual oil compressibility:

$$COILR = -\frac{1}{VOILR} \cdot \frac{dVOILR}{dP}$$

Three compressibility models are available:

### Constant SOR model

$$\text{'ZERO'} \quad \frac{1}{SOILR} \cdot \frac{dSOILR}{dP} = 0$$

The residual oil saturation remains constant throughout the simulation. This is the simplest model, but not physical, since it implies the residual oil has a negative compressibility. As the pressure increases and the pore volume increases, the volume of residual oil must increase at the same rate.

### Constant compressibility model

$$\text{'CONSTANT'} \quad COILR = CONSTANT$$

The initial compressibility of the residual oil is calculated and used throughout the simulation.

### Flash compressibility model

**'FLASH'**

The residual oil volume is determined by flashing the residual oil composition at the cell pressure. However, if the cell pressure drops below the bubble point of the residual oil, then the calculation will switch to the 'CONSTANT' method for that cell, using the previous single-phase value of the residual oil compressibility in that cell. The calculation will revert to the 'FLASH' method if the pressure increases above the residual oil bubble point.

This keyword is followed by one item, specifying the compressibility model.

DEFAULT: ZERO

## Example

```
SOROPTS
FLASH /
```

## SORWMIS

## Miscible residual oil saturation tables

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTMISC (item 1 in keyword [MISCIBLE](#) in the RUNSPEC section) tables of miscible residual oil saturation versus water saturation, each terminated by a slash. "[Miscible flood modeling](#)" in the *ECLIPSE Technical Description* contains details of how the effective residual oil saturation tables are used in the calculation of the gas and oil relative permeabilities and PVT properties. See also "[Solvent model](#)" in the *ECLIPSE Technical Description* for further information when the four-component solvent model is employed.

The SORWMIS keyword can only be used in runs which use the miscible flood option (keyword [MISCIBLE](#) in the RUNSPEC section) and where oil, water and gas are all present. For miscible flood simulations involving the water phase the SORWMIS keyword may be omitted, in which case the program assumes a miscible residual oil saturation of zero.

Each table consists of 2 columns of data:

1. The water saturation.

Values should be between 0 and 1 and should increase monotonically down the column.

2. The corresponding miscible residual oil saturation.

Values should be between 0 and 1 and should be level or increasing down the column

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSMISC (item 2 in keyword [MISCIBLE](#)).

### Example

With NTMISC=2 and NSMISC ≥3:

```
SORWMIS
 .00 .00
 .30 .00
1.00 .00 /
 .00 .00
 .25 .07
 .80 .11 /
```

## SOWCR

## Scaled critical oil-in-water saturations

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The SOWCR and ISOWCR keywords specify the critical oil-in-water saturation (that is the largest oil saturation for which the oil relative permeability is zero in an oil-water system) within each grid cell. The oil flow across each grid face in an oil-water system is calculated from a transformed oil-water relative permeability curve obtained by linearly scaling the tabulated oil-water relative permeability data between the new critical oil-in-water saturation defined using an SOWCR keyword, and the new maximum oil saturation (see under keywords [SWL](#), [SGL](#) in the PROPS section). The SOWCR keyword also permits scaling of the oil-water relative permeability table used in computing the flow of oil between grid cells and well connections.

Seven keywords are provided to allow the critical oil-in-water saturation for each grid cell to be scaled independently.

These keywords are:

SOWCR Critical oil-water saturation for the non-directional saturation function tables

SOWCRX Critical oil-water saturation for the +X face of each grid cell

SOWCRX- Critical oil-water saturation for the -X face of each grid cell

SOWCRY Critical oil-water saturation for the +Y face of each grid cell

SOWCRY- Critical oil-water saturation for the -Y face of each grid cell

SOWCRZ Critical oil-water saturation for the +Z face of each grid cell

SOWCRZ- Critical oil-water saturation for the -Z face of each grid cell

In radial grids the same directional keywords should be used to represent the critical oil-in-water saturations for flows in the +R, -R, +T, -T, +Z, -Z directions respectively.

None of the SOWCR keywords should be used if either oil or water is absent from the model. The keyword [ENDSCALE](#) should be specified in RUNSPEC.

If both directional and irreversible end-point scaling is requested, using switches 'DIRECT' and 'IRREVERS' in the ENDSALE keyword in RUNSPEC, then the critical oil-water saturations for oil flow across the +X and -X faces of a grid cell are set using the keywords SOWCRX, SOWCRX-. Similarly SOWCRY, SOWCRY- are used for the +Y, -Y faces and the keywords SOWCRZ, SOWCRZ- for the +Z, -Z faces. Scaling of the well connection relative permeability tables for any well connections in the grid cell is performed using the SOWCR keyword.

When the end-point scaling is requested to be directional and reversible, using the switch 'DIRECT' but not 'IRREVERS' in ENDSALE, the keyword SOWCRX defines the critical oil-water saturations for the +X and -X faces of each grid cell. Keyword SOWCRY is used for both the +Y, -Y faces and the keyword SOWCRZ for both the +Z, -Z faces of each grid cell. Scaling of well connection relative permeability tables uses data entered under the SOWCR keyword.

If ENDSALE is specified in RUNSPEC without the switch 'DIRECT', then none of the directional forms of the SOWCR keyword are allowed. The SOWCR keyword then defines the new critical oil-water saturation for flow out of each face of the grid cell and for oil flows between the grid cell and well connections.

Each SOWCR keyword should be followed by one real number for each grid block in the current input box specifying the critical oil-water saturation within the grid block. The saturation should be in the range 0.0 to 1.0 inclusive. The data must be terminated by a slash(/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If any of the keywords SOWCR, SOWCRX, SOWCRX-, SOWCRY, SOWCRY-, SOWCRZ, SOWCRZ- are omitted in a model where they could be accepted, then the critical oil-in-water saturation for an oil relative permeability calculation defaults to the value used in the appropriate relative permeability table.

ECLIPSE 100

If the Hysteresis model (switch 'HYSTER' in keyword SATOPTS) is active then the SOWCR data scales the drainage curve. The imbibition curve can be scaled by using the equivalent ISOWCR (ISOWCRX, ISOWCRX- etc.) keyword.

ECLIPSE 300

If the ODD3P relative permeability and capillary pressure hysteresis model has been selected, the primary end-point scaling is specified using the PSORG, PSGRO, PSORW, PSWRO, PSGRW and PSWRG keywords and the hysteresis end-point scaling is specified using the HSORG, HSGRO, HSORW, HSWRO, HSGRW and HSWRG keywords

See also keywords SGL, SWL, ENPTVD in the PROPS section.

See "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for details of the endpoint scaling procedure.

**Note:** When consistency warning messages involving SOWCR are reported by ECLIPSE, in some cases this may be referred to using the alternative name SOCRW. (It should be noted that this is not accepted as an alternative keyword name.)

## SPECGRID Specification of grid characteristics

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword repeats the specification of dimensions and other properties describing the simulation grid, as defined in the RUNSPEC section.

The SPECGRID keyword use is optional. The data specified in this keyword is not actually used. It only serves a checking function.

It is normally output by grid pre-processors (such as the FloGrid program) so that the program can verify that the same properties are used in both data sets. A error message is issued if agreement between the program and the pre-processor is not reached.

Following the keyword line there is a single record containing the following items, and ending with a slash (/):

1. The number of grid blocks in the I (X or radial) direction (NDIVIX, specified in RUNSPEC keyword [DIMENS](#))

DEFAULT: 1

2. The number of grid blocks in the J (Y or theta) direction (NDIVIY, specified keyword [DIMENS](#))

DEFAULT: 1

3. The number of grid blocks in the K (Z or depth) direction (NDIVIZ, specified keyword [DIMENS](#))

DEFAULT: 1

*ECLIPSE 100 only*

4. The number of reservoirs (NUMRES)

Each reservoir has its own coordinate system.

DEFAULT: 1

*ECLIPSE 100 only*

5. Type of coordinates

T Cylindrical (radial) coordinates.

F Cartesian coordinates.

DEFAULT: F

*ECLIPSE 300*

**Note:** Only the first 3 items have any use in this simulator. The 4<sup>th</sup> and 5<sup>th</sup> items can be read in, but are ignored.

See also keywords [DIMENS](#), [NUMRES](#), [COORDSYS](#) and [COORD](#).

```

## SPECHA

## Oil component specific heat

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can only be used with the [THERMAL](#) option.

SPECHA specifies the first coefficient of the oil component liquid specific heats, for each EoS region.

For multi-component simulations, the oil phase molar enthalpy is the mole fraction weighted sum of the component enthalpies:

$$h_o = \sum_{c=1}^{N_c} x_c \cdot h_c \cdot mw_c \quad \text{Eq. 3.176}$$

where

$x_c$  is the mole fraction of component  $c$  in the oil phase, and

$mw_c$  is the component molecular weight.

The component liquid enthalpy  $h_c$  has the form

$$h_c = C_{p1c} \cdot (T - T_{st}) + \frac{1}{2} \cdot C_{p2c} \cdot (T - T_{st})^2 \quad \text{Eq. 3.177}$$

where

$C_{p1c}$  is the first coefficient of the component liquid specific heat entered with this keyword

$C_{p2c}$  is the second coefficient of the component liquid specific heat entered with the [SPECHB](#) keyword, and

$T_{st}$  is the standard temperature defined with keyword [STCOND](#).

---

**Note:** It is common in thermal simulation to specify the component liquid specific heats with keyword SPECHA. Then to obtain the enthalpies of gaseous components, a heat of vaporization for each component is supplied with keyword [HEATVAP](#). Alternatively, one can specify gas component enthalpies with keyword [SPECHG](#) and obtain the liquid enthalpies by again specifying the component heats of vaporization with keyword [HEATVAP](#). Either SPECHA or SPECHG must be set for each run. Only two of the three keywords SPECHG, SPECHA and HEATVAP should be specified. For further information please see "[Enthalpy](#)" in the *ECLIPSE Technical Description*.

---

This keyword should only be used for thermal runs with volatile hydrocarbon components. For [DEADOIL](#) runs, use the [OILSPECH](#) keyword.

The data record contains one value for each component:

- liquid hydrocarbon component specific heats,  $N_c$  values, one for each component  
 UNITS: kJ/kg/K (METRIC), Btu/lb/°R (FIELD), J/gm/K (LAB), kJ/kg/K (PVT-M)  
 DEFAULT: 0.0

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

## Example

SPECHS specifies the first coefficient of the oil component solid phase specific heats, for each EoS region.

For multi-component simulations, the solid phase molar enthalpy is the mole fraction weighted sum of the component enthalpies:

$$h_s = \sum_{c=1}^{N_c} s_c \cdot h_c \cdot mw_c \quad \text{Eq. 3.183}$$

where

$s_c$  is the mole fraction of component  $c$  in the oil phase, and

$mw_c$  is the component molecular weight.

The component solid enthalpy  $h_c$  has the form

$$h_c = C_{p1c} \cdot (T - T_{st}) + \frac{1}{2} \cdot C_{p2c} \cdot (T - T_{st})^2 \quad \text{Eq. 3.184}$$

where

$C_{p1c}$  is the first coefficient of the component solid specific heat entered with this keyword

$C_{p2c}$  is the second coefficient of the component solid specific heat entered with the [SPECHT](#) keyword, and

$T_{st}$  is the standard temperature defined with keyword [STCOND](#).

The data record contains one value for each component:

- Liquid hydrocarbon component specific heats,  $N_c$  values, one for each component

UNITS: kJ/kg/K (METRIC), Btu/lb/°R (FIELD), J/gm/K (LAB), kJ/kg/K (PVT-M)

DEFAULT: 0.0

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

## Initial polymer concentrations

This keyword sets the initial polymer concentration in runs where the initial conditions are specified by enumeration.

The keyword should be followed by one real number for every grid block specifying the initial polymer concentration. The data field should be terminated by a slash (/).

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB)

Grid blocks are ordered with the X axis index cycling fastest (from 1 to NDIVIX), followed by the Y axis index (from 1 to NDIVIY), and finally the Z axis index (from 1 to NDIVIZ). NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword [DIMENS](#). Repeat counts may be used for repeated values (for example 115\*0.18). Note that spaces must not be inserted on either side of the asterisk (\*).

See also the keywords [PRESSURE](#), [SGAS](#), [RS](#), [PBUB](#), [RV](#), [PDEW](#) and [SWAT](#) in the SOLUTION section.

Refer to "[Polymer flood model](#)" in the *ECLIPSE Technical Description* for further information.

---

**Note:** When adsorption is active, the concentration specified here will be honored and extra adsorped polymer is added to the rock so that it is in equilibrium with the input fluid concentration.

---

---

**Note:** If a non-zero concentration is specified in cells containing none of the host phase, the concentration will be automatically reset to zero. This behavior can be turned off using [item 165](#) in [OPTIONS](#).

---

### Example

With NDIVIX=10, NDIVIY=1 and NDIVIZ=2 specified in RUNSPEC keyword [DIMENS](#):

```

This keyword may be used with the solvent model as described in "Solvent model" in the *ECLIPSE Technical Description*.

The data comprises NTSFUN (see keyword [TABDIMS](#)) tables of gas/solvent saturation functions, each terminated by a slash (/).

The tables consist of 3 columns of data. The first column is the phase fraction of either the gas or the solvent ( $S_{gas} / (S_{gas} + S_{solvent})$  or  $S_{solvent} / (S_{gas} + S_{solvent})$ ). The next two columns are respectively the relative permeability multiplier for the gas and the solvent ( $K_{rg}^*$  and  $K_{rs}^*$ ).

The relative permeabilities of the 2 components are given by:

$$K_{rg} = K_{rgt}(S_{gas} + S_{solvent})K_{rg}^* \quad \text{Eq. 3.192}$$

$$K_{rs} = K_{rgt}(S_{gas} + S_{solvent})K_{rs}^*$$

where  $K_{rgt}$  is the total gas phase relative permeability input using the [SGFN](#) keyword.

Column:

1. The phase fraction.  
Values should span the range 0 to 1 and increase monotonically down the column.
2. The corresponding gas relative permeability multiplier.  
Values should be between 0 and 1 and should be level or increasing down the column.
3. The corresponding solvent relative permeability multiplier.  
Values should be between 0 and 1 and should be level or increasing down the column.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (see keyword [TABDIMS](#)).

## Example

With NTSFUN=2 and >NSSFUN ≥6

x	SCHEDULE

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/). The set of records must end with a blank record, containing only a slash (/).

1. Secondary well name or well name template

A template enclosed in quotes can be used to refer to multiple wells. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. The secondary well name must have been previously associated with a well segment of an existing multisegment well using the [WSEGWELL](#) keyword.

2. Testing interval

This must be greater than zero.

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

The secondary well is tested at the beginning of the first timestep that starts after the specified interval has elapsed since it was closed. Subsequent tests are performed at each timestep that starts after the specified interval has elapsed since the previous test.

If the testing interval is very small (for example, 1 day), the well is tested at the beginning of each timestep (unless of course the timesteps are smaller than this).

The test is applied to secondary wells which have been shut because the segment pressure has reached the injection or production limit or because the well to which the segment belongs has been shut.

End the data record with a slash (/).

End the set of records with a blank record containing just a slash.

## STHERMX1 Thermal expansion coefficient for solid phase

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies the first thermal expansion coefficient for each of the  $N_c$  hydrocarbon components in the solid phase. It can only be used in runs with solids (keyword [SOLID](#) in the RUNSPEC section).

The expression used to calculate component solid densities is the following:

$$\rho_c = \frac{\rho_{ref_c}}{\left[1 - c_{P_c}(P - P_{ref_c})\right] \left[1 + c_{T1_c}(T - T_{ref_c})\right]} \quad \text{Eq. 3.193}$$

where

$\rho_{ref,c}$  is the reference density, specified with keyword [SDREF](#),

$c_{P_c}$  is the component solid compressibility, specified with keyword [SCREF](#),

$P_{ref_c}$  is the reference pressure, specified with keyword [SPREF](#),

$T_{ref_c}$  is the reference temperature, specified with keyword [STREF](#),

$c_{T1_c}$  is the thermal expansion coefficient, specified with this keyword.

There should be one value for each component:

UNITS: 1/K (METRIC), 1/°R (FIELD), 1/K (LAB), 1/K (PVT-M)

DEFAULT: 0.0

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of [TABDIMS](#). The use of multiple EoS regions is discussed in "Equations of state regions" in the *ECLIPSE Technical Description*.

## STOG

## Oil-gas surface tension versus pressure

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword supplies tables of oil-gas surface tension versus pressure. They are used by two facilities in ECLIPSE: the SURFTENS option and multisegment wells. The keyword should not be present if neither of these options are in use.

The SURFTENS option calculates a pressure-dependent adjustment to the capillary pressure. It is activated by requesting the SURFTENS option in the RUNSPEC section keyword SATOPTS. If the STOG keyword is not supplied, the oil-gas capillary pressure retains the values specified in the keyword SGFN, SGOF or SLGOF, independently of the pressure.

The keyword may also be used if there are any multisegment wells in the run. The phase interfacial tensions are required by the drift flux model (see "The drift flux slip model" in the *ECLIPSE Technical Description*). If surface tension data is supplied for the table corresponding to the well's PVT region number (see WELSPPCS keyword item 11), the interfacial tension is taken from this table. If there is no surface tension data supplied for the well's PVT table number, the interfacial tension is calculated from a built-in correlation.

The data comprises NTPVT (see keyword TABDIMS in the RUNSPEC section) tables of oil-gas surface tension versus pressure.

Each table consists of two records, each record terminated with a slash (/).

### Record 1

A reference oil phase pressure, at which the oil-gas capillary pressure has the values specified in keyword SGFN, SGOF or SLGOF.

(This data item is only used by the SURFTENS option. It is not needed to calculate the interfacial tension in the multisegment well drift flux model, and the value entered here does not affect its results.)

UNITS: barsa (METRIC), psia (FIELD), atma (LAB)

### Record 2

A table consisting of two columns of data.

1. The oil phase pressure. Values should increase monotonically down the column.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB)

2. The corresponding oil-gas surface tension.

UNITS: N/m (METRIC), lbf/in (FIELD), dynes/cm (LAB)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NPPVT (see keyword TABDIMS in the RUNSPEC section).

### Calculations for the SURFTENS option

The oil-gas capillary pressures (entered in keyword SGFN, SGOF or SLGOF) are adjusted according to the ratio of the surface tension at the grid block oil phase pressure to the surface tension at the reference pressure. The capillary pressures input in the SGFN, SGOF or SLGOF keyword are assumed to be at the reference pressure specified in the STOG keyword.

Thus the effective oil-gas capillary pressure is:

$$P_{cog} \text{ (oil pressure)} = P_{cog} \text{ (input by user)} \frac{ST \text{ (oil pressure)}}{ST \text{ (reference pressure)}} \quad \text{Eq. 3.194}$$

**Note:** The surface tension is only used as a ratio in the SURFTENS option, and hence the units used does not affect the results of the calculation.

## Example

With NTPVT=1 and NPPVT ≥ 11:

```
STOG
--
-- REFERENCE PRESSURE
--
--      5545 /
--
-- PRESSURE    SURFACE TENSION
--
-- 1674          6.0
-- 2031          4.7
-- 2530          3.3
-- 2991          2.2
-- 3553          1.28
-- 4110          0.72
-- 4544          0.444
-- 4935          0.255
-- 5255          0.155
-- 5545          0.090
-- 7000          0.050      /
```

## STONE

### Requests Stone II oil relative permeabilities

The default three-phase relative permeability is the linear combination described in "[Saturation functions](#)" in the *ECLIPSE Technical Description*. As an alternative, this keyword requests the use of the Stone's method II.

The STONE keyword contains no items.

STONE is an alias for [STONE2](#).

	SCHEDULE

This keyword, which has no associated data, is used to specify that the three-phase oil relative permeability values are to be calculated using the modified Stone's formula number 1. The STONE1 keyword should only be used in three-phase runs.

ECLIPSE uses the default three-phase oil relative permeability model if the keywords STONE1, [STONE2](#), [STONE](#), [IKU3P](#) or [ODD3P](#) are omitted from the [PROPS](#) section of the input data file. Tabulated output of the three-phase oil relative permeability values may be obtained using the mnemonic SOF2 or SOF3 in the [RPTPROPS](#) keyword.

The minimum oil saturation used by the STONE1 model can optionally be input as a table of minimum oil saturation versus either water or gas saturation, by using the [SOMWAT](#) or [SOMGAS](#) keyword. If neither of these keywords are present, the minimum oil saturation is taken as  $\text{MIN}(S_{\text{owcr}}, S_{\text{ogcr}})$ , the minimum of the critical oil-to-water saturation and the critical oil-to-gas saturation.

See "[Saturation functions](#)" in the *ECLIPSE Technical Description* for a description of three-phase oil relative permeability models available in ECLIPSE.

### Example

x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies the value of the exponent which is to be applied to the combination of saturation terms which are used in the calculation of the oil relative permeability when Stone's first three phase relative permeability model has been specified. The STONE1EX keyword should only be used in three-phase runs for which [STONE1](#) has also been specified.

The data associated with this keyword consists of one exponent value per saturation table. The number of saturation tables is specified in item 1 (NTSFUN) of keyword [TABDIMS](#) in the RUNSPEC section. If hysteresis is being modeled, which is defined by the [SATOPTS](#) keyword in the RUNSPEC section, the exponent values assigned to the drainage and imbibition tables should be equal for each saturation region.

The value of the exponent is constrained to lie between a minimum value of 0.01 and a maximum value of 100.0. If the value for the first table is defaulted, the exponent will be assigned a value of 1.0. Where values are defaulted for the second and successive tables, these will be assigned to the value of the exponent for the previous table.

See "[Saturation functions](#)" in the *ECLIPSE Technical Description* for a description of three-phase oil relative permeability models available in ECLIPSE.

### Example

With NTSFUN =3:

```
STONE1EX
1.0 /
4.0 /
1.0 /
```

## STONE2

	SUMMARY
	SCHEDULE

This keyword, which has no associated data, is used to specify that the three-phase oil relative permeability values are to be calculated using the modified form of Stone's model number 2. The STONE2 keyword should only be used in three-phase runs.

ECLIPSE uses the default three-phase oil relative permeability model if the keywords [STONE1](#), STONE2, [STONE](#), [IKU3P](#) or [ODD3P](#) are omitted from the PROPS section of the input data file. Tabulated output of the three-phase oil relative permeability values may be obtained using the mnemonic SOF2 or SOF3 in the [RPTPROPS](#) keyword.

See "[Saturation functions](#)" in the *ECLIPSE Technical Description* for a fuller description of the three-phase oil relative permeability models available in ECLIPSE.

Note that any negative oil relative permeabilities produced by Stone's model 2 are automatically changed to zero by ECLIPSE.

### Example

```
STONE2
```

## STONEPAR **Modify the Stone I three-phase oil relative permeability**

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword sets two coefficients, A and B, which define a modification of the Stone I three-phase relative permeability (see the [STONE1](#) keyword). These modify the mobile oil value,  $S_{om}$ . This is described in more detail in "[Saturation functions](#)" in the *ECLIPSE Technical Description*.

The STONEPAR keyword allows you to make the mobile oil value  $S_{om}$  a function of the gas saturation. In the absence of STONEPAR this is fixed as the minimum of the critical oil saturations in water or gas,  $\text{MIN}(S_{owcr}, S_{ogcr})$ . STONEPAR makes this a function of  $S_g$  as:

$$S_{om} = S_{ogcr} X_g^A + S_{owcr} (1 - X_g)^A + B S_{gm}^2 X_g (1 - X_g) \quad \text{Eq. 3.195}$$

where:

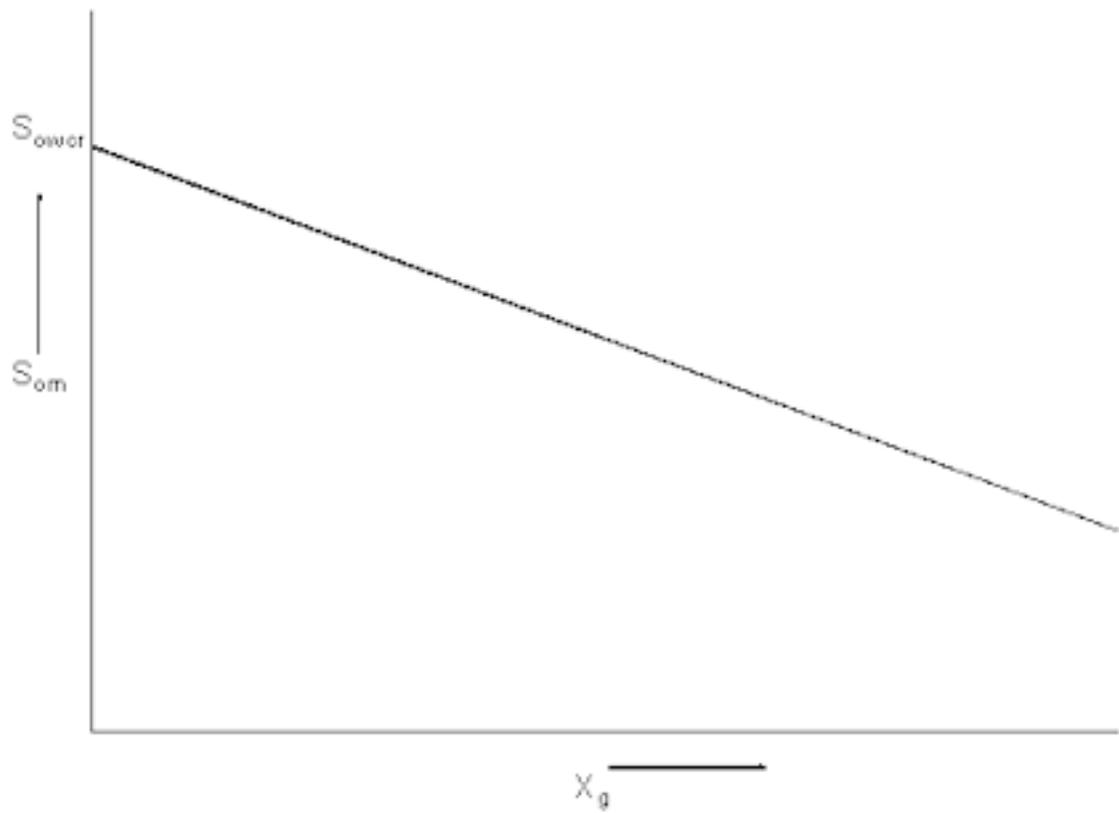

$$S_{gm} = 1 - S_{wco} - S_{ogcr} \quad \text{Eq. 3.196}$$

$$X_g = \frac{S_g}{S_{gm}} \quad \text{Eq. 3.197}$$

This expression interpolates  $S_{om}$  between  $S_{ogcr}$  when the gas saturation is at its maximum value and  $S_{owcr}$  when the gas saturation is at its minimum value - so that  $S_{om}$  reduces to its correct two-phase limits. Values of A=1 and B=0 would yield linear interpolation between these limits.

STONEPAR is followed by the two parameters, followed by a slash (/).

1. Interpolation parameter A  
DEFAULT: 1.0
2. Interpolation parameter B  
DEFAULT: 0.0.

*Figure 3.16. Linear interpolation for Som between Sogcr and Sowcr*

The B value enables curvature to be added to the interpolation. A positive value of B would yield an interpolant of the form:

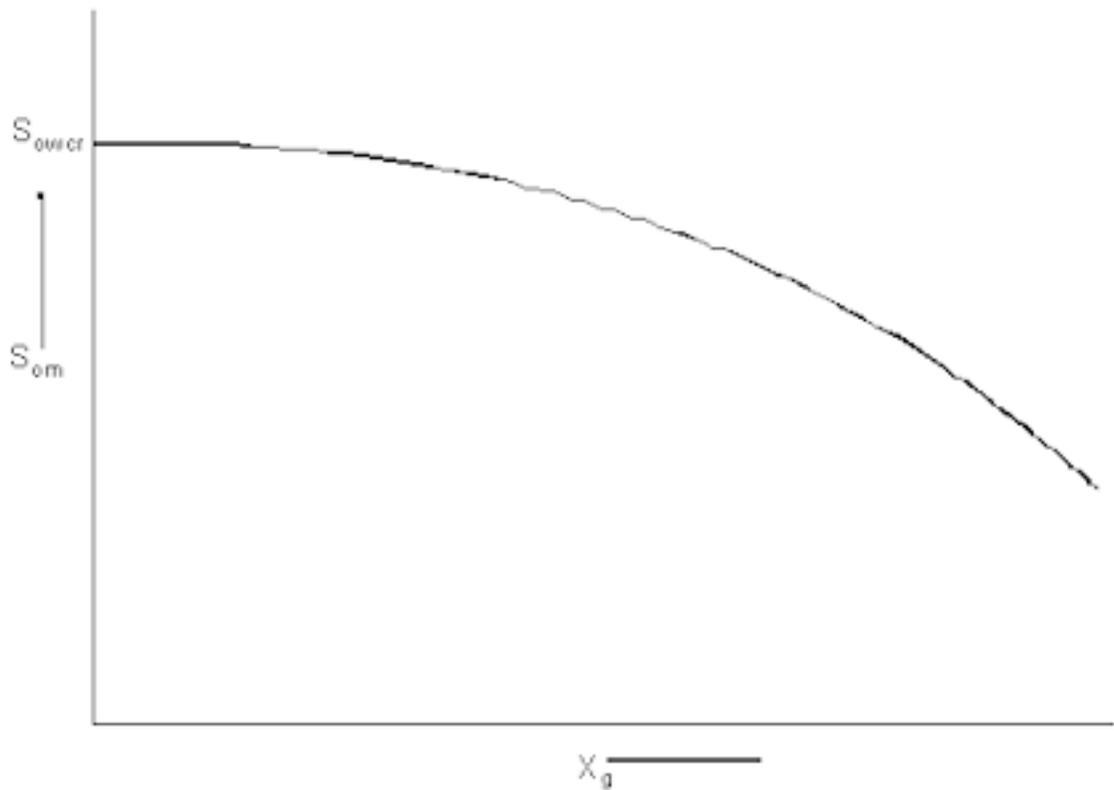

Figure 3.17. Curved interpolation for  $S_{om}$  between  $S_{ogcr}$  and  $S_{owcr}$

The default values of A and B are 1 and 0 respectively. Great care should be taken if negative values of B are used to avoid negative values.

Note that using STONEPAR with default values is not the same as omitting the keyword.

## Example

```
STONEPAR  
--Interpolate Som with positive curvature.  
1.0 0.05 /
```

## STOPROD

## Stoichiometric coefficients for products

	ECLIPSE 100

This keyword defines the stoichiometric coefficients for the products in each chemical reaction.

The keyword is followed by one record for each reaction defined by the [REACTION](#) keyword. Each record contains  $N_c$  items, one for each component,  $N_c + 1$  items if water is included, or  $N_c + N_w$  if the multi-component water model is included (for example, in the case of surfactant adsorption or desorption).

DEFAULT: 0

Items should be defaulted or set to zero for components that are not products. Otherwise they should be set to the stoichiometric coefficient of the component in the corresponding reaction.

See "[Chemical reactions](#)" in the *ECLIPSE Technical Description*.

## Example

For a run with four components  $C_{12}H_{26}$ ,  $C_3H_8$ ,  $O_2$ ,  $CO_2$  and water, the two reactions

can be defined using the [STOREAC](#) and STOPROD keywords:

```

STOREAC
--HEAVY LIGHT O2 CO2 H2O
  1      0   18.5  0   0 /
  0      1    5    0   0 /

STOPROD
--HEAVY LIGHT O2 CO2 H2O
  0      0    0   12  13 /
  0      0    0    3   4 /

```

## Oil-water surface tension versus pressure

This keyword supplies tables of oil-water surface tension versus pressure. They are used by two facilities in ECLIPSE: the SURFTENS option and multisegment wells. The keyword should not be present if neither of these options are in use.

The SURFTENS option calculates a pressure-dependent adjustment to the capillary pressure. It is activated by requesting the SURFTENS option in the RUNSPEC section keyword SATOPTS. If the STOW keyword is not supplied, the oil-water capillary pressure retains the values specified in the keyword SWFN or SWOF, independently of the pressure.

The keyword may also be used if there are any multisegment wells in the run. The phase interfacial tensions are required by the Drift Flux model (see "The drift flux slip model" in the *ECLIPSE Technical Description*). If surface tension data is supplied for the table corresponding to the well's PVT region number (see WELSPECS keyword item 11), the interfacial tension is taken from this table. If there is no surface tension data supplied for the well's PVT table number, the interfacial tension will be calculated from a built-in correlation.

The data comprises NTPVT (see keyword TABDIMS in the RUNSPEC section) tables of oil-water surface tension versus pressure.

Each table consists of two records, each record terminated with a slash (/).

### Record 1

A reference oil phase pressure, at which the oil-water capillary pressure has the values specified in keyword SWFN or SWOF.

(This data item is only used by the SURFTENS option. It is not needed to calculate the interfacial tension in the multisegment well drift flux model, and the value entered here does not affect its results.)

UNITS: barsa (METRIC), psia (FIELD), atma (LAB)

### Record 2

A table consisting of two columns of data.

1. The oil phase pressure. Values should increase monotonically down the column.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB)

2. The corresponding oil-water surface tension.

UNITS: N/m (METRIC), lbf/in (FIELD), dynes/cm (LAB)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NPPVT (see keyword TABDIMS in the RUNSPEC section).

### Calculations for the SURFTENS option

The oil-water capillary pressures (input in keyword SWFN or SWOF) are adjusted according to the ratio of the surface tension at the grid block oil phase pressure to the surface tension at the reference pressure. The capillary pressures input in the SWFN or SWOF keyword are assumed to be at the reference pressure specified in the STOW keyword.

Thus the effective oil-water capillary pressure is:

$$P_{cow} \text{ (oil pressure)} = P_{cow} \text{ (input by user)} \frac{ST \text{ (oil pressure)}}{ST \text{ (reference pressure)}} \quad \text{Eq. 3.198}$$

**Note:** The surface tension is only used as a ratio in the SURFTENS option, and hence the units used does not affect the results of the calculation.

## Example

With NTPVT=1 and NPPVT ≥6:

```

STOW
--
-- REFERENCE PRESSURE
--
    5500      /
--
-- PRESSURE    SURFACE TENSION
--
    1000      10.0
    2000      9.8
    3000      8.6
    4000      7.4
    5000      5.3
    6000      1.2  /

```

## STREF

## Reference temperatures for solid phase

In a run with  $N_c$  components this keyword specifies the reference temperatures at which solid densities are defined. The keyword can be used in runs with solids (keyword [SOLID](#) in the RUNSPEC section).

In a live-oil thermal run, the component solid densities are given by:

$$\rho_c = \frac{\rho_{ref_c}}{\left[1 - c_{P_c}(P - P_{ref_c})\right] \left[1 + c_{T1_c}(T - T_{ref_c})\right]} \quad \text{Eq. 3.199}$$

where

$\rho_{ref,c}$  is the reference density, specified with keyword [SDREF](#),

$c_{P_c}$  is the component solid compressibility, specified with keyword [SCREF](#),

$P_{ref_c}$  is the reference pressure, specified with keyword [SPREF](#),

$T_{ref_c}$  is the reference temperature, specified with this keyword,

$c_{T1_c}$  is the thermal expansion coefficient, specified with keyword [STHERMX1](#).

There should be one value for each component:

UNITS: K (METRIC), °R (FIELD), K (LAB), K (PVT-M)

DEFAULT: the standard temperature set with keyword [STCOND](#)

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "Equations of state regions" in the *ECLIPSE Technical Description*.

## Example

For a two component run, with one EoS region:

```
STREF
527.4 527.4 /

This keyword is being replaced by new keywords for setting traction, stress and displacement boundary conditions. Please refer to keywords [GMTRABC](#), [GMPSTBC](#) and [GMDISBC](#).

This keyword allows either traction or displacement boundary conditions to be specified on all boundaries. A traction at a boundary surface is a force/unit area. If a particular boundary is not specified in this keyword, then that boundary is defaulted to a rigid boundary.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. A character string specifying the boundary to which the traction or velocity boundary condition is applied

This must be one of the following:

I+ Specify the boundary condition on the outer I+ edge

I- Specify the boundary condition on the outer I- edge

J+ Specify the boundary condition on the outer J+ edge

J- Specify the boundary condition on the outer J- edge

K+ Specify the boundary condition on the outer K+ edge

K- Specify the boundary condition on the outer K- edge

DEFAULT: There is no default for this item; it must be specified.

The K- boundary is the top boundary of the simulation, K+ is the bottom.

2. An integer specifying the type of boundary condition on this face

This must be one of the following:

- 1 A total normal traction is specified on the boundary denoted in item 1. The magnitude of this normal traction is set in item 3. The sign of the traction is +ve for tension, -ve for compression. (See also item 6 of the [GEOMECH](#) keyword.)

- 2 A normal rock displacement velocity is specified on the boundary denoted in item 1.

- 3 A given traction with X, Y, Z components. A single X, Y, Z traction component is set in item 3 and the component name is set in item 13. Separate lines are needed to set different components. As for Type 1, the sign of the stress is +ve for tension, -ve for compression. (See also item 6 of the [GEOMECH](#) keyword.)

- 4 A rock displacement velocity with X, Y, Z components. A single X, Y, Z velocity component is set in item 6 and the component name must be set in item 13. Separate lines are needed to set different components.

For boundary condition types 3 and 4, the X, Y, Z components conform to the X, Y, Z directions as specified in the [COORD](#) keyword for corner point geometry.

DEFAULT: 2

3. A normal traction on this boundary, if the boundary condition type in item 2 is 1  
X or Y or Z component of a given traction, if the boundary condition type in item 2 is 3. The component direction is set in item 13 below. Normal component or X component if type in item 2 is 3.  
The sign of the traction is +ve for tension, -ve for compression. See the example below. (See also item 6 of the [GEOMECH](#) keyword.)

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

DEFAULT: 0

4. Y component if type in item 2 is 3  
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)
5. Z component if type in item 2 is 3  
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)
6. A normal rock velocity on this boundary, if the boundary condition type in item 2 is 2  
X or Y or Z component of a rock velocity vector, if the boundary condition type in item 2 is 4.  
This is typically 0 to specify a rigid boundary.

Velocity vector orientation follows the orientation of the coordinate system.

UNITS: m/day (METRIC), ft/day (FIELD), cm/hr (LAB), m/day (PVT-M)

DEFAULT: 0

7. First block to be modified in the I direction  
DEFAULT: 1 if an I- face
8. Last block to be modified in the I direction  
DEFAULT: NX if an I+ face
9. First block to be modified in the J direction  
DEFAULT: 1 if a J- face
10. Last block to be modified in the J direction  
DEFAULT: NY if a J+ face
11. First block to be modified in the K direction  
DEFAULT: 1 if a K- face
12. Last block to be modified in the K direction

DEFAULT: NZ if a K+ face

13. A character string that gives the component of traction or velocity if the boundary type in item 2 is either 3 or 4. This must be one of 'X', 'Y' or 'Z' and is required for type 3 or type 4 boundaries.

DEFAULT: None. It must be specified if item 2 is either 3 or 4

## Examples

### Example 1

```

-- set a 3000 psi total compressive traction on the x+ and y+ boundaries
-- set a 3000 psi overburden pressure (compressive)
-- note that the 'K-' direction is positive downwards
STRESBC

## STRESBCL Stress boundary conditions for coupled stress and fluid flow with an LGR

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is being replaced by new keywords for setting traction, stress and displacement boundary conditions. Please refer to keywords [GMTRABCL](#), [GMPSTBCL](#), and [GMDISBCL](#).

This keyword specifies boundary conditions when a coupled rock stress and fluid flow calculation is required. It is only applicable when the keyword [GEOMECH](#) has been specified in the `RUNSPEC` section.

This keyword allows either traction or displacement boundary conditions to be specified on all boundaries in a local grid refinement. A traction at a boundary surface is a force/unit area. If a particular boundary is not specified in this keyword, then that boundary is defaulted to a rigid boundary.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form  $n^*$ , where  $n$  is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. A character string specifying the boundary to which the traction or velocity boundary condition is applied

This must be one of the following:

I+ Specify the boundary condition on the outer I+ edge

I- Specify the boundary condition on the outer I- edge

J+ Specify the boundary condition on the outer J+ edge

J- Specify the boundary condition on the outer J- edge

K+ Specify the boundary condition on the outer K+ edge

K- Specify the boundary condition on the outer K- edge

DEFAULT: There is no default for this item; it must be specified.

The K- boundary is the top boundary of the simulation, K+ is the bottom.

2. An integer specifying the type of boundary condition on this face

This must be one of the following:

- 1 A total normal traction is specified on the boundary denoted in item 1. The magnitude of this normal traction is set in item 3. The sign of the traction is +ve for tension, -ve for compression. (See also item 6 of the `GEOMECH` keyword.)

- 2 A normal rock displacement velocity is specified on the boundary denoted in item 1.

- 3 A given traction with X, Y, Z components. A single X, Y, Z traction component is set in item 3 and the component name is set in item 13. Separate lines are needed to set different components.

As for Type 1, the sign of the stress is +ve for tension, -ve for compression. (See also item 6 of the `GEOMECH` keyword.)

- 4 A rock displacement velocity with X, Y, Z components. A single X, Y, Z velocity component is set in item 6 and the component name must be set in item 13. Separate lines are needed to set different components.

For boundary condition types 3 and 4, the X, Y, Z components conform to the X, Y, Z directions as specified in the `COORD` keyword for corner point geometry.

DEFAULT: 4 for K+ face, and 2 for I-/I+, J-/J+ and K- faces.

3. Name of the local grid refinement
4. A normal traction on this boundary, if the boundary condition type in item 2 is 1. X or Y or Z component of a given traction, if the boundary condition type in item 2 is 3. The component direction is set in item 13 below. Normal component or X component if type in item 2 is 3.

The sign of the traction is +ve for tension, -ve for compression. See the example below. (See also item 6 of the `GEOMECH` keyword.)

UNITS: bars (`METRIC`), psi (`FIELD`), atm (`LAB`), atm (`PVT-M`)

DEFAULT: 0

5. Y component if type in item 2 is 3  
UNITS: bars (`METRIC`), psi (`FIELD`), atm (`LAB`), atm (`PVT-M`)
6. Z component if type in item 2 is 3  
UNITS: bars (`METRIC`), psi (`FIELD`), atm (`LAB`), atm (`PVT-M`)
7. A normal rock velocity on this boundary, if the boundary condition type in item 2 is 2  
X or Y or Z component of a rock velocity vector, if the boundary condition type in item 2 is 4.  
This is typically 0 to specify a rigid boundary.  
Velocity vector orientation follows the orientation of the coordinate system.  
UNITS: m/day (`METRIC`), ft/day (`FIELD`), cm/hr (`LAB`), m/day (`PVT-M`)  
DEFAULT: 0
8. First block to be modified in the I direction  
DEFAULT: 1 if an I- face
9. Last block to be modified in the I direction  
DEFAULT: NX if an I+ face
10. First block to be modified in the J direction  
DEFAULT: 1 if a J- face
11. Last block to be modified in the J direction  
DEFAULT: NY if a J+ face
12. First block to be modified in the K direction

DEFAULT: 1 if a K- face

13. Last block to be modified in the K direction

DEFAULT: NZ if a K+ face

14. A character string that gives the component of traction or velocity if the boundary type in item 2 is either 3 or 4. This must be one of 'X', 'Y' or 'Z' and is required for type 3 or type 4 boundaries.

DEFAULT: None. It must be specified if item 2 is either 3 or 4

## Examples

### Example 1

```
-- set a 3000 psi total compressive traction on the x+ and y+ boundaries
-- set a 3000 psi overburden pressure (compressive)
-- note that the 'K-' direction is positive downwards
STRESBCL
-- side type LGR total traction
'I+' 1 'LGR1' -3000 /
'J+' 1 'LGR1' -3000 /
'K-' 1 'LGR1' -3000 /
/
```

### Example 2

```
-- Velocities in X dir on I- and I+ boundaries are zero
-- Displacements in Y and Z dirs on I- and I+ boundaries are free
-- Velocities in Y dir on J- and J+ boundaries are zero
-- Displacements in X and Z dirs on J- and J+ boundaries are free
-- Velocities in Z dir on K- and K+ boundaries are zero
-- Displacements in X and Y dirs on K- and K+ boundaries are free

STRESBCL
-- side type LGR SXYZ SHEARS VXYZ range comp
'I-' 4 'LGR1' 3* 0 6* 'X' /
'I-' 3 'LGR1' 0 9* 'Y' /
'I-' 3 'LGR1' 0 9* 'Z' /
'I+' 4 'LGR1' 3* 0 6* 'X' /
'I+' 3 'LGR1' 0 9* 'Y' /
'I+' 3 'LGR1' 0 9* 'Z' /
'J-' 4 'LGR1' 3* 0 6* 'Y' /
'J-' 3 'LGR1' 0 9* 'Z' /
'J-' 3 'LGR1' 0 9* 'X' /
'J+' 4 'LGR1' 3* 0 6* 'Y' /
'J+' 3 'LGR1' 0 9* 'Z' /
'J+' 3 'LGR1' 0 9* 'X' /
'K-' 4 'LGR1' 3* 0 6* 'Z' /
'K-' 3 'LGR1' 0 9* 'X' /
'K-' 3 'LGR1' 0 9* 'Y' /
'K+' 4 'LGR1' 3* 0 6* 'Z' /
'K+' 3 'LGR1' 0 9* 'X' /
'K+' 3 'LGR1' 0 9* 'Y' /
/

## STVP

## Surface tension with respect to pressure

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This provides the variation of surface tension with pressure. This should decrease with increasing pressure, falling to a low value near  $P_{\text{sat}}$ .

This is an alternative means of obtaining surface tensions for the **MISCIBLE** option. If **STVP** is not entered the Macleod-Sugden correlation is used to obtain surface tensions.

A value of the reference surface tension,  $s_0$ , is still required. This may be entered with **MISCSTR**, **MISCSTRP**. If not, the largest value in any of the **STVP** tables is used.

**STVP** is a pressure table - one is required for each pressure table (**PVTNUM**) region.

A table consisting of two columns of data.

1. The pressure. Values should increase monotonically down the column.

UNITS: barsa (**METRIC**), psia (**FIELD**), atma (**LAB**), atma (**PVT-M**)

2. The corresponding surface tension.

UNITS: dynes/cm (**METRIC**), dynes/cm (**FIELD**), dynes/cm (**LAB**), dynes/cm (**PVT-M**)

## Example

```

STVP
  1  10
100  8
200  1
300  0 /

```

## STWG

## Water-gas surface tension versus pressure

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword supplies tables of the water-gas interfacial tension versus pressure, which are used in the drift flux calculation for multisegment wells (see "The drift flux slip model" in the *ECLIPSE Technical Description*). If surface tension data is supplied for the table corresponding to the well's PVT region number (see [WELSPECS](#) keyword item 11), the interfacial tension is taken from this table. If there is no surface tension data supplied for the well's PVT table number, the interfacial tension is calculated from a built-in correlation.

The keyword should only be used if multisegment wells are present. It is not required by the SURFTENS option.

The data comprises NTPVT (see keyword [TABDIMS](#) in the RUNSPEC section) tables of water-gas surface tension versus pressure.

Each table consists of two records, each record terminated with a slash (/).

## Record 1

A reference oil phase pressure.

This data item is not needed to calculate the interfacial tension in the drift flux model. The value entered here will not affect its results.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB)

## Record 2

A table consisting of two columns of data.

1. The pressure. Values should increase monotonically down the column.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB)

2. The corresponding water-gas interfacial tension.

UNITS: N/m (METRIC), lbf/in (FIELD), dynes/cm (LAB)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NPPVT (see keyword [TABDIMS](#) in the RUNSPEC section).

## Example

With NTPVT=1 and NPPVT ≥6:

```

STWG
--
-- REFERENCE PRESSURE
--      5000          /
--
-- PRESSURE    SURFACE TENSION
--
1000          10.0
2000           9.8
3000           8.6
4000           7.4
5000           5.3
6000           1.2  /

```

## SUMTHIN

**Reduces the amount of SUMMARY data output**

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
x	SUMMARY
x	SCHEDULE

This keyword reduces the amount of data saved in the summary output files. This is achieved by only allowing one datum to be recorded for each SUMMARY keyword in a given time period. This time period is defined by the only item in this keyword. The first timestep in each period is output, with all subsequent output suppressed. Data are also recorded each report timestep regardless of the time since the last data were output.

---

**Note:** SUMTHIN will not change the timesteps used by ECLIPSE. This keyword does not change the way that the simulation is solved, it simply prevents the simulation from writing some data to the summary files. This means that data are not output at regular times. If you wish to achieve this use [RPTONLY](#).

---

The SUMTHIN keyword contains one item, the time period for which only one set of data will be output. This should be followed by a slash (/). If the time period entered is zero, thinning will be switched off.

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

See also the keyword [RPTONLY](#).

**Example**

One set of data will be output in each 50 day period (in FIELD units). As a result the first timestep in each 50 day period will be written to the summary files, along with any report timesteps. This means that the first timestep between 0 and 50 is output, then the first timestep between 50 and 100 and so on.

```
SUMTHIN
50.0 /
```

## SURF

x	ECLIPSE 100

## Initial surfactant concentrations

This keyword sets the initial surfactant concentration in runs where the initial conditions are specified by enumeration.

The keyword should be followed by one real number for every grid block specifying the initial surfactant concentration. The data field should be terminated by a slash (/).

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB)

Grid blocks are ordered with the X axis index cycling fastest (from 1 to NDIVIX), followed by the Y axis index (from 1 to NDIVIY), and finally the Z axis index (from 1 to NDIVIZ). NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword [DIMENS](#). Repeat counts may be used for repeated values (for example 115\*0.18). Note that spaces must not be inserted on either side of the asterisk (\*).

See also the keywords [PRESSURE](#), [SGAS](#), [RS](#), [PBUB](#), [RV](#), [PDEW](#) and [SWAT](#) in the SOLUTION section.

Refer to "[Surfactant model](#)" in the *ECLIPSE Technical Description* for more information.

### Notes

- When adsorption is active, the concentration specified here will be honored and extra adsorped surfactant is added to the rock so that it is in equilibrium with the input fluid concentration.
- If a non-zero concentration is specified in cells containing none of the host phase, the concentration will be automatically reset to zero. This behavior can be turned off using [item 165](#) in [OPTIONS](#).

### Example

With NDIVIX=10, NDIVIY=1 and NDIVIZ=2 specified in RUNSPEC keyword [DIMENS](#):

```
SURF
10*0.0
9*0.0 0.5 /
```

## SURFACT

### Enables the surfactant model

This indicates that the surfactant model is required (see "[Surfactant model](#)" in the *ECLIPSE Technical Description*).

The keyword has no associated data.

## SURFACTW Enables modeling of changes of wettability in the surfactant model

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword enables the modeling of changes of wettability of the rock due to the accumulation of surfactant. It can be used in addition to the [SURFACT](#) keyword, or instead of it since it also activates the surfactant model.

Assuming that the usual [SATNUM](#) keyword defines oil-wet immiscible saturation functions (input with keywords [SWFN](#), [SOF2](#), [SOF3](#) or [SWOF](#)), the user defines additional immiscible saturation functions with these same keywords and these are then taken to model the water-wet situation. The keyword [SURFNUM](#) in the [REGIONS](#) section **must** be used to define the region (water-wet immiscible saturation function table) number of each grid block.

In calculating the immiscible relative permeabilities, a weighted average of  $F$  times the oil-wet value and  $(1 - F)$  times the water-wet value is used. The fraction,  $F$ , is a function of the adsorbed surfactant concentration, and **must** be defined by tables input using the [SURFADDW](#) keyword in the [REGIONS](#) section; the number of the table used being that given in the [SURFNUM](#) keyword.

See "[Surfactant model](#)" in the *ECLIPSE Technical Description* for further information.

The SURFACTW keyword has no associated data.

## SURFADDW Tables of adsorbed surfactant concentration versus fractional saturation functions

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTSFUN (item 1 of keyword [TABDIMS](#)) tables of concentration of adsorbed surfactant versus the fraction of the oil-wet and water-wet saturation functions, to use in calculating the immiscible relative permeabilities when the wettability of the rock changes.

The tables describe the transition between oil-wet immiscible conditions and water-wet immiscible conditions as a function of the adsorbed surfactant concentration. The option to model wettability changes resulting from surfactant accumulation must be enabled with keyword [SURFACTW](#) in the RUNSPEC section.

Each table consists of 2 columns of data and should be terminated by a slash (/):

1. Concentration of adsorbed surfactant

The values should increase monotonically down the column.

UNITS: kg/kg (METRIC), lb/lb (FIELD), gm/gm (LAB), kg/kg (PVT-M)

2. Weighting of oil-wet to water-wet saturation function.

A value of 1.0 implies that only the oil-wet saturation functions will be used (as defined by [SATNUM](#)) and a value of 0.0 implies purely water-wet saturation functions (as defined by [SURFNUM](#)).

The value should not be greater than 1.0 or less than 0.0

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (item 3 of keyword [TABDIMS](#)).

---

**Note:** NTSFUN tables must be supplied; however only the SURFNUM table numbers are used. If any table after the first is defaulted, then that table is copied from the previous table.

---

### Example

With NTSFUN=4 and NSSFUN ≥4

```

SURFADDW
0 1.0
 2 1.0 / dummy table corresponding to a SATNUM table value
/ default the second table to the first table
0 1.0
20 1.0
600 0.8
1800 0.4/
/ default fourth table to the third table

```

## SURFADS

## Surfactant adsorption functions

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTSFUN (see keyword [TABDIMS](#)) tables of surfactant adsorption functions, each terminated by a slash (/), describing the adsorption of surfactant by the rock formation. Each table consists of 2 columns of data:

1. The local surfactant concentration in the solution surrounding the rock.  
The values should increase monotonically down the column.  
UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB)
2. The corresponding saturated concentration of surfactant adsorbed by the rock formation.  
These values should increase monotonically down the column.

---

**Note:** The monotonicity constraint can be lifted by entering a non-zero value in [item 76](#) of the `OPTIONS` keyword.

---

UNITS: kg/kg (METRIC), lb/lb (FIELD), gm/gm (LAB)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (see keyword [TABDIMS](#)).

---

**CAUTION:** The first row in the adsorption tables should consist of a pair of zeroes.

---

See "[Surfactant model](#)" in the *ECLIPSE Technical Description* for further information.

Surfactant adsorption functions can also be specified using the [ADSORP](#) keyword.

### Example

With NTSFUN=2 and NSSFUN ≥5

```

SURFADS
.0000 .00000
.0003 .00005
.0005 .00007
.0008 .00008
.0010 .00008 /
.0000 .00000
.0010 .00010 /

```

## SURFCAPD Surfactant capillary de-saturation functions

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTSFUN (see keyword [TABDIMS](#)) tables of surfactant capillary de-saturation functions terminated by a slash (/). The de-saturation function describes the transition between immiscible conditions (low surfactant concentration) and miscibility (high surfactant concentration) as a function of the dimensionless capillary number. Each table consists of 2 columns of data:

1. The log of the capillary number ( $\log_{10}(CAPN)$ )
 

The values should increase monotonically down the column and should lie in the range -20 to 20.
2. The miscibility function at the value of the log capillary number.
 

A value of 0 implies immiscible conditions and a value of 1 miscible conditions.

The values should not be greater than 1 or less than 0

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (see keyword [TABDIMS](#)).

**Note:** NTSFUN tables must be supplied; however, only the [SATNUM](#) table numbers are used, and any tables referred to by [SURFNUM](#) and not by SATNUM is ignored. If any table after the first is defaulted, then that table is copied from the previous table.

See "[Surfactant model](#)" in the *ECLIPSE Technical Description* for further information.

### Example

With NTSFUN=2 and NSSFUN ≥4

```

SURFCAPD
-10  0.0
-3   0.0
-2   1.0
10   1.0  /
/ default the second table to the first table

## SURFESAL Effective salinity coefficient for surfactant

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword may only be used when the multi-component brine model (keyword [BRINE](#) in conjunction with keyword [ECLMC](#) in the RUNSPEC section) is active in conjunction with the surfactant option (keyword [SURFACT](#) in the RUNSPEC section).

The SURFESAL keyword activates the effective salinity calculation for surfactant properties and defines the parameter,  $\alpha^s$ , in the expression for the effective salinity

$$C_{SE} = \frac{C_-}{1 - \alpha^s X^s} \quad \text{Eq. 3.200}$$

where

$C_{SE}$  denotes the effective salinity for the surfactant

$C_-$  denotes the anion concentration

$X^s$  denotes the fraction of anionic surfactant sites occupied by divalent cations

$\alpha^s$  denotes the effective salinity parameter

See "[Brine tracking](#)" in the *ECLIPSE Technical Description* for details of this option.

The keyword should be followed NTSFUN records of data (see item 1 in keyword [TABDIMS](#)), each containing a single non-negative real number. Each record must be terminated by a slash (/).

UNITS: dimensionless

DEFAULT: 0.0

### Example

For NTSFUN=2:

```
SURFESAL
-- alpha
  0.80 /
  0.65 /
```

## SURFNUM

## Surfactant miscible region numbers

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies the saturation table numbers used by the surfactant model to calculate the relative permeabilities when a high surfactant concentration implies the oil and water are miscible. The usual [SATNUM](#) keyword is used to specify the immiscible saturation functions.

The keyword should be followed by one integer for every grid block in the current input box, specifying the miscible (high surfactant) saturation function region to which it belongs. The region number should not be less than 1 or greater than NTSFUN (see RUNSPEC section keyword [TABDIMS](#)). The data must be terminated by a slash (/).

The saturation functions are specified using the [SWFN](#), [SOF2](#), [SOF3](#) or [SWOF](#) keywords. A non-zero capillary pressure entered in the [SWFN](#) or [SWOF](#) keyword is ignored.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

The SURFNUM keyword should be specified when the [SURFACT](#) option has been specified. If this keyword is undefined or only partially specified when the [SURFACT](#) option has been specified, the unspecified miscible saturation region numbers will default to 1.

---

**Note:** When end-point scaling has been specified via the [ENDSCALE](#) option, no end-point scaling will be applied to the saturation table used for the miscible saturation functions.

---

### Example

With NTSFUN=4 specified in keyword [TABDIMS](#); NDIVIX=10, NDIVIY=10 and NDIVIZ=1 specified in RUNSPEC keyword [DIMENS](#); and no input [BOX](#) set

```
SATNUM
 50*1 50*2 /
SURFNUM
 50*3 50*4 /
```

## SURFOPTS **Surfactant options**

	ECLIPSE 100
X	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword sets optional parameters for the ECLIPSE 300 surfactant model. See the "[Surfactant model](#)" in the *ECLIPSE Technical Description* for further information.

1. The minimum water saturation for surfactant effects.

DEFAULT:  $1 \text{ e}^{-6}$

For cells with small water saturations, a small amount of surfactant will give a high concentration of surfactant in the water phase, which could have a large effect on the capillary pressure. To prevent numerical errors effecting the solution, surfactant concentrations are disregarded for cells where the minimum water saturation is below a threshold given by this item.

### Example

```
SURFOPTS
2.0e-6 /
```

## SURFROCK **Specifies rock properties for the surfactant model**

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTSFUN (see keyword [TABDIMS](#)) tables specifying the rock properties which are required for the Surfactant model. each table should be terminated by a slash (/) and requires the following items of data:

1. The adsorption index to be used for this rock type.

Possible values for the adsorption index are 1 or 2.

If a value of 1 is selected, then the surfactant adsorption isotherm is retraced whenever the local surfactant concentration in the solution decreases.

If a value of 2 is selected, then no surfactant desorption may occur.

2. The mass density of this rock type at reservoir conditions.

This quantity is used in the calculation of the surfactant loss due to adsorption.

UNITS: kg/rm<sup>3</sup> (METRIC), lb/rb (FIELD), gm/rcc (LAB)

### Notes

- If the Polymer Flood Model is being used, then the mass density is ignored. The rock mass density is taken from the [PLYROCK](#) keyword.
- When non-zero initial surfactant concentrations are specified via the [SURF](#) or [TVDP](#) keywords, the concentration specified in that keyword will be honored and extra adsorped surfactant is added to the rock so that it is in equilibrium with the input fluid concentration.

See "[Surfactant model](#)" in the *ECLIPSE Technical Description* for further information.

### Example

With NTSFUN=2

```
SURFROCK
2  2340  /
1  2520  /
```

## SURFST

## Water/oil surface tension versus surfactant concentration

## SURFSTES Water/oil surface tension versus surfactant and salt concentrations

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword should only be used for surfactant studies when the salt sensitivity option has been activated (keyword [BRINE](#) in the RUNSPEC section). See the "[Surfactant model](#)" in the *ECLIPSE Technical Description* for further information.

The data comprises NTPVT (see item 2 in keyword [TABDIMS](#)) items of oil-water surface tension, each terminated by a slash (/). These describe the effect on the oil-water surface tension of increasing the concentration of surfactant and salt in the solution. Each table consists of up to NPPVT (see RUNSPEC keyword [TABDIMS](#)) sets of data records. Each set of records within a table consists of up to NPPVT records of data items to allow the specification of a full two dimensional solution surface tension function with respect to surfactant concentration and effective salinity. The first record of each elementary set of records contains the following items of data:

1. The surfactant concentration.

Values should increase monotonically down the column.

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB), kg/sm<sup>3</sup> (PVT-M)

2. The corresponding value of the oil-water surface tension at the surfactant concentration given by item 1 and a salt concentration given by item 1 in the corresponding [ESSNODE](#) table.

UNITS: N/m (METRIC), lbf/in (FIELD), dynes/cm (LAB), N/m (PVT-M)

The data for each table is terminated by a null record (that is a record with no data before the terminating slash).

See the "[Surfactant model](#)" in the *ECLIPSE Technical Description* for further information.

### Example

With NTPVT=2 and NPPVT ≥3

```

## SURFVISC Surfactant solution viscosity function

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The data comprises NTPVT (see keyword [TABDIMS](#)) tables of surfactant viscosity functions, each terminated by a slash (/), describing the effect on the viscosity of pure water of increasing the concentration of surfactant in solution. Each table consists of 2 columns of data:

- The surfactant concentration in the solution.  
The values should increase monotonically down the column.  
UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB)
- The solution water viscosity at this surfactant concentration and the reference pressure (entered with the [PVTW](#) keyword).  
UNITS: cP (METRIC), cP (FIELD), cP (LAB), cP (PVT-M)

If the Polymer Flood Model is active, then the viscosity input in the SURFVISC keyword will be multiplied by the polymer viscosity multiplier supplied in the [PLYVISC](#) or [PLYVISCS](#) keywords.

---

**Note:** The viscosity entered in this keyword at zero surfactant concentration should be equal to the viscosity entered in keyword PVTW (or [PVTWSALT](#), whichever is used).

---

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NPPVT (see keyword [TABDIMS](#)).

See "[Surfactant model](#)" in the *ECLIPSE Technical Description* for further information.

### Example

With NTPVT=1 and NPPVT ≥3

```
SURFVISC
.00 0.34
.01 0.38
.02 0.40 /
```

## SURFNUM Water-wet saturation function region and oil/water fraction table numbers

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by one integer for every grid block specifying the (high-salinity) water-wet saturation function region to which it belongs. The region number should not be less than 1 or greater than NTSFUN (see item 1 of keyword [TABDIMS](#)). The data must be terminated by a slash (/).

The (high salinity) water-wet saturation function region number specifies the saturation table (input using [SWFN](#), [SOF3](#) and related keywords in the PROPS section) to be used to calculate relative permeabilities and capillary pressures in each grid block.

If the [LOWSALT](#) option has also been specified, the water-wet curves are computed as a weighted average between the low salinity water-wet saturation functions ([LSLTWNUM](#) region numbers) and the high salinity water-wet saturation functions (SURFNUM region numbers). In this case, the salinity weighting factors are taken from the [LSALTFNC](#) keyword according to the region numbers specified by the [LWSLTNUM](#) keyword.

The table number specified here also defines the associated table number for the [SURFADDW](#) keyword. This specifies the weighting between immiscible water-wet and oil-wet saturation functions as a function of adsorbed surfactant concentration. The SURFNUM keyword can be used only if the [SURFACTW](#) keyword has been entered in the RUNSPEC section.

Grid blocks are ordered with the X-axis index cycling fastest, followed by the Y- and Z-axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

---

**Note:** The SURFNUM keyword or its alias [HWSNUM](#) must be specified if the [SURFACTW](#) option has been specified.

The [LSLTWNUM](#) keyword or its alias [LWSNUM](#) must be specified if the [LOWSALT](#) and [SURFACTW](#) options have been specified.

The [LWSLTNUM](#) keyword or its alias [LSNUM](#) must be specified if the [LOWSALT](#) option has been specified.

---

### Example

With NTSFUN=4 specified in keyword [TABDIMS](#); NDIVIX=8, NDIVIY=6 and NDIVIZ=5 specified in RUNSPEC keyword [DIMENS](#); and no input [BOX](#) set:

```
SURFNUM
144*3 96*4 /
```

# SWAT

## Initial water saturations

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by one real number for every grid block specifying the initial water saturation. The data field should be terminated by a slash (/).

Grid blocks are ordered with the X-axis index cycling fastest (from 1 to NNDIVIX), followed by the Y-axis index (from 1 to NNDIVIY), and finally the Z-axis index (from 1 to NNDIVIZ). NNDIVIX, NNDIVIY and NNDIVIZ are specified in RUNSPEC keyword [DIMENS](#). Repeat counts may be used for repeated values (for example 115\*0.22). Note that spaces must not be inserted on either side of the asterisk (\*).

This keyword may be used to specify the initial solution explicitly, as an alternative to equilibration using [EQUIL](#). It will be expected if the [PRESSURE](#) keyword is present, indicating explicit initialization, and if a water phase is present.

For the Mixed Hydrostatic Equilibration option, initial saturations should be specified together with items 1 and 2 of the [EQUIL](#) keyword and the [NEI](#) keyword. For more information, refer to "[Initializing the study](#)" in the *ECLIPSE Technical Description*.

When using explicit initialization, you must ensure that the initial solution is stable and physically reasonable.

### Example

With NNDIVIX=8, NNDIVIY=6, NNDIVIZ=5 specified in RUNSPEC keyword [DIMENS](#):

```
SWAT
48*0
48*0.04
48*0.2
48*0.7
48*1 /
```

## SWATINIT

## Initial water saturations for capillary pressure scaling

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword allows you to input a water distribution and to scale the water-oil capillary pressure curves such that this water distribution is honored in the equilibrated initial solution. Note that any water saturation value that cannot be honored because it is below the water contact is reset to the maximum water saturation in the subsequent equilibration calculation.

The scaled maximum water capillary pressures (PPCW) can be output to the print file. This can be used to check for unphysically high maximum capillary pressures, which can be limited by using the [PPCWMAX](#) keyword.

In ECLIPSE 100, to output PPCW data, use the mnemonic SWATINIT in the [RPTSOL](#) keyword.

In ECLIPSE 300, to output PPCW data, use the mnemonic PPCW in the RPTSOL keyword.

The SWATINIT keyword may only be used if the end point scaling option is active (keyword [ENDSCALE](#) in the RUNSPEC section).

---

**Note:** If the [ENDSCALE](#) keyword is not present in the RUNSPEC section, ECLIPSE 100 will assume that it is, and use the [ENDSCALE](#) defaults.

---

The keyword should be followed by one real number for every grid block in the current input box, specifying the required water saturation. The data field should be terminated by a slash (/).

Grid blocks are ordered with the X-axis index cycling fastest (from 1 to NDIVIX), followed by the Y-axis index (from 1 to NDIVIY), and finally the Z-axis index (from 1 to NDIVIZ). NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword [DIMENS](#). Repeat counts may be used for repeated values (for example 115\*0.22). Note that spaces must not be inserted on either side of the asterisk (\*).

See also the [PCW](#) and [PPCWMAX](#) keywords in the PROPS section and the [EQUIL](#) keyword in the SOLUTION section.

Further information can be found in "[Matching initial water distribution](#)" in the *ECLIPSE Technical Description*.

### Notes

If a grid block is given a water saturation less than 1.0 below the oil water contact (where  $P_c=0$ ), then the SWATINIT saturation is not honored. The SWATINIT saturation below the oil water contact will be honored under [item 74](#) in OPTIONS and [item 143](#) in OPTIONS3 for a different scaling. The capillary pressure is given by:

$$P_c = (PCW - P_{cmin}) \left( \frac{P_{ct} - P_{cmin}}{P_{cmax} - P_{cmin}} \right) + P_{cmin} \quad \text{Eq. 3.201}$$

for switch equal 5.

and

$$P_c = (P_{cmax} - PCW) \left( \frac{P_{ct} - P_{cmin}}{P_{cmax} - P_{cmin}} \right) + PCW \quad \text{Eq. 3.202}$$

for switch equal 7.

where

$P_{ct}$  Capillary pressure from the table

$P_{cmax}$  Maximum  $P_c$  in the table

$P_{cmin}$  Minimum  $P_c$  in the table

PCW Maximum / Minimum  $P_c$  from the PCW data.

- If a cell is given saturation corresponding to a zero capillary pressure (typically 1.0) above the contact, then the  $P_c$  curve cannot be scaled to honor the saturation, hence the  $P_c$  curve is left unscaled.
- If the SWATINIT saturation is less than the connate water saturation for a cell, the initial water saturation will be reset to the connate saturation and the capillary pressure will be scaled according to this value.
- The SWATINIT saturation may not be exactly honored if the fine grid block equilibration option is used in the EQUIL keyword.
- If the PCW keyword has been used, then this is ignored in regions where SWATINIT is set.
- If the Leverett J-function calculation for the water-oil capillary pressure has been activated through the [JFUNC](#) keyword, then J-function calculation is ignored in regions where SWATINIT is set.
- The SWATINIT saturation is not honored if the capillary pressure curve is a constant. The input capillary pressure curve needs to be monotonically decreasing with increasing water saturation.

## Example

With `NDIVIX=20`, `NDIVIY=6` and `NDIVIZ=5` specified in `RUNSPEC` keyword [DIMENS](#):

```
SWATINIT
120*0
120*0.1
120*0.5
120*0.7
120*1 /
```

## SWCR

## Scaled critical water saturations

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The SWCR and ISWCR keywords specify the critical water saturation (that is the largest water saturation for which the water relative permeability is zero) within each grid cell. The water flow across each grid face is calculated from a transformed water relative permeability curve obtained by linearly scaling the tabulated relative permeability data between the new critical water saturation defined using an SWCR keyword, and the new maximum water saturation (see under keyword [SWU](#) in the PROPS section). The SWCR keyword also permits scaling of the relative permeability table used in computing the flow of water between grid cells and well connections.

Seven keywords are provided to allow the critical water saturation for each grid cell to be scaled independently. These keywords are:

SWCR Critical water saturation for the non-directional saturation function tables

SWCRX Critical water saturation for the +X face of each grid cell

SWCRX- Critical water saturation for the -X face of each grid cell

SWCRY Critical water saturation for the +Y face of each grid cell

SWCRY- Critical water saturation for the -Y face of each grid cell

SWCRZ Critical water saturation for the +Z face of each grid cell

SWCRZ- Critical water saturation for the -Z face of each grid cell

In radial grids the same directional keywords should be used to represent the critical water saturations for flows in the +R, -R, +T, -T, +Z, -Z directions respectively.

None of the SWCR keywords should be used if water is not present in the model. The keyword [ENDSCALE](#) should be specified in the RUNSPEC section.

If both directional and irreversible end-point scaling is requested, using switches 'DIRECT' and 'IRREVERS' in the ENDSCALE keyword in RUNSPEC, the critical water saturations for water flow across the +X and -X faces of a grid cell are set using the keywords SWCRX, SWCRX-. Similarly SWCRY, SWCRY- are used for the +Y, -Y faces and the keywords SWCRZ, SWCRZ- for the +Z, -Z faces. Scaling of the well connection relative permeability tables for any well connections in the grid cell are performed using the SWCR keyword.

When the end-point scaling is requested to be directional and reversible, using the switch 'DIRECT' but not 'IRREVERS' in ENDSCALE, the keyword SWCRX defines the critical water saturations for the +X and -X faces of each grid cell. Keywords SWCRY, SWCRZ are used for both the +Y, -Y faces and the +Z, -Z faces of each grid cell respectively. Scaling of well connection relative permeability tables uses data entered under the SWCR keyword.

If ENDSCALE is specified in RUNSPEC without the switch 'DIRECT', then none of the directional forms of the SWCR keyword are allowed. The SWCR keyword then defines the new critical water saturation for flow out of each face of the grid cell and for water flows between the grid cell and well connections.

Each SWCR keyword should be followed by one real number for each grid block in the current input box specifying the critical water saturation within the grid block. The saturation should be in the range 0.0 to 1.0 inclusive. The data must be terminated by a slash(/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If any of the keywords SWCR, SWCRX, SWCRX-, SWCRY, SWCRY-, SWCRZ, SWCRZ- are omitted in a model where they could be accepted then the critical water saturation for a water relative permeability calculation defaults to the value used in the appropriate relative permeability table.

If the Hysteresis model (switch 'HYSTER' in keyword SATOPTS) is active then the SWCR data scales the drainage curve. The imbibition curve can be scaled by using the equivalent ISWCR (ISWCRX, ISWCRX-, ...) keyword.

ECLIPSE 300

If the ODD3P relative permeability and capillary pressure hysteresis model has been selected, the primary end-point scaling is specified using the PSORG, PSGRO, PSORW, PSWRO, PSGRW and PSWRG keywords and the hysteresis end-point scaling is specified using the HSORG, HSGRO, HSORW, HSWRO, HSGRW and HSWRG keywords

See also keywords SWU, SWL, ENPTVD in the PROPS section.

See "Saturation table scaling" in the *ECLIPSE Technical Description* for details of the end-point scaling procedure.

## SWF3

## Three phase water saturation functions

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword should only be used when the IKU three-phase relative permeability model has been requested using the [IKU3P](#) keyword or when the ODD3P three-phase relative permeability and capillary pressure hysteresis model has been requested using the [ODD3P](#) keyword or when the water BAKER three-phase relative permeability and capillary pressure hysteresis model has been requested using the [BAKER1](#) or [BAKER2](#) keywords in the PROPS section.

The data consists of tables of two-phase water saturation functions, each terminated with a slash (/). Each table consists of 4 columns of data:

Column:

1. The water saturation.

Values should be between 0 and 1 and should increase monotonically down the column.

2. The corresponding water in oil relative permeability measured in the absence of gas.

Values should be between 0 and 1 and should be level or increasing down the column. The first value in the column must be 0.

3. The corresponding water in gas relative permeability measured in the absence of oil.

Values should be between 0 and 1 and should be level or increasing down the column. The first value in the column must be 0.

For the ODD3P option, the relative permeability values between the critical and maximum saturations are not used and may be defaulted.

4. The corresponding water-oil capillary pressure.

Values should be level or decreasing down the column.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

The number of tables supplied should be equal to the number of saturation tables in the run, specified in item 1 of keyword [TABDIMS](#) in the RUNSPEC section.

The number of rows should be less than or equal to the maximum number of rows of saturation data specified in item 3 of [TABDIMS](#).

**Note:** The critical saturation for each relative permeability function is established by determining the highest saturation in the table for which the relative permeability is notionally zero, that is, less than a small threshold value. Relative permeability values which are lower than this threshold value will be treated as zero. For ECLIPSE 100 and ECLIPSE 300 the default threshold values are  $1.0 \times 10^{-6}$  and  $1.0 \times 10^{-20}$  respectively. These values may be modified using the [TOLCRIT](#) keyword.

See also "[Saturation functions](#)" in the *ECLIPSE Technical Description*.

## Example

With one saturation table:

```

SWF3
.22 .00 .00 7.0
.30 .00 .07 4.0
.40 .05 .15 3.0

```

.50	.12	.24	2.5
.60	.21	.33	2.0
.80	.44	.65	1.0
.90	.76	.83	.5
1.00	1.00	1.00	.0 /

## 2D table of water relative permeability

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is an alternative to the [SWFN](#) keyword, allowing the three-phase relative permeability of water to be input directly as a function of oil and gas saturations in a two dimensional table.

The data comprises NTSFUN (see item 1 of keyword [TABDIMS](#) in the RUNSPEC section) tables of water relative permeability, tabulated against both oil and gas saturations, each terminated by a slash (/).

Each table consists of a number of records:

- Record 1:           The oil saturation values  
  
Values should be between 0 and 1 and should increase monotonically. The number of oil saturation values should not exceed NSSFUN (see item 3 of keyword [TABDIMS](#)).
- Subsequent records (a maximum of NSSFUN records)   The gas saturation.  
  
Followed by the water relative permeability values for this gas saturation at all the corresponding oil saturations entered in Record 1.  
  
The water relative permeabilities should be monotonically decreasing, with a final value of zero. The number of water relative permeability values should not exceed the number of oil saturation values entered in Record 1. The record may be truncated at any point provided that the last relative permeability value is zero.

The columns of data must also comply with the following constraints:

- The gas saturation (the first item in the second and subsequent records) should increase monotonically down the column. The water relative permeability for each oil saturation should decrease monotonically down the column and should end in a zero value.
- The relative permeability must also be zero for any point on the table in which  $S_{oil} + S_{gas} \geq 1.0$ .
- Default values may not be placed within the table.

The entire table may be defaulted provided that the table is not the first. Defaulted tables are replaced with a copy of the previous table.

ECLIPSE 100

The water/oil capillary pressure must be provided using the [PCW32D](#) keyword.

ECLIPSE 300

The water/oil capillary pressure can be provided using the [SWFN](#) keyword. The relative permeability data entered with the [SWFN](#) keyword will be ignored.

The keyword cannot be used with the end-point scaling, hysteresis and miscible options.

### Example

With NTSFUN=1 and NSSFUN ≥ 11

/
```

## SWFN

## Water saturation functions

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises NTSFUN (see item 1 of keyword [TABDIMS](#) in the RUNSPEC section) tables of water saturation functions, each terminated by a slash (/).

Each table consists of 3 columns of data:

1. The water saturation.

Values should be between 0 and 1 and should increase monotonically down the column.

2. The corresponding water relative permeability.

Values should be between 0 and 1 and should be level or increasing down the column.

The first value in the column must be 0.

3. The corresponding water-oil capillary pressure.

Values should be level or decreasing down the column. Note, however, that if [SWATINIT](#) is used, then the water-oil capillary pressures must be monotonically decreasing.

In gas-water systems (that is with no active oil phase), the water-gas capillary pressure should be entered here.

UNITS: bars ([METRIC](#)), psi ([FIELD](#)), atm ([LAB](#)), atm ([PVT-M](#))

Default values (represented by 1\*) may be inserted as required in columns 2 and 3. When the table is read in, defaults are replaced by values computed by linear interpolation.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than [NSSFUN](#) (see item 3 of keyword [TABDIMS](#)).

The entire table may be defaulted provided the table is not the first. Defaulted tables are replaced with a copy of the previous table.

The keyword families

(i) [SWOF](#), [SGOF](#), [SLGOF](#)

(ii) [SWFN](#), [SGFN](#), [SGWFN](#), [SOF2](#), [SOF3](#), [SOF32D](#)

provide two alternative formats for inputting the saturation functions. Do not mix keywords from the two families in the same run. In gas-water runs, of if you are using the ECLIPSE 100 Miscible Flood or Solvent options, the saturation functions must be input with keywords from family (ii).

ECLIPSE 100

In gas-water runs the gas and water saturation functions may be input together using the [SGWFN](#) keyword as an alternative to using both [SGFN](#) and [SWFN](#).

---

**Note:** The critical saturation for each relative permeability function is established by determining the highest saturation in the table for which the relative permeability is notionally zero, that is, less than a small threshold value. Relative permeability values which are lower than this threshold value will be treated as zero. For ECLIPSE 100 and ECLIPSE 300 the default threshold values are  $1.0 \times 10^{-6}$  and  $1.0 \times 10^{-20}$  respectively. These values may be modified using the [TOLCRIT](#) keyword.

---

## Example

With NTSFUN=2 and NSSFUN ≥8:

```
SWFN
.2200 .0000 7.0000
.3000 .0700 4.0000
.4000 .1500 3.0000
.5000 .2400 1*
.6000 .3300 2.0000
.8000 .6500 1.0000
.9000 .8300 1*
1.0000 1.0000 .0000 /
.18 .00 0
.32 .07 0
.50 .31 0
.60 .38 0
.80 .57 0
1.00 1.00 0 /
```

**Note:** Slow run times may result if the relative permeability changes abruptly over a small saturation interval, especially if IMPES is used. ECLIPSE honors the data input and does not attempt to overcome convergence problems by retabulating over equally spaced saturation intervals. If chopped relative permeability data is used to minimize dispersion, ECLIPSE performs best in fully-implicit mode if the relative permeability rises steeply from zero (immobility) rather than from a small value.

## SWGCR

## Scaled critical water saturations in gas

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies the critical water saturation in gas within each grid cell. This is available when the [IKU3P](#), [BAKER1](#) or [BAKER2](#) three phase relative permeability model is being used and the two-phase water-gas relative permeabilities are specified using the [SWF3](#) keyword. The critical water saturation in oil is obtained from [SWCR](#).

Seven keywords are provided to allow the critical water saturation in gas for each grid cell to be scaled independently. These keywords are:

**SWGCR** Critical water saturation in gas for the non-directional saturation function tables

**SWGCRX** Critical water saturation in gas for the +X face of each grid cell

**SWGCRX-** Critical water saturation in gas for the -X face of each grid cell

**SWGCRY** Critical water saturation in gas for the +Y face of each grid cell

**SWGCRY-** Critical water saturation in gas for the -Y face of each grid cell

**SWGCRZ** Critical water saturation in gas for the +Z face of each grid cell

**SWGCRZ-** Critical water saturation in gas for the -Z face of each grid cell

In radial grids the same directional keywords should be used to represent the critical water saturations in gas for flows in the +R, -R, +T, -T, +Z, -Z directions respectively.

None of the SWGCR keywords should be used if water is not present in the model. The keyword [ENDSCALE](#) should be specified in the RUNSPEC section.

If both directional and irreversible end-point scaling are requested, using switches 'DIRECT' and 'IRREVERS' in the ENDSCALE keyword in RUNSPEC, the critical water saturations in gas for flow across the +X and -X faces of a grid cell are set using the keywords SWGCRX and SWGCRX-. Similarly the keywords SWGCRY and SWGCRY- are used for the +Y and -Y faces and the keywords SWGCRZ and SWGCRZ- for the +Z and -Z faces respectively. Scaling of the well connection relative permeability tables for any well connections in the grid cell is performed using the values specified via the SWGCR keyword.

When the end-point scaling is requested to be directional and reversible, using the switch 'DIRECT' but not 'IRREVERS' in ENDSCALE, the keyword SWGCRX defines the critical water saturations in gas for the +X and -X faces of each grid cell. Keywords SWGCRY and SWGCRZ are used for both the +Y and -Y faces and the +Z and -Z faces of each grid cell respectively. Scaling of the well connection relative permeability tables for any well connections in the grid cell is performed using the values specified via SWGCR keyword.

If ENDSCALE is specified in RUNSPEC without the switch 'DIRECT', none of the directional forms of the SWGCR keyword are allowed. The SWGCR keyword then defines the critical water saturation in gas for flow out of each face of the grid cell and for flows between the grid cell and well connections.

Each SWGCR keyword should be followed by one real number for each grid block in the current input box specifying the critical water saturation in gas within the grid block. The saturation should be in the range 0.0 to 1.0 inclusive. The data must be terminated by a slash(/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If any of the keywords SWGCR, SWGCRX, SWGCRX-, SWGCRY, SWGCRY-, SWGCRZ or SWGCRZ- are omitted in a model where they could be accepted, the critical water saturation in gas for a water relative permeability calculation defaults to the value specified in the appropriate relative permeability table.

If the Hysteresis model (switch 'HYSTER' in keyword SATOPTS) is active, the SWGCR data scales the drainage curve. The imbibition curve can be scaled by using the corresponding ISWGCR (ISWGCRX, ISWGCRX-, ...) keywords. (The IKU3P three phase relative permeability model does not support hysteresis.)

See "Saturation table scaling" in the *ECLIPSE Technical Description* for details of the end-point scaling procedure.

# SWINGFAC Swing and profile factors for FIELD gas contract

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The SWINGFAC keyword turns on the gas field operations model and defines the swing factors and profile factors for the FIELD. (If you want to apply separate gas supply contracts to two or more groups, use keyword [GSWINGF](#) instead.) The following features of the model are activated when the keyword is first entered:

- Group and field gas rate targets are applied to **sales** gas rates instead of **gross** gas production rates.
- The delivery capacity is calculated at the beginning of each timestep.
- In ECLIPSE 100, any automatic compressors (specified with keyword [GASFCOMP](#) or [NETCOMPA](#)) will be turned on and off as required to meet the field gas target.

The swing factors and profile factors themselves are used to set the field gas production target and to adjust the DCQ when the simulation is advanced using the keyword [GASYEAR](#) or [GASPERIO](#) instead of [DATES](#), [TIME](#) or [TSTEP](#). The FIELD is automatically placed under Guide Rate Control to meet any gas rate targets imposed, unless Prioritization is requested with the keyword [GCONPRI](#).

See "[Gas field operations model](#)" in the *ECLIPSE Technical Description* for further details.

The SWINGFAC keyword is followed by 24 numbers, terminating with a slash (/).

- The first 12 numbers are the **swing factors** for each month in sequence from January to December.
- The second 12 numbers are the **profile factors** for each month in sequence from January to December.

A warning is printed if the profile factor for any month is greater than that month’s swing factor. If this is so, obeying the swing requirement may not guarantee the field could produce its target rate profile.

## Normalized profile factors

In order to produce the required ACQ for a given DCQ, the profile factors should be normalized such that the sum over all months of {profile factor × number of days in month}

= 365.25, with February allocated 28.25 days.

If this “normalization requirement” is obeyed, then when leap years are taken into account every fourth year, the average annual production at a constant DCQ is DCQ × 365.25, which is the ACQ. A warning is printed if the profile factors are not normalized.

## Example

```

SWINGFAC
-- JAN FEB MAR APR MAY JUN JUL AUG SEP OCT NOV DEC
  12*1.67
  2*1.5036 3*1.0024      3*0.5012      3*1.0024      1.5036 /
    
```

## SWL,ISWL Scaled connate water saturations

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The different forms of this keyword specify the connate water saturation (that is the smallest water saturation in a water saturation function table) within each grid cell. The oil-water (or gas-water) capillary pressure used in computing the water flow across each grid face is calculated from a transformed water capillary pressure curve obtained by linearly scaling the tabulated capillary pressure data between the new connate water saturation defined using an SWL keyword, and the new maximum water saturation (see under the keyword [SWU](#) in the PROPS section). The SWL keyword also permits scaling of the water capillary pressure table used in computing the initial water saturation distribution.

Seven keywords are provided to allow the connate water saturation for each grid cell to be scaled independently. These keywords are:

SWL Connate water saturation for the non-directional saturation function tables

SWLX Connate water saturation for the +X face of each grid cell

SWLX- Connate water saturation for the -X face of each grid cell

SWLY Connate water saturation for the +Y face of each grid cell

SWLY- Connate water saturation for the -Y face of each grid cell

SWLZ Connate water saturation for the +Z face of each grid cell

SWLZ- Connate water saturation for the -Z face of each grid cell

In radial grids the same directional keywords should be used to represent the connate water saturations for flows in the +R, -R, +T, -T, +Z, -Z directions respectively.

None of the SWL keywords should be used if water is not present in the model. The keyword [ENDSCALE](#) should be specified in the RUNSPEC section.

If both directional and irreversible end-point scaling is requested, using switches 'DIRECT' and 'IRREVERS' in [ENDSCALE](#), connate water saturations for water flow across the +X and -X faces of a grid cell are set using the keywords SWLX, SWLX-. Similarly SWLY, SWLY- are used for the +Y, -Y faces and the keywords SWLZ, SWLZ- for the +Z, -Z faces. Scaling of the oil-water (or gas-water) capillary pressure tables in the equilibration algorithm are performed using the SWL keyword.

When the end point scaling is requested to be directional and reversible, using the switch 'DIRECT' but not 'IRREVERS' in [ENDSCALE](#), the keyword SWLX defines the connate water saturations for the +X and -X faces of each grid cell. Keywords SWLY, SWLZ are used for both the +Y, -Y faces and the +Z, -Z faces of each grid cell respectively. Scaling of oil-water (or gas-water) capillary pressure data for the equilibration algorithm is done with the SWL keyword.

If [ENDSCALE](#) is specified in RUNSPEC without the switch 'DIRECT', then none of the directional forms of the SWL keyword are allowed. The SWL keyword then defines the new connate water saturation for computing the water flow across each grid cell face and the transformed capillary pressure table used in the equilibration procedure.

Each SWL keyword should be followed by one real number for each grid block in the current input box specifying the connate water saturation within the grid block. The saturation should be in the range 0.0 to 1.0 inclusive. The data must be terminated by a slash(/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If any of the keywords SWL, SWLX, SWLX-, SWLY, SWLY-, SWLZ, SWLZ- are omitted in a model where they could be accepted then the connate water saturation for an oil-water (or gas-water) capillary pressure calculation defaults to the value used in the appropriate water saturation function table.

If a connate water saturation is entered using the SWLPC keyword then this saturation will be used when scaling the capillary pressure curves. The connate water saturation entered using SWL is only used to scale the oil relative permeability curves.

If the Hysteresis model (switch 'HYSTER' in keyword SATOPTS) is active then the SWL data scales the drainage curve. The imbibition curve can be scaled by using the equivalent ISWL (and ISWLX, ISWLX-,...) keyword.

See also keywords SWLPC, SWU and ENPTVD in the PROPS section.

---

**Note:** In some cases, where messages relating to end-point scaling are emitted, for example, when checking that the scaled end-points are consistent, reference is made to SWCO as an alternative to SWL.

---

See "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for details of the endpoint scaling procedure.

## SWLPC

## Scaled connate water saturations, for Pc curves only

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The SWLPC and ISWLPC keywords scales the connate water end point of the oil-water capillary pressure curves without scaling the corresponding oil relative permeability curves.

The SWLPC keyword should not be used unless water is present in the model (keyword [WATER](#) in the RUNSPEC section). The keyword [ENDSCALE](#) should be specified in the RUNPSEC section.

The SWLPC keyword should be followed by one real number for each grid block in the current input box, specifying the connate water saturation within the grid block. The saturation should be in the range 0.0 to 1.0 inclusive. The data must be terminated by a slash (/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If SWLPC is not specified, the oil-water (or gas-water) capillary pressure scaling is performed using the connate water saturation specified with the [SWL](#) family of keywords (SWL, SWLX, SWLX-, SWLY, SWLY-, SWLZ, SWLZ-). If in turn any of the keywords SWL, SWLX, SWLX-, SWLY, SWLY-, SWLZ, SWLZ- are omitted, then the connate water saturation for an oil-water (or gas-water) capillary pressure calculation defaults to the value used in the appropriate water saturation function table.

If the hysteresis model (switch 'HYSTER' in keyword [SATOPTS](#)) is active then the SWLPC data will scale the drainage curve. The imbibition curve can be scaled by using the equivalent [ISWLPC](#) keyword.

See also keywords SWL and [ENPTVD](#) in the PROPS section.

See "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for details of the endpoint scaling procedure.

## SWOF

## Water / oil saturation functions versus water saturation

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The SWOF keyword may be used in runs containing both oil and water as active phases, to input tables of water relative permeability, oil-in-water relative permeability and water-oil capillary pressure as functions of the water saturation. If gas is also an active phase in the run, the gas/oil saturation functions must be input with either keyword [SGOF](#) or [SLGOF](#).

The data comprises NTSFUN (see item 1 in keyword [TABDIMS](#) in the RUNSPEC section) tables of water/oil saturation functions, each terminated by a slash (/).

Each table consists of 4 columns of data:

1. The water saturation.

Values should be between 0 and 1 and should increase monotonically down the column.

The first value in the column is interpreted as the connate water saturation. The last value in the column is interpreted as  $S_w = 1 - S_{or}$ .

2. The corresponding water relative permeability.

Values should be between 0 and 1 and should be level or increasing down the column.

The first value in the column must be 0 (zero).

3. The corresponding oil relative permeability when only oil and water are present.

Values should be between 0 and 1 and should be level or decreasing down the column.

If gas is also present in the run, the first value in the column (that is  $k_{row}$  at  $S_o = S_{omax} = 1 - S_{wco}$ ) must be the same as  $k_{rowg}$  at  $S_g = 0$  set in keyword [SGOF](#) or [SLGOF](#). The last value in the column must be zero.

4. The corresponding water-oil capillary pressure.

Values should be level or decreasing down the column.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

Default values (represented by 1\*) may be inserted as required in columns 2, 3 and 4. When the table is read in, defaults are replaced by values computed by linear interpolation.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (see item 3 in keyword [TABDIMS](#)).

The entire table may be defaulted provided the table is not the first. Defaulted tables are replaced with a copy of the previous table.

The keyword families

(i) [SWOF](#), [SGOF](#) and [SLGOF](#)

(ii) [SWFN](#), [SGFN](#), [SGWFN](#), [SOF2](#) and [SOF3](#)

provide two alternative formats for inputting the saturation functions. Do not mix keywords from the two families in the same run. In gas-water runs, or if you are using the ECLIPSE 100 miscible flood or solvent options, the saturation functions must be input with keywords from family (ii).

For two dimensional tables the following keywords can also be used: [SOF32D](#), [SGF32D](#), [SWF32D](#).

See "[Saturation functions](#)" in the *ECLIPSE Technical Description* for more information, and a description of the methods used to compute three phase relative permeabilities.

**Note:** The critical saturation for each relative permeability function is established by determining the highest saturation in the table for which the relative permeability is notionally zero, that is, less than a small threshold value. Relative permeability values which are lower than this threshold value will be treated as zero. For ECLIPSE 100 and ECLIPSE 300 the default threshold values are  $1.0 \times 10^{-6}$  and  $1.0 \times 10^{-20}$  respectively. These values may be modified using the [TOLCRIT](#) keyword.

## Example

With NTSFUN=2 and NSSFUN ≥ 8:

```

SWOF
-- Sw      Krw      Krow      Pcow
.2200     .0000     1.0000     7.0000
.3000     .0700     0.4000     4.0000
.4000     .1500     0.1250     3.0000
.5000     1*       0.0649     1*
.6000     .3300     0.0048     2.0000
.8000     .6500     0.0        1.0000
.9000     .8300     0.0        1*
1.0000    1.0000     0.0        .0000    / table 1
.18      .00      1.00      0
.32      .07      0.38      0
.50      .31      0.05      0
.60      .38      0.004     0
.80      .57      0.0        0
1.00     1.00     0.0        0          / table 2

```

**Note:** Slow run times may result if the relative permeability changes abruptly over a small saturation interval, especially if IMPES is used. ECLIPSE honors the data input and does not attempt to overcome convergence problems by retabulating over equally spaced saturation intervals. If chopped relative permeability data is used to minimize dispersion, ECLIPSE performs best in fully-implicit mode if the relative permeability rises steeply from zero (immobility) rather than from a small value.

## SWU,ISWU

## Scaled saturation table maximum water saturations

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The different forms of this keyword specify the maximum water saturation (that is the largest water saturation in a water saturation function table) within each grid cell. The scaled maximum water saturation is used to determine the scaled forms for both oil-water (or gas-water) capillary pressure curves and the water relative permeability curves. The scaled form of the capillary pressure curves is obtained by linearly scaling the tabulated capillary pressure data between the new connate water saturation (see keyword [SWL](#) in the PROPS section) and the new maximum water saturation defined using an SWU keyword. A similar linear transformation is used to produce the scaled water relative permeability curves using the new critical water saturation (see keyword [SWCR](#) in the PROPS section) and the new maximum water saturation defined using an SWU keyword. The scaled capillary pressure and relative permeability curves are then used to compute the water flow out of each grid cell face, the water flow between grid cells and well connections and in the equilibration algorithm.

Seven keywords are provided to allow the maximum water saturation for each grid cell to be scaled independently. These keywords are:

SWU Maximum water saturation for the non-directional saturation function tables

SWUX Maximum water saturation for the +X face of each grid cell

SWUX- Maximum water saturation for the -X face of each grid cell

SWUY Maximum water saturation for the +Y face of each grid cell

SWUY- Maximum water saturation for the -Y face of each grid cell

SWUZ Maximum water saturation for the +Z face of each grid cell

SWUZ- Maximum water saturation for the -Z face of each grid cell

In radial grids the same directional keywords should be used to represent the maximum water saturations for flows in the +R, -R, +T, -T, +Z, -Z directions respectively.

None of the SWU keywords should be used if water is not present in the model. The keyword [ENDSCALE](#) should be specified in the RUNSPEC section.

If both directional and irreversible end-point scaling is requested, using switches 'DIRECT' and 'IRREVERS' in the ENDSALE keyword in RUNSPEC, then the maximum water saturations for computing the water flow across the +X and -X faces of a grid cell are set using the keywords SWUX, SWUX-. Similarly SWUY, SWUY- are used for the +Y, -Y faces and the keywords SWUZ, SWUZ- for the +Z, -Z faces. Scaling of the oil-water (or gas-water) capillary pressure tables in the equilibration algorithm and scaling of the relative permeability curves to compute flows between grid cells and well connections are performed using the SWU keyword.

When the end point scaling is requested to be directional and reversible, using the switch 'DIRECT' but not 'IRREVERS' in ENDSALE, the keyword SWUX defines the maximum water saturations for the +X and -X faces of each grid cell. Keywords SWUY, SWUZ are used for both the +Y, -Y faces and the +Z, -Z faces of each grid cell respectively. The maximum water saturation values for use in equilibration procedure and for computing the well connection flows are entered using the SWU keyword.

If ENDSALE is specified in RUNSPEC without the switch 'DIRECT', then none of the directional forms of the SWU keyword are allowed. The SWU keyword then defines the new maximum water saturation for

computing the water flows between adjacent grid cells, well connection flows and in the equilibration algorithm.

Each SWU keyword should be followed by one real number for each grid block in the current input box specifying the maximum water saturation within the grid cell. The saturation should be in the range 0.0 to 1.0 inclusive. The data must be terminated by a slash(/).

Grid blocks are ordered with the X-axis index cycling fastest followed by the Y and Z indices. Repeat counts may be used for repeated values (for example 10\*0.21). Note that spaces must not be inserted on either side of the asterisk.

If any of the keywords SWU, SWUX, SWUX-, SWUY, SWUY-, SWUZ, SWUZ- are omitted in a model where they could be accepted then the maximum water saturation for capillary pressure and relative permeability calculations defaults to the value used in the appropriate water saturation function table.

If the Hysteresis model (switch 'HYSTER' in keyword SATOPTS) is active then the SWU data scales the drainage curve. The imbibition curve can be scaled by using the equivalent ISWU (ISWUX, ISWUX-, ...) keyword.

See also keywords SWL, SWCR, ENPTVD in the PROPS section.

See "Saturation table scaling" in the *ECLIPSE Technical Description* for details of the end-point scaling procedure.

## Table dimensions

The data consists of some or all of the following items which describe the sizes of saturation and PVT tables used in the run, and also the number of fluid-in-place regions. The data must be terminated by a slash (/).

1. NTSFUN The number of saturation tables entered using [SGFN](#) in the PROPS section for example. (Different saturation tables may be used in different parts of the reservoir - see [SATNUM](#) in the REGIONS section.)
2. NTPVT The number of PVT tables entered using [PVTG](#) and [PVTO](#) in the PROPS section for example. (Different PVT tables may be used in different parts of the reservoir - see [PVTNUM](#) in the REGIONS section.)

DEFAULT: 1

3. NSSFUN The maximum number of saturation nodes in any saturation table - for example [SGFN](#) and [SGOF](#) in the PROPS section.

DEFAULT: 20

*ECLIPSE 100*

DEFAULT: 50

*ECLIPSE 300*

4. NPPVT The maximum number of pressure nodes in any PVT table ([PVTG](#), [PVTO](#), [PVDG](#) and [PVDO](#) for example), or in any rock compaction table ([ROCKTAB](#)).

DEFAULT: 20

*ECLIPSE 100*

DEFAULT: 50

*ECLIPSE 300*

5. NTFIP The maximum number of FIP regions defined using [FIPNUM](#) in the REGIONS section.

DEFAULT: 1

This may also be set using item 1 of the [REGDIMS](#) keyword. If it is set in both places, the greater of the two settings is used. Additionally, if item 1 of [DYNRDIMS](#) is defined, the greatest of the three settings is used.

*ECLIPSE 100*

6. NRPVT

The maximum number of  $R_s$  nodes in a live oil PVT table ([PVTO](#) or [PVCO](#)) or  $R_v$  nodes in a wet gas PVT table ([PVTG](#)). This item is ignored unless either [DISGAS](#) or [VAPOIL](#) is specified in the RUNSPEC section. In API tracking runs this number needs to be the maximum number of distinct valued  $R_s$  nodes across all the PVT tables.

*ECLIPSE 300*

The maximum number of  $R_s$  nodes in a live oil PVT table ([PVTO](#) or [PVCO](#)).

DEFAULT: 20

*ECLIPSE 300 only*

7. The maximum number of  $R_v$  nodes in a wet gas PVT table ([PVTG](#)).

DEFAULT: 20

8. NTENDP The number of saturation end-point versus depth tables is specified.

This item may also be specified by item 3 of keyword [ENDSCALE](#); if set in both places the maximum of the two values will be used.

- DEFAULT: 1
- ECLIPSE 300 only* 9. The number of equation of state regions for reservoir conditions. The maximum value which can be specified in this item is 10.
- DEFAULT: 1
- ECLIPSE 300 only* 10. The number of equation of state regions for surface conditions. The maximum value which can be specified in this item is 10.
- DEFAULT: Value in item 9.
- ECLIPSE 300 only* 11. The maximum number of flux regions.
- This item may also be specified by item 4 of keyword [REGDIMS](#); if set in both places the maximum of the two values will be used.
- DEFAULT: 10
- ECLIPSE 300 only* 12. The maximum number of thermal regions.
- DEFAULT: 1
13. NTROCC The number of rock tables (see keyword [ROCK](#)).
- 
- ECLIPSE 100 only*
- Note:** If the dataset contains no other rock-related keywords, this value must be set explicitly to a value greater than zero in order to allow a dataset which contains the [ROCKNUM](#) keyword to be read. If it is defaulted, [PVTNUM](#) will be used instead.
- 
- ECLIPSE 300 only*
- This value also sets the number of rock tables for keywords [ROCKTAB](#), [ROCKTABH](#) and [ROCKPAMA](#).
- DEFAULT: number of pressure tables
- ECLIPSE 300 only* 14. The maximum number of pressure maintenance regions (see keyword [GPMAINT](#)).
- DEFAULT: 0
- ECLIPSE 300 only* 15. The maximum number of temperature dependent K-value tables.
- (Thermal option only)
- DEFAULT: 0
- A maximum of nine temperature dependent K-value tables are allowed.
- ECLIPSE 300 only* 16. NTALPHA The number of transport coefficient table ([ALPHA](#), [ALPHAD](#), [ALPHAI](#)) regions
- DEFAULT: NTPVT
- ECLIPSE 300 only* 17. Asphaltene: the maximum number of rows in the [ASPKDAM](#) keyword table when permeability damage is not correlated to porosity change.
- DEFAULT: 10
- ECLIPSE 300 only* 18. Asphaltene: the maximum number of rows in the [ASPREWG](#) keyword table.
- DEFAULT: 10
- ECLIPSE 300 only* 19. Asphaltene: the maximum number of rows in the [ASPVISO](#) table when a look-table is used to model the oil viscosity changes with asphaltene precipitate

DEFAULT: 10

20. Not used

*ECLIPSE 300 only*

21. Asphaltene: the maximum number of columns in the [ASPPW2D](#) keyword table

DEFAULT: 5

22. Asphaltene: the maximum number of rows in the [ASPPW2D](#) keyword table

DEFAULT: 5

*ECLIPSE 300 only*

23. Asphaltene: the maximum number of rows in the [ASPWETF](#) keyword table

DEFAULT: 5

*ECLIPSE 300 only*

24. The number of composition dependent K-value tables.

DEFAULT: 0

A maximum of nine composition dependent K-value tables are allowed.

*ECLIPSE 100 only*

25. Reserved.

## Example

Two saturation and pressure tables with 50 nodes in each table.

## TBASIS

## Specify basis for tensor permeabilities

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies the basis for the permeability tensor. If tensor permeabilities are entered then the discretization will account for the tensor permeabilities in a consistent manner.

The keyword should be followed by a single item followed by a slash (/).

1. Specify the basis in which the permeability tensor is defined. The permeability tensor  $K$  is assumed to be diagonal and is specified by its physical components  $K_{11} = \text{PERMX}$ ,  $K_{22} = \text{PERMY}$ ,  $K_{33} = \text{PERMZ}$ ,  $K_{12} = \text{PERMXY}$ ,  $K_{23} = \text{PERMYZ}$  and  $K_{31} = \text{PERMZX}$ .

The tensor may be specified in one of the following bases:

- 1  $K_i$  is defined in the Cartesian  $x$ ,  $y$  and  $z$  axes.
- 2  $K_i$  is defined in each corner point cell relative to the coordinate system formed by joining the midpoints of opposite faces in a corner point cell.
- 3  $K_i$  is defined in the bedding plane by the vectors obtained by joining the midpoints of opposite faces in the corner point cell in the logical  $i$  and  $j$  directions. The third basis vector is chosen normal to the bedding plane.

DEFAULT: 2

See "[Tensor permeability](#)" in the *ECLIPSE Technical Description* for further information.

## Initial tracer concentrations

The keyword specifies the initial concentration of a tracer in each grid block. The actual keyword to be used is a concatenated name of up to 8 characters in length, which consists of the following segments:

### ECLIPSE 100

Segment:

1. Characters 1-4 must be the character string TBLK
2. Character 5 must be the letter F or S

For a tracer whose associated stock tank phase can only exist in the free state, the letter F (free) must be used. This case includes all water phase tracers, oil phase tracers unless [VAPOIL](#) is specified in the RUNSPEC section, and gas phase tracers unless [DISGAS](#) is specified in RUNSPEC.

For a tracer whose associated stock tank phase can exist in the solution state (for example, gas when [DISGAS](#) is specified in the RUNSPEC section, and oil when [VAPOIL](#) is in RUNSPEC) the letter S (solution) is allowed. A tracer that is embedded in such a phase requires both the free and solution component concentrations to be initialized.

3. Characters 6-8 must be the name of the tracer which is being initialized.

If a unit for tracer amount has been supplied in item 3 of keyword [TRACER](#), then the unit of tracer concentration is

UNITS: TR/sm<sup>3</sup> ([METRIC](#)), TR/stb for liquid phase tracers, TR/Mscf for gas phase tracers ([FIELD](#)), TR/scc ([LAB](#))

where TR is the unit supplied for the tracer.

### ECLIPSE 300

Segment:

1. Characters 1-4 must be the character string TBLK
2. Characters 5-8 must be the name of the tracer which is being initialized.

The keyword should be followed by one real number for every grid block specifying the initial tracer concentration. The data field should be terminated by a slash (/).

Grid blocks are ordered with the X axis index cycling fastest (from 1 to [NDIVIX](#)), followed by the Y axis index (from 1 to [NDIVIY](#)), and finally the Z axis index (from 1 to [NDIVIZ](#)). [NDIVIX](#), [NDIVIY](#) and [NDIVIZ](#) are specified in RUNSPEC keyword [DIMENS](#).

Repeat counts may be used for repeated values (for example 115\*0.22). Note that spaces must not be inserted on either side of the asterisk (\*).

## Notes

Values can also be set using the full range of data manipulation keywords such as [EQUALS](#), [MULTIREG](#) or [OPERATE](#).

## Examples

### Example 1

ECLIPSE 100

Where **DISGAS** is specified; **NDIVIX=8**, **NDIVIY=6** and **NDIVIZ=3** are specified in **RUNSPEC** keyword **DIMENS**; and the gas phase tracer is **SGS**:

```
TBLKFSGS
48*0.0
48*1.0
48*1.0 /
TBLKSSGS
48*0.0
48*0.0
48*0.0 /
```

### Example 2

Where **NDIVIX=2**, **NDIVIY=3** and **NDIVIZ=3** are specified in **RUNSPEC** keyword **DIMENS** and the water phase tracer is **WT1**:

```
TBLKFWT1
18*1.0 /
```

	SCHEDULE

This keyword can only be used with the THERMAL option (see "[Thermal option](#)" in the *ECLIPSE Technical Description*).

The data consists of the following items, describing the dimensions of the TCB table data to be used in the run.

1. The number of temperature cutback tables.  
DEFAULT: 1
2. The maximum number of rows in any TCB table.  
DEFAULT: 10

The use and interpretation of temperature cutback tables is discussed in the definition of the keyword [WELLTCBT](#).

## TCRIT

## Critical temperatures

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

In a run with  $N_c$  components, this keyword associates a critical temperature with each component.

The keyword should be followed by  $N_c$  values.

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

UNITS: K (METRIC), °R (FIELD), K (LAB), K (PVT-M)

DEFAULT: There are no component-wise default values. The users are recommended not to default these to the internal default value.

## Example

```
TCRIT
140 270 450 670 /
```

**Note:**

For live oil properties - a component can be made nonvolatile or non-condensable using the [CVTYPE](#) keyword. This keyword will also reset the component critical temperature, to  $10^4$  for nonvolatile components and to  $10^{-6}$  for non-condensable components. For back-compatibility with earlier versions of ECLIPSE, components with critical temperatures of  $10^4$  and above will also be assumed to be nonvolatile, while those with temperatures of  $10^{-6}$  will be assumed to be non-condensable. For surface calculations, the volatility types are set by default to the reservoir values. If different volatility types are required at the surface, the [CVTYPES](#) keyword can be used. In this case the [TCRITS](#) keyword should also be used to ensure the correct critical temperatures are used in the surface calculations.

The Thermal option is described in "[Thermal option](#)" in the *ECLIPSE Technical Description*.

## TECBDI

**Initial tectonic boundary conditions**

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies initial tectonic boundary conditions when initial stress calculation INIT is specified with the keyword **GEOMECH** in the RUNSPEC section.

Use of this keyword allows initial tectonic loadings to be specified on side boundaries (X-, X+, Y-, and Y+). A tectonic loading at side face is a force/unit area. If a particular boundary is not specified, then that boundary is defaulted to a rigid boundary.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. A character string specifying the boundary to which the velocity boundary condition is applied

This must be one of the following:

X+ Specify the boundary condition on the outer X+ edge

X- Specify the boundary condition on the outer X- edge

Y+ Specify the boundary condition on the outer Y+ edge

Y- Specify the boundary condition on the outer Y- edge

DEFAULT: There is no default for this item; it must be specified.

2. A tectonic loading which is a normal traction on this boundary.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

DEFAULT: 0

3. First block to be modified in the X direction

DEFAULT: 1 if an X- face

4. Last block to be modified in the X direction

DEFAULT: NX if an X+ face

5. First block to be modified in the Y direction

DEFAULT: 1 if a Y- face

6. Last block to be modified in the Y direction

DEFAULT: NY if a Y+ face

7. First block to be modified in the Z direction

DEFAULT: 1 if a Z- face

8. Last block to be modified in the Z direction

DEFAULT: NZ if a Z+ face

## Example

```
-- Set a 3000 psi total compressive traction on the X+, X-, Y+ and Y- boundaries  
TECBDI  
X+ -3000 /  
X- -3000 /  
Y+ -3000 /  
Y- -3000 /  
/
```

x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies initial tectonic boundary conditions in an LGR when initial stress calculation INIT is specified with the keyword **GEOMECH** in the RUNSPEC section.

This keyword allows initial tectonic loadings to be specified on side boundaries (X-, X+, Y-, and Y+) in a local grid refinement. A tectonic loading at side face is a force/unit area. If a particular boundary is not specified, then that boundary is defaulted to a rigid boundary.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. A character string specifying the boundary to which the velocity boundary condition is applied

This must be one of the following:

X+ Specify the boundary condition on the outer X+ edge

X- Specify the boundary condition on the outer X- edge

Y+ Specify the boundary condition on the outer Y+ edge

Y- Specify the boundary condition on the outer Y- edge

DEFAULT: There is no default for this item; it must be specified.

2. Name of the local grid refinement.
3. A tectonic loading which is a normal traction on this boundary.  
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)  
DEFAULT: 0
4. First block to be modified in the X direction  
DEFAULT: 1 if an X- face
5. Last block to be modified in the X direction  
DEFAULT: NX if an X+ face
6. First block to be modified in the Y direction

x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies the initial temperature values for each cell. It can be used with an explicit initialization (see "Specifying the initial state of a run in ECLIPSE 300" in the *ECLIPSE Technical Description*) in simulations where temperature variation is allowed - for example, with the Thermal option (keyword [THERMAL](#) in the RUNSPEC section) - or with a Peng-Robinson or Soave-Redlich-Kwong Equation of State.

The initial temperature can also be set using the [TEMPVD](#) or [RTEMP](#) keyword, or in Thermal simulations by using the [GETSOL](#) keyword to read TEMP data from a Restart file.

This keyword cannot be used with the [EQUIL](#) keyword. Instead, temperature data should be entered using either the [TEMPVD](#) keyword or [RTEMP](#) keyword.

The keyword should be followed by  $N_x N_y N_z$  values in normal order, with the X index changing fastest.

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

This keyword can also be used with the [EQUALS](#) keyword.

### Example

```
TEMPI
100*240 100*250 100*260 100*270 100*280 /
```

## TEMPNODE Temperature nodes for polymer solution viscosity

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword describes the nodal values for temperature, to be used in the calculation of the polymer solution viscosity when the temperature option ([TEMP](#)) is active. The data comprises NTPVT (see RUNSPEC keyword [TABDIMS](#)) tables of temperature values, each terminated by a slash (/).

Each table consists of up to NPPVT (see RUNSPEC keyword [TABDIMS](#)) values of the temperature. Within each table the values should be positive and strictly increasing.

UNITS: °C (METRIC), °F (FIELD), °C (LAB)

The number of entries in each table must correspond to the number of polymer solution viscosity entries used in the [PLYVISCT](#) keyword or to the number of polymer-solution/brine viscosity entries used in the [PLYVSCST](#) keyword.

### Example

With NTPVT=2 and NPPVT ≥ 4:

```

TEMPNODE
  10
  50
  100
  150 /
  10
  150 /

```

## TEMPTVD

## Requests flux limited transport for the temperature option

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword requests the use of the flux limited transport scheme for the temperature option. Flux limited transport is a higher-order method that reduces numerical dispersion of the energy and hence the temperature.

The option is not available in cases with local grid refinement; in these cases the keyword is ignored.

The method is analogous to the flux limited scheme for single phase tracers initiated with the [TRACTVD](#) keyword.

See "[Control of numerical diffusion](#)" in the *ECLIPSE Technical Description* for further information.

The TEMPTVD keyword has no associated data.

### Example

```
TEMPTVD
```

## TEMPVD

## Temperature versus depth data

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises a table of temperature versus depth data for each equilibration region. Each table consists of 2 columns of data, and is terminated with a slash (/).

The maximum number of rows in the table is set in item 3 in keyword [EQLDIMS](#).

Column:

1. Depth values.

The values should increase monotonically down the column.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

2. The corresponding temperature values.

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

For depth values outside the interval specified, constant value extrapolation is performed.

The temperature value is obtained for each cell, and this is used to evaluate equation of state expressions during the run. Note that the temperature does not change - that is, heat is not transported around the reservoir by fluid flows. All fluid properties, such as density and viscosity, use the cell temperatures. There is a small extra CPU cost in using the TEMPVD option.

*Thermal option*

In thermal simulations this keyword can be used to set the initial temperature in the reservoir.

Temperatures can also be set using the [RTEMP](#) keyword, or if an explicit initialization is used, the [TEMPI](#) keyword can be used.

### Example

```
TEMPVD
4000 220
6000 245
/
```

## THANALB

### Use analytic water densities

x	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can only be used with the THERMAL option (keyword **THERMAL** in the RUNSPEC section).

THANALV requests that analytic oil viscosities be used, as described in the section "Viscosity" in the *ECLIPSE Technical Description*. In **LIVEOIL** runs, analytic formulae can also be specified for each component using the **OILVISCC** or **OILVISCF** keywords. Alternatively oil viscosities can be looked up from the **OILVISCT** table in both **DEADOIL** and **LIVEOIL** runs.

If both the **PVCO** and **VISCREF** keywords are specified, a pressure dependence modifies the above temperature dependent viscosities. The oil viscosity at the prevailing pressure is then calculated as follows:

$$\mu_o = \mu(T) \frac{\mu(P)}{\mu(P_{\text{ref}})} \quad \text{Eq. 3.203}$$

where

$\mu(T)$  Viscosity from the THANALV keyword.

$\mu(P)$  Viscosity from the PVCO keyword at the prevailing pressure.

$\mu(P_{\text{ref}})$  Viscosity as entered by the PVCO keyword at the reference pressure as defined by the VISCREF keyword.

This keyword contains no items.

# THCGAS

## Gas phase thermal conductivity

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword may only be used when the ECLIPSE 300 Thermal option (keyword [THERMAL](#) in the RUNSPEC section) is active.

This keyword should be used with the [THCROCK](#) keyword.

The THCGAS keyword defines the thermal conductivities of the gas phase. This will be used to determine a porosity weighted average of the phase and rock conductivities (THCAVE), which will then be used to calculate the thermal conduction of heat in the reservoir.

$$THCAVE = \varphi \frac{(THCOIL + THCGAS + THCWATER + THCSOLID)}{NPHAS} + (1-\varphi)THCROCK$$

In the expression above  $\varphi$  is the grid porosity and NPHAS denotes the number of phases in the model. A heat conduction multiplier is then calculated and applied at each timestep to take into account the fluid saturations.

See "[Thermal option](#)" in the *ECLIPSE Technical Description* for details of this option.

Refer also to keywords [THCOIL](#), [THCWATER](#), and [THCSOLID](#).

The keyword should be followed by one non-negative real number for every grid block in the current input box, specifying the gas phase thermal conductivities. The data must be terminated by a slash (/).

UNITS: kJ/m/day/K (METRIC), Btu/ft/day/°R (FIELD), J/cm/hr/K (LAB), kJ/m/day/K (PVT-M)

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*208.4). Note that spaces must not be inserted on either side of the asterisk.

### Example

```
THCGAS
1200*25.0 /
```

## THCOIL

This keyword specifies the matrix to fracture thermal conductivity value for each matrix cell in a dual-porosity reservoir, for the THERMAL option (keyword [THERMAL](#) in the RUNSPEC section).

The keyword should be followed by  $(N_x N_y N_z)/2$  values in normal order, with the X index changing fastest.

UNITS: kJ/m/day/K (METRIC), Btu/ft/day/°R (FIELD), J/cm/hr/K (LAB), kJ/m/day/K (PVT-M)

The Dual Porosity and Dual Permeability options are discussed in more detail in "[Dual porosity](#)" of the *ECLIPSE Technical Description*.

The Thermal option is described in "[Thermal option](#)" in the *ECLIPSE Technical Description*.

**Example**

Set conductivities for a 10\*10 cross section,

```
THCONMF
100*3 /
```

## THCONR

## Thermal conductivity of rock and fluids

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword may only be used when either the ECLIPSE 100 Temperature option (keyword [TEMP](#) in the RUNSPEC section) or the ECLIPSE 300 Thermal option (keyword [THERMAL](#) in the RUNSPEC section) is active.

The THCONR keyword supplies the combined rock and fluid thermal conductivities as a porosity weighted average of the phase and rock conductivities (THCAVE), which will then be used to calculate the thermal conduction of heat in the reservoir.

See "[Temperature option](#)" and "[Thermal option](#)" in the *ECLIPSE Technical Description* for details of these options.

For the ECLIPSE 300 Thermal Option only, this keyword **must not** be used with either [THCROCK](#), [THCOIL](#), [THCGAS](#), [THCWATER](#) or [THCSOLID](#).

The keyword should be followed by one non-negative real number for every grid block in the current input box, specifying the combined rock and fluid thermal conductivities. The data must be terminated by a slash (/).

UNITS: kJ/m/day/K (METRIC), Btu/ft/day/°R (FIELD), J/cm/hr/K (LAB), kJ/m/day/K (PVT-M)

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*208.4). Note that spaces must not be inserted on either side of the asterisk.

**Note:** For the ECLIPSE 300 Thermal Option only, the thermal conductivity of the reservoir can also be dependent on the gas saturation via the [THCONSF](#) keyword.

### Example

```
THCONR
1200*25.0 /
```

## THCONSF

## Saturation-dependence of conductivity

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword may be used if the THERMAL option is active (keyword [THERMAL](#) in the RUNSPEC section).

This keyword can only be used with the thermal conductivities specified in [THCONR](#). This keyword **must not** be used with [THCROCK](#), [THCOIL](#), [THCGAS](#), [THCWATER](#) or [THCSOLID](#).

The THCONSF keyword is used to set up a multiplier,  $A$ , which is a function of  $S_g$ . Using this keyword, it is assumed that the thermal conductivity of a rock filled with liquid is independent of whether the liquid is oil or water and is the same whatever the porosity of the rock:

$$A = A(S_g), \Lambda = (1 - \alpha S_g) \quad \text{Eq. 3.204}$$

with  $\alpha$  in the range 0 to 1. This keyword specifies the value of  $\alpha$ .

Thermal transmissibilities are calculated in a similar manner to the flow transmissibilities with the thermal conductivities being used instead of the permeabilities. These thermal transmissibilities can also be multiplied by a saturation-dependent factor,  $A$ , as described above.

The keyword should be followed by  $N_x N_y N_z$  values in normal order, with the X index changing fastest.

The thermal option is described in "[Thermal option](#)" in the *ECLIPSE Technical Description*.

### Example

Set values for a 10\*10 cross section,

```
THCONSF
100*0.1 /
```

## THCROCK Thermal conductivity of rock

	ECLIPSE 100

	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword may only be used when the ECLIPSE 300 Thermal option (keyword [THERMAL](#) in the RUNSPEC section) is active.

This keyword must not be used with the [THCONR](#) keyword.

The [THCROCK](#) keyword defines the thermal conductivities of the rock. This will be used to determine a porosity weighted average of the phase and rock conductivities ([THCAVE](#)), which will then be used to calculate the thermal conduction of heat in the reservoir.

$$\text{THCAVE} = \varphi \frac{(\text{THCOIL} + \text{THCGAS} + \text{THCWATER} + \text{THCSOLID})}{\text{NPHAS}} + (1-\varphi)\text{THCROCK}$$

In the above expression is the  $\varphi$  grid porosity and [NPHAS](#) denotes the number of phases in the model. A heat conduction multiplier is then calculated and applied at each timestep to take into account the fluid saturations.

See "[Thermal option](#)" in the *ECLIPSE Technical Description* for details of this option.

Refer also to keywords [THCOIL](#), [THCGAS](#), [THCWATER](#) and [THCSOLID](#).

The keyword should be followed by one non-negative real number for every grid block in the current input box specifying the rock thermal conductivities. The data must be terminated by a slash (/).

UNITS: kJ/m/day/K ([METRIC](#)), Btu/ft/day/°R ([FIELD](#)), J/cm/hr/K ([LAB](#)), kJ/m/day/K ([PVT-M](#))

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*208.4). Note that spaces must not be inserted on either side of the asterisk.

### Example

```
THCROCK
1200*25.0 /
```

## THCSOLID Solid phase thermal conductivity

	ECLIPSE 100

	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword may only be used when the ECLIPSE 300 Thermal option (keyword [THERMAL](#) in the RUNSPEC section) is active.

This keyword should be used with the [THCROCK](#) keyword.

The [THCSOLID](#) keyword defines the thermal conductivities of the solid phase. This will be used to determine a porosity weighted average of the phase and rock conductivities ([THCAVE](#)), which will then be used to calculate the thermal conduction of heat in the reservoir.

$$\text{THCAVE} = \varphi \frac{(\text{THCOIL} + \text{THCGAS} + \text{THCWATER} + \text{THCSOLID})}{\text{NPHAS}} + (1-\varphi)\text{THCROCK}$$

In the expression above  $\varphi$  is the grid porosity and NPHAS denotes the number of phases in the model. A heat conduction multiplier is then calculated and applied at each timestep to take into account the fluid saturations.

See "[Thermal option](#)" in the *ECLIPSE Technical Description* for details of this option.

Refer also to keywords [THCOIL](#), [THCGAS](#) and [THCWATER](#).

The keyword should be followed by one non-negative real number for every grid block in the current input box, specifying the solid phase thermal conductivities. The data must be terminated by a slash (/).

UNITS: kJ/m/day/K ([METRIC](#)), Btu/ft/day/°R ([FIELD](#)), J/cm/hr/K ([LAB](#)), kJ/m/day/K ([PVT-M](#))

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*208.4). Note that spaces must not be inserted on either side of the asterisk.

## THERMEX1 Thermal expansion coefficient

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies the first thermal expansion coefficient for each of the  $N_c$  liquid hydrocarbon components.

The expression used to calculate oil component liquid densities is the following:

$$\rho_c = \frac{\rho_{ref_c}}{\left[1 - c_{P_c}(P - P_{ref_c})\right] \left[1 + c_{T1_c}(T - T_{ref_c})\right]} \quad \text{Eq. 3.205}$$

where

$\rho_{ref,c}$  is the reference density, specified with keyword [DREF](#),

$c_{P_c}$  is the oil component liquid compressibility, specified with keyword [CREF](#),

$P_{ref_c}$  is the reference pressure, specified with keyword [PREF](#)

$T_{ref_c}$  is the reference temperature, specified with keyword [TREF](#),

and  $c_{T1_c}$  is the thermal expansion coefficient, specified with this keyword.

There should be one value for each component:

UNITS: 1/K (METRIC), 1/°R (FIELD), 1/K (LAB), 1/K (PVT-M)

DEFAULT: 0.0

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of [TABDIMS](#). The use of multiple EoS regions is discussed in "Equations of state regions" in the *ECLIPSE Technical Description*.

### Example

```

THERMEX1
-- thermal expansion coefficients for a system with 3 hydrocarbon
-- components
3.5E-06 3.5E-06 4.5E-06 /

```

## THERMNUM Thermal region numbers

	<b>ECLIPSE 100</b>
x	<b>ECLIPSE 300</b>
x	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The THERMNUM keyword should be followed by one integer for every grid block in the current input box specifying the thermal region to which it belongs. The region number should not be less than 0 or greater than the number of thermal regions, specified with TABDIMS item 12.

For DEADOIL runs, the thermal region number should be set to 0 for those grid blocks that have a constant temperature throughout the run. The temperature is set to the initial temperature, and the thermal conductivity of the block is set to 0. This option is not available for LIVEOIL simulations.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example, 115\*2). Note that spaces must not be inserted on either side of the asterisk.

### Example

```
THERMNUM
144*1 96*0 /
```

## THFLXTF

## Heat transmissibility factor for flux boundary option

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword should only be used in a Thermal [USEFLUX](#) run, and only if the base full field model was an ECLIPSE 300 Blackoil model or a Compositional model.

For any type of simulation, the transmissibilities are taken from the base run and stored in the flux file.

For a Thermal simulation the heat transmissibilities are needed. However, these are not calculated from a full field non-thermal simulation.

So, for a USEFLUX case where the base run is non-thermal, and the reduced run is thermal, the heat transmissibilities are calculated as follows:

$$\Psi_{ni} = \alpha \times \gamma_{ni}$$

where

$\Psi_{ni}$  is the heat transmissibility between cells  $n$  and  $i$

$\gamma_{ni}$  is the flow transmissibility between cells  $n$  and  $i$

and  $\alpha$  is the heat transmissibility factor, defined using this keyword.

DEFAULT: 0.0

The flux boundary option is discussed in more details in "[Flux boundary conditions](#)" in the *ECLIPSE Technical Description*.

### Example

```
THFLXTF
0.12 /
```

## THPRES

## Threshold pressures

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword sets the threshold pressures for flow between adjacent equilibration regions. The threshold pressure switch THPRES must be set in keyword EQLOPTS in the RUNSPEC section. The facility prevents flow between adjacent equilibration regions until the potential difference exceeds the specified threshold value. Thereafter the potential difference for flow across equilibration region boundaries is reduced by the appropriate threshold value.

When the Threshold Pressure option is active (THPRES specified in keyword EQLOPTS), each interface between adjacent equilibration regions has its own threshold pressure. In fact, if the threshold pressures are irreversible (that is, if the switch IRREVERS is also specified in keyword EQLOPTS), each interface has two threshold pressures, one for flow in each direction.

The threshold pressure is set to zero for any interface not specified with the THPRES keyword. If the threshold pressures are irreversible, the threshold pressure should be specified separately for each direction; otherwise it is set to zero for the direction not specified.

Threshold pressures can be output to the Print file using the argument THPRES in keyword RPTSOL.

The THPRES keyword should be followed by a number of data records, terminated with a line containing just a slash (/). Each record consists of three numbers, and is terminated with a slash. The numbers represent:

1. From equilibration region number (I)  
Must not exceed NTEQUL (see keyword EQLDIMS).
2. To equilibration region number (J)  
Must not exceed NTEQUL.
3. Threshold pressure for flow from region I to region J.

If this quantity is defaulted (by terminating the record after item 2), the threshold pressure for this interface (and this direction if the threshold pressures are irreversible) will be calculated by the program from the initial conditions. It is set equal to the maximum potential difference between communicating cells across the interface, for any phase that is present in the upstream cell. (Thus, for example, the oil potential difference in the water zone does not influence the threshold pressure.)

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

End the record with a slash (/).

Terminate the set of records with a line containing just a slash.

See also the THPRESFT keyword.

## Example

NTEQUL=3, irreversible threshold pressures:

```

.....
-- RUNSPEC section
EQLDIMS
3 /
EQLOPTS
THPRES IRREVERS /
-- SOLUTION section
THPRES
1 2 12.0 /
2 1 5.0 /
1 3 7.0 /
.....

```

```
3 1 7.0 /
2 3 /
```

Since individual threshold pressure values have been set by the user, in either direction, between regions 1 and 2, and also regions 1 and 3, these values will be used. If there is communication between regions 2 and 3, threshold pressure values will be calculated from the conditions at the start of the run; otherwise they will be set to zero. The same principle will apply for communication between regions 3 and 2. Threshold pressures can be output to the Print file using the argument THPRES in keyword [RPTSOL](#).

## THPRESFT Sets up a threshold pressure for a fault

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The THPRESFT keyword can be used to set up a threshold pressure for a fault previously defined using the [FAULTS](#) keyword. The threshold pressure switch THPRES must be set in keyword [EQLOPTS](#) in the RUNSPEC section. The facility prevents flow occurring between adjacent grid blocks either side of the fault until the potential difference exceeds the specified threshold value. Thereafter the potential difference for flow across the fault is reduced by the appropriate threshold value.

The keyword is followed by any number of data records, terminated with a blank record containing just a slash (/). Each record contains the following two items of data, and is terminated with a slash (/).

1. Fault name (as specified in the [FAULTS](#) keyword), or a fault name root.  
A fault name root, ending with an asterisk (\*), can be used to refer to several faults in one record.
2. Threshold pressure.  
UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)  
DEFAULT: 0.0

The set of records must end with a blank record containing only a slash (/).

See also the keywords [FAULTS](#) and [THPRES](#).

### Notes

- If a fault is referred to twice in one or more THPRESFT keywords, the threshold pressure is taken from the last entry.
- The fault threshold pressure can be used in combination with the equilibration region based threshold pressure option (keyword [THPRES](#)). If two threshold pressures are applied to the flow between the same two grid blocks, the acting threshold pressure is taken as the maximum of the two threshold pressures.
- Threshold pressures cannot be set for a fault which crosses a local grid or coarsened region.

### Example

See the [FAULTS](#) keyword example.

```

THPRESFT
--
'zigzag'      10.0      /
'block'       1.2      /
/

```

## THSTT97

## Use IAPWS 97 steam table

This keyword can only be used with the THERMAL option (keyword [THERMAL](#) in the RUNSPEC section).

If the keyword THSTT97 is used, the properties of water and steam will be based on an analytic formulation, as detailed by *The International Association for the Properties of Water and Steam* in the *IAPWS Industrial formulation 1997* (IAPWS-IF97). The water and steam densities, the saturation pressures and temperatures, and the water and steam energies and enthalpies will be calculated using the IAPWS-IF97 formulation.

## Specify run title

This enables a run title to be set up, which is included in the Print file headers. The syntax is rather different from that of other keywords, the line after the `TITLE` keyword being read directly.

No quotes or slash characters are required.

In ECLIPSE 300, the `TITLE` keyword may be specified more than once in the dataset, and may be changed. Any changed title will be used in all subsequent Print file headers. In addition to the use of the `TITLE` keyword, a primary title is read by the program when the job is submitted, and this fixed title is output in addition to any specified using the `TITLE` keyword. The primary title is normally supplied to the job submission macro.

### Example

```
TITLE  
Fifth run in series - increased production rate
```

	SUMMARY
	SCHEDULE

This keyword should only be used in runs which use the miscible flood option (keyword [MISCIBLE](#) in the RUNSPEC section) or the solvent model (keyword [SOLVENT](#)). The keyword is obligatory in these runs. It has no effect on the polymer model (keyword [POLYMER](#)) where keyword [PLMIXPAR](#) must be used instead.

The data consists of NTMISC (see keyword [MISCIBLE](#)) records of Todd-Longstaff mixing data. Each record consists of the following items of data, terminated by a slash (/).

1. Todd-Longstaff mixing parameter for the viscosity calculation.

The value of the mixing parameter for each miscibility region should be in the range 0.0 to 1.0 inclusive.

The mixing parameter has no associated units.

2. Todd-Longstaff mixing parameter for the density calculation.

DEFAULT: Same value as the viscosity mixing parameter set in item 1.

This second data item is ignored when TLMIXPAR is used in a Polymer Flood Model.

---

**Note:** The format of this keyword was changed for the 95A release. In pre-95A datasets, the second item was previously a character string (DEN or NODEN) instead of a real number denoting the density mixing parameter. Pre-95A datasets having the DEN / NODEN flag set must have their TLMIXPAR keyword data modified, or they will report an error. DEN corresponds to defaulting the density mixing parameter, and NODEN corresponds to setting the second mixing parameter to 0.0. No change need be made if the DEN / NODEN flag was defaulted.

---

---

**Note:** From the 2011.1 release onwards it is possible for simulations to use both the polymer and the solvent or miscible flood option. as noted above, mixing parameters for the Polymer Model should be specified with keyword [PLMIXPAR](#).

---

### Example

With NTMISC=5:

```

-- RUNSPEC section:
MISCIBLE
 5 /
--PROPS section:
TLMIXPAR
0.35 /
0.57 /
0.19 /
0.0 /
1.0 0.7 /

```

## Tracer concentration regions

The keyword specifies the region numbers to be used for initializing the concentration of a tracer in each grid block and specify link cells to tables of initial tracer concentration with respect to depth.

The actual keyword to be used is a concatenated name of up to 8 characters in length, which consists of the following segments:

### ECLIPSE 100

1. Characters 1-4 must be the character string TNUM.
2. Character 5 must be the letter F or S.

For a tracer whose associated stock tank phase can only exist in the free state, the letter F (free) must be used. This case includes all water phase tracers, oil phase tracers unless [VAPOIL](#) is specified in the RUNSPEC section, and gas phase tracers unless [DISGAS](#) is specified in RUNSPEC.

For a tracer whose associated stock tank phase can exist in the solution state (for example gas when [DISGAS](#) is specified in the RUNSPEC section, and oil when [VAPOIL](#) is in RUNSPEC) the letter S (solution) is allowed. A tracer which is embedded in such a phase requires both the free and solution component concentrations to be initialized.

3. Characters 6-8 must be the name of the tracer which is to be initialized, as specified in keyword [TRACER](#) in the PROPS section. Surfactant concentrations can be input using the character string SUR and foam concentrations using FOA.

### ECLIPSE 300

1. Characters 1-4 must be the character string TNUM.
2. Characters 5-8 must be the name of the tracer that is being initialized, as specified in keyword [TRACER](#) in the PROPS section.

The keyword should be followed by one integer for every grid block in the current input box, specifying the initial tracer concentration region number to which it belongs. The region number should not be less than 1 or greater than NTTRVD (see item 4 in keyword [EQLDIMS](#)). The data must be terminated by a slash (/).

Grid blocks are ordered with the X axis index cycling fastest (from 1 to NDIVIX), followed by the Y axis index (from 1 to NDIVIY), and finally the Z axis index (from 1 to NDIVIZ). NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword [DIMENS](#). Repeat counts may be used for repeated values (for example 115\*0.22). Note that spaces must not be inserted on either side of the asterisk (\*).

See "[Tracer tracking](#)" in the *ECLIPSE Technical Description* for further information.

ECLIPSE 100

These keywords can now be used in conjunction with [ADD](#), [ADDREG](#), [MULTIPLY](#) or [MULTIREG](#), in addition to [EQUALS](#), [EQUALREG](#) and [COPYBOX](#).

## Examples

### Example 1

ECLIPSE 100

Where [DISGAS](#) is specified; NDIVIX=8, NDIVIY=6 and NDIVIZ=3 are specified in RUNSPEC keyword [DIMENS](#); the gas phase tracer is 'SGS'; and NTTRVD ≥ 2 in [EQLDIMS](#) item 4:

```
TNUMFSGS
48*1
48*2
48*2 /
TNUMSSGS
48*1
48*1
48*1 /
```

### Example 2

Where  $NDIVIX=2$ ,  $NDIVIY=3$  and  $NDIVIZ=3$  are specified in RUNSPEC keyword [DIMENS](#); the water phase tracer is 'WT1'; and  $NTTRVD \geq 4$  in [EQLDIMS](#) item 4:

```
TNUMFWT1
12*1 6*4 /
```

### Example 3

```
TNUMTRAA
48*2
48*3
48*1 /
```

ECLIPSE 300

## TOLCRIT

## Specify tolerance for critical saturations

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The way in which the initial relative permeability critical table saturations are determined can be modified by using the TOLCRIT keyword.

By default the critical saturation for a given relative permeability function is set to the last saturation table entry for which the relative permeability is notionally zero; in practice, the criterion used for zero is less than a threshold value which by default is  $1.0 \times 10^{-6}$  for ECLIPSE 100 and  $1.0 \times 10^{-20}$  for ECLIPSE 300.

The default threshold can be changed by specifying TOLCRIT. Relative permeability values which are lower than this threshold will be treated as zero for the purposes of determining the critical saturation. Consideration should be given to the choice of this threshold value when modeling saturation functions with low initial values of relative permeability and when comparing results between simulators.

The keyword is followed by a single item and terminated by a slash(/):

Tolerance used to determine critical saturations

Values should be between 0 and 1.

DEFAULT:

1.0E-6 (ECLIPSE 100)

1.0E-20 (ECLIPSE 300)

See "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for more information.

## Example

```
TOLCRIT
1.0E-8 /
```

# TOPS

## Depths of the top face of each grid block

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The keyword should be followed by one number for every grid block in the current input box, specifying the depth at the top of each grid block.

The data must be terminated by a slash (/).

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

Every TOPS value in the top plane (K = 1) must be specified in one way or another by the end of the GRID section. Values in lower planes (K > 1) that are not specified are computed by adding the gross grid block thickness (DZ) to the TOPS value for the corresponding grid block in the plane above.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0.127). Note that spaces must not be inserted on either side of the asterisk.

### Example

# TOPT

## Preset tuning options

	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword has a number of preset tuning options. All the options set can be defined by combinations of other keywords.

The keyword contains an item of data, terminated with a slash (/). The item should be one of the following:

- DEFAULT This is the default item; no changes are made, the current tuning setting for the simulator are used.
- AIM1 This is equivalent to the DEFAULT settings, this option is only maintained for backward compatibility reasons.
- 2001A This setting reestablishes the 2001A tuning setting, and is additionally activated by [item 69](#) in OPTIONS3

- The limit on the timestep after a well alteration is set to 5 days for an [IMPES](#) run and 20 days for an [AIM](#) or [FULLIMP](#) run. See item 11 in the [TSCRIT](#) keyword. During history matching, quite often the report steps will be close together (for example every month), with well modifications after every report. The limit of 20 days after a well modification prevents a month timestep, and was consequently changed for the 2002A release.

- The implicit cells are controlled using the [AIMCON](#) keyword. The settings used here reproduce the 2001A settings:

Set open well cells, and all cells with the same inner solver direction as implicit (item 1 in AIMCON).

Reevaluate the set of implicit cells every 5<sup>th</sup> timestep (item 4 in AIMCON).

Use 2001A default for implicit cell selection (item 5 in AIMCON).

Do not select any implicit cells based on solution change (item 7 in AIMCON).

The TOPT keyword with this item for an AIM run is equivalent to the following combination of keywords:

```

TSCRIT
-- 1-- 2-- 3-- 4-- 5-- 6-- 7-- 8-- 9--10--11--12--13-- .....
 1* 1* 1* 1* 1* 1* 1* 1* 1* 1* 20 1* 1* /
AIMCON
-- 1-- 2-- 3-- 4-- 5-- 6-- 7-- 8-- 9--10--
 1 1* 1* 5 -1.0 1 -1.0 /
    
```

AIMCHOP This setting is suitable for AIM runs for which AIM1 gives high numbers of implicit cells and/or severe timestep chops. It is a similar to the AIM1 setting, but with the following modifications:

- The maximum increase factor after a timestep is 1.5 (item 4 in TSCRIT).
- The maximum decrease factor after a timestep is 0.125 (item 5 in TSCRIT).
- Cells with a normalized solution change of over a quarter (item 7 in AIMCON) of 0.1 the solution change target (item 10 in TSCRIT) is implicit, up to a maximum of 5% (item 6 in AIMCON) of the reservoir cells.

The TOPT keyword with this item is equivalent to the following combination of keywords:

```
TSCRIT
-- 1-- 2-- 3-- 4-- 5-- 6-- 7-- 8-- 9--10--11--12--13-- .....
  1* 1* 1* 1.5 .125 1* 1* 1* 1* .1 1* 1* 1* /
AIMCON
-- 1-- 2-- 3-- 4-- 5-- 6-- 7-- 8-- 9--10--
  2 1* 1* 1 .5 5 .25 5 5 1 /
```

AIMLOOSE This setting is suitable for AIM runs where large areas of the reservoir may need to be implicit (for example for a sector model with many small cells near a gas injector). It is similar to the AIM1 setting, but with the following modifications:

- No limits are placed on the number of implicit cells (items 6 and 8 of the AIMCON keyword). If large numbers of cells are made implicit this increases the memory requirements.
- The TOPT keyword with this item is equivalent to the following combination of keywords

```
AIMCON
-- 1-- 2-- 3-- 4-- 5-- 6-- 7-- 8-- 9--10--
  2 1* 1* 1 .5 100 .25 100 5 1 /
```

**Note:** This option only changes the values specified, and does not reset all the default tuning values. Consequently, tuning keywords that appear before TOPT in the SCHEDULE section take effect if their values are not altered by the TOPT keyword.

## Example

```
TOPT
  AIMCHOP /
```

## TPAMEPS

## Tables of volumetric strain values

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is specific to the coal bed methane option and the [ROCKPAMA](#) Palmer-Mansoori rock compaction model.

The data comprises NTCREG (see keyword [REGDIMS](#), item 6) tables of volumetric strain values to be used in the Palmer-Mansoori model as a function of the coal gas concentrations. The table consists of [NCOMPS](#) +1 columns of data in ECLIPSE 300 and 2 columns of data in ECLIPSE 100. If the [SOLVENT](#) model is activated in ECLIPSE 100, the keyword [TPAMEPSS](#) should be used to specify the solvent strain term.

Column:

1. The surface coal gas concentration

Values should increase monotonically down the column.

UNITS:  $\text{sm}^3/\text{m}^3$  (METRIC),  $\text{Mscf}/\text{ft}^3$  (FIELD),  $\text{scc}/\text{cc}$  (LAB)

2. The corresponding volumetrics strain term (eps)

Values should be level or increasing down the column. This look up value replaces the term

$$\varepsilon_i \frac{\beta P}{1 + \beta P}$$

in the normal Palmer-Mansoori formulation. See the [ROCKPAMA](#) keyword.

UNITS: Dimensionless

3. [[NCOMPS](#) +1] The corresponding volumetric strain term for the remaining components.

Values should be level or increasing down the column.

UNITS: Dimensionless

The entire table may be defaulted, provided the table is not the first. Defaulted tables are replaced with a copy of the previous table. In a given table that is not defaulted, there must be the same number of entries in each column and the number of rows should not be less than 2 or greater than [NSSFUN](#) (see item 3 of keyword [TABDIMS](#)).

---

**Note:** The first column refers to the coal gas of the component, IC, with the corresponding strain value as given in columns IC+1, IC=1, ... [NCOMPS](#), and is not the total coal gas concentration.

---

The coal region number [COALNUM](#) is used to look up the table.

See also the "Coal Bed Methane Model" in the *ECLIPSE Technical Description* for further information.

### Example

With ([NCOMPS](#) =1 for ECLIPSE 300), NTCREG=1 specified in keyword [REGDIMS](#) and [NSSFUN](#)  $\geq$  14 specified in keyword [TABDIMS](#):

## TRACER

## Set up tracers

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword sets up a number of passive tracers, associating each of them with a particular fluid used in the study.

In a compositional run, the fluid is one of the hydrocarbon or water components. In a black oil model, fluid refers to one of the stock tank phases.

The keyword should be followed by one line for each tracer introduced. Each line must contain the data items listed below, and is terminated by a slash (/). The set of records must end with a blank record, containing only a slash (/).

1. Tracer name

Up to 3 characters (ECLIPSE 100).

Up to 4 characters (ECLIPSE 300).

---

**CAUTION:** Tracer names starting with 'F', 'S', 'T' or a number are not recommended since these may create naming ambiguities for postprocessors.

---

2. The name of the fluid associated with the tracer:

Stock tank phase name: OIL, WAT or GAS.

Component name, defined by [CNAMEs](#) for a hydrocarbon component or [WNAMEs](#) for a water component.

If the tracer is associated with a water component and WNAMEs, has not been used, use the default name which is set as follows:

WATER if there is only one water component

WATnn if there is more than one water component, for example use WAT02 to associate a tracer with the second water component.

---

**Note:** For a partitioned tracer this will be regarded as the free phase.

---

3. Units for tracer amount (for example 'kg')

UNITS: Arbitrary, but must be consistent with what is used in [TBLK](#) and [TVDP](#).

DEFAULT: 'sm3' (METRIC), 'stb' or 'Mscf' (FIELD), 'scf' (LAB)

In field units, oil and water phase tracers have 'stb' as default, whereas gas phase tracers have 'Mscf'.

4. The 'solution' phase of a partitioned tracer:

Stock tank phase name: OIL, WAT, GAS or MULT.

MULT indicates a multi-partitioned tracer, that is a tracer that partitions into two or more phases, and which is a generalization of the standard partitioned tracers. When MULT is specified the actual phases into which the tracer partitions must be specified together with the K(P) tables in keyword [TRACERKM](#).

ECLIPSE 100

ECLIPSE 300

ECLIPSE 100

ECLIPSE 100

This item need only be supplied if partitioned tracers are being used (see keyword [PARTTRAC](#)).

ECLIPSE 100

5. The number of the K(P) table to use for this partitioned tracer within a wellbore.

This item need only be supplied if partitioned tracers are being used (see keywords [PARTTRAC](#), [TRACERKP](#) and [TRACERKM](#)).

ECLIPSE 100

6. The phase which is used for adsorption calculation of a multi-partitioned tracer, that is a tracer with [MULT](#) specified in item 4. If adsorption is active (see keywords [TRADS](#) and [ADSORP](#)), this item species the phase concentration that will be used when calculating adsorption.

Stock tank phase name: OIL, WAT, GAS or ALL.

ALL indicates that adsorption will be based on the overall, pore-volume averaged tracer concentration.

DEFAULT: the phase specified in item 2.

This item need only be supplied if partitioned tracers are being used in conjunction with adsorption.

---

**Note:** Some reported tracer quantities can be prone to rounding errors if the model is made of cells with exceeding small pore volumes. This might happen if modeling a core when using [FIELD](#) or [METRIC](#) units. In this situation the solution is to convert to [LAB](#) units.

---

## TRACERKM Specifies the K(P) tables for the generalized, multi-partitioned tracer option

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword should only be used when either the environmental tracer option or the surfactant option is active and the [PARTTRAC](#) keyword has been entered in the RUNSPEC section. The keyword can only be used in conjunction with multi-partitioned tracers, that is, tracers with MULT specified in the 4th item of the [TRACER](#) keyword.

The data comprises NKPTMX+2 records (see item 2 of keyword [PARTTRAC](#)) of data each terminated by a slash (/).

### First record

The first record consists of two items of data:

1. Three-character name of partitioned tracer as defined in the [TRACER](#) keyword.
2. Type of partition function specification. This item must currently be set to STANDARD indicating that tables of partition coefficients are entered as a function of pressure.

### Second record

The second record contains a list of the phases that the tracer partitions into. The options are:

O (oleic), A (aqueous) and G (gaseous).

The first phase specified in the list is taken as the reference phase and must correspond to the phase specified in the item 2 of the [TRACER](#) keyword.

### Remaining records

The following NKPTMX records hold tables of partition coefficients for each region. Each table, having at most NPKPMX (item 3 of keyword [PARTTRAC](#)) rows of data, applies to its corresponding partitioning region, defined by keyword [TRKPF](#) in the REGIONS section.

Each table consists of two or more columns, and is terminated by a slash (/). The number of columns must equal the number of phases specified in the second record. Column

1. Pressure

Values must be monotonically increasing.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

2. Value of partitioning functions K(P).

Each column defines the partitioning functions between a phase and the reference phase in the order that the phases are defined in the second record. For example, if a tracer partitions between three phases there will be two columns of partitioning functions.

### Example

With NKPTMX=3 for partitioned tracer PT1 partitioning into three phases:

```
TRACERKM
PT1 STANDARD /
```

```
A O G /
-- PRES K1(O/A) K2(G/A)
    10    1.1    5.7
    50    1.5    6.8
    90    1.7    9.1
/
-- PRES K1(O/A) K2(G/A)
    10    1.2    5.0
    50    1.7    5.9
    90    1.9    6.4
/
/ -- Default third table to second table
```

## TRACERKP Specifies the K(P) tables for the partitioned tracer option

	SCHEDULE

This keyword should only be used when either the Environmental Tracer option or the Surfactant options is active and the `PARTTRAC` keyword has been entered in the `RUNSPEC` section.

The data comprises `NKPTMX` (item 2 of keyword `PARTTRAC`) tables specifying the partitioning function. Each table, having at most `NPKPMX` (item 3 of keyword `PARTTRAC`) entries, applies to its corresponding partitioning region, defined by keyword `TRKPF` in the `REGIONS` section.

Each table consists of 2 columns, and is terminated by a slash (/).

Column:

1. Pressure

Values must be monotonically increasing

UNITS: barsa (`METRIC`), psia (`FIELD`), atma (`LAB`), atma (`PVT-M`)

2. Value of partitioning function K(P)

### Example

With 1 table and 3 pressure values:

```
TRACERKP
2000 0.00012
 2600 0.00014
 3310 0.00015
/
```

## TRACERS

## Dimensions and options for tracers

	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data consists of some or all of the following items of data which describe the tracers employed during the run and options for the tracer tracking algorithm (see "Tracer tracking" in the *ECLIPSE Technical Description*). The data must be terminated by a slash (/).

1. The maximum number of passive oil tracers entered using keyword `TRACER` in the PROPS section.  
DEFAULT: 0
2. The maximum number of passive water tracers entered using keyword `TRACER` in the PROPS section.  
DEFAULT: 0
3. The maximum number of passive gas tracers entered using keyword `TRACER` in the PROPS section.  
DEFAULT: 0
4. The maximum number of environmental tracers (tracers that are adsorbed or decay) if using the Environmental Tracer option (see "Environmental tracers" in the *ECLIPSE Technical Description*).  
DEFAULT: 0
5. Invokes the use of a numerical diffusion control algorithm for the calculation of single phase tracer concentrations in tracer tracking runs.

DIFF or SPECIAL

Use a numerical diffusion control algorithm. If the `TRACTVD` keyword is present in the PROPS section, the flux limited transport scheme is used. Otherwise, the cascade algorithm will be used. When the `DIFF` option is used when multisegment wells are present, the tracer equations still uses the standard well model and hence the multisegment well tracer summary keywords are not relevant. The `DIFF` option is not available in combination with `PARALLEL`.

NODIFF or STANDARD

No diffusion control scheme is used, that is ECLIPSE's standard fully implicit solver is used.

DEFAULT: NODIFF

---

**Note:** When `TRACITVD` is used to activate implicit TVD scheme, this parameter is ignored.

---

6. The maximum number of non-linear iterations to be used by the tracer solution method.  
DEFAULT: 12
7. The minimum number of non-linear iterations to be used by the tracer solution method.  
DEFAULT: 1

---

**Note:** The following items should only be used with great care and after reading "Treating passive tracers as non-linear" in the *ECLIPSE Technical Description*.

---

8. Treat passive tracer as non-linear?  
DEFAULT: 'NO'
9. One-off linear convergence tightening factor.

DEFAULT: Will not be applied

10. One-off non-linear convergence tightening factor.

DEFAULT: Will not be applied

11. Subsequent convergence tightening factors (applied to both linear and non-linear values, timestep limits will also be modified; see the **TIGHTEN** keyword).

DEFAULT: 1.0

12. Number of times item 11 may be applied.

DEFAULT: 0

## Example

Five passive water tracers

```
TRACERS  
1* 5 1* 0 DIFF 15 /
```

## TRACITVD

## Requests implicit flux limited transport for tracers

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword requests the use of the implicit flux limited transport scheme for the tracer calculation. Flux limited transport is a higher-order TVD (total variance diminishing) scheme that reduces numerical dispersion of the tracer. (The implicit TVD is implemented with three alternative limiters.)

The TRACITVD keyword is available for single phase tracers, that is water tracers and hydrocarbon tracers in phases that do not dissolve in the complementary phase. The TRACITVD keyword does not work in combination with parallel.

See "[Control of numerical diffusion](#)" in the *ECLIPSE Technical Description* for further information.

#### 1. TVD flux limiter

This must be one of the following:

- 1 Van Leer limiter
- 2 Minmod limiter
- 3 Super Bee limiter

DEFAULT: 1

---

**Note:** The use of implicit TVD with large timestep can result in non-physical effects for tracers for a subset of problems. The default Van Leer limiter should handle most situations. The minmod limiter is relatively diffusive; it can be used to reduce possible tracer effects. SuperBee is the limiter that can produce the sharpest tracer fronts; however, it may potentially have larger effects. Effects can be reduced by various tuning methods (see note below).

---

#### 2. A flag to select whether tracer solutions at both the previous and the current time should be used to compute TVD flux limiter. Tracer solution at the previous time should only be used when tracer moves a small distance relative to grid size within a timestep. The default is strongly recommended.

YES uses tracer solutions at both the previous and the current time

NO uses tracer solutions only at the previous time

DEFAULT: YES

---

**Note:** The default settings should be applied for most cases requesting implicit flux limiting scheme.

---

**Note:** The implicit flux limiting TVD scheme is a useful option to problems using non-uniform grid or requiring tracer dispersion and diffusion. For such cases, the implicit TVD scheme can provide significant speed-up compared to the explicit TVD scheme. Implicit TVD can significantly improve solution accuracy over the standard fully implicit solver by reducing numerical diffusion in the tracer equation.

---

**Note:** Timestep tuning is useful for reducing artificial effects, typified by the over/under shooting of tracer concentrations beyond physical ranges. A large timestep can cause the implicit tracer equation to fail to converge, due to the error caused by the flow equation not being adequately converged. In addition, it can

be helpful to tune with the **TIGHTEN** keyword which can help the flow equation to converge. When flow and tracer equations are converged, non-physical effects in general are greatly diminished or disappear.

---

**Note:** A viable alternative is to use the Minmod mode, which can be helpful to somewhat reduce such effects without using timestep tuning or tightening. Proper tuning will improve the quality of tracer solution by computing sharp fronts with little or no non-physical effects.

---

## Examples

### Example 1

The TRACITVD keyword can, with strong recommendation, be used with no associated data:

```
TRACITVD  
/
```

### Example 2

The TRACITVD keyword can also be used with a chosen implicit flux limiter:

```
TRACITVD  
2 YES/
```

## Enable the tracking option

The TRACK option enables a division of hydrocarbons in the original reservoir to be tracked through into recovered surface volumes.

The TRACK keyword contains the following items of data:

- Specify whether the division of the fluids is to be done at the gas-oil contact, or at a specified depth, or solely on regions defined by the user with the [TRACKREG](#) keyword. The item should be GOC, DEPTH or REGONLY.  
 DEFAULT: GOC
- Specify the required depth if DEPTH is selected in item 1.  
 UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)  
 DEFAULT: 0.0
- Request normalization of the recovered volumes. Specify N for normalization.  
 DEFAULT: unnormalized.
- Specify a list of components to be tracked, or ALL for all the components.  
 DEFAULT: ALL

### Example

```
TRACK
DEPTH 9640 N ALL /
```

	REGIONS
x	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is being replaced by new keywords for setting traction boundary conditions. Please refer to keyword [GMTRABC](#).

This keyword allows traction boundary conditions to be specified on all boundaries. A traction at a boundary surface is a force/unit area. If not specified, then that boundary is defaulted to a rigid boundary unless a displacement condition is given with the keyword [DISPBC](#) or a principal stress boundary condition is given with keyword [PSTRBC](#).

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. A character string specifying the boundary to which the traction boundary condition is applied

This must be one of the following:

I+ Specify the boundary condition on the outer I+ edge

I- Specify the boundary condition on the outer I- edge

J+ Specify the boundary condition on the outer J+ edge

J- Specify the boundary condition on the outer J- edge

K+ Specify the boundary condition on the outer K+ edge

K- Specify the boundary condition on the outer K- edge

DEFAULT: There is no default for this item; it must be specified.

The K- boundary is the top boundary of the simulation, K+ is the bottom.

2. An integer specifying the type of boundary condition on this face

This must be one of the following:

- 1 A total normal traction is specified on the boundary denoted in item 1. The magnitude of this normal traction is set in item 3.

- 2 A given traction with X, Y, Z components. A single X, Y, Z traction component is set in item 3 and the component name is set in item 4. Separate lines are needed to set different components.

DEFAULT: If a boundary of a cell or face is not specified with traction, stress or displacement boundary conditions, default is a rigid boundary as specified in [DISPBC](#) item 2.

3. A normal traction on this boundary, if the boundary condition type in item 2 is 1, or an X or Y or Z component of a given traction, if the boundary condition type in item 2 is 2. The component direction is set in item 4 below.

UNITS: bars ([METRIC](#)), psi ([FIELD](#)), atm ([LAB](#)), atm ([PVT-M](#))

DEFAULT: 0

4. A character string that gives the component of traction if the boundary type in item 2 is 2. This must be one of 'X', 'Y' or 'Z'.

DEFAULT: None. It must be specified if item 2 is 2

5. First block to be modified in the I direction

DEFAULT: 1 if an I- face

6. Last block to be modified in the I direction

DEFAULT: NX if an I+ face

7. First block to be modified in the J direction

DEFAULT: 1 if a J- face

8. Last block to be modified in the J direction

DEFAULT: NY if a J+ face

9. First block to be modified in the K direction

DEFAULT: 1 if a K- face

10. Last block to be modified in the K direction

DEFAULT: NZ if a K+ face

## Example

```

-- set a 3000 psi total compressive traction on the i+, i-, j+ and j- boundaries
-- set a 3000 psi overburden pressure (compressive stress is -ve)
-- note that the 'K-' direction is positive downwards
TRACTBC
-- side type total
--      traction
-- 'I+'  1  -3000 /
-- 'I-'  1   3000 /
-- 'J+'  1  -3000 /
-- 'J-'  1   3000 /
-- 'K-'  1  -3000 /
/

```

## TRACTBCL Traction boundary conditions in a local grid refinement

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is being replaced by new keywords for setting traction boundary conditions. Please refer to keyword [GMTRABCL](#).

This keyword specifies traction boundary conditions when a coupled stress calculation is specified with the keyword [GEOMECH](#) in the RUNSPEC section.

Use of this keyword allows traction boundary conditions to be specified on all boundaries of a local grid refinement. A traction at a boundary surface is a force/unit area. If a particular boundary is not specified, then that boundary is defaulted to a rigid boundary unless a displacement condition is given with the keyword [GMDISBCL](#) or a principal stress boundary condition is given with keyword [GMPSTBCL](#).

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. A character string specifying the boundary to which the traction boundary condition is applied

This must be one of the following:

I+ Specify the boundary condition on the outer I+ edge

I- Specify the boundary condition on the outer I- edge

J+ Specify the boundary condition on the outer J+ edge

J- Specify the boundary condition on the outer J- edge

K+ Specify the boundary condition on the outer K+ edge

K- Specify the boundary condition on the outer K- edge

DEFAULT: There is no default for this item; it must be specified.

The K- boundary is the top boundary of the simulation, K+ is the bottom.

2. An integer specifying the type of boundary condition on this face This must be one of the following:

- 1 A total normal traction is specified on the boundary denoted in item 1. The magnitude of this normal traction is set in item 4.

- 2 A given traction with X, Y, Z components. A single X, Y, Z traction component is set in item 4 and the component name is set in item 5. Separate lines are needed to set different components.

DEFAULT: If a boundary of a cell or face is not specified with traction, stress or displacement boundary conditions, default is a rigid boundary as specified in [GMDISBCL](#) item 2.

3. Name of the local grid refinement

4. A normal traction on this boundary, if the boundary condition type in item 2 is 1, or an X or Y or Z component of a given traction, if the boundary condition type in item 2 is 2. The component direction is set in item 5 below.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

DEFAULT: 0

5. A character string that gives the component of traction if the boundary type in item 2 is 2. This must be one of 'X', 'Y' or 'Z'.

DEFAULT: None. It must be specified if item 2 is 2

6. First block to be modified in the I direction

DEFAULT: 1 if an I- face

7. Last block to be modified in the I direction

DEFAULT: NX if an I+ face

8. First block to be modified in the J direction

DEFAULT: 1 if a J- face

9. Last block to be modified in the J direction

DEFAULT: NY if a J+ face

10. First block to be modified in the J direction

DEFAULT: 1 if a K- face

11. Last block to be modified in the J direction

DEFAULT: NZ if a K+ face

## Example

```

-- For the local grid refinement LGR1 set a 3000 psi total compressive traction on
the i+, i-, j+ and j- boundaries
-- set a 3000 psi overburden pressure (compressive stress is -ve)
-- note that the 'K-' direction is positive downwards
TRACTBCL
-- side type total
--           traction
  'I+'  1  'LGR1'  -3000 /
  'I-'  1  'LGR1'   3000 /
  'J+'  1  'LGR1'  -3000 /
  'J-'  1  'LGR1'   3000 /
  'K-'  1  'LGR1'  -3000 /
/

```

## TRACTVD

**Requests explicit flux limited transport for tracers**

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword requests the use of the explicit flux limited transport scheme for the tracer calculation. Flux limited transport is a higher-order TVD (total variance diminishing) scheme that reduces numerical dispersion of the tracer (The explicit TVD is implemented with the Van Leer limiter).

The TRACTVD keyword is available for single phase tracers, that is water tracers and hydrocarbon tracers in phases that do not dissolve in the complementary phase. The TRACTVD keyword only supports analytical aquifer facility, but does not work in combination with [PARALLEL](#).

To activate the TRACTVD options, item 5 must be set to 'DIFF' in the RUNSPEC section keyword [TRACERS](#).

See "[Control of numerical diffusion](#)" in the *ECLIPSE Technical Description* for further information.

The TRACTVD keyword has no associated data.

**Example**

```
TRACTVD
```

## TRADS

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

## Tracer adsorption functions

This keyword should only be used when the Environmental Tracer option is active (see the 4th data item in the [TRACERS](#) keyword). The TRADS keyword inputs data describing the adsorption of a tracer on to the rock formation. The keyword should be concatenated with the tracer name.

For example:

TRADSXXX is the keyword required to input adsorption data for tracer XXX as specified in the [TRACER](#) keyword.

The data comprises NTSFUN (see keyword [TABDIMS](#)) tables of tracer adsorption functions, each terminated by a slash (/), describing the adsorption of tracer by the rock formation. Each table applies to its corresponding saturation function region, defined by keyword [SATNUM](#) in the REGIONS section (if NTSFUN > 1).

Each table consists of 2 columns of data. Column:

1. The local tracer concentration in the solution surrounding the rock.

The values should increase monotonically down the column.

The units are those of tracer concentration. By default the concentrations are dimensionless, and can be thought of as:

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/stb for liquid phase tracers, Mscf/Mscf for gas phase tracers (FIELD), scc/scc (LAB)

If a unit has been specified for this tracer in keyword TRACER, the units employed here are:

UNITS: TR/ $\text{sm}^3$  (METRIC), TR/stb for liquid phase tracers, TR/Mscf for gas phase tracers (FIELD), TR/scc (LAB)

where TR is the unit supplied for this tracer.

2. The corresponding saturated concentration of tracer adsorbed on to the rock formation.

These values should increase monotonically down the column.

Units are (for dimensionless tracers, which are thought of as volume fractions as stated above):

UNITS:  $\text{sm}^3/\text{kg}$  (METRIC), stb/lb for liquid phase tracers, Mscf/lb for gas phase tracers (FIELD), scc/gm (LAB)

or (for tracers given units in keyword TRACER):

UNITS: TR/kg (METRIC), TR/lb (FIELD), TR/gm (LAB)

where TR is the unit supplied for this tracer.

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSSFUN (see keyword [TABDIMS](#)).

---

**CAUTION:** The first row in the adsorption tables should consist of a pair of zeroes.

---

**Note:** When adsorption is specified for a partitioned tracer, the adsorped amount is calculated based on the tracer concentration in the solution phase. For the generalized, multi-partitioned tracers (that is a tracer with

MULT specified in the 4th item of the TRACER keyword) the concentration to be used in adsorption calculations can be changed by setting the 6th item of the TRACER keyword.

---

See "[Environmental tracers](#)" in the *ECLIPSE Technical Description* for further information.

Tracer adsorption functions can also be specified using the [ADSORP](#) keyword.

## Example

With NTSFUN=2 and NSSFUN≥5 for tracers WT1 and WT2

```
TRADSWT1

This keyword can be used to specify global-local connections explicitly, rather than have ECLIPSE work them out. If this keyword is entered, then ECLIPSE does not calculate any additional global-local connections for the current refinement. This keyword must be specified when using local grid refinements in an unstructured grid (see the [EXTFIN](#), [EXTHOST](#) and [EXTREPGL](#) keywords). The keyword should be specified between the corresponding [EXTFIN](#) and [ENDFIN](#) pair.

The keyword is followed by any number of records, each terminated with a slash (/). End the set of records with a slash.

The items in each record are:

1. IL, JL, KL The coordinates of the local cell.
2. IG, JG, KG The coordinates of the connecting global cell.
3. TRAN The transmissibility for the connection.

UNITS: cP.rm<sup>3</sup>/day/bars (METRIC), cP.rb/day/psi (FIELD), cP.rcc/hr/atm (LAB), cP.rm<sup>3</sup>/day/atm (PVT-M)

DEFAULT: 0.0

### Example

```

## Transmissibilities in the radial direction

This keyword specifies the transmissibility values explicitly, replacing those calculated by the program. This keyword specifies the transmissibility values in the radial direction, for runs using radial geometry.

The keyword should be followed by one non-negative real number for every grid block in the current input box. The data must be terminated by a slash (/).

The values specified overwrite the R-direction transmissibilities calculated by ECLIPSE for the +R face of each grid block. Thus, a value specified for block (I,J,K) is the transmissibility between blocks (I,J,K) and (I+1,J,K).

UNITS: cP.rm<sup>3</sup>/day/bars (METRIC), cP.rb/day/psi (FIELD), cP.rcc/hr/atm (LAB), cP.rm<sup>3</sup>/day/atm (PVT-M)

Grid blocks are ordered with the R axis index cycling fastest, followed by the theta and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0). Note that spaces must not be inserted on either side of the asterisk.

The TRANR keyword is entirely optional. Any transmissibilities that are not altered remain at the values calculated by ECLIPSE from the GRID data.

### Example

```

-- IR1-IR2 JT1-JT2 KZ1-KZ2
BOX
  5  5  3  8  4  6  /

## Y-direction transmissibility values

This keyword specifies the transmissibility values explicitly, replacing those calculated by the program. The TRANY keyword applies to transmissibilities in the Y-direction.

The keyword should be followed by one non-negative real number for every grid block in the current input box. The data must be terminated by a slash (/).

The values specified overwrite the Y-direction transmissibilities calculated by ECLIPSE for the +Y face of each grid block. Thus, a value specified for block (I,J,K) is the transmissibility between blocks (I,J,K) and (I, J+1, K).

UNITS: cP.rm<sup>3</sup>/day/bars (METRIC), cP.rb/day/psi (FIELD), cP.rcc/hr/atm (LAB), cP.rm<sup>3</sup>/day/atm (PVT-M)

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0). Note that spaces must not be inserted on either side of the asterisk.

---

**Note:** TRANY does not affect non-neighbor connections due to faults.

---

The TRANY keyword is entirely optional. Any transmissibilities that are not altered remain at the values calculated by ECLIPSE from the GRID data.

### Example

```

-- IR1-IR2 JT1-JT2 KZ1-KZ2
BOX
  1  4  3  3  4  6  /
TRANY
12*0 /

```

## Z-direction transmissibility values

This keyword specifies the transmissibility values explicitly, replacing those calculated by the program. The TRANZ keyword applies to transmissibilities in the Z-direction.

The keyword should be followed by one non-negative real number for every grid block in the current input box. The data must be terminated by a slash (/).

The values specified overwrite the Z-direction transmissibilities calculated by ECLIPSE for the +Z face of each grid block. Thus, a value specified for block (I,J,K) is the transmissibility between blocks (I, J, K) and (I, J, K+1).

UNITS: cP.rm<sup>3</sup>/day/bars (METRIC), cP.rb/day/psi (FIELD), cP.rcc/hr/atm (LAB), cP.rm<sup>3</sup>/day/atm (PVT-M)

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*0). Note that spaces must not be inserted on either side of the asterisk.

---

**Note:** TRANZ does not affect non-neighbor connections.

---

The TRANZ keyword is entirely optional. Any transmissibilities that are not altered remain at the values calculated by ECLIPSE from the GRID data.

### Example

```

-- IR1-IR2 JT1-JT2 KZ1-KZ2
BOX
  1  11  1  19  7  7  /
TRANZ
209*0 /

```

## Enable use of transport coefficients

This keyword enables use of transport coefficients. These are entered using the [ALPHA](#), [ALPHAD](#) and [ALPHAI](#) keywords, and are used to control the flow of individual components. These allow the user to boost or hold back the flow of given components as functions of their mole fractions, and hence model fingering effects, particularly in gas injection processes at adverse mobility ratios (see "[Transport coefficients](#)" in the *ECLIPSE Technical Description*).

TRCOEF contains a data item, terminated by a slash (/), used to identify which component is used to look up the transport coefficients.

### Example

Enable the use of transport coefficients. These will be entered as functions of the first component mole fraction.

```
TRCOEF
1 /
```

## TRDCY

## Tracer decay data

This keyword should only be used when the environmental tracer option is active (see item 4 in the [TRACERS](#) keyword). The TRDCY keyword inputs data describing the decay of a tracer. The keyword should be concatenated with the tracer name. For example:

TRDCYXXX is the keyword required to input decay data for tracer XXX, as specified in the [TRACER](#) keyword.

The data comprises NTPVT (see keyword [TABDIMS](#)) tables of tracer decay data, each terminated by a slash (/). Each table applies to its corresponding PVT region, defined by keyword [PVTNUM](#) (if NTPVT > 1).

Each table consists of one item of data for each phase that the tracer exists in.

1. The tracer decay half-life. The specified value should be greater than zero.

UNITS: day (METRIC), day (FIELD), hr (LAB)

DEFAULT: 1E20 days (METRIC), 1E20 days (FIELD), 1E20 hrs (LAB)

---

**Note:** When used with the partitioned tracer option, decay applies to the tracer in the solution phase. when used with the generalized, multi-partitioned tracer option (that is a tracer with MULT specified in item 4 of the TRACER keyword) independent decay half-lives can be entered for each phase that the tracer exists in.

---

---

**Note:** If decay is activated for a tracer together with adsorption, the amount of the tracer adsorped on the rock will also decay according to the half-life specified in TRDCY. For a multi-partitioned tracer with individual, phase specific decay parameters a separate decay half-life can be entered for the amount of adsorped tracer. The decay half-life for adsorped tracer is entered after the parameters for each phase.

---

See "[Environmental tracers](#)" in the *ECLIPSE Technical Description* for further information.

## Example

With NTPVT=2 for single phase tracers WT1 and WT2 and partitioned tracers PT1, PT2 and PT3:

```

TRACER
  WT1  WAT  /
  WT2  WAT  /
  PT1  OIL  1*  WAT  / -- two-phase standard partitioned tracer
  PT2  OIL  1*  MULT / -- two-phase multi-partitioned tracer
  PT3  WAT  1*  MULT / -- two-phase multi-partitioned tracer
/
...
TRDCYWT1
  10.0 /
  10.0 /
TRDCYWT2
  40.0 /
  40.0 /
TRDCYPT1      -- decay parameters apply to solution phase
  30 /
  30 /
TRDCYPT2      -- separate decay parameters for each phase
  30 10 /      -- no decay of adsorped tracer
  30 10 /
TRDCYPT3      -- separate decay parameters for each phase
  30 10 5 /    -- separate decay parameter for adsorped tracer
  30 10 5 /

```

## TRDIF

## Tracer diffusion data

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The TRDIF keyword inputs the tracer diffusion coefficient. The keyword should be concatenated with the tracer name.

For example:

TRDIFXXX is the keyword required to input the diffusion coefficient for tracer XXX as specified in the [TRACER](#) keyword.

The data comprises NTPVT (see keyword [TABDIMS](#)) tables of diffusion data, each terminated by a slash (/). Each table applies to its corresponding PVT region, defined by keyword [PVTNUM](#) (if NTPVT > 1).

Each table consists of one diffusion coefficient for each phase that the tracer exists in.

UNITS: m<sup>2</sup>/day (METRIC), ft<sup>2</sup>/day (FIELD), cm<sup>2</sup>/hr (LAB)

**Note:** When used with the partitioned tracer option, the diffusion applies to the solution phase. When used with the generalized, multi-partitioned tracer option (that is a tracer with MULT specified in item 4 of the TRACER keyword) independent diffusion coefficients can be entered for each phase that the tracer exists in.

See "[Environmental tracers](#)" in the *ECLIPSE Technical Description* for further information.

**Note:** Heterogeneous diffusion can be input by making use of the dispersion keywords [DISPDIMS](#), [TRDIS](#), [DISPERSE](#) and [TRNHD](#).

## Example

With NTPVT=2 for single phase tracers WT1 and WT2 and partitioned tracers PT1 and PT2:

```

TRACER
  WT1  WAT  /
  WT2  WAT  /
  PT1  OIL  1*  WAT  /
  PT2  OIL  1*  MULT /
/
...
TRDIFWT1
  3E-5 /
  3E-5 /
TRDIFWT2
  0.05 /
  0.05 /
TRDIFPT1  -- diffusion coefficients apply to solution phase
  4E-5 /
  4E-5 /
TRDIFPT2  -- separate diffusion coefficients for each phase
  5E-4  9E-4/
  5E-4  9E-4/

```

## TRDIS

## Tracer dispersion table numbers

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The TRDIS keyword inputs the tracer dispersion table numbers. The keyword should be concatenated with the tracer name.

For example:

TRDISXXX is the keyword required to input the dispersion table numbers for tracer XXX as specified in the [TRACER](#) keyword.

---

**Note:** In order to activate the dispersion option for a brine tracer, the required keyword is TRDISBRI.

---

The data comprises NTPVT (see keyword [TABDIMS](#)) tables of dispersion table numbers, each terminated by a slash (/). Each table applies to its corresponding PVT region, defined by keyword [PVTNUM](#) (if NTPVT > 1). The dispersion tables themselves are entered with the [DISPERSE](#) keyword.

Each table consists of the following items of data:

1. The tracer dispersion table number for coefficient  $D_1$ .
2. The tracer dispersion table number for coefficient  $D_2$ .
3. The tracer dispersion table number for coefficient  $D_3$ .
4. The tracer dispersion table number for coefficient  $D_4$ .
5. The tracer dispersion table number for coefficient  $D_5$ .
6. The tracer dispersion table number for coefficient  $D_6$ .
7. The tracer dispersion table number for coefficient  $D_7$ .
8. The tracer dispersion table number for coefficient  $D_8$ .
9. The tracer dispersion table number for coefficient  $D_9$ .

---

**CAUTION:** Whilst for simplicity we use (x,y,z) below, these are not actually the coordinates used. The coordinate system used for dispersion actually follows the rock layers; that is, we actually require data for, and do the calculations in, the i-direction, the j-direction and the k-direction. These may not be the same as (x,y,z) coordinates.

---

The form of dispersion used, to which the table numbers refer, is given by the formula:

$$\left[ \frac{\partial}{\partial x} \frac{\partial}{\partial y} \frac{\partial}{\partial z} \right] \cdot \begin{bmatrix} D_1(|v_x|, c) & D_2(|v_y|, c) & D_3(|v_z|, c) \\ D_4(|v_x|, c) & D_5(|v_y|, c) & D_6(|v_z|, c) \\ D_7(|v_x|, c) & D_8(|v_y|, c) & D_9(|v_z|, c) \end{bmatrix} \cdot \begin{bmatrix} \partial / \partial x \\ \partial / \partial y \\ \partial / \partial z \end{bmatrix} \cdot S_p c \quad \text{Eq. 3.206}$$

where

$c$  is the tracer concentration,

$S_p$  is the host phase saturation, and

the  $v$  terms are the velocities in the normal directions to the faces of the cell.

Note that for a brine tracer, if the `DSPDEINT` keyword has been used, then the *c* terms in the lookup tables are replaced with the cell's water density.

---

**Note:** The option does not work with two-phase or partitioned tracers.

---

See also keywords `DISPDIMS`, `DISPERSE` and `DSPDEINT`.

---

**Note:** This keyword can be used in conjunction with the diffusion (`TRDIF`) option.

---

## Example

With `NTPVT=2` for tracers `WT1` and `WT2`:

```
TRDISWT1
 1 2 2 2 1 2 2 2 1/
 1 2 2 2 1 2 2 2 1/
TRDISWT2
 1 2 2 2 3 2 2 2 1/
 1 1 2 3 4 5 3 2 1/
```

## Reference temperatures

In a run with  $N_c$  components this keyword specifies the reference temperatures at which fluid densities are defined. The keyword can be used either in a run which uses the Zudkevitch Joffe equation, or in a Thermal run (keyword [THERMAL](#) in the RUNSPEC section).

In a live-oil thermal run, the oil component liquid densities are given by:

$$\rho_c = \frac{\rho_{ref_c}}{\left[1 - c_{P_c}(P - P_{ref_c})\right] \left[1 + c_{T1_c}(T - T_{ref_c})\right]} \quad \text{Eq. 3.207}$$

where

$\rho_{ref,c}$  is the reference density, specified with keyword [DREF](#)

$c_{P_c}$  is the oil component liquid compressibility, specified with keyword [CREF](#)

$P_{ref_c}$  is the reference pressure specified with keyword [PREF](#)

$T_{ref_c}$  is the reference temperature, specified with this keyword

$c_{T1_c}$  is the thermal expansion coefficient, specified with keyword [THERMEX1](#).

There should be one value for each component:

UNITS: K (METRIC), °R (FIELD), K (LAB), K (PVT-M)

DEFAULT: the standard temperature set with keyword [STCOND](#)

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered in item 9 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "Equations of state regions" in the *ECLIPSE Technical Description*.

## Example

```
TREF
527.4
527.4 /
```

## TREFS

	SUMMARY
	SCHEDULE

## Reference temperatures for surface EoS

This optional keyword supplies reference temperatures for use in the surface calculations. The default, if this is not supplied, is for these to follow the reservoir values supplied with [TREF](#).

UNITS: K (METRIC), °R (FIELD), K (LAB), K (PVT-M)

### Example

```
TREFS
527.4 527.4 /
```

If multiple equations of state are being used, a set of data should be entered for each surface EoS. The number of surface equation of state regions is entered in item 10 of [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of State Regions](#)" in the *ECLIPSE Technical Description*.

## TREFT

## Reference temperatures

This keyword can only be used with the thermal option (keyword [THERMAL](#) in the RUNSPEC section).

TREFT is an alias for [TREF](#). This keyword was introduced to facilitate export of thermal data from PVT *i*. It makes no difference to the simulator whether this keyword or the older TREF keyword is used.

## TRKPF

## Defines tracer partitioning regions

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword should only be used when the partitioned tracer option is active (see the [PARTTRAC](#) keyword). The TRKPF keyword inputs the region/table number which specifies the partitioning function to use for each grid block. The keyword should be concatenated with the tracer name. For example:

TRKPFXXX is the keyword required to input adsorption data for tracer XXX as specified in the [TRACER](#) keyword.

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

In ECLIPSE 100 these keywords can now be used in conjunction with [ADD](#), [ADDREG](#), [MULTIPLY](#) or [MULTIREG](#), in addition to [EQUALS](#), [EQUALREG](#) and [COPYBOX](#).

### Example

With NKPTMX=2 specified in the [PARTTRAC](#) keyword; NDIVIX=8, NDIVIY=6 and NDIVIZ=5 specified in RUNSPEC keyword [DIMENS](#); and no input [BOX](#) set:

```
TRKPFTRA
144*1 96*2 /
```

## TRNHD

## Enables speed-up of dispersion calculation for non-homogeneous diffusion

x	ECLIPSE 100
	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The TRNHD keyword enables simplifications to be made to the dispersion calculation when dispersion is only being used to enable nonhomogeneous constant coefficient diffusion. In effect it is used when all the tables in the matrix in [TRDIS](#) are set to constants (that is there is no dependence on velocity or concentration) and all the off-diagonal terms in the table are to be set to zero. The keyword should be concatenated with the tracer name. For example:

TRNHDXXX is the keyword required to inform ECLIPSE that the dispersion coefficients for tracer XXX as specified in the [TRACER](#) keyword are diagonal and independent of velocity and concentration.

This keyword has no associated data.

### Example

```
TRNHDWT1
TRNHDWT2
```

## TRPLPORO Use the triple porosity model

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies that the run will use the specialist version of multi porosity which models vuggy carbonates as a triple porosity (matrix, fracture, vugs) system.

In ECLIPSE 300 this keyword activates the multi-porosity option to perform the simulation. In ECLIPSE 100 input and coding similar to the ECLIPSE 300 multi-porosity option is used, although there is no general multi-porosity treatment available in ECLIPSE 100. See "[Triple porosity](#)" in the *ECLIPSE Technical Description*.

The keyword should be followed by one data item, defining the number of matrix porosities required (NOT the total number of porosities - it excludes the fracture). This is the same usage as [NMATRIX](#) for standard multi porosity. For the purpose of this usage, vugs are defined as additional matrix porosities. The number of matrix porosities must be either 2 (if only vugs with connections to the fracture are modeled, so that the porosities are matrix and connected vugs) or 3 (if additional vugs connected only to the matrix are also modeled, so that the porosities are matrix, connected vugs and isolated vugs). The data item should be followed by a slash (/).

This keyword is an alternative to [NMATRIX](#); the two keywords may not be used together in the same deck.

This model is not compatible with the use of block to block connections ([BTOBALFA](#) or [BTOBALFV](#)) or with the use of [DPNUM](#) to create a single porosity region in a dual porosity run.

ECLIPSE 100

---

**Note:** This keyword cannot be used in parallel runs (that is if the [PARALLEL](#) keyword is present).

---

### Example

```
TRPLPORO
3 /
```

## TRROCK

## Specifies the tracer-rock properties

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword should only be used when the environmental tracer option is active (see item 4 in the [TRACERS](#) keyword). The data comprises NTSFUN (see keyword [TABDIMS](#)) tables specifying the rock properties that are required for the tracer adsorption model. Each table of rock properties applies to its corresponding saturation function region, defined by keyword [SATNUM](#) (if NTSFUN >1).

Each table consists of either 2 or 3 items of data, terminated by a slash (/):

1. The adsorption index to be used for this rock type.

Possible values for the adsorption index are 1 or 2.

If a value of 1 is selected, then the tracer adsorption isotherm is retraced whenever the local tracer concentration in the solution decreases.

If a value of 2 is selected, then no tracer desorption may occur.

2. The mass density of this rock type at reservoir conditions.

This quantity is used in the calculation of the tracer loss due to adsorption.

UNITS: kg/rm<sup>3</sup> (METRIC), lb/rb (FIELD), gm/rcc (LAB)

---

**Note:** If either the polymer or surfactant models are active, then the mass density entered here will be ignored. The rock mass density will be taken from the [PLYROCK](#) keyword if present, or otherwise from the [SURFROCK](#) keyword.

---

3. The adsorption initialization model (an integer, either 1 or 2).

This item controls the initial distribution of tracer when adsorption is active.

Two options are available:

- 1 The input tracer concentration partitions between the fluid and rock, conserving the input mass of tracer. (The total mass of tracer equals the input concentration in the fluid.)
- 2 The input tracer concentration will be honored and extra adsorbed tracer is added to the rock, to be in equilibrium with the input fluid concentration.

DEFAULT: 1

The rock mass for a grid block is given by:

$$\text{Rock mass} = V\rho_r \frac{(1-\varphi)}{\varphi} \quad \text{Eq. 3.208}$$

where

$V$  is the block pore volume (at reference pressure)

$\rho_r$  is the rock density, item 2 above

$\varphi$  is the block porosity

The rock mass can be output using 'ROCKMASS' in the [RPTSOL](#) keyword.

See also the [TRADS](#) and "Environmental tracers" in the *ECLIPSE Technical Description* for further information.

## Example

With NTSFUN=3

```
TRROCK
2  0.00012 /
1  0.00014  1 /
1  0.00015  2 /
```

# TSCRIT

## Timestepping criteria

x	<b>ECLIPSE 300</b>
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword sets a number of values used to control the timestepping of the simulator through the schedule. The data consists of some or all of the following data items, terminated with a slash (/). items not specified take their default values.

1. Length of the initial timestep.  
 UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)  
 DEFAULT: 1.0 Fully implicit or AIM (all unit sets)  
 DEFAULT: 0.25 IMPES (all unit sets)
2. Minimum timestep.  
 UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)  
 DEFAULT: 0.02 (all unit sets)  
 DEFAULT: 0.0002 Thermal option (all unit sets)
3. Maximum timestep.  
 UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)  
 DEFAULT: 50 (all unit sets)
4. Maximum step length increase factor.  
 DEFAULT: 2  
 DEFAULT: 1.5 Thermal option
5. Maximum step length decrease factor  
 DEFAULT: 0.5
6. Target TTE (time truncation error).  
 DEFAULT: 0.2 Fully implicit, AIM or IMPSAT  
 DEFAULT: 0.05 IMPES  
 Thermal option  
 DEFAULT: 1.0E+20
7. Maximum TTE.  
 DEFAULT: 10 or 100 (if `OPTIONS3 item 14 > 0`) Fully implicit or IMPSAT  
 DEFAULT: 0.5 IMPES  
 DEFAULT: 2.0 AIM  
 Thermal option  
 DEFAULT: 1.0E+20 (not used by default)
8. Target throughput ratio.  
 Note this value is the worst taken over all cells and flowing components.  
 DEFAULT: Not used Fully implicit  
 DEFAULT: 0.5 IMPES or AIM
9. Maximum worst throughput ratio.

DEFAULT: Not used Fully implicit

DEFAULT: 1.0 IMPES, AIM or IMPSAT

10. Target normalized solution change.

DEFAULT: 0.2 Fully implicit or AIM

DEFAULT: 0.05 IMPES

If [item 14](#) in `OPTIONS3` is set to a non-zero value, then the above default values will be increased by a factor of 10.

*Thermal option*

DEFAULT: 100

Changing this value will change the default value for item 13 of keyword `CVCRIT`.

11. Length of timestep after a well modification and is active due to well control modifications or a well opening/closing.

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

DEFAULT: 40 Fully implicit, AIM or IMPSAT (all unit sets)

DEFAULT: 10 IMPES (all unit sets)

If [item 69](#) in `OPTIONS3` is set to a non-zero value, then the above default values will be halved.

*Thermal option*

DEFAULT: 5 for Thermal simulations (all unit sets)

12. Target pressure change.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

DEFAULT: 100 atm

13. Maximum normalized solution change.

DEFAULT: 10 or 100 (if [item 14](#) in `OPTIONS3` > 0) Fully implicit

DEFAULT: 2.0 AIM

DEFAULT: 0.5 IMPES

*Thermal option*

DEFAULT: 1.0E+20 (not used by default)

14. Target average throughput ratio across field (IMPSAT only)

DEFAULT: 0.25

15. Target saturation change (ECLIPSE thermal option only).

DEFAULT: 0.3

16. Maximum saturation change (ECLIPSE thermal option only).

DEFAULT: 0.9

17. Target temperature change (ECLIPSE thermal option only).

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

DEFAULT: 1.0E+20 (not used by default)

Changing this value will change the default value for item 14 of keyword `CVCRIT`.

18. Maximum temperature change (ECLIPSE thermal option only).  
UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)  
DEFAULT: 1.0E+20 (not used by default)
19. Maximum number of consecutive forced timesteps before stopping the run (ignored if <0)  
DEFAULT: -1
20. Maximum number of reduced timesteps before stopping the run (ignored if <0)  
DEFAULT: -1
21. Target solid saturation change (CO2STORE option only)  
DEFAULT: 0.05
22. Maximum solid saturation change (CO2STORE option only)  
DEFAULT: 0.2

---

**CAUTION:** Changing these criteria can adversely affect the stability.

---

The TTE and solution change values are normalized to unity - that is a 0.05 solution change represents and is equivalent to a saturation change of this order.

---

**Note:** Data input with the TSCRIT keyword are not stored for flexible restarts. The keyword must be re-specified in the restart run (outside of any SKIPREST keywords) in order for changes to take effect.

---

## Example

Set an initial timestep of 0.1 days, and a maximum timestep of 100 days.

```
TSCRIT  
0.1 1* 100 /
```

## Advances simulator to new report time(s)

The keyword should be followed by up to 1000 real numbers, each of which is a time interval through which the simulator is to be advanced. The data should be terminated with a slash (/).

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

After each timestep a report of the current state of the reservoir is produced (see the [RPTSCHED](#) keyword).

Note that repeat counts (for example 6\*30.5) can be used if required (with no spaces before or after the asterisk).

### Example

```
TSTEP
31 28 31 30 31 30
31 31 30 31 30 31 /
```

## TUNING

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

## Sets simulator control parameters

The TUNING keyword should be used with great care. In general, the only parameters which may need to be altered from their default values are TSINIT, TSMAXZ and LITMAX. For example, Coning studies usually require a small timestep initially or following a significant well rate change in order to avoid a timestep chop. Changes to other parameters, and in particular to the convergence controls in section 2, are not recommended. See also the keyword [NEXTSTEP](#), and "[Convergence reports](#)" in the *ECLIPSE Technical Description*.

The data comprises 3 records, each of which must be terminated by a slash (/). If a slash is encountered before the end of a record, the remaining items in the record are not altered.

## ECLIPSE 100

Default TUNING parameters are reset by the RUNSPEC section keywords [IMPES](#) and [IMPLICIT](#).

## Record 1: Timestepping controls

1. TSINIT Maximum length of next timestep  
UNITS: day (METRIC), day (FIELD), hr (LAB)  
DEFAULT: 1.0 (all unit sets)
2. TSMAXZ Maximum length of timesteps after the next  
UNITS: day (METRIC), day (FIELD), hr (LAB)  
DEFAULT: 365.0 (all unit sets)
3. TSMINZ Minimum length of all timesteps  
UNITS: day (METRIC), day (FIELD), hr (LAB)  
DEFAULT: 0.1 (all unit sets)
4. TSMCHP Minimum choppable timestep  
UNITS: day (METRIC), day (FIELD), hr (LAB)  
DEFAULT: 0.15 (all unit sets)
5. TSFMAX Maximum timestep increase factor  
DEFAULT: 3.0
6. TSFMIN Minimum timestep cutback factor  
DEFAULT: 0.3
7. TSFCNV Factor by which timestep is cut after convergence failure  
DEFAULT: 0.1
8. TFDIFF Maximum increase factor after a convergence failure  
DEFAULT: 1.25
9. THRUPT Maximum throughput ratio  
DEFAULT: 1E20 (Implicit), 0.2 (IMPES)

10. TMAXWC Maximum length of the next timestep following a well modification  
UNITS: day (METRIC), day (FIELD), hr (LAB)  
DEFAULT: No limit

## **Record 2: Time truncation and convergence controls**

1. TRGTTE Target time truncation error  
DEFAULT: 0.1 (Implicit), 1.0 (IMPES)
2. TRGCNV Target non-linear convergence error  
DEFAULT: 0.001 (Implicit) 0.5 (IMPES)
3. TRGMBE Target material balance error  
DEFAULT: 1.0E-7
4. TRGLCV Target linear convergence error  
DEFAULT: 0.0001 (Implicit), 0.00001 (IMPES)
5. XXXTTE Maximum time truncation error  
DEFAULT: 10.0
6. XXXCNV Maximum non-linear convergence error  
DEFAULT: 0.01 (Implicit), 0.75 (IMPES)
7. XXXMBE Maximum material balance error  
DEFAULT: 1.0E-6
8. XXXLCV Maximum linear convergence error  
DEFAULT: 0.001 (Implicit), 0.0001 (IMPES)
9. XXXWFL Maximum well flow rate convergence error  
DEFAULT: 0.001
10. TRGFIP Target Fluid-in-place error for LGR runs  
DEFAULT: 0.025
11. TRGSFT Target surfactant change (Surfactant Model only)  
DEFAULT: No limit
12. THIONX Threshold for damping in ion exchange calc. (Multi-Comp. Brine Model only)  
DEFAULT: 0.01
13. TRWGHT Weighting factor for active tracer updates when called from Newton Loop.  
(=0 fully decoupled; =1 fully coupled)  
DEFAULT: 1

The Maximum values should always be greater than the Target values. ECLIPSE 100 iterates to meet the target values but the timestep is accepted if all the maximum tolerances have been satisfied.

### Record 3: Control of Newton and linear iterations

1. NEWTMX Maximum number of Newton iterations in a timestep  
DEFAULT: 12 (Implicit), 4 (IMPES)
2. NEWTMN Minimum number of Newton iterations in a timestep  
DEFAULT: 1
3. LITMAX Maximum number of linear iterations in a Newton iteration  
DEFAULT: 25
4. LITMIN Minimum number of linear iterations in a Newton iteration  
DEFAULT: 1
5. MXWSIT Maximum number of iterations within well flow calculation  
DEFAULT: 8
6. MXWPIT Maximum number of iterations for BHP in THP controlled wells  
DEFAULT: 8
7. DDPLIM Maximum pressure change at last Newton iteration  
UNITS: bars (METRIC), psi (FIELD), atm (LAB)  
DEFAULT: 1.0E6 (all unit sets)
8. DDSLIM Maximum saturation change at last Newton iteration  
DEFAULT: 1.0E6 (all unit sets)
9. TRGDPR Target maximum pressure change in a timestep  
UNITS: bars (METRIC), psi (FIELD), atm (LAB)  
DEFAULT: 1.0E6 (Implicit), 100.0 (IMPES) (all unit sets)
10. XXXDPR Maximum tolerable pressure change in a timestep  
UNITS: bars (METRIC), psi (FIELD), atm (LAB)

See also keyword [TUNINGDP](#).

---

**Note:** The TUNING data is kept on the restart file so that it will apply to any subsequent restart run unless it is reset in the restart run. Whenever TUNING is declared with the TSINIT field defaulted, then TSINIT is set equal to 1.0.

---

## Examples in ECLIPSE 100

### Example 1

To set all the default values explicitly:

```
TUNING
1 365 0.1 0.15 3 0.3 0.1 1.25 0.75 /
0.1 0.001 1E-7 0.0001
```

```

10      0.01      1E-6      0.001      0.001      /
12  1  25  1  8  8  4*1E6      /

```

### Example 2

To limit the next timestep to one tenth of a day, and to impose an upper limit of 10 days for all subsequent timesteps:

```

TUNING
0.1  10.0  /
      /
      /

```

### Example 3

To set **IMPES** defaults with relaxed material balance:

```

IMPES
/
TUNING
2*  1E-5  3*  1E-4  /
      /

```

### Example 4

To ensure that pressure and saturation changes are small at the last Newton iteration. In this case it is also advisable to set a minimum of 3 linear iterations or to tighten the convergence of the linear equations to avoid the situation where the non-linear equations are required to be solved to a higher accuracy than the linear equations:

```

TUNING
/
/
      LITMIN      DDPLIM      DDSLIM
12  1  25  3  8  8  0.0001  0.0001  /

```

### Example 5

To run the Chappelaar Nolen Coning study with relaxed controls:

```

TUNING
/ TIM.TRC  NLN.BNC  MAT.BAL  LIN.CNV
0.1      0.5      0.0001  .001
10.0     1.0      0.001   .01
/
12  1  25  1  8  8
/

```

### Example 6

To obtain consistency of an **IMPES** run with older versions of ECLIPSE 100 by increasing the throughput constraint to a large value, making it ineffectual:

```

TUNING
1  365  0.1  0.15  3  0.3  0.1  1.25  1.0E10  /
/
/

```

## ECLIPSE 300

This keyword should be used with great care. In general, the only parameters that may need to be altered from their default values are the first three, which control the initial timestep and the minimum and maximum timestep.

This keyword duplicates some of the functionality of the [TSCRIT](#) and the [CVCRIT](#) keywords.

The TUNING keyword is copied from ECLIPSE 100 and therefore has a number of parameters that are not used in ECLIPSE 300.

These unused parameters are read in as normal and then ignored by ECLIPSE 300. The default values may differ from those in ECLIPSE 100.

The data comprises 3 sections each of which must be terminated by a slash (/). If a slash is encountered before the end of a section, the remaining items in the section are not altered.

### Record 1:Timestepping controls

1. Maximum length of next timestep.  
 UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)  
 DEFAULT: 1.0 Fully Implicit (first step), 0.5 IMPES (first step), No Action Subsequent timesteps (all unit sets)
2. Maximum length of all timesteps  
 UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)  
 DEFAULT: 50 (all unit sets)
3. Minimum length of all timesteps  
 UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)  
 DEFAULT: 0.02, 0.0002 (Thermal option) (all unit sets)
4. Not used.
5. Maximum timestep increase factor  
 DEFAULT: 2.0
6. Minimum timestep cutback factor  
 DEFAULT: 0.3
7. Not used.
8. Not used.
9. Maximum throughput ratio  
 DEFAULT: Not used Fully Implicit  
 DEFAULT: 1.0 IMPES, AIM or IMPSAT
10. Length of the next timestep following a well modification (same at item 11 of [TSCRIT](#)) and is active due to well control modifications or a well opening/closing.  
 UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

DEFAULT: 40 Fully implicit, AIM or IMPSAT; 10 IMPES; 5 for Thermal simulations

If [item 69](#) in OPTIONS3 is set to a non-zero value, then the above default values for FULLIMP, AIM, IMPSAT and IMPES will be halved.

## Record 2: Time truncation and convergence controls

1. Target TTE (time truncation error).

DEFAULT: 0.2 Fully Implicit, AIM or IMPSAT; 0.05 IMPES; 1.0E+20 for Thermal simulations

2. Maximum non-linear convergence error.

DEFAULT: 0.001

3. Maximum material balance error.

DEFAULT: 0.000001

4. Target reduction in the square of the relative residual norm in the linear solver.

DEFAULT: Improvement by factor of 1.0E-10 in the **square** of the residual.

**This is the required reduction in RMS<sup>2</sup>.**

5. Maximum TTE (Time Truncation Error)

DEFAULT: 10 or 100 (if OPTIONS3 item [14](#) > 0) Fully Implicit or IMPSAT; 0.5 IMPES; 2.0 AIM; 1.0E+20 for Thermal simulations

6. Not used.

7. Not used.

8. Not used.

9. Not used.

10. Not used.

11. Tolerance on the square of the absolute residual norm in the linear solver.

12. Target normalized solution change.

DEFAULT: 0.2 Fully Implicit, 0.05 IMPES or AIM

13. Maximum normalized solution change.

DEFAULT: 10 Fully Implicit, 0.5 IMPES or AIM

14. Maximum fugacity (phase equilibrium) error convergence criterion.

DEFAULT: 0.001

## Record 3: Control of Newton and linear iterations

1. Maximum number of non-linear iterations in a timestep.

DEFAULT: 20 Fully Implicit, 15 Fully Implicit and Thermal, 6 IMPES, 12 AIM

2. Minimum number of non-linear iterations in a timestep.

DEFAULT: 1, 2 (Thermal option)

3. Maximum number of linear iterations (LITMAX)

- DEFAULT: 40, 20 if using the [JALS](#) solver or [CPR](#) solver
4. Minimum number of linear iterations in a Newton iteration  
DEFAULT: 1
  5. Maximum number of iterations within well flow calculation  
DEFAULT: 40
  6. Not used.
  7. Maximum pressure change at last Newton iteration  
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)  
DEFAULT: no-limit
  8. Maximum saturation change at last Newton iteration.  
DEFAULT: no-limit
  9. Target maximum pressure change in a timestep.  
UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)  
DEFAULT: 100 atm
  10. Not used.

### Example in ECLIPSE 300

```
TUNING
1 365 0.1 1* 3 0.3 2* 0.75 /
4* 10 /
12 1 25 1 3* 1E6 /
```

## TUNINGDP

## Resets the simulator control parameters for high throughput cases

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The TUNINGDP keyword, like the TUNING keyword, should be used with great care. Using the keyword followed by just a slash (/) modifies the simulator convergence parameters, since the default parameters with the keyword present are not the same as the defaults with the keyword absent.

The convergence parameters set in this keyword have been found to be suitable in a number of high throughput cases, typically dual porosity runs. The keyword has two effects: firstly the linear equations are solved to a tighter tolerance and secondly the non-linear equations are assumed to be converged when the change in solution over a Newton iteration falls below a critical value, irrespective of the non-linear convergence error. Essentially, convergence is assumed when **either** the residual is small **or** the solution change is small. The convergence criterion on the material balance error is unaffected, and must still be satisfied to achieve convergence.

The convergence criterion on the solution change (items 3 and 4) can override the criterion on the residual, and thus has the potential to allow a poorly converged solution to be accepted with a higher than normal residual.

Note that the TRGLCV and XXXLCV parameters are also set in the TUNING keyword and are reset by keywords [IMPES](#) and [IMPLICIT](#).

The TUNINGDP keyword should be followed by some or all of the following items of data terminated by a slash (/). If a slash is encountered before the end of the record, the remaining items assume their default values given below.

- TRGLCV Target linear convergence error  
 DEFAULT: 0.00001 (if TUNINGDP is present)  
 DEFAULT: 0.0001 (if TUNINGDP is not present)
- XXXLCV Maximum linear convergence error  
 DEFAULT: 0.0001 (if TUNINGDP is present)  
 DEFAULT: 0.001 (if TUNINGDP is not present)
- TRGDDP Maximum pressure change during a Newton iteration, allowing convergence when the residual is still above its convergence criterion.  
 UNITS: bars (METRIC), psi (FIELD), atm (LAB)  
 DEFAULT: 1.0 (if TUNINGDP is present) (all unit sets)  
 DEFAULT: 0.0 (if TUNINGDP is not present) (all unit sets)
- TRGDDS Maximum saturation change during a Newton iteration allowing convergence when the residual is still above its convergence criterion  
 DEFAULT: 0.01 (if TUNINGDP is present)  
 DEFAULT: 0.0 (if TUNINGDP is not present)

See also keyword [TUNING](#).

## Example

Use the TUNINGDP defaults for a high throughput case:

```
TUNINGDP  
/
```

## TUNINGH

## Tuning parameters for gradient calculations

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

TUNINGH can be used to reset the convergence criteria for the linear equations solved for the Gradient option. If it is not specified, the criteria are the same as for the simulation (keyword [TUNING](#)).

The keyword should be followed by some or all of the following data items, ending with a slash (/).

GRGLCV Target linear convergence error  
 DEFAULT: 0.0001 (or TRGLCV in [TUNING](#) if specified)

GXXLCV Maximum linear convergence error  
 DEFAULT: 0.001 (or XXXLCL in [TUNING](#) if specified)

GMSLCV Reduction in RMS  
 DEFAULT: 1.0E-20

LGTMIN Minimum number of linear iterations  
 DEFAULT: 1 (or LITMW in [TUNING](#) if specified)

LGTMAX Maximum number of linear iterations  
 DEFAULT: 25 (or LITMAX in [TUNING](#) if specified)

These parameters just change the default parameters of the linear solver for the gradient calculation, independently of the values used for the Newton iterations (see "[Solution of the linear equations](#)" in the *ECLIPSE Technical Description*).

When using Local Grid Refinement, values specified for TUNINGH will also override data in [TUNINGL](#); otherwise, tuning parameters specified in TUNINGL are used for the local component of the linear equations.

The *GMSLCV* criterion measures a reduction in *RMS*, and is deemed to be satisfied, if for each phase  $p$ ,

$$\frac{\|R_p\|_2}{\|R_p^o\|_2} < GMSLCV \quad \text{Eq. 3.209}$$

where

$$\|R_p\|_2 = \sqrt{\frac{\sum_{i=1}^N \left(\frac{R_{i,p}}{PV_i}\right)^2}{N}} \cdot \Delta t \cdot \bar{B}_p \quad \text{Eq. 3.210}$$

with

$R_p$  = linear residual for phase  $p$

$R_p^o$  = initial linear residual for phase  $p$

$R_{i,p}$  = residual for phase  $p$  in grid cell  $i$

$PV_i$  = pore volume for cell  $i$

$N$  = total number of active cells

$\Delta T$  = timestep

$\bar{B}_p$  = field average formation volume factor for phase  $p$

### Example

```
TUNINGH
0.001 0.01 0.00001 /
```

## TUNINGL

# Simulator control parameters for local grids

x	<b>ECLIPSE 100</b>
	<b>ECLIPSE 300</b>
x	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

TUNINGL can be used to set the simulator control parameters for local grids. The keyword data is the same as for [TUNING](#).

The data entered with keyword TUNINGL applies to **all** local grids.

The [TUNINGS](#) keyword may also be used to set control parameters individually for specific local grids.

## TUNINGS

## Simulator control parameters for individual local grids

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

TUNINGS can be used to set the simulator control parameters for a nominated local grid.

Tuning data for local grids can also be set using the keyword [TUNINGL](#); this will apply to **all** local grids, except for any which have their tuning data set individually with TUNINGS.

The data comprises 4 records, each of which must be terminated by a slash (/). If a slash is encountered before the end of a record, the remaining items in the record are not altered.

### Record 1

Record 1 is the name of the local grid to which the subsequent tuning data applies.

### Records 2 to 4

Records 2 to 4 are the same as records 1 to 3 in the [TUNING](#) and [TUNINGL](#) keywords.

### Example

To limit the next timestep to one tenth of a day, and to impose an upper limit of 10 days for all subsequent timesteps and limit the timestep to 5 days after each well modification in local grid LGRPOW:

```
TUNINGS
LGRPOW
0.1 10.0 8* 5 /
/
/
```

## TVDP

## Initial tracer concentration versus depth tables

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

The keyword specifies the depth tables to be used for initializing the concentration of a tracer in each grid block. The actual keyword to be used is a concatenated name of up to 8 characters in length, which consists of the following segments.

Segment:

1. Characters 1-4 must be the character string TVDP
2. (ECLIPSE 100 only) Character 5 must be the letter F or S.

For a tracer whose associated stock tank phase can only exist in the free state, the letter F (free) must be used. This case includes all water phase tracers, oil phase tracers unless **VAPOIL** is specified in the RUNSPEC section, and gas phase tracers unless **DISGAS** is specified in RUNSPEC.

For a tracer whose associated stock tank phase can exist in the solution state (for example, gas when **DISGAS** is specified in the RUNSPEC section, and oil when **VAPOIL** is in RUNSPEC) the letter S (solution) should be specified as well as F. Thus, such a tracer which can partition between two phases requires both the free and solution component concentrations to be initialized.

ECLIPSE 100

3. Characters 6-8 must be the name of the tracer which is to be initialized. Surfactant concentrations can be input using the character string SUR and foam concentrations using FOA.

ECLIPSE 300

4. Characters 5-7 must be the name of the tracer which is to be initialized

The data comprises NTTRVD (see keyword **EQLDIMS**) tables of initial tracer concentration versus depth, one for each tracer concentration region, to allow a particular tracer to be initialized.

Each table consists of 2 columns of data, and must be terminated by a slash (/). Column:

1. Depth values.

The values should increase monotonically down the column.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

2. The corresponding initial tracer concentration values.

Values are should be  $\geq 0.0$

There must the same number of entries in each column of a given table. This number should not be less than 2 or greater than NSTRVD (see keyword **EQLDIMS**).

ECLIPSE 100 only

If a unit for tracer amount has been supplied in item 3 of keyword **TRACER**, then the unit of tracer concentration is

UNITS: TR/sm<sup>3</sup> (METRIC), TR/stb for liquid phase tracers, TR/Mscf for gas phase tracers (FIELD), TR/scc (LAB)

where TR is the unit supplied for the tracer. For gas phase tracers the field units are TR/Mscf.

See also keyword **TNUM**.

ECLIPSE 100 only

---

**Note:** From 2011.1 onwards any non-zero concentrations specified for cells containing none of the host phase are automatically reset to zero. Previous behavior can be restored using [item 165](#) in **OPTIONS**.

---

## Examples

### Example 1

ECLIPSE 100

Where VAPOIL specified, NTTRVD=1, NSTRVD=2, oil phase tracer VOL:

```
TVDPFVOL
2000.0 0.0
6000.0 0.0 /
TVDPSVOL
2000.0 1.0
6000.0 1.0 /
```

### Example 2

Where VAPOIL not specified, NTTRVD=2, NSTRVD=2, oil phase tracer OR1:

```
TVDPFOR1
3000.0 1.0
4000.0 1.0 /
4000.0 0.0
5000.0 0.0 /
```

### Example 3

ECLIPSE 300

Where NTTRVD=1, NSTRVD=3, Tracer TRA

```
TVDPTRA
1000.0 0.34
4000.0 0.35
6000.0 0.39 /
```

## TZONE

## Controls the transition zone option

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The TZONE keyword can only be used when the end-point scaling option is active (see keywords [ENDSCALE](#) in the RUNSPEC section).

The keyword should be followed by up to 3 logical switches, either T for True or F for False (**no** quotes). The three switches apply to the three phases: oil, water and gas.

If a phase switch is set True then the critical saturations for that phase will be modified to be the initial immobile saturation in regions where the saturation is below the input critical value.

If the oil phase switch is set True, ECLIPSE modifies [SOWCR](#) only for oil-water or oil-water-miscible gas runs, and [SOGCR](#) is only modified in oil-gas runs.

If the water phase switch is set True, ECLIPSE modifies [SWCR](#).

If the gas phase switch is set True, ECLIPSE modifies [SGCR](#) only for gas-water or oil-gas runs.

Output of the processed end points used in the simulation can be requested with SOWCR, SOGCR, SWCR and SGCR in the [RPTSOL](#) and [RPTRST](#) keywords, but the output is headed by arguments PSOWCR, PSOGCR, PSWCR and PSGCR respectively.

See "[Saturation table scaling](#)" in the *ECLIPSE Technical Description* for details of the endpoint scaling procedure.

### Example

```
TZONE
F T F /
```

## **U**

This section contains an alphabetic listing of keywords starting with the letter U.

## UDADIMS

## Dimensions for the user defined arguments facility

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The UDADIMS keyword enables users to define argument quantities in the SCHEDULE section for well keywords:

- [WALKALIN](#), [WCONINJE](#), [WECON](#), [WFOAM](#), [WSALT](#), [WSURFACT](#), [WAPI](#), [WCONPROD](#), [WELLSTRE](#), [WPOLYMER](#), [WSOLVENT](#), [WTRACER](#), [WELDRAW](#), [WTADD](#), [WTMULT](#), [WINJEDET](#), [WECONCMF](#), [WINJTEMP](#)

and group keywords:

- [GCONPRI](#), [GCONPROD](#), [GCONINJE](#), [GECON](#), [GCONSALE](#), [GCONSUMP](#), [GRUPFUEL](#), [GRUPSALE](#), [GTADD](#), [GTMULT](#).

and segment keyword:

- [WSEGTABL](#)

and connection keywords:

- [CECON](#), [CSKIN](#)

and keyword:

- [LINCOM](#).

The User Defined Arguments (UDAs) are specified by a corresponding [UDQ](#), which can either be constants, or be composed of ECLIPSE summary keywords in conjunction with a number of mathematical functions. The required values for UDAs are taken from the corresponding UDQs. A UDA can only be used after the initialization of the corresponding UDQ

The data consists of some or all of the following items which specify dimensions associated with the UDAs. The data must be terminated by a slash (/).

1. The number of keyword arguments in which UDQs replace numeric values.  
DEFAULT: 0
2. item 2 is retained for the sake of back-compatibility.  
DEFAULT: 0
3. The total number of unique instances in which a UDQ is used in a keyword argument.  
DEFAULT: 100

item 3 differs from item 1 in the sense that if only the oil rate argument of [WCONPROD](#) is specified by a UDQ, then item 1 equals 1. But if this argument is used separately in two lines of [WCONPROD](#) data, then item 3 equals 2.

---

**Note:** Only well, group or field UDQs are acceptable in the user defined arguments.

---

---

**Note:** In the pre-2010.1 version, items 1 and 2 were used for well and group UDAs respectively.

---

## UDQ

## User defined quantities

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The UDQ keyword enables users to define summary quantities in the SCHEDULE section. The user defined quantities can either be constants, or composed of ECLIPSE summary quantities in conjunction with a number of mathematical functions. User defined quantities are identified by a "U" as the second character of the name. Connection, field, group, region, segment, well, aquifer and block quantities are permitted. With the exception of the field mnemonics these quantities are vectors with elements for each corresponding entity. The user defined summary quantities can be output by including them in the SUMMARY section using the conventional syntax. Since the user defined quantity will not be defined at this point, additional care should be taken to ensure that the quantity names match their later initializations. User defined summary quantities that are not initialized will return the value specified by item 3 of the UDQPARAM keyword.

User defined quantities can be used in two modes; either a value can be assigned to elements of the quantity, or the quantity can be defined in terms of existing ECLIPSE summary quantities. Elements of the arrays which are not assigned a value are marked as undefined. Internally these elements remain undefined, however when they are output in the form of a summary vector or tested in an ACTION (ACTIONG, ACTIONR, ACTIONW, ACTIONS, ACTIONX) keyword, undefined elements are set to the value specified by item 3 of the UDQPARAM keyword.

User defined quantities can be also used for user defined arguments (UDA) in the SCHEDULE section for well keywords:

- WALKALIN, WCONINJE, WECON, WELDRAW, WFOAM, WSALT, WSURFACT, WAPI, WCONPROD, WELLSTRE, WPOLYMER, WSOLVENT, WTRACER, WTADD, WTMULT, WINJEDET, WECONCMF

and group keywords:

- GCONPRI, GCONPROD, GCONINJE, GECON, GCONSALE, GCONSUMP, GRUPFUEL, GRUPSALE, GTADD, GTMULT

and connection keywords:

- CECON, CSKIN

and keyword:

- LINCOM.

The user defined arguments are specified by a corresponding UDQ and keyword UDADIMS.

---

**Note:** UDAs require one timestep to take effect after the keyword containing the UDA is read.

---

**Note:** ECLIPSE 300 does not output the summary quantities at initial time (T=0), while ECLIPSE 100 does. Typically the undefined value, item 3 of UDQPARAM keyword, is output. It should be noted that it is possible to change the value at timestep zero by using ASSIGN and putting the UPDATE status ON. See below.

---

A user defined quantity is initialized by either entering an assignment or a definition, with the order of evaluation following the order of initialization. User defined quantities may refer to other user defined quantities providing they have already been initialized. Assignment differs from definition in that assignment is processed immediately, whilst a definition is evaluated after the following timestep. By default a definition will be recalculated at every timestep but this can be overridden by the user. Similarly, once a quantity is initialized units can also be specified.

The number of user defined quantities is specified in RUNSPEC using the **UDQDIMS** keyword and additional parameters can be set using the **UDQPARAM** keyword.

The **UDQ** keyword is followed by any number of records, each containing the following items of data and terminated by a slash (/). The set of records must end with a blank record, containing only a slash (/).

1. Operation to perform

**ASSIGN** Assign a numeric value to elements of a quantity. The operation will initialize the quantity and set the update item to **OFF**.

**DEFINE** Define a mathematical expression with which to update the elements of the quantity. The operation will initialize the quantity and set the update item to **ON**.

**UNITS** Specify the units that will be written along with the summary data. The quantity must already be initialized in order to perform this operation. This data has no effect on the calculation of the quantity and is used for reporting only.

**UPDATE** Specify when next to evaluate the quantity definition. The quantity must already be initialized in order to perform this operation.

2. Name of the quantity

The name of the quantity must start 'CU', 'FU', 'GU', 'RU', 'SU', 'WU', 'AU' or 'BU' depending on whether it is a vector of connection, field, group, region, segment, well, aquifer and block elements. Quantity names must not exceed 8 characters in length, with only the first 5 being significant in the case of region quantities. If this is an **ASSIGN** record then particular elements can be selected using the syntax outlined below.

3. Data for operation.

For an **ASSIGN** record this should be a numerical value.

For a **DEFINE** record this should be a mathematical expression involving a combination of the functions and data described below. The expression should evaluate to either a vector of the same type as being defined, or a scalar. If the expression evaluates to a scalar all elements of the vector will inherit this value.

For a **UNITS** operation this should be a character string of not more than 8 characters

For an **UPDATE** operation this should be one of **ON**, **OFF** or **NEXT** depending on whether the definition is to be evaluated at all, none, or just the next timestep.

## Syntax for specifying particular elements

An **ASSIGN** record can target a subset of the elements in a vector. Similarly, whilst a **DEFINE** record applies to a quantity as a whole, a subset of elements can be supplied as an argument to the functions introduced below. When a unique element of a vector is specified as an argument in a quantity definition, the argument is treated as a scalar. When a subset of a vector is supplied as an argument in a quantity definition the remaining elements in the vector remain undefined.

The following syntax should be followed.

Connection quantities:

**COFR-** COFR for all connections for all wells. Treated as a vector.

---

COFR P1-	COFR for all connections belonging to well 'P1'. Treated as a vector.
COFR P1 1 2 3 -	COFR for the connection in block (1,2,3) belonging to well P1. Specifies a single element and will be treated as a scalar argument.
COFR 'P*' '-1' '-1' 3 -	COFR for all connections belonging to wells with names beginning with 'P' in layer 3. Treated as a vector regardless of the number of matching connections.

Field quantities:

FOPR - Field quantities are always scalar arguments.

Group quantities:

GOPR - GOPR for all groups. Treated as a vector.

GOPR G1 - GOPR for group 'G1'. Specifies a single element and will be treated as a scalar argument.

ECLIPSE 100

---

**Note:** In extended network modeling cases (see "[The extended network model](#)" in the *ECLIPSE Technical Description*), group UDQs will inherit their type (group or network group) from the right hand side of their definition. In the case of scalar assignments these UDQs are of standard group type unless previously defined as network group type.

---

Region quantities: Inter-region quantities such as ROFT are not permitted within user defined quantities.

ROIP -	ROIP for all regions and all <a href="#">FIP</a> sets, including the <a href="#">FIPNUM</a> set. Treated as a vector.
ROIP_NUM -	ROIP for all regions in the FIPNUM set. Treated as a vector.
ROIP_ONE -	ROIP for all regions in the FIP set 'ONE'. Treated as a vector.
ROIP_ONE 1 -	ROIP for region 1 in the FIP set 'ONE'. Specifies a single element and will be treated as a scalar argument. A FIP set name must be given if a region index is specified. Use NUM for the FIPNUM set.

---

**Note:** If a non-default region set is required, the name of the region set must be specified in the last three characters of the UDQ name, just as it would for the SUMMARY vector. So for a UDQ based on quantities in FIP set 'ONE', a suitable name would be RUXXXONE. Region quantities from more than one FIP set cannot be used in the same UDQ.

---

Segment quantities:

SOFR -	SOFR for all segments belonging to all multisegment wells. Treated as a vector.
SOFR 'P*' -	SOFR for all segments belonging to all multisegment wells with names beginning with 'P'. Treated as a vector.
SOFR 'P*' 1 -	SOFR for segment 1 belonging to all multisegment wells with names beginning with 'P'. Treated as a vector regardless of the number of matching segments.

SOFR P1 1 - SOFR for segment 1 belonging to the multisegment well 'P1'. Specifies a single element and will be treated as a scalar argument.

Well quantities:

WOPR- WOPR for all wells. Treated as a vector

WOPRP1 - WOPR for well 'P1'. Specifies a single element and will be treated as a scalar argument.

WOPR 'P\*' - WOPR for all wells with names beginning with 'P'. Treated as a vector regardless of the number of matching wells.

---

**Note:** Lumped completion properties beginning with 'W' (for example WOPRL) are input in the same manner as well quantities except that the completion number should be appended directly to the end of the mnemonic (for example WOPRL5)

---

Aquifer quantities:

AAQR - AAQR for all aquifers. Treated as a vector

AAQR X - AAQR for aquifer number X. Specifies a single element and will be treated as a scalar argument.

Block quantities:

BOSAT- BOSAT for all active blocks. Treated as a vector

BOSAT X Y Z - BOSAT for block coordinates X Y Z. Specifies a single element and will be treated as a scalar argument.

---

**Note:** Well and group names containing template characters should be enclosed in quotes.

---

**Note:** Local SUMMARY keywords beginning with LB, LC or LW are not available for use in quantity definitions.

---

## Functions available for quantity definitions

The following functions are available for use in quantity definitions. Without brackets, the functions are evaluated in order of decreasing precedence, with binary functions of equal precedence evaluated left to right and unary functions of equal precedence evaluated right to left. Brackets can be used to reorder the evaluation as required.

Binary functions take two arguments, one from the left and one from the right. Note, the majority of binary functions operate on the intersection of the two vectors, that is the output is only defined if both corresponding input elements are defined. A smaller number of the binary functions operate on the union of the two vectors, that is the output is defined if either of the corresponding input elements are defined. The binary functions are elemental, operating on each element in turn. As a consequence both the left and right functions need either to be of the same type, for example, a well vector, or one of the arguments needs to be

a scalar. If one argument is a vector and the other a scalar, the scalar value is applied to all elements in the vector.

Unary functions take a single argument usually supplied in a following bracket. The Unary functions are either elemental, or return a scalar value. The majority of the unary functions only operate on defined elements although a few also operate on undefined elements.

User defined quantity definitions are evaluated as real numbers constrained to lie in the range specified by item 2 of the [UDQPARAM](#) keyword. Values exceeding this range will be limited and ECLIPSE will issue a message notifying the user. Similarly, should an argument fall outside the domain of a function then the element will be returned undefined and the user notified.

Function	Precedence and Type		Description
(			Opening bracket.
)			Closing bracket.
[			Start of table argument list.
]			End of table argument list.
,			Separator for table arguments.
-	6	unary elemental	Sign change of defined element.
ABS ( )	6	unary elemental	Absolute value of defined elements.
AVEA ( )	6	unary scalar	Arithmetic average of defined elements.
AVEG ( )	6	unary scalar	Geometric average of defined elements. The result will be undefined if the input vector contains zero or negative elements.
AVEH ( )	6	unary scalar	Harmonic average of defined elements. The result will be undefined if the input vector contains zero elements.
DEF ( )	6	unary elemental	1 if the element is defined, otherwise the result is undefined.
EXP ( )	6	unary elemental	Exponential of defined elements.
IDV ( )	6	unary elemental (all elements)	1 if the element is defined, zero if the element is undefined.
LN ( )	6	unary elemental	Natural logarithm of defined elements.
LOG ( )	6	unary elemental	Base 10 logarithm of defined elements.
MAX ( )	6	unary scalar	Maximum of defined elements.
MIN ( )	6	unary scalar	Minimum of defined elements.
NORM1 ( )	6	unary scalar	1 norm of defined elements.
NORM2 ( )	6	unary scalar	2 norm of defined elements.
NORMI ( )	6	unary scalar	Infinity norm of defined elements.
NINT ( )	6	unary elemental	Nearest integer to defined elements.
PROD ( )	6	unary scalar	Product of defined elements.

Function	Precedence and Type	Description
RANDN ( )	6 unary elemental	Normally distributed random number with zero mean and unit variance. The seed for the random number generator can be set using item 1 of the <a href="#">UDQPARAM</a> keyword. The input argument is used purely to determine the size of the vector and the defined/undefined elements.
RANDU ( )	6 unary elemental	Uniformly distributed random number between -1 and 1. The seed for the random number generator can be set using item 1 of the <a href="#">UDQPARAM</a> keyword. The input argument is used purely to determine the size of the vector and the defined/undefined elements.
RRNDN ( )	6 unary elemental	<p>“Really random” normally distributed random number with zero mean and unit variance. This is the same as the RANDN function, but the seed for the random number generator is computed (using a unique number generated from the HH:MM:SS of the 24-hour clock) for each simulation.</p> <p>A base simulation case seed value will be used in restart simulations unless <a href="#">UDQDIMS</a> item 11 is set to ‘Y’.</p>
RRNDU ( )	6 unary elemental	<p>“Really random” uniformly distributed random number between -1 and 1. This is the same as the RANDU function, but the seed for the random number generator is computed (using a unique number generated from the HH:MM:SS of the 24-hour clock) for each simulation.</p> <p>A base simulation case seed value will be used in restart simulations unless <a href="#">UDQDIMS</a> item 11 is set to ‘Y’.</p>
SORTA ( )	6 unary elemental	Position of the element in an ascending sort of defined elements.
SORTD ( )	6 unary elemental	Position of the element in a descending sort of defined elements.
SUM ( )	6 unary scalar	Sum of defined elements.
UNDEF ( )	6 unary elemental	1 if the element is undefined, otherwise the result is undefined.
TU* [ ]	6 unary elemental	<p>The value from the specified user defined table associated with the values of the elements in each of the arguments. The table must be defined in a <a href="#">UDT</a> keyword, and the interpolation method used for each argument is specified in the table.</p> <p>There must be one argument for each dimension in the table, separated by commas. All arguments must either be the same type of vector quantity or scalar. The function returns a scalar if all arguments are scalar, or the same type of vector as its vector arguments.</p> <p>It is not possible to have further computations inside the square brackets - each table argument must be a simple one word mnemonic. However, table arguments can themselves be <a href="#">UDQ</a> s if a more complicated expression is required.</p>
<=	5 binary intersection	1 if the left argument is less than or equal to the right argument, else 0. The tolerance to check for equality is specified by item 4 of the <a href="#">UDQPARAM</a> keyword.

Function	Precedence and Type		Description
>=	5	binary intersection	1 if the left argument is greater than or equal to the right argument, else 0. The tolerance to check for equality is specified by item 4 of the UDQPARAM keyword.
<	5	binary intersection	1 if the left argument is less than the right argument, else 0.
>	5	binary intersection	1 if the left argument is greater than the right argument, else 0.
==	5	binary intersection	1 if the left argument is equal to the right argument, else 0. The tolerance to check for equality is specified by item 4 of the UDQPARAM keyword.
!=	5	binary intersection	1 if the left argument is not equal to the right argument, else 0. The tolerance to check for equality is specified by item 4 of the UDQPARAM keyword.
^	4	binary intersection	Exponentiation.
*	3	binary intersection	Multiplication.
/	3	binary intersection	Division.
+	2	binary intersection	Addition.
-	2	binary intersection	Subtraction.
UADD	1	binary union	Union of the two vectors with intersecting elements added together.
UMAX	1	binary union	Union of the two vectors with the maximum of intersecting elements taken.
UMIN	1	binary union	Union of the two vectors with the minimum of intersecting elements taken.
UMUL	1	binary union	Union of the two vectors with intersecting elements multiplied together.

Table 3.50: Functions of UDQ

## Data available for quantity definitions

Any of the quantities available to the [ACTIONX](#) keyword can be included in a quantity definition. The above syntax should be used. In addition the following simulator performance keywords are available and return scalar values.

ELAPSED Returns the elapsed time in seconds.

MSUMLINS Returns the total number of linear iterations since the start of the run.

MSUMNEWT Returns the total number of Newton iterations since the start of the run.

NEWTON Returns the number of Newton iterations used for each timestep.

TCPU Returns the current CPU usage in seconds.

TIME Returns the current simulation time.

TIMESTEP Returns the timestep length.

## Initialization of quantities

A quantity is initialized using the first ASSIGN or DEFINE record referencing the quantity in the UDQ data. Upon initialization the elements of the quantity are undefined. When they are output or used with in an ACTION (ACTIONG, ACTIONR, ACTIONW, ACTIONS, ACTIONX) keyword, undefined elements are replaced by the value specified in item 3 of UDQPARAM keyword.

## Processing of quantity assignments

A quantity assignment is processed upon reading a UDQ ASSIGN record. If a subset of a vector is specified then the assignment applies only to these elements, leaving the remaining elements unaltered. Consider a simulation with four wells named P11, P12, P32 and P33. The following UDQ assignments:

```
ASSIGN WUMW1 'P*1*' 1.0 /
ASSIGN WUMW1 P12 2.0 /
```

would result in the user defined well vector:

	P11	P12	P32	P33
WUMW1	1.0	2.0	UNDEFINED	UNDEFINED

---

**Note:** A quantity assignment sets the UPDATE status of the vector to OFF.

---

## Evaluation of quantity definitions

A quantity definition is an expression that is used to update every element in the vector after every timestep. Additional consideration maybe required if a definition includes operations on subsets of vectors. Again, consider a simulation with four wells named P11, P12, P32 and P33, and the following UDQ definition:

```
DEFINE WUMW1 WOPR 'P*1*' + WOPR 'P*2*' /
```

Internally, the following vectors will be generated. Recall a well vector has an element for every well in the simulation and if only a subset of the wells are selected the remaining elements are left undefined:

	P11	P12	P32	P33
WOPR 'P*1*'	WOPR P11	WOPR P12	UNDEFINED	UNDEFINED
+				
WOPR 'P*2*'	UNDEFINED	WOPR P12	WOPR P32	UNDEFINED
=				

WUMW1      UNDEFINED 2 x WOPR P12 UNDEFINED UNDEFINED

Since the addition function acts on the intersection of the defined elements P12 is the only well for which WUMW1 is defined. All other wells would return the specified value for an undefined element. A similar result is obtained in the following example in which we accumulate on a user defined quantity:

```
ASSIGN WUMW1 P1 1 /
DEFINE WUMW1 WUMW1 * WOPR /
```

for which the calculation would be:

	P11	P12	P32	P33
WUMW1	1	UNDEFINED	UNDEFINED	UNDEFINED
*				
WOPR	WOPR P11	WOPR P12	WOPR P32	WOPR P33
=				
WUMW1	WOPR P11	UNDEFINED	UNDEFINED	UNDEFINED

The key point to note is that binary functions act sequentially on corresponding elements. If we wish to add together elements from different positions in a vector this must be done on an individual basis as scalars. For example:

```
DEFINE FUMW1 WOPR P11 + WOPR P12 /
```

Alternatively, if the intention is to combine vectors then functions that act on the union of the defined elements should be considered. For example in a simulation with the FIPNUM set and two additional FIP sets named 'ONE' and 'TWO', each with the three regions, we could consider the definition:

```
DEFINE RUMW1 ROIP_NUM UMAX RGIP_ONE UMIN RWIP_TWO /
```

which would generate the vectors:

	NUM set			ONE set			TWO set		
ROIP_NUM	X	X	X	U	U	U	U	U	U
UMAX									
RGIP_ONE	U	U	U	X	X	X	U	U	U
UMIN									
RWIP_TWO	U	U	U	U	U	U	X	X	X
=									
RUMW1	ROIP_NUM			RGIP_ONE			RWIP_TWO		

where X represents a value and U an undefined element. Note, in this case the choice of union functions is not significant since the defined portions of the vectors do not overlap.

**Note:** A quantity definition applies to every element in the vector. A quantity definition cannot be applied to selected elements only.

**Note:** A quantity definition sets the UPDATE status of the vector to ON.

## How to define a cumulative quantity

```

UDQ

ASSIGN FU_CAPXQ 0.0 /
-- Set drilling cost for every well
ASSIGN WU_DRCST 1.0e6 /
-- Set the CAPEX as the drilling cost multiplied by the number of times it happens in
a timestep
DEFINE WU_CAPEX WU_DRCST * WPWE0 /
-- Field CAPEX is the sum of well CAPEX
DEFINE FU_CAPEX SUM(WU_CAPEX) /
-- Cumulative CAPEX
ASSIGN FU_CAPXT 0.0 /
DEFINE FU_CAPXT FU_CAPXT + FU_CAPEX /
DEFINE FU_CAPXQ FU_CAPXQ + FU_CAPEX /
--
/

```

**Note:** Both FU\_CAPXT and FU\_CAPXQ are defined in (almost) exactly the same way but only FU\_CAPXT will give the desired behavior.

The only difference is that FU\_CAPXQ is initialized at the beginning of the UDQ definitions, whereas FU\_CAPXT is initialized just before its definition. As stated above the UDQs are evaluated in the order in which they are first initialized. This means that at each timestep, FU\_CAPXQ is evaluated before FU\_CAPEX, whereas FU\_CAPXT is evaluated after it. Thus, when FU\_CAPXQ is evaluated, the FU\_CAPEX term being added is still undefined (that is 0) so nothing is added and the cumulative does not

grow. By contrast, FU\_CAPXT is evaluated after FU\_CAPEX (because it is first initialized after it) and so behaves as expected.

## How to use conditional UDQs

A UDQ can take a certain value depending on a predefined condition. In the example below

```
UDQ
DEFINE FUBOOL WBHP I > 3573 /
DEFINE WUMULT ((1-FUBOOL)*2.5) +(FUBOOL*1.5)/
/
```

The value of WUMULT, 2.5 or 1.5 in this example, depends on the value of BHP in well I. The same syntax can be used for a multiple condition.

```
UDQ
DEFINE FUBL1 WBHP I > 3573 /
DEFINE FUBL2 WWIR I < 6200 /
DEFINE WUMULT (FUBL1*1)+((1-FUBL1)*((FUBL2*2)+((1-FUBL2)*3)))/
/
```

## How to use UDQs for time-derivative calculation

As the UDQs are evaluated in the same order they have been defined or assigned, UDQs can be used to calculate a function time derivative. In the example, WUBHP2 is a timestep ahead of WUBHP1 when updating WUBHPDT, hence this later is the derivative of the BHP of the well P with regard to time.

```
UDQ
ASSIGN WUBHP1 0.0 /
DEFINE WUBHP2 WBHP P /
DEFINE WUBHPDT ((WUBHP2- WUBHP1) / Timestep) /
DEFINE WUBHP1 WUBHP2 /
UNITS WUBHP1 PSIA /
UNITS WUBHP2 PSIA /
/
```

x	ECLIPSE 300
	<b>SPECIAL</b>
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data consists of some or all of the following items, specifying dimensions associated with the UDQ keyword. The data must be terminated by a slash (/).

1. The maximum number of functions, including brackets, permitted in a quantity definition. See the UDQ keyword for the list of available functions.  
DEFAULT: 16
2. The maximum number of items permitted in a quantity definition.  
DEFAULT: 16
3. The maximum number of user defined connection quantities.  
DEFAULT: 0
4. The maximum number of user defined field quantities.  
DEFAULT: 0
5. The maximum number of user defined group quantities.  
DEFAULT: 0
6. The maximum number of user defined region quantities.  
DEFAULT: 0
7. The maximum number of user defined segment quantities.  
DEFAULT: 0
8. The maximum number of user defined well quantities.  
DEFAULT: 0
9. The maximum number of user defined aquifer quantities.  
DEFAULT: 0
10. The maximum number of user defined block quantities.  
DEFAULT: 0
11. Specifies whether a new random number generator seed is computed for restart runs. This affects the UDQ functions RRNDN and RRNDU. If this item is set to 'Y', then a new seed will be computed for restart simulations, hence the restart simulation random value sequence will differ from that of the base simulation. If this item is defaulted or set to 'N', then restart simulations will use the same seed as the base simulation, hence the restart simulation random value sequence will be the same as that of the base simulation.  
DEFAULT: N

## Example

```
UDQDIMS
8 8 2 2 2 2 2 2 2 2 Y /
```

x	SCHEDULE

The UDT keyword enables users to define lookup tables in the SCHEDULE section. These can then be used to assign values to user defined quantities in a UDQ keyword.

Tables can have any number of dimensions between 1 and 4, any number of interpolation points per dimension, and any number of values in the table itself. The maximum number of tables, interpolation points, values and dimensions permitted in any one dataset is set using the UDTDIMS keyword.

The UDT keyword is followed by a varying number of records depending on the required dimension of the table, each terminated by a slash (/). The set of records must end with a blank record, containing only a slash (/), to indicate the end of the UDT keyword.

## Record 1: Basic data for table

## 1. Table name

A name, which must be unique, which will be used to identify the table in UDQ definitions. The name must begin with 'TU' and cannot exceed 8 characters in length.

## 2. Number of dimensions in this table (NUMDIM)

An integer value between 1 and MUDTDS, the maximum number of UDT table dimensions, which is specified in item 4 in UDTDIMS. Note that it is not possible to set this value to be greater than 4.

## Records 2 to NUMDIM+1

## 1. The type of interpolation to be used for this dimension.

This is one of 'NV', 'LC', 'LL' or 'ID'

'NV' dimensions will use the nearest value.

'LC' dimensions will be linearly interpolated within the table but clamped to the first or last value as appropriate when outside it.

'LL' dimensions will be linearly interpolated within the table and linearly extrapolated outside it.

'ID' dimensions will use the name or identifier associated with the element rather than the value. If there is no match found, the table lookup will return the undefined value specified by item 3 of the UDQPARAM keyword. The first match found will always be used.

## 2. The interpolation points for this dimension.

- For 'ID' dimensions, these will be character strings, which can optionally use wildcard characters. This dimension type is only available for group or well mnemonics as data items.
- For all other dimensions, these will be numerical values, which must be entered in ascending order.

## Records NUMDIM+2 onwards

Each record contains multiple values, one for each interpolation point in the first dimension, terminated with a slash.

The first record corresponds to the first interpolation point in each dimension other than the first. The second record corresponds to the second interpolation point in the second dimension, and the first point for subsequent dimensions, and so on.

At the end of the records for the points for the second dimension, there is a record containing only a slash, to indicate the end of this dimension.

The next record will correspond to the first interpolation point in the second dimension, the second point in the third dimension, and the first point in the fourth dimension.

This pattern repeats, with a record containing only a slash every time we complete a dimension. So after the record which corresponds to the last point in the second dimension and the last point in the third dimension, there will be two records containing only slashes.

Note that we always have to terminate the second dimension with a slash, even if the dimension is 1 because it is a one-dimensional table.

## Examples

### Example 1

This is a generic example showing the structure of a four-dimensional table:

```

RUNSPEC
UTDDIMS
(max tables) (max rows) (max points) (max dims)/
...
SCHEDULE
UDT

/
--we've now entered all values for this table
/
--we've now entered all tables in this UDT keyword

```

## Example 2

This is a simple table with one dimension which will be linearly interpolated within the table but clamped to the first or last value as appropriate when outside it

```

RUNSPEC

UTDDIMS
1 8 4 1 /
...
SCHEDULE

UDT
'TUTESTA' 1/
'LC' 4.0E+06 5.0E+06 6.0E+06 7.0E+06 /
-- the next row contains four values, one for each point in the
-- first and only dimension
40 50 60 70 /
/ -- this slash terminates the second dimension, which in this
-- case is 1
/ -- this slash terminates the UDT keyword

```

## Example 3

This is a sample table with 3 dimensions. The first dimension will be evaluated using linear interpolation and extrapolation, the second using the nearest value, and the third using the ID of the elements. The first dimension has three interpolation points, the other two dimensions have two each.

```

RUNSPEC

UDTDIMS
1 20 4 3/
...
SCHEDULE

UDT
'TUTESTB' 3 /
'LL' 1 2 3 /
'NV' 2 4 /
'ID' 'W2' '*' /
-- the next two rows are both for the first 'ID' dimension'
1 2 3 / -- values corresponding to the first 'NV' dimension
2 4 6 / -- values corresponding to the second 'NV' dimension
/ -- this slash terminates the 'NV' dimensions
-- the next two rows are both for the second 'ID' dimension'
10 11 12 / -- values corresponding to the first 'NV' dimension
20 22 24 / -- values corresponding to the second 'NV' dimension
/ -- this slash terminates the 'NV' dimensions
/ -- this slash terminates the 'ID' dimensions
/ -- this slash terminates the UDT keyword

```

So, if in a UDQ keyword we had a table reference like

```

UDQ
DEFINE WUTESTB TUTESTB[WOPR,WGPR,WWPR]

```

with wells W1 and W2, then the result of the table reference would be a well vector with two elements. We'd start off with the first element of the well vector, which is well W1.

WOPR would be evaluated for W1, and then linear interpolation/extrapolation used.

WGPR would be evaluated for W1, and then the "nearest value" method of interpolation used.

WWPR is not evaluated at all, because the third dimension of the table uses the 'ID' method. Instead we use the well name for its first element, which is W1, and compare it with the names associated with the interpolation points. The name does not match the first point 'W2', but it does match the second point which is the wildcard character '\*'.

So, for the third dimension, we will be using the second set of values: the two rows starting with 10 and ending with 24.

For the second dimension, we will look to see whether the value of WGPR for W1 is closer to 2 or to 4. If it is closer to 2, we will use row 10 11 12. If it is closer to 4, we will use row 20 22 24.

And finally we will do linear interpolation or extrapolation based on where the value of WOPR lies with relation to the interpolation points for the first dimension, which are 1 2 3.

So, if WGPR for W1 is 2, and WOPR for W1 is 1.5, the result would be 10.5 - we'd take row 10 11 12, and then interpolate half way between the first two values.

This process is then repeated for well W2. This time we will be using the first block of values: the two rows starting with 1 and ending with 6, since this block has the name 'W2'. Assuming for simplicity that W2 and W1 have the same values for WGPR and WOPR, then this time the result will be 1.5.

We now have well vector WUTESTB as our result, with values 10.5 and 1.5. Units can be assigned to it within the UDQ keyword as required.

## UDTDIMS

## Dimensions for the user defined tables facility

ECLIPSE 300

This keyword indicates that gradient, or sensitivity, information produced by the simulator for history matching purposes is to be unencoded.

---

**Note:** The “ unencodedhmd ” license feature is required in order to use this keyword.

---

This keyword has no associated data.

It affects the following areas of functionality:

- When used in conjunction with "[Gradient option](#)" in the *ECLIPSE Technical Description*, this keyword indicates that the HMD file produced by the Gradient option is to be unencoded. By default, the sensitivities contained in the HMD file are encoded and can only be interpreted by SimOpt. If unencoded sensitivities are required for use in an external program, an unencoded gradients license feature is also required.
- When used in conjunction with the "[Adjoint gradient screening](#)" in the *ECLIPSE Technical Description*, this keyword indicates that the sensitivities written to the restart files are unencoded. By default, these sensitivities are encoded.

## UNIFIN

### Indicates that input files are unified

This indicates that input files (for example Restart files), which may be either multiple or unified, are unified. The default, if this keyword is not specified, is to use multiple (non-unified) files.

See "[File handling in ECLIPSE](#)" in the *ECLIPSE Technical Description*.

This keyword has no associated data.

## USECUPL

## Tells ECLIPSE to read a reservoir coupling file

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The USECUPL keyword may be used in either the master run or a slave run if you wish it to read group flows or constraints from a reservoir coupling file (see "Reservoir coupling files" in the *ECLIPSE Technical Description*).

The file may be used for two purposes:

- In the master run, it can take the place of one or more of the slave reservoirs. Their slave runs are not activated, that is not specified in the `SLAVES` keyword. Instead the associated master groups are instructed in keyword `GRUPMAST` to take their production and injection rates from the reservoir coupling file.
- A slave run may be performed on its own, instead of being activated by the master run. It reads from this file the constraints that the master run originally applied to its slave groups over the course of the simulation, and apply them again in the same sequence. It expected to find the applied constraints of all its slave groups (identified with the `GRUPSLAV` keyword) on this file.

The file must previously have been written by the master run when it was controlling each of the slave reservoirs. Keyword `DUMPCUPL` instructs the Master Run to write a Reservoir Coupling file.

The USECUPL keyword is followed by a record containing two items of data, terminated with a slash (/). The data items are:

1. The root name of the reservoir coupling file to be read

If the original coupled runs were performed over a series of restarts, there should be a sequence of reservoir coupling files, each having the root name of the data file of the master run that wrote it. In this case, you should enter the name of the **last** file in the sequence. Each file has a header that contains the root name of the data file from which it was restarted. Thus ECLIPSE is able to establish the chain of Reservoir Coupling files to be used, provided that they are all present. The chain can contain up to 20 restarts. ECLIPSE must be re-dimensioned if more are required.

2. The formatted/unformatted status of the input Reservoir Coupling file (a single character)

U ECLIPSE looks for an unformatted file (.CPL)

F ECLIPSE looks for a formatted file (.FCP)

Note that the formatted/unformatted status of the input Reservoir Coupling file can be chosen independently of keyword `FMTIN` in the `RUNSPEC` section.

---

**Note:** The USECUPL instruction is **not** carried over on the Restart file. If you wish to restart the run and continue reading the reservoir coupling file, you must include the USECUPL keyword in the restart run's `SCHEDULE` section. A suitable place for the keyword is at the beginning of the `SCHEDULE` section.

---

### Example

```
USECUPL
restart2 U /
```

## USEFLUX

## Use a flux file

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword activates the flux boundary conditions option and specifies the name of a Flux file. Only those cells in active flux regions (set with keyword [FLUXREG](#)) are active during the run.

The keyword is followed by two items of data enclosed in quotes, and terminated with a slash (/).

1. The rootname of the Flux file to be used.
  2. Extrapolation flag
    - YES Allow extrapolation beyond the end of the [DUMPFLUX](#) run.
    - NO Issue an Error if the run continues beyond the end of [DUMPFLUX](#) run
- DEFAULT: NO

For further information see "[Flux boundary conditions](#)" in the *ECLIPSE Technical Description*.

See also the following keywords:

[FLUXNUM](#) Set flux region numbers.

[FLUXREG](#) Set the active flux regions.

[FLUXTYPE](#) Specify the type of flux boundary conditions.

[THFLXTF](#) Set the heat transmissibility factor for a non-thermal base run to a thermal reduced run.

[FLUXOPTS](#) Specify that the reduced run is a thermal run. This keyword should be used in the non-thermal full field model if a thermal sector model will be used at a later stage.

ECLIPSE 100

ECLIPSE 300

ECLIPSE 300

There currently exists a number of limitations regarding the use of the flux boundary condition option, please see the "[Current limitations](#)" under the "[Flux boundary conditions](#)" section in the *ECLIPSE Technical Description*.

## Importing ECLIPSE 100 flux files into ECLIPSE 300

Flux files generated by ECLIPSE 100 can be imported into ECLIPSE 300 provided that the pressure boundary condition has not been selected in [FLUXTYPE](#). In order to transform oil and gas pseudo component rates generated by the black oil model into the compositional model, the compositions must be input using the following keywords:

[XSTC](#) Oil composition at surface conditions.

[YSTC](#) Gas composition at surface conditions.

[XSTC](#) and [YSTC](#) need only be specified when importing ECLIPSE 100 Flux files into an ECLIPSE 300 model, to convert oil and gas flows into component flows. ECLIPSE 300 Flux files already contain component flows. Flux files generated by ECLIPSE 300 cannot be imported into ECLIPSE 100.

ECLIPSE 300

**Note:** When doing a reduced run from a restart, the [GRID](#) file from the restart run must also be present in order for the simulation to initialize correctly.

---

**Note:** A thermal reduced run can only be carried out from an ECLIPSE 300 base run.

---

## Example

Use a Flux file with root name FLUX7.

```
USEFLUX  
'FLUX7' /
```

## USENOFLO Perform a useflux run with no flux file

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword enables a USEFLUX run to be performed without a Flux file. The flux region has no-flow boundary conditions, instead of reading the boundary flows or pressures from the Flux file.

The [USEFLUX](#) keyword should still be supplied, but the FLUX file name is ignored (and can be defaulted) if the USENOFLO keyword is present.

The USENOFLO option could be useful as a means of simulating just a section of the reservoir (for example, the drainage region of a well, for which no-flow boundary conditions may be a reasonable approximation) in isolation, without having to perform a [DUMPFLUX](#) run.

As well as imposing no-flow boundary conditions, there are two other consequences of applying the USENOFLO keyword:

- In addition to the boundary flows or pressures, the Flux file would normally supply the average pressure,  $R_s$  and  $R_v$  in the field. These are used, for example, to transform well flows between surface rate and reservoir volume rate. In a USENOFLO run, the average pressure,  $R_s$  and  $R_v$  in the flux region is used instead. Thus the correspondence between surface rate and reservoir volume rate differs from a standard USEFLUX run.
- The Flux file also contains information on the well flows outside the flux region, which is used for group control calculations when the group contains wells both within and outside the region. In a USENOFLO run this information is not present; thus group controls should not be applied in these circumstances.

See "[Flux boundary conditions](#)" in the *ECLIPSE Technical Description* for information on the Flux Boundary option.

## Run contains vaporized oil in wet gas

This indicates that the run contains vaporized oil in wet gas.

The keyword may be used only if both [OIL](#) and [GAS](#) are present.

If gas has a constant and uniform vaporized oil concentration, and if the pressure never drops below the dew point, then the model can be run more efficiently by omitting the [OIL](#) and [VAPOIL](#) keywords from the [RUNSPEC](#) section, treating the gas as a dry gas, and declaring a constant  $R_v$  value with keyword [RVCONST](#) or [RVCONSTT](#) in the [PROPS](#) section. The simulation is run as a dry gas problem with no oil, but the calculations take into account the constant vaporized oil concentration.

The keyword has no associated data.

When using the [BLACKOIL](#) keyword in ECLIPSE 300 this option is automatically selected if the [PVTG](#) keyword is present.

## VAPPARS Oil vaporization controls

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword should be used only if the model allows both gas solution in the oil phase and oil vaporization in the gas phase (both keywords `DISGAS` and `VAPOIL` present in the `RUNSPEC` section).

The data field should contain two real numbers and should be terminated by a slash (/). Both numbers are dimensionless, and are intended to be used as parameters for history matching and sensitivity studies.

The first parameter determines the propensity of oil to vaporize in the presence of undersaturated gas. If this parameter is set to zero, the standard black oil model behavior is selected (all oil vaporizes as long as there is any undersaturated gas in the block). Larger values inhibit vaporization especially in blocks where a lot of oil has already vaporized. This parameter typically takes a value between 0 and 5.

The second parameter determines the propensity of remaining oil to get heavier (that is of  $R_s$  to decrease) as lighter fractions vaporize. If this parameter is set to zero, the standard black oil model behavior is selected (the  $R_s$  of remaining oil does not change as oil vaporizes). Larger values increase the differentiation between light and heavy fractions. This parameter should normally be set to a small value (less than 1).

If this keyword is not present in runs containing both live oil and wet gas, both parameters are defaulted to zero, giving standard black oil model behavior.

Note that in any system containing both dissolved gas and vaporized oil, the maximum rates of increase of  $R_s$  and  $R_v$  (set using `DRSDT` and `DRVDT`) are initially set to large values by ECLIPSE. The constraints imposed by the VAPPARS parameters will be disabled by the subsequent specification of either the `DRSDT` or `DRVDT` keywords. Similarly, the limits imposed by the `DRSDT` or `DRVDT` keywords will be disabled by the subsequent specification of the VAPPARS keyword.

The VAPPARS parameters (`vap1` and `vap2`) act to reduce the maximum allowed values of  $R_s$  and  $R_v$  in a grid block by the relations

$$R_v = R_{v \text{ sat}} \left( \frac{S_o}{S_{o \text{ max}}} \right)^{\text{vap1}} \quad \text{Eq. 3.211}$$

$$R_s = R_{s \text{ sat}} \left( \frac{S_o}{S_{o \text{ max}}} \right)^{\text{vap2}} \quad \text{Eq. 3.212}$$

where

$S_{o \text{ max}}$  is the largest oil saturation reached in the grid block so far.

As  $S_o$  decreases due to vaporization, further vaporization becomes more inhibited. Large values of `vap1` and `vap2` may cause convergence difficulties.

This keyword enables the treatment of non-Darcy effects in inter-block flow, and specifies the non-Darcy flow coefficient. This is commonly known as  $\beta$ , the non-Darcy flow coefficient, and is entered in units of  $\text{atma.s}^2.\text{g}^{-1}$  (the Forchheimer) in all unit sets. Dake [Ref. 30] shows a typical value of  $\beta = 10^7 \text{cm}^{-1}$ , which is 9.86 Forchheimer units.

See "Non-Darcy flow" in the *ECLIPSE Technical Description* for a more detailed discussion. The maximum deviation from Darcy flow is given in the REPORT section of the Print file, for example:

```
Maximum deviation from Darcy flow      0.000259
```

**Note:** For ECLIPSE 100, this correction applies only to the gas phase and the maximum deviation is printed out if the mnemonic FFORG is used in RPTSOL and/or RPTSCHED.

**Note:** For ECLIPSE 100, by default, the non-Darcy flow calculation specified via the VDFLOW keyword (or the VDFLOWR keyword) is not applied to the well inflow calculation. This can be enabled by setting item 218 of the OPTIONS keyword to 2; in this case, for wells or well completions for which D-Factor calculations have been specified via the WDFAC keyword, the WDFACCOR keyword or item 12 of the COMPDAT keyword (or item 13 of the COMPDATL keyword), these will supersede those due to the VDFLOW or VDFLOWR keyword.

**Note:** For ECLIPSE 300, the non-Darcy flow calculation specified using the VDFLOW keyword (or the VDFLOWR keyword) is not applied to the well inflow calculations.

See also keyword VDFLOWR.

This keyword is an alternative to [VDFLOW](#) allowing input of the non-Darcy flow coefficient on a **region-by-region** basis. The data comprises NTSFUN (see item 1 of keyword [TABDIMS](#) in the RUNSPEC section) records, each containing a single data item terminated with a slash(/).

1. The non-Darcy flow coefficient. This is commonly known as  $\beta$ , the non-Darcy flow coefficient, and is entered in units of  $\text{atma.s}^2.\text{g}^{-1}$  (the Forchheimer) in all unit sets. Dake [[Ref. 30](#)] in chapter 8 shows a typical value of  $\beta = 10^7 \text{cm}^{-1}$ , which is 9.86 Forchheimer units.

See "[Non-Darcy flow](#)" in the *ECLIPSE Technical Description* for a more detailed discussion. The maximum deviation from Darcy flow is given in the REPORT section of the Print file, for example:

```
Maximum deviation from Darcy flow      0.000259
```

If flow occurs between two regions with differing non-Darcy flow coefficients, the average value is used.

**Note:** For ECLIPSE 100, this correction applies only to the gas phase and the maximum deviation is printed out if the mnemonic FFORG is used in [RPTSOL](#) and/or [RPTSCHED](#).

**Note:** For ECLIPSE 100, by default, the non-Darcy flow calculation specified via the VDFLOWR keyword (or the [VDFLOW](#) keyword) is not applied to the well inflow calculation. This can be enabled by setting [item 218](#) of the [OPTIONS](#) keyword to 2; in this case, for wells or well completions for which D-Factor calculations have been specified via the [WDFAC](#) keyword, the [WDFACCOR](#) keyword or item 12 of the [COMPDAT](#) keyword (or item 13 of the [COMPDATL](#) keyword), these will supersede those due to the VDFLOWR or VDFLOW keyword.

**Note:** For ECLIPSE 300, the non-Darcy flow calculation specified via the VDFLOW keyword (or the VDFLOWR keyword) is not applied to the well inflow calculations.

See also keyword [VDFLOW](#).

The data comprises of a set of tables for the capillary number and Forchheimer models of **gas** velocity dependent relative permeability. The number of tables should be equal to the number of saturation tables in the run, specified by the [TABDIMS](#) keyword or defaulted to 1.

Each table consists of the following items of data, and is terminated with a slash (/).

For further details on this option, please refer to "[Non-Darcy flow](#)" in the *ECLIPSE Technical Description*. The capillary number and Forchheimer models for the velocity dependent relative permeabilities are set with the keyword [VELDEP](#).

items in each table:

1. The  $m_g$  parameter.

This parameter controls the variability of the critical gas saturation with normalized capillary number. The lower limit value of zero implies the critical gas saturation is always zero regardless of capillary number. A large positive value means the critical gas saturation hardly changes during the run.

2. The  $n_{1g}$  parameter.

This parameter, along with  $n_{2g}$  parameter, controls the weighting between the miscible and immiscible relative permeability curves.

3. The  $n_{2g}$  parameter.

This parameter along with  $n_{1g}$  parameter controls the weighting between the miscible and immiscible relative permeability curves.

4. The base capillary number for gas,  $N_{cbg}$

This is the threshold value of capillary number above which the VDRP effect is thought to be active.

5. The gas Forchheimer  $a_g$  parameter.

This value must be specified for the B<sub>1</sub> Forchheimer model.

6. The gas Forchheimer  $b_g$  parameter.

This value must be specified for the B<sub>1</sub> Forchheimer model.

7. The gas Forchheimer  $c_g$  parameter.

8. The gas Forchheimer  $d_g$  parameter.

9. The gas Forchheimer  $\beta_{dg}$  parameter.

This value must be specified for the B<sub>2</sub> Forchheimer model.

All the above items default to 0.0. Warnings will be given if, for the particular models chosen in the [VELDEP](#) keyword, non-zero values are required.

UNITS: All items are dimensionless except for items 5 and 9 which have a unit which is a combination of the Forchheimer unit, Forch (where  $9.86 \text{ Forch} = 10^7 \text{ cm}^{-1}$ ), and the permeability unit (mD):

- item 5 has units of Forch(mD)<sup>d</sup>
- item 9 has units of Forch/(mD)<sup>d</sup>

where  $d$  is the  $d_g$  specified in item 8.

See also the [VDKRO](#) keyword and the [VELDEP](#) keyword in RUNSPEC.

## Example

Gas capillary number and  $B_1$  Forchheimer dependency have been requested using the [VELDEP](#) keyword in the RUNSPEC section. There are 2 saturation regions.

```
.....

	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises of a set of tables for a capillary number based model of velocity dependent relative permeability for near wellbore **gas** flow in a gas condensate reservoir. The number of tables should be equal to the number of saturation tables in the run, specified by the [TABDIMS](#) keyword or defaulted to 1.

This model is based on the work of Whitson, Fevang and Saevareid. For further details on this option, see "[Non-Darcy flow](#)" in the *ECLIPSE Technical Description*.

The data in this keyword are used in equations and . The capillary number and Forchheimer models for the velocity dependent relative permeabilities are set with the keyword [VELDEP](#), with the gas condensate capillary number model activated by setting item 5 of this keyword to 1 (and item 2 to 0).

Each table consists of the following items of data, and is terminated with a slash (/):

1. The  $n$  exponent.

This exponent is used in the calculation of the transition function that combines the immiscible (user supplied) relative permeability curve with the miscible (straight line) relative permeability curve.

UNITS: dimensionless

DEFAULT: 0.65

2. The  $\alpha_c^0$  coefficient.

This coefficient is used in the capillary number scaling parameter.

UNITS: dimensionless

DEFAULT: 1.0E4

### Example

There are 2 saturation regions.

```
VDKRGC
-- n      alpha0
   0.65  1.0e4  /
   0.70  1.5e4  /

	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data comprises of a set of tables for the capillary number and Forchheimer models of **oil** velocity dependent relative permeability data. The number of tables should be equal to the number of saturation tables in the run, specified by the `TABDIMS` keyword or defaulted to 1.

Each table consists of the following items of data, and is terminated with a slash (/).

For further details on this option, refer to "[Non-Darcy flow](#)" of the *ECLIPSE Technical Description*. The capillary number and Forchheimer models for the velocity dependent relative permeabilities are set with the keyword `VELDEP`.

Items in each table:

1. The  $m_o$  parameter.

This parameter controls the variability of the critical oil saturation with normalized capillary number. The lower limit value of zero implies the critical oil saturation is always zero regardless of capillary number. A large positive value means the critical oil saturation hardly changes during the run.

2. The  $n_{1o}$  parameter.

This parameter, along with the  $n_{2o}$  parameter, controls the weighting between the miscible and immiscible relative permeability curves.

3. The  $n_{2o}$  parameter.

This parameter, along with the  $n_{1o}$  parameter, controls the weighting between the miscible and immiscible relative permeability curves.

4. The base capillary number for oil,  $N_{cbo}$ .

This is the threshold value of capillary number above which the VDRP effect is thought to be active.

5. The oil Forchheimer  $a_o$  parameter.

This value must be specified for the B<sub>1</sub> Forchheimer model.

6. The oil Forchheimer  $b_o$  parameter.

This value must be specified for the B<sub>1</sub> Forchheimer model.

7. The oil Forchheimer  $c_o$  parameter.

8. The oil Forchheimer  $d_o$  parameter.

9. The oil Forchheimer  $\beta_{do}$  parameter.

This value must be specified for the B<sub>2</sub> Forchheimer Model.

All the above items default to 0.0. Warnings will be given if, for the particular models chosen in the `VELDEP` keyword, non-zero values are required.

UNITS: All items are dimensionless except for items 5 and 9 which have a unit which is a combination of the Forchheimer unit, Forch (where  $9.86 \text{ Forch} = 10^7 \text{ cm}^{-1}$ ), and the permeability unit (mD):

- item 5 has units of Forch(mD)<sup>d</sup>

- item 9 has units of Forch/(mD)<sup>d</sup>

where  $d$  is the  $d_o$  specified in item 8.

See also the [VDKRG](#) keyword and the [VELDEP](#) keyword in RUNSPEC.

## Example

Oil capillary number has been requested via the [VELDEP](#) keyword in RUNSPEC.

```
VDKRO

0.0  4.0  -1.5  2.0E-07  0.0  0.0  0.0  0.0  1*  /
```

## VE

## The vertical equilibrium model is used

This indicates that the vertical equilibrium model is required. The keyword may optionally be followed by a single item to activate the compressed VE model.

The data should be terminated by a slash (/).

### 1. Type of VE model

**COMPRESS** The compressed vertical equilibrium model is used: columns of cells is compressed into a single cell.

**NOCOMP** The standard VE model is to be used.

**DEFAULT:** NOCOMP

See "[Vertical equilibrium](#)" in the *ECLIPSE Technical Description* for more details.

---

**CAUTION:** This keyword is banned if the **COMPRESS** option is used in a parallel run.

---

**Note:** The end-point scaling option/initial mobile fluid end point correction should not be used with the vertical equilibrium option.

---

### Example

The standard VE model is to be used

```
VE
NOCOMP /
```

	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword can be used to write out debug information (to the Debug file) about the internal tables used by the compressed VE option and the full (3D) VE option (keyword [VE](#) in the RUNSPEC section).

In the compressed VE case, the tables can be output in the form of a GRAF user file which can be read directly into the GRAF program.

The keyword should be followed by 7 integers, and optionally an LGR name, terminated with a slash (/). The first 6 integers define the box of cells for which the debug output will be generated. The 7<sup>th</sup> integer controls the form of the debug output.

1. IX1 First cell on X axis to be included in output
2. IX2 Last cell on X axis to be included in output
3. JY1 First cell on Y axis to be included in output
4. JY2 Last cell on Y axis to be included in output
5. KZ1 First cell on Z axis to be included in output
6. KZ2 Last cell on Z axis to be included in output

The values must satisfy:

$$1 \leq IX1 \leq IX2 \leq NDIVIX$$

$$1 \leq JY1 \leq JY2 \leq NDIVIY$$

$$1 \leq KZ1 \leq KZ2 \leq NDIVIZ \text{ (where NDIVIX, NDIVIY and NDIVIZ are specified in RUNSPEC keyword [DIMENS](#))}$$

7. Debug switch
  - 0 Output in tabular form
  - 1 Output as GRAF user data

(Only if COMPRESS is specified in keyword [VE](#))

DEFAULT: 0

8. LGR control string
  - ' ' Output cells in global grid and all local grids
  - GLOBAL Output cells in global grid only
  - lgr name Output cells in the named local grid

This item will be ignored if Local Grid Refinement is not used (see "[Local grid refinement and coarsening](#)" in the *ECLIPSE Technical Description*).

DEFAULT: ' '

---

**Note:** The output can be quite large, and hence only small numbers of cells should be output from large models.

---

## Example

```
VEDEBUG
-- IX1 IX2 IY1 IY2 IZ1 IZ2 SWITCH
   4   4   5   5   1   3   0   /
```

## VEFIN

## Controls vertical equilibrium model

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

VEFIN may be used in LGR runs with vertical equilibrium in the global grid (keyword **VE** in the RUNSPEC section), to control the vertical equilibrium model in the local grid systems. VEFIN should be placed after the keyword introducing the local grid (**CARFIN** or **RADFIN**) and before the local grid data is terminated with **ENDFIN**.

The keyword can be used to specify that a local grid uses the vertical equilibrium model. In addition it allows you to control the accuracy of the global host cells' representation for VE calculations, approximating the local grid systems.

The keyword is followed by one record containing two items of data, which relate to the local grid system introduced in the preceding **CARFIN** or **RADFIN** keyword:

1. Vertical Equilibrium flag:

YES If vertical equilibrium is required in the local grid.

NO To use dispersed flow in the local grid.

DEFAULT: NO

2. NVEPT The maximum number of distinct depths used to describe a global grid cell hosting the local grid. (VE calculations use a table of depth versus volume for each cell.)

If NVEPT is set to zero or negative, the original global description of the cell will be used (that is up to 8 distinct depths).

If NVEPT is set to a large number, the global cell description honors the distinct depths of the local grid system. This means that the global cell contact depths are calculated using exactly the same data as the local grid system. (NVEPT needs to be set greater than 8 multiplied by the maximum number of local grid cells contained within any one global grid cell hosting the refinement.)

If the number of local cells contained within any global cell in the refinement is large, the amount of computer time required to set up the initial data can become excessive, and the extra points will give no increase in accuracy. However, if NVEPT is set less than the number of distinct local grid depths within a global cell, then only NVEPT equally spaced distinct depths will be used. Note that if NVEPT is quite small (10 to 20), this is still a better approximation of the local system than the original (NVEPT = 0) description of the global cell.

In general it is unlikely to be worth setting NVEPT to a value greater than 50.

DEFAULT: 0 (which applies the original description of the global cell.)

---

**Note:** The equilibration option selected by the item 9 in the **EQUIL** keyword is **not** affected by the VEFIN setting. If VE equilibration is requested (item 9 of **EQUIL** set to 0 in VE runs) then the local grid also uses VE equilibration. The VE equilibration option can be useful in cases with no capillary pressure where an accurate initial oil distribution is required; however, this is not in initial equilibrium. If a standard equilibration is required, which includes a transition zone if the capillary pressure is non-zero, then an equilibration region should be defined to cover the local refinement and item 9 of **EQUIL** should be set non-zero. Note that a value of 1 requests block-centered equilibration.

---

## Examples

### Example 1

Specify VE in the local grid.

```
VEFIN  
YES /
```

### Example 2

Increase the number of distinct depths used to represent the global host cell (with no VE in the local grid)

```
VEFIN  
--      NVEPT  
NO      40  /
```

## Fraction of VE relative permeability curves used

If the vertical equilibrium option is being used (keyword **VE** in the RUNSPEC section), this keyword can be used to specify the relative fractions of the rock relative permeability curve and VE relative permeabilities to be used in the run.

The value of VEFAC can either be specified as a single parameter for the whole field using this keyword, or it can be specified on a cell-by-cell basis using the VEFACV keyword. The corresponding keywords VEFACP and VEFACPV can be used to specify the relative fractions of the rock and VE curves for capillary pressures.

DEFAULT: 1.0

If the default value is taken, relative permeabilities derived from the Vertical Equilibrium Model are used, replacing the rock curves entered using keywords such as [SWFN](#).

By setting VEFAC to a value less than 1.0, it is possible to mix the VE and rock curves; a fraction (1.0 - VEFAC) of the rock curve and VEFAC of the VE curve is taken.

See also keywords [VEFACV](#), [VEFACP](#), [VEFACPV](#).

### Example

```
VEFRAC
0.9 /
```

## VEFRACP

## Fraction of VE pseudo capillary pressure to be used

## Velocity dependent relative permeability settings

The data consists of the following items, describing the options available within the VDRP Model.

- This item controls which Capillary Number Model is active for the **oil** phase. The 3 models available are selected by setting this item to 1, 2 or 3.  
DEFAULT: 0 (indicates this model is inactive)
- This item controls which Capillary Number Model is active for the **gas** phase. The 3 models available are selected by setting this item to 1, 2 or 3.  
DEFAULT: 0 (indicates this model is inactive)
- This item controls which Forchheimer Model is active for the **oil** phase. The 2 models available are selected by setting this item to 1 or 2.  
DEFAULT: 0 (indicates this model is inactive)
- This item controls which Forchheimer Model is active for the **gas** phase. The 2 models available are selected by setting this item to 1 or 2.  
DEFAULT: 0 (indicates this model is inactive)
- This item controls whether an alternative model for Capillary Number effects in near wellbore flows in gas condensate reservoirs is active for the **gas**, or gas and oil, phases. This model is activated for the gas phase only by setting this item to 1, and activated for gas and oil phases by setting this item to 2. When using this alternative model, item 2 must be set to zero.  
DEFAULT: 0 (indicates this model is inactive)

The description of the Velocity Dependent Relative Permeability (VDRP) model is discussed in "[Non-Darcy flow](#)" in the *ECLIPSE Technical Description*. The maximum deviation from non-Darcy flow is given in the REPORT section of the Print file, for example:

```
Maximum deviation from Darcy flow      .000259
```

This keyword does not work with black oil runs since the VDRP Model is intended for gas condensate systems.

Properties of the capillary number and Forchheimer models for the oil and gas are set with the keywords [VDKRO](#) and [VDKRG](#) respectively.

Properties of the alternative model for capillary number effects in near wellbore flow in gas condensate reservoirs have default values, but these values may be modified using [VDKRGC](#) keyword in the PROPS section.

VDRP effects (both capillary number and Forchheimer) may be modeled in the generalized pseudo-pressure calculation by setting item 4 to YES in the keyword [PICOND](#).

### Example

The  $N_1$  models for oil and gas capillary number dependency are required along with the  $B_1$  model or the Forchheimer effect applied to gas only.

```
VELDEP
1 1 0 1 0 /

	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is generated by VFP *i* when it is working in its compositional mode. It contains data that was used by VFP *i* to generate the VFPPROD and/or VFPINJ keywords. ECLIPSE 300 checks the data for consistency between the simulator fluid model and that used by VFP *i*. A warning message is printed if there is an inconsistency.

The keyword is followed by a line containing the following items of data, terminated with a slash (/).

- Water density at standard conditions  
UNITS: kg/m<sup>3</sup> (METRIC), lb/ft<sup>3</sup> (FIELD), gm/cc (LAB), kg/m<sup>3</sup> (PVT-M)
- Molecular weight of water  
UNITS: kg/kg-M (METRIC), lb/lb-M (FIELD), gm/gm-M (LAB), kg/kg-M (PVT-M)
- Standard pressure  
UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)
- Standard temperature  
UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)
- Units system
- Number of components

### Example

```
VFPCHECK
1022.0 18.02 1.0132 15.5556 METRIC 15 /
```

## VFPCHK

## Sets threshold BHP for VFP table checks

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

When production well VFP tables are read in, they are checked to ensure that curves of BHP versus flow rate at adjacent THP values do not cross. If a crossing is detected (that is if the BHP increases with decreasing THP) a warning message is printed. It may cause well convergence problems or hunting between control modes. However, crossings may also occur if some BHP values are set artificially high to indicate conditions where the flow is supersonic or exceeds specified erosion velocity limits (see keywords "SONICPRS" and "ERODEVEL" in the *VFPi User Guide*). These are legitimate, and serve to prevent the well from operating at these conditions. The VFP table check can be thresholded (to report only crossover BHPs below a given value), or even turned off entirely, with the keyword VFPCHK. The keyword should be entered before the VFPPROD keywords to which it should apply.

The VFPCHK keyword is followed by a single real number terminated with a slash (/), which sets the threshold BHP value for the checks. Any crossover BHPs at or above the threshold value will be ignored by the checks. A zero or negative value turns off the checks entirely.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: 1.0E10

If this keyword is not present, checks are performed with the default threshold BHP value.

**CAUTION:**

When ECLIPSE 300 encounters a crossing curve, it attempts to correct this internally by reducing the higher BHP value (on the lower THP curve) to lie below the lower BHP value (on the higher THP curve), so that the BHP increases with increasing THP. However, if the BHP values had been made artificially high on purpose to distinguish regimes of supersonic or erosional flow, the correction removes this distinction and allow the well to operate under these conditions. It is therefore important to use VFPCHK to prevent ECLIPSE 300 altering points that have been given artificially high BHP values for this purpose.

**Example**

```
VFPCHK
1.0E5 /
```

	SOLUTION
	SUMMARY
x	SCHEDULE

This is a table of BHP versus FLO and versus THP.

At least one table is needed if any of the injection wells require THP calculations. The VFPINJ keyword can only enter one table at a time, so if there is more than one table, each table must be entered under a separate VFPINJ keyword.

See also keyword [WVFPDP](#).

The maximum dimensions of the tables must be set in the RUNSPEC section keyword VFPIDIMS.

The table consists of the following records of data, each record terminated with a slash (/).

---

**Note:** If the actual simulation conditions fall outside the range given in this table, linear extrapolation is used. This can produce unrealistic results and should be avoided (by ensuring that the VFP table covers all conditions that will arise during the simulation).

---

### Record 1: Basic data for table

The last three items may be defaulted, for back-compatibility with earlier versions.

1. Table number

In integer between 1 and NMSVFT, the maximum number of injection well VFP tables, which is the third item in [VFPIDIMS](#).

2. Bottom hole datum depth for table.

Any difference between the bottom hole datum depth of the VFP table and the bottom hole datum depth of the wells that use the table is taken into account by a simple hydrostatic correction.

This item is ignored if the table is used to determine branch pressure drops in the Network option

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

3. Definition of the flow rate variable FLO.

OIL oil injection rate

WAT water injection rate

GAS gas injection rate

*ECLIPSE 300 only*

WG hydrocarbon wet gas rate

*ECLIPSE 300 only*

TM total molar rate

4. Definition of the fixed pressure values given in "[Record 3:THP values](#)".

*ECLIPSE 300 only*

THP tubing head pressure

This is interpreted as the inlet pressure if the table is used to determine injection network branch pressure drops in the Network option.

ECLIPSE does not accept anything other than THP.

DEFAULT: THP

5. Unit convention of the VFP table.

METRIC, FIELD, LAB or PVT-M.

If this item is present, ECLIPSE checks that the VFP table has the same unit convention as the run and issues an error message if they are not the same.

DEFAULT: The same unit convention as the ECLIPSE run.

6. Definition of the tabulated quantity in the body of the table, records 4 onwards.

BHP Bottom hole pressure

This is interpreted as the outlet pressure if the table is used to determine injection network branch pressure drops in the Network option.

ECLIPSE will not accept anything other than BHP.

DEFAULT: BHP

## Record 2:FLO (flow rate) values

Enter in ascending order, terminated with a slash (/).

The number of values, NFLO, must be between 2 and MXSFLO, which is the first item in VFPIIDIMS.

Volume rate: UNITS:  $\text{sm}^3/\text{day}$  (METRIC),  $\text{stb}/\text{day}$  for oil or liquid (FIELD),  $\text{Mscf}/\text{day}$  for gas (FIELD),  $\text{scc}/\text{hr}$  (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

Molar rate: UNITS:  $\text{kg-M}/\text{day}$  (METRIC),  $\text{lb-M}/\text{day}$  (FIELD),  $\text{gm-M}/\text{hr}$  (LAB),  $\text{kg-M}/\text{day}$  (PVT-M)

ECLIPSE 300

## Record 3:THP values

Enter in ascending order, terminated with a slash (/).

The number of values, NTHP, must be between 1 and MXSTHP, which is the second item in VFPIIDIMS. If only one value is entered, the derivative of the BHP with respect to the THP is treated as unity.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

## Records 4 to NTHP+3

NTHP successive records each containing the following items, and each terminated with a slash (/).

1. NT (THP value number).
2. BHP at 1<sup>st</sup> FLO value and NT<sup>th</sup> THP value.
3. BHP at 2<sup>nd</sup> FLO value and NT<sup>th</sup> THP value.
- .... ..

NFLO +1 BHP at last FLO value and NT<sup>th</sup> THP value.

All combinations of  $\text{NF} = 1$  to NFLO and  $\text{NT} = 1$  to NTHP must be covered.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

## Examples

### Example 1

VFP table for water injector, NFLO=5, NTHP=1:

```
VFPINJ
 1 7.00000E+03 WAT THP FIELD BHP /

# VFPPDIMS

## Production well VFP table dimensions

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The data consists of some or all of the following items which describe the dimensions of the production well vertical flow performance tables entered in the SCHEDULE section using keyword VFPPROD. The data must be terminated by a slash (/).

1. The maximum number of flow values per table  
 DEFAULT (ECLIPSE 100): 0  
 DEFAULT (ECLIPSE 300): 1
2. The maximum number of tubing head pressure values per table  
 DEFAULT (ECLIPSE 100): 0  
 DEFAULT (ECLIPSE 300): 1
3. The maximum number of water fraction values per table  
 DEFAULT (ECLIPSE 100): 0  
 DEFAULT (ECLIPSE 300): 1
4. The maximum number of gas fraction values per table  
 DEFAULT (ECLIPSE 100): 0  
 DEFAULT (ECLIPSE 300): 1
5. The maximum number of Artificial Lift Quantities per table  
 DEFAULT (ECLIPSE 100): 0  
 DEFAULT (ECLIPSE 300): 1
6. The maximum number of production well VFP tables  
 DEFAULT (ECLIPSE 100): 0  
 DEFAULT (ECLIPSE 300): 1

---

**Note:** Production well VFP tables can use a significant amount of computer storage, as the reserved memory is proportional to the product of all the above numbers. It is therefore good practice to keep these maximum dimensions as close as possible to the actual maximum dimensions of the tables entered.

---

### ECLIPSE 100

To help select the most appropriate values, if the mnemonic 'VFPPROD=2', or higher, is entered in the RPTSCHEM keyword then a table is produced comparing the actual maximum dimensions of the VFP tables with the dimensions input here. Enter 'VFPPROD=3' if you do not wish to have the contents of the VFP tables printed as well.

### Example

```
VFPPDIMS
5 4 3 1 1 3 /
```

## VFPPROD

## Inputs a VFP table for production wells

	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This is a table of BHP versus FLO, THP, WFR, GFR and ALQ, or THT (Tubing Head Temperature) versus FLO, THP, WFR, GFR and ALQ, where:

FLO is the oil, liquid or gas production rate, or, in compositional mode, the hydrocarbon wet gas production or total molar rate.

WFR is the water-oil ratio, water cut or water-gas ratio, or, in compositional mode, the water-wet gas ratio or water molar fraction.

GFR is the gas-oil ratio, gas-liquid ratio or oil-gas ratio, or, in compositional mode, the hydrocarbon mean molecular weight.

ALQ is a 5<sup>th</sup> variable that can be used to incorporate an additional look-up parameter, such as the level of artificial lift.

Any combination of these variable definitions can be used, as long as they do not become infinite during the simulation.

For example, an oil well may have

FLO oil or liquid rate, or, in compositional mode, the wet gas or molar rate.

WFR water-oil ratio or water cut, or, in compositional mode, the water-wet gas ratio or water molar fraction.

GFR gas-oil ratio or gas-liquid ratio, or, in compositional mode, the mean molecular weight.

A gas well should have

FLO gas rate, or, in compositional mode, the wet gas or molar rate.

WFR water-gas ratio, or, in compositional mode, the water-wet gas ratio or water molar fraction.

GFR oil-gas ratio (in gas-water runs only one value = 0.0 is required).

## ECLIPSE 100

If the [RSCONST](#) keyword is used, the variables must be

FLO oil or liquid rate

WFR water-oil ratio or water cut

GFR gas-oil ratio.

## ECLIPSE 100

If the [RVCONST](#) keyword is used, the variables must be

FLO gas rate

WFR water-gas ratio

GFR oil-gas ratio.

At least one table is needed if any of the production wells require THP calculations. The VFPPROD keyword can only enter one table at a time, so if there is more than one table, each table must be entered under a separate VFPPROD keyword.

---

**Note:** If the actual simulation conditions fall outside the range given in this table, linear extrapolation is used. This can produce unrealistic results and should be avoided (by ensuring that the VFP table covers all conditions that will arise during the simulation).

---

The maximum dimensions of the tables must be set in the RUNSPEC section keyword `VFPPDIMS`.

See also keywords `VFPTABL`, `VFPCHK`, `WVFPDP`, `WVFPEXP` and `WHTEMP`.

The table consists of seven records of data, each record terminated with a slash (/).

## Record 1: Basic data for table

The last four items may be defaulted, for back-compatibility with earlier versions.

### 1. Table number

An integer between 1 and `NMMVFT`, the maximum number of production VFP tables, which is item 6 in `VFPPDIMS`.

Each production VFP table must have a unique table number irrespective of whether the body of the table holds pressures or temperatures.

### 2. Bottom hole datum depth for table.

Any difference between the bottom hole datum depth of the VFP table and the bottom hole datum depth of the wells that use the table are taken into account by a simple hydrostatic correction.

This item is ignored if the table is used to determine branch pressure drops in the network option.

If the table is used to determine segment pressure drops in the multisegment well model, this item is interpreted as either the length or the depth span of the representative length of tubing for which the table was calculated.

UNITS: m (`METRIC`), ft (`FIELD`), cm (`LAB`), m (`PVT-M`)

### 3. Definition of the flow rate variable FLO in record 2.

OIL Oil production rate

LIQ Liquid (oil + water) production rate

GAS Gas production rate

*ECLIPSE 300 only*

WG Hydrocarbon wet gas rate

*ECLIPSE 300 only*

TM Total molar rate

### 4. Definition of the water fraction variable WFR in record 4.

WOR Water-oil ratio

WCT Water cut (water-liquid ratio)

	WGR	Water-gas ratio
ECLIPSE 300 only	WWR	Water-wet gas ratio
ECLIPSE 300 only	WTF	Water molar fraction

ECLIPSE 300

---

**Note:** Water-wet gas ratio is defined as  $f_w^{\text{vol}} / f_h^{\text{vol}}$ , where  $f_w^{\text{vol}}$  is the volume flow rate of water at surface conditions, and  $f_h^{\text{vol}}$  is the molar rate of hydrocarbon flow, converted to a gas volume rate at standard conditions.

Water molar fraction is defined as  $f_w^m / (f_h^m + f_w^m)$ , where  $f_w^m$  is the molar flow rate of water at surface conditions, and  $f_h^m$  is the molar rate of hydrocarbon flow.

---

5. Definition of the gas fraction variable GFR in record 5.

	GOR	Gas-oil ratio
	GLR	Gas-liquid ratio
	OGR	Oil-gas ratio
ECLIPSE 300 only	MMW	Mean molecular weight

6. Definition of the fixed pressure values given in record 3.

THP Tubing head pressure

This is interpreted as the outlet pressure if the table is used to determine production network branch pressure drops in the network option, or segment pressure drops in the multisegment well model.

ECLIPSE will not accept anything other than THP.

DEFAULT: THP

7. Definition of the artificial lift quantity (ALQ) in record 6

	GRAT	Lift gas injection rate (for gas lift)
	IGLR	Injection gas-liquid ratio (for gas lift)
	TGLR	Total gas-liquid ratio (for gas lift)
	PUMP	Pump rating (for pump)
	COMP	Compressor power (for compressor)
ECLIPSE 100 only	DENO	Surface density of oil (See keyword <a href="#">WALQCALC</a> )
ECLIPSE 100 only	DENG	Surface density of gas (See keyword <a href="#">WALQCALC</a> )
	BEAN	Choke diameter (multisegment wells)

' ' Undefined.

This item informs ECLIPSE of the ALQ definition that was used to generate the VFP table (for example by VFP *i*). However, in general ECLIPSE uses the ALQ only as a look-up parameter to interpolate the table, and attaches no physical significance to its definition. An exception to this is when gas lift is the artificial lift method and is used in conjunction with any one of the following options:

- The gas lift optimization facility
- Limits to the total lift gas applied to a group (keyword [GLIFTLIM](#))
- Including lift gas flows in the pressure loss calculations of network branches (network option keyword [GRUPNET](#) item 6 or [NODEPROP](#) item 4).

In these cases, the ALQ **must** be GRAT, because ECLIPSE adds the well ALQs to give the group lift gas rates. ALQs are not additive in this respect if they refer to IGLR or TGLR. The VFP *i* program may be used to convert VFP tables constructed with the IGLR or TGLR definition into tables where the ALQ is GRAT. If the ALQ is undefined, ECLIPSE assumes it is GRAT, and an error message is issued if it is defined as IGLR or TGLR.

---

**Note:** In the presence of artificial lift gas, the produced gas reported (for example using the FGPR, GGPR and WGPR summary keywords) does not include produced lift gas, only produced formation gas.

---

Another use of the ALQ is to represent the oil or gas surface density. VFP *i* can produce a table spanning a range of oil or gas surface densities, and ECLIPSE interpolates it at the current surface density. This is useful in API tracking runs, and also in the Network option when wells in different PVT regions produce into the network. See the keyword [WALQCALC](#) for information.

DEFAULT: ' ' (none or undefined)

#### 8. Unit convention of the VFP table.

METRIC, FIELD, LAB or PVT-M

If this item is present, ECLIPSE checks that the VFP table has the same unit convention as the run and issues an error message if they are not the same.

DEFAULT: The same unit convention as the ECLIPSE run

#### 9. Definition of the tabulated quantity in the body of the table, record 7 onwards.

TEMP Tubing Head Temperature (THT)

BHP Bottom hole pressure

A BHP is interpreted as the inlet pressure if the table is used to determine production network branch pressure drops in the Network option, or segment pressure drops in the multisegment well model.

ECLIPSE will not accept anything other than BHP or TEMP.

DEFAULT: BHP

## Record 2:FLO (flow rate) values

Enter in ascending order, terminated with a slash (/).

The number of values, NFLO, must be between 2 and MXMFLO, which is item 1 in VFPPDIMS.

Volume rate: UNITS:  $\text{sm}^3/\text{day}$  (METRIC), stb/day for oil or liquid (FIELD), Mscf/day for gas (FIELD), scc/hr (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

ECLIPSE 300

Molar rate: UNITS: kg-M/day (METRIC), lb-M/day (FIELD), gm-M/hr (LAB), kg-M/day (PVT-M)

## Record 3:THP values

Enter in ascending order, terminated with a slash (/).

The number of values, NTHP, must be between 1 and MXMTHP, which is item 2 in VFPPDIMS. If only one value is entered, the derivative of the BHP w.r.t. the THP is treated as unity.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

## Record 4:WFR values

Enter in ascending order, terminated with a slash (/).

The number of values, NWFR, must be between 1 and MXMWFR, which is item 3 in VFPPDIMS. If only one value is entered, the BHP is treated as independent of the water fraction.

For WOR or WCT: UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

For WGR or WWR: UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/Mscf (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

ECLIPSE 300

For WTF: UNITS: dimensionless

## Record 5: GFR values

Enter in ascending order, terminated with a slash (/).

The number of values, NGFR, must be between 1 and MXMGFR, which is the item 4 in VFPPDIMS. If only one value is entered, the BHP is treated as independent of the gas fraction.

For GOR or GLR: UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), Mscf/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

For OGR: UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/Mscf (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

ECLIPSE 300

For MMW: UNITS: dimensionless

## Record 6:ALQ values

Enter in ascending order, terminated with a slash (/).

The number of values, NALQ, must be between 1 and MXMALQ, which is item 5 in VFPPDIMS. If only one value is entered, the BHP is treated as independent of the artificial lift quantity.

When ALQ = GRAT:                    UNITS: sm<sup>3</sup>/day (METRIC), Mscf/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

When ALQ = IGLR or TGLR: UNITS: sm<sup>3</sup>/sm<sup>3</sup> (METRIC), Mscf/stb (FIELD), scc/scc (LAB), sm<sup>3</sup>/sm<sup>3</sup> (PVT-M)

ECLIPSE 100 only

When ALQ = DENO or DENG: UNITS: kg/m<sup>3</sup> (METRIC), lb/ft<sup>3</sup> (FIELD), gm/cc (LAB), kg/m<sup>3</sup> (PVT-M)

When ALQ = BEAN:                    UNITS: mm (METRIC), 1/64<sup>th</sup> in (FIELD)

The units for PUMP or COMP depend on the definition of the pump rating or compressor power used in the construction of the VFP table.

(See item 7 of Record 1.)

## Records 7 to NTHP\*NWFR\*NGFR\*NALQ+6

NTHP\*NWFR\*NGFR\*NALQ successive records each containing the following items, and each terminated with a slash (/).

1. NT (THP value number).
  2. NW (WFR value number)
  3. NG (GFR value number)
  4. NA (ALQ value number)
  5. BHP or THT at
    - 1st FLO value
    - NT<sup>th</sup> THP value
    - NW<sup>th</sup> WFR value
    - NG<sup>th</sup> GFR value
    - NA<sup>th</sup> ALQ value
  6. BHP or THT at
    - 2<sup>nd</sup> FLO value
    - NT<sup>th</sup> THP value
    - NW<sup>th</sup> WFR value
    - NG<sup>th</sup> GFR value
    - NA<sup>th</sup> ALQ value
- .....
- NFLO+4 BHP or THT at
- last FLO value

NT<sup>th</sup> THP value

NW<sup>th</sup> WFR value

NG<sup>th</sup> GFR value

NA<sup>th</sup> ALQ value

All combinations of

NF = 1 to NFLO

NT = 1 to NTHP

NW = 1 to NWFR

NG = 1 to NGFR

NA = 1 to NALQ must be covered.

For THT:

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

For BHP:

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

VFP tables created by the VFP *i* program may contain some BHP values set to 1.0E10. This value indicates that the particular combination of flowing conditions is physically impossible, as the fluid in the well bore would exceed the sonic velocity. This may occur, for example, at high flow rates and GOR values and low THP values. The artificially high BHP ensures that during the simulation the well flowing conditions will not enter the forbidden region of unphysical combinations of flowing conditions.

However, because ECLIPSE interpolates linearly between adjacent points in the table, the 1.0E10 values influence the interpolated BHP all the way out to the “physical” table points adjacent to the forbidden region. The sharp change in BHP around these points may cause the wells to behave in an unexpected manner. You are therefore recommended to change any 1.0E10 values in the table to a pressure slightly greater than the reservoir pressure. This should reduce the sharp change in interpolated BHP, while still preventing the well conditions from entering the “forbidden region”. If ECLIPSE detects any 1.0E10 values when reading the VFP<sub>PROD</sub> data, it prints a warning message inviting you to replace them with a lower pressure.

This can be avoided by instructing VFP *i* to use another pressure value to indicate supersonic flow (see the “VFPi User Guide”, and keyword SONICPRS in the VFP *i* manual). A suitable value would be a round number (therefore easily recognizable) that is slightly greater than the maximum expected reservoir pressure.

If a pressure of less than 1.0E10 is used to indicate supersonic flow, you may get a warning message when the table is read saying that the BHP increases with decreasing THP. In this case, you may use the [VFPCHK](#) keyword to set the threshold BHP to the value used to indicate supersonic flow, to prevent these values from triggering the warning.

---

**CAUTION:**

When ECLIPSE 300 encounters a crossing curve, it attempts to correct this internally by reducing the higher BHP value (on the lower THP curve) to lie below the lower BHP value (on the higher THP curve),

so that the BHP increases with increasing THP. However, if the BHP values had been made artificially high on purpose to distinguish regimes of supersonic or erosional flow, the correction removes this distinction and allow the well to operate under these conditions. It is therefore important to use VFPCHK to prevent ECLIPSE 300 altering points that have been given artificially high BHP values for this purpose.

The VFP *i* program can be used to transform existing VFP tables in a number of ways. It can replace any 1.0E10 values with a more reasonable user-defined value. It can transform the ALQ definitions for gas lift into the additive GRAT definition. It can remove the unstable side of the VFP curves (to the left of the minimum), replacing it with lines of constant BHP, which may be useful in curing simulator problems caused by wells suddenly dying (see keyword [WVFPEXP](#)). It also contains extensive graphical facilities for examining and editing VFP tables in cross-section and displaying them in 3D.

## Example

VFP table for producer, NFLO=5, NTHP=2, NWFR=1, NGFR=3, NALQ=1:

```

VFPPROD

## VFPTABL

## Set method of VFP table interpolation for ALQ

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

By default, VFP tables are interpolated linearly in all variables (FLOW, THP, WFR, GFR, ALQ). However, there is an option to apply cubic spline interpolation for the ALQ (Artificial Lift Quantity) variable. This option is primarily intended to be useful for the gas lift optimization facility (see "[Gas lift optimization](#)" in the *ECLIPSE Technical Description*), in which the gradient of the wells' performance with reference to the lift gas injection rate is important for deciding which wells could gain the most benefit from an increased lift gas supply.

With linear interpolation, the gradient of the wells' performance with respect to the ALQ value can change abruptly at each tabulated ALQ point. This may result in the optimal lift gas allocation rate to each well being biased towards the tabulated ALQ values in the VFP table. Interpolation based on cubic splines causes the gradient to change more smoothly over the table, while still honoring the values at the tabulated points.

The VFPTABL keyword is followed by a single integer (either 1 or 2), terminated with a slash (/).

1. Use linear interpolation for all variables in the VFP tables.
2. Use cubic spline interpolation for the ALQ variable in the production well VFP tables, and linear interpolation for the other variables. If there are more than 20 ALQ values in a table, linear interpolation is used for this table regardless of the method requested.

If this keyword is not present, linear interpolation is used for all variables.

This keyword enables the default Ezrokhi coefficients for the aqua viscosity calculation to be overwritten. The data consists of a table composed of a series of 3 coefficients for each component which may dissolve in the aqua phase. In [GASSOL](#), these components are specified using the [SOLUAQA](#) table; in [CO2STORE](#), [GASWAT](#) and thermal [KWTABTn](#), Ezrokhi's coefficients are specified for all components, although it should be noted that the coefficients for component H2O are automatically taken to be zero, irrespective of alternative user-supplied inputs. This keyword associates a contribution of each dissolved component into the aqua viscosity calculation. See also "[GASSOL solution in the aqueous phase](#)" in the *ECLIPSE Technical Description*.

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered as item 9 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

This keyword is thus compatible with the [CO2STORE](#), [GASWAT](#), [GASSOL](#) and [KWTABTn](#) (THERMAL) options.

### Examples

#### Example 1

Input data for a four-component study:

```
VISCAQA
2.42E-7 0.0 1.20E-9
2.22E-7 0.0 1.11E-9
2.00E-7 0.0 1.01E-9
2.01E-7 0.0 1.02E-9
/
```

#### Example 2

With two reservoir EoS regions and four-component study:

```
VISCAQA
2.42E-7 0.0 1.20E-9
2.22E-7 0.0 1.11E-9
2.00E-7 0.0 1.01E-9
2.01E-7 0.0 1.02E-9
/
2.42E-7 0.01 1.20E-9
2.22E-7 0.02 1.11E-9
2.00E-7 0.03 1.01E-9
2.01E-7 0.04 1.02E-9
/
```

This keyword should only be used for runs with the ECLIPSE 100 Temperature option (see keyword [TEMP](#)) or the ECLIPSE 300 Thermal option (see keyword [THERMAL](#)). With the ECLIPSE 100 Temperature option it is required when the [OILVISCT](#) or [WATVISCT](#) keyword is present. With the ECLIPSE 300 Thermal option the keyword is optional, and is only used if pressure dependent oil or water viscosities are required.

The data comprises NTPVT (see keyword [TABDIMS](#)) records describing the reference conditions for the viscosity values in the viscosity versus temperature tables. Each record consists of some or all of the following items of data terminated by a slash (/).

1. The reference pressure  
UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)
2. The reference Rs value. ECLIPSE 100 only.  
This data item is only required if the model contains dissolved gas (see keyword [DISGAS](#)).  
UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), Mscf/stb (FIELD), scc/scc (LAB)
3. The reference API gravity. ECLIPSE 100 only.  
This data item is only required if the API Tracking option is active (see keyword [API](#)).  
UNITS: °API

### Example

With NTPVT=2:

```
VISCREF
3000 1.24 /
3000 1.24 /

x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is part of the VISAGE geomechanics workflow. This workflow is activated by the presence of the [VISAGE](#) keyword in the RUNSPEC section.

This workflow is described in the "[Geomechanics external to ECLIPSE](#)" section of the *ECLIPSE Technical Description*. In this workflow, external calculations are performed using the ECLIPSE fluid simulation results to compute the geomechanical response of the reservoir to changes in pressure, fluid saturations/composition and temperature. These external calculations are performed at particular report steps in the simulation, these report steps are known as stress steps.

The keyword should be followed by a list of report dates at which stress step calculations are required.

Each stress step date must be on a separate line terminated by a slash (/). The data is terminated by a null record (a slash on a line by itself).

A date consists of the following items of data:

- The day of the month  
An integer between 1 and 31.
- The name of the month abbreviated to three characters  
JAN, FEB, MAR, APR, MAY, JUN, JULY, AUG, SEP, OCT, NOV or DEC.  
JUL is an acceptable alternative to JULY.
- The year  
A positive 4 digit integer.
- The time  
A string of the format HH:MM:SS.SSSS  
DEFAULT: 00:00:00

---

**Note:** If a stress step date does not correspond to a report date then it will have no effect. Duplicate dates are ignored (that is, the simulator will act as though that particular stress step date had only been specified once). Any stress step dates which are specified as being before the simulation start date are ignored.

---

**Note:** If this keyword is present more than once, the combined list of dates specified in all the VISDATES keywords is treated as the stress step dates for the simulation.

---

### Example

## VISOPTS

## VISAGE geomechanics workflow options

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies options for use in the VISAGE geomechanics workflow. This workflow is activated by the presence of the [VISAGE](#) keyword in the RUNSPEC section.

This workflow is described in the "[Geomechanics external to ECLIPSE](#)" section of the *ECLIPSE Technical Description*. In this workflow, external calculations are performed using the ECLIPSE fluid simulation results to compute the geomechanical response of the reservoir to changes in pressure, fluid saturations/composition and temperature. These external calculations are performed by particular report steps in the simulations, these report steps are known as stress steps.

The data consists of some or all of the following items. The data must be terminated by a slash (/).

- Whether this is a VISAGE workflow initialization run.

YES GRID, INIT and initial restart data are output, and the run is switched to NOSIM with the report steps that would be performed written to the EDESC communication file.

NO Output of GRID, INIT and initial restart data is not required, and only stress steps are written to the VDESC communication file.

DEFAULT: NO

- Whether the run is to exit at the next stress step encountered.

YES Exit the simulation when the next stress step is encountered.

NO Continue the simulation when the next stress step is encountered.

DEFAULT: NO

- Whether the dynamic stress step mechanism is active.

YES If the field pressure has changed by more than the relative tolerance in item 4 since the last stress step, then the next report step will be treated as a stress step.

NO There are no dynamic stress steps.

DEFAULT: NO

- The relative tolerance on the field pressure for a dynamic stress step. This must not be a negative value.

When the change in field pressure since the previous stress step (or since the beginning of the simulation if there have been no stress steps) divided by the pressure at the previous stress step (or initial pressure if there have been no stress steps) exceeds this tolerance, a dynamic stress step will be triggered as long as item 3 of this keyword is set to ' YES '.

DEFAULT: 0.05

- Not used in this release

- Whether the existing restart frequency is to be maintained.

YES If there are [RPTRST](#) requests to reduce the frequency of the restart files, then these should be honored in the current run.

NO The VISAGE workflow default restart frequency (RPTRST argument BASIC=2) should be used.

DEFAULT: NO

7. Whether the existing restart content is to be maintained.

YES If there are additional RPTRST contents over and above those required for the VISAGE workflow (mnemonics BASIC=2 and ROCKC), then these should be honored in the current run.

NO Only the content required for the VISAGE workflow should be output to the restart files.

DEFAULT: NO

8. Whether it is an error or a warning to not re-specify well connections (which are required in order to recompute well connection factors after a change of permeability) before the first timestep when performing a restart.

ERROR (or E) It is an error, and no simulation will be performed.

WARN (or W) It is a warning, and simulation will proceed using the well connection factors from the restart file.

DEFAULT: ERROR

## Example

The example below is not a VISAGE workflow initialization run and it will stop when it next encounters a stress step. It has the dynamic stress step mechanism active and it will treat a report step as a stress step if the relative change in the field pressure since the last stress step is greater than 0.1 (that is 10%). Any user inputs for restart frequency and content will be honored in this run. If well connections have not been re-specified before the first timestep, it will produce an error.

```
VISOPTS  
NO YES YES 0.10 1* YES YES ERROR/
```

## VREFW

## Reference viscosity and viscosibility for water components

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

VREFW specifies the water viscosity and viscosibility at a reference pressure for each of the  $N_w$  water components.

The water component viscosities, at pressure  $P$ , are calculated from:

$$\mu_w = \mu_{ref_w} / (1 + Y + Y^2/2)$$

$$Y = -c_{V_w} \cdot (P - P_{ref_w})$$

where

$\mu_{ref_w}$  is the reference viscosity, specified with this keyword

$c_{V_w}$  is the viscosibility, specified with this keyword

$P_{ref_w}$  is the reference pressure, specified with keyword [PREFW](#)

The keyword is followed by 2 x  $N_w$  values.

1. The first  $N_w$  values represent the reference viscosity for each water component:

UNITS: cP (METRIC), cP (FIELD), cP (LAB), cP (PVT-M)

DEFAULT: 0.3 cP.

2. The second  $N_w$  values represent the viscosibility at the reference pressure for each water component:

UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB), 1/atm (PVT-M)

DEFAULT: 0.0.

If multiple equations of state are being used, a set of data should be entered for each reservoir EoS. The number of reservoir equation of state regions is entered in item 9 of keyword [TABDIMS](#). The use of multiple EoS regions is discussed in "[Equations of state regions](#)" in the *ECLIPSE Technical Description*.

See "[Water components](#)" in the *ECLIPSE Technical Description* for further details of the water component option.

### Example

```
VREFW
0.31 0.32
0.0 0.0 /
```

## W

This section contains an alphabetic listing of keywords starting with the letter W.

## WADVANCE Assign advance import gas to a well

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword assigns a supply of advance import gas to a well supplying gas for reinjection (see keywords [GINJGAS](#), [WINJGAS](#), [GRUPINJE](#) and [WELLINJE](#)). When gas from this well is reinjected, the advance gas is used for reinjection prior to the gas produced by this well from the reservoir. If the reinjection requirements can be met by the advance gas stream alone, then no produced gas is reinjected. If the advance and available produced gas streams together are not sufficient to satisfy the reinjection requirements, make-up gas, if specified for the injection group or well, are used to make up the shortfall.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/). The set of records must be ended by a blank record, containing only a slash.

1. Well name, well name root or well list name

A well name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several wells in one record. Alternatively a well list name, enclosed in quotes and beginning with an asterisk (\*), may be used. Well lists are constructed with the keyword [WLIST](#).

2. The name of the wellstream (defined using the [WELLSTRE](#) keyword) which defines the composition of the advance gas.
3. The maximum rate at which advance gas can be supplied.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC), Mscf/day (FIELD), scc/hr (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

By setting the [item 30](#) in the [OPTIONS3](#) keyword, an alternative mixing tank treatment may be invoked, where the advance gas is mixed with the produced gas and gas from this mixing tank is reinjected. The fraction of advance gas in this mixture is equal to the ratio of the specified advance gas rate (item 3) to the sum of the specified advance gas rate and the available gas production rate. With this option, the advance gas is not used in preference to the produced gas.

If advance gas is used, the injection calculation may have to be iterated to match the injection gas composition with the injection rate (see keyword [GCONTOL](#)).

---

**Note:** Advance gas is assigned to the source well supplying the gas, while make-up gas is assigned to the group or well having the injection target.

---

### Example

Advance gas is assigned to well W3 at a maximum rate of 4100 Mscf/day.

```
WADVANCE
W3 STR1 4100 /
```

## WAGHALT

## WAGHYSTR **WAG** hysteresis parameters

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword activates the WAG hysteresis model and supplies the data items required by the model. The WAG hysteresis model can only be used if the hysteresis option has been requested (see keyword [SATOPTS](#) in the RUNSPEC section).

The keyword should be followed by NTSFUN (see keyword [TABDIMS](#) in the RUNSPEC section) records of data, each terminated by a slash (/). The entire table may be defaulted provided the table is not the first one. Defaulted tables are replaced with a copy of the previous table. The NTSFUN records apply to the corresponding saturation table numbers.

Each record should consist of some or all of the following items of data:

1. Land's parameter,  $C$

This parameter governs the trapped gas saturation on imbibition and the shape of the imbibition curve. The trapped gas saturation is given by:

$$Sg_{trap} = Sg_{cr} + \frac{(Sg_m - Sg_{cr})}{(1 + C \cdot (Sg_m - Sg_{cr}))}$$

where

$Sg_{trap}$  is the trapped gas saturation

$Sg_m$  is the maximum gas saturation attained

$Sg_{cr}$  is the critical gas saturation.

Land's parameter should be greater than zero. If the parameter is too small the trapped gas saturation is close to  $Sg_m$  and the subsequent imbibition relative permeability curve is steep. An unphysically steep curve is likely to lead to convergence problems.

2. The Secondary Drainage reduction factor,  $\alpha$

The reduction factor should be greater than zero. The greater the value of  $\alpha$  the greater will be the reduction in gas mobility on secondary drainage.

DEFAULT: 0.0

3. Gas model flag

YES Use the WAG Hysteresis Model for the gas phase relative permeability.

NO Turn off the WAG Model and use the drainage curve.

DEFAULT: YES

4. Residual oil flag

YES Use the trapped gas saturation to modify the residual oil ( $SOM$ ) in the STONE 1 three-phase oil relative permeability model. No action is taken unless the [STONE1](#) keyword has been entered.

NO Do not modify the oil relative permeability.

DEFAULT: YES

## 5. Water model flag

YES Apply the WAG Hysteresis Wetting Phase Model to the water phase.

NO Do not apply the WAG hysteresis model. Note that the Hysteresis Model specified in the [EHYSTR](#) keyword applies.

DEFAULT: YES

## 6. Imbibition curve linear fraction

This is the fraction of the curve between  $S_{g_m}$  and  $S_{g_{trap}}$  that uses a linear transformation. A non-zero value for the linear fraction prevents the potential infinite gradient in the imbibition curve when using the Carlson analytic model.

DEFAULT: 0.1

## 7. Three-phase model threshold saturation

This is the water saturation threshold above the connate value at which the gas (non-wetting) phase hysteresis switches from the two-phase model to the three-phase model. In the two-phase model a secondary drainage process follows the imbibition curve. However, if the water saturation exceeds the connate saturation by the given threshold, at the beginning of the secondary drainage process a three-phase secondary drainage curve is followed. This value is also used as a percentage change in gas saturation to allow switching from drainage to imbibition curve and vice-versa. This threshold allows better control of the numerical sensitivity of the system, preventing it from being too unstable.

DEFAULT: 0.001

## 8. Residual oil modification fraction

This is the fraction of the trapped gas saturation subtracted from the residual oil (*SOM*) in the STONE 1 three-phase oil relative permeability model. The value should lie between zero and 1.

DEFAULT: 1.0

The hysteresis models are described in more detail under "[Hysteresis in WAG floods](#)" in the *ECLIPSE Technical Description*.

## Notes

- In some situations the switching from the drainage to imbibition curve and vice-versa can be so sensitive to numerical errors that the loss of precision at a restart is enough to give differing answers between the base case and the restart run. In these exceptional cases it is recommended not to use the restart simulations at the points of switching curves. This allows better control of the numerical sensitivity of the system, preventing it from being different to the base simulations.
- The usage of the gas and water relative permeability versus saturation tables differs between conventional hysteresis and WAG hysteresis. For conventional hysteresis, the imbibition tables define the imbibition saturation functions. For WAG hysteresis, if this is applied to the gas phase, the imbibition table gas phase relative permeability specifies the three-phase relative permeability rather than the imbibition relative permeability. Similarly, if this is applied to the water phase, the imbibition table water relative permeability specifies the three-phase relative permeability. Hence the process of selecting or deselecting WAG hysteresis will, in general, require changes to the imbibition saturation function tables for the gas and water relative permeabilities.

**ECLIPSE 100**

- WAGHYSTR cannot be specified in a restart run unless it has been specified in the base run and any intermediate restart runs.

**ECLIPSE 300**

- Versions prior to 2012.1 did not support parallel restarts if the WAGHYSTR keyword was specified. For the 2012.1 version, the restart records associated with the WAG hysteresis option have been restructured in order to support the various possible combinations of serial/parallel base case and serial/parallel restart case and similarly for successive restarts.
- For the 2012.1 version onwards, WAGHYSTR can be specified in a restart run without having been specified in the base run and vice versa. A similar relaxation applies to successive restarts. However, careful consideration should be given as to whether a temporally partial modeling of WAG hysteresis is appropriate for a given reservoir model. In particular, if WAGHYSTR is first specified in a restart run, no previous WAG history will be available and the simulation results will be different to those where WAG hysteresis has been modeled throughout. Similarly, if WAGHYSTR is specified in the base case but not in the restart case, the WAG history from the base case will not be preserved or used for the restart run and the simulation results will again be different to those where WAG hysteresis has been modeled throughout.
- For versions prior to 2012.1, the WAG hysteresis restart record written by a parallel base case has been found in some cases to be incomplete and problems of this kind are now detected and reported. In such cases, the recommended workaround is to rerun the base case in serial using the previous version or in serial or parallel using the 2012.1 or later version. Alternatively, the incomplete WAG hysteresis restart record may be bypassed by setting [item 279](#) of the OPTIONS3 keyword to 2. However, in this case, the previous WAG history will be lost.
- When reading from a pre-2012.1 restart record, it is not possible to perform a parallel restart run. Only a serial run is possible. This limitation is inherited from the restriction on pre-2012.1 version WAG hysteresis records for which parallel restarts are not supported. If a parallel restart from a pre-2012.1 version is required, the recommended workaround is to perform an initial short serial run and write a 2012.1 version restart record. This may then be used to run any subsequent restarts in parallel.
- The use of the restructured WAG hysteresis records for the 2012.1 version can be reverted to the pre-2012.1 restart record type by setting item 279 of the OPTIONS3 keyword to 1. However, in this case, all of the limitations which apply to the pre-2012.1 versions will also be reinstated, in particular, no support for parallel restarts, potentially incomplete parallel base case restart records and no facility for selecting or deselecting WAG hysteresis with each successive restart.
- In some cases it has been found that reading restarts which contain WAG hysteresis records created by the 2009.1 and 2009.2 versions fails with a message referring to an incorrect header record. This is associated with an attempt to read a UDA/UDQ restart record when none was defined. Under these circumstances [item 282](#) of the OPTIONS3 keyword may be set to 1 to bypass the reading of the nonexistent UDA/UDQ record thereby resulting in the correct reading of the WAG hysteresis record. (This does not address the problems associated with the incorrect size of the WAG hysteresis which can occur in some cases with restarts written by parallel runs using versions prior to 2012.1.

## Example

With NTSFUN=3:

```
WAGHYSTR
2.0 1.0 YES YES YES 0.2 /
2.0 1.0 YES NO /
2.0 /
```

## WAITBAL

## Prevents PRORDER and GDRILPOT actions being performed until network is balanced

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword can be used in conjunction with the network option (see "[Network option](#)" in the *ECLIPSE Technical Description*) to request that the drilling of new wells and other production rule actions to enhance production should not occur until the network has been balanced.

At each network balancing iteration, the well and group production rates are determined at the latest iterate of the nodal pressures. If a group production target cannot be met, actions may be taken to increase production, such as drilling a new well (see keyword [PRORDER](#)). New wells may also be drilled to maintain a group's production potential above a specified value (see keyword [GDRILPOT](#)). By default, all such actions except for automatic compressor switching (keyword [NETCOMPA](#)) are performed whenever required to increase the production rate in **any** network balancing iteration. However, it is possible that an intermediate balancing iteration with high nodal pressures and consequentially low well productivities may cause such an action to be taken prematurely. This can be prevented by using the WAITBAL keyword to request that these actions should not be performed until the network is properly balanced. Then if more flow is required once the network has converged, an appropriate action is performed and the network must be balanced again. Using this option therefore requires more network balancing iterations in total.

The keyword is followed by one item of data, terminated with a slash (/).

- Flag indicating whether PRORDER and GDRILPOT actions should wait until the network is balanced.

NO The actions are performed at any iteration of the network balancing calculation.

YES The actions are only performed if required after the network balancing iterations have converged.

(The word may be abbreviated; only the first character is significant)

DEFAULT: NO

End the data record with a slash (/).

## ECLIPSE 300

**Note:** ECLIPSE 300 always waits until the network is balanced before deciding whether to open a new well from the drilling queue; this is equivalent to having item 1 permanently set to YES.

### Example

```
WAITBAL
YES /
```

## WALKALIN Sets alkaline concentration for water injection wells

This keyword is used to specify the concentration of alkaline in the water injection well when the surfactant flood model and/or the polymer flood model are active.

The keyword is followed by any number of records, each containing the following data:

1. Well name, well name template, well list or well list template.

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. The concentration of alkaline in the water injection stream. This quantity can be a user defined argument (UDA), and can be set with keywords [UDQ](#) and [UDADIMS](#).

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB), kg/sm<sup>3</sup> (PVT-M)

End data record with a slash (/).

End the set of records with a blank record, containing just a slash (/).

### Example

```

WALKALIN
  INJ1  0.3 /
  INJ2  0.2 /
/

```

## WALQCALC Defines the well ALQ to be the oil or gas surface density

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to equate the ALQ value in a well to its oil surface density or its gas surface density. VFP *i* can produce a VFP table that spans a range of oil or gas surface densities, and the WALQCALC keyword instructs ECLIPSE to interpolate it at the current surface density of the oil or gas that the well is producing, by setting its ALQ equal to that value. This option is useful in API tracking runs, and also when the same table is used by several wells in different PVT regions. (A similar option can also be applied to branch pressure drops in the network option; see "[Network option](#)" in the *ECLIPSE Technical Description*, and see also keywords [GRUPNET](#) and [BRANPROP](#).)

The WALQCALC keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

### 1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

A well name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several wells in one record. Alternatively a well list name, enclosed in quotes and beginning with an asterisk (\*), may be used. Well lists are constructed with the keyword [WLIST](#).

### 2. ALQ definition for the well

A well name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several wells in one record. Alternatively a well list name, enclosed in quotes and beginning with an asterisk (\*), may be used. Well lists are constructed with the keyword [WLIST](#).

DENO The well's ALQ is equated to its oil surface density, in kg/m<sup>3</sup> (METRIC), lb/ft<sup>3</sup> (FIELD), gm/cc (LAB), kg/m<sup>3</sup> (PVT-M)

DENG The well's ALQ is equated to its gas surface density, in kg/m<sup>3</sup> (METRIC), lb/ft<sup>3</sup> (FIELD), gm/cc (LAB), kg/m<sup>3</sup> (PVT-M)

NONE The well's ALQ will **not** be automatically set equal to its oil or gas surface density

DEFAULT: NONE

End the data record with a slash (/).

End the set of records with a blank record containing just a slash.

---

**Note:** If DENO or DENG is chosen for a well, the VFP table that it uses **must** be constructed using the same definition of the ALQ in item 7 of the first record of the [VFPPROD](#) keyword.

---

**CAUTION:** Obviously the ALQ cannot also be used for artificial lift when it is equated to the well's oil or gas surface density. Thus the surface density definition must **not** be used in circumstances when the ALQ is assumed to be the lift gas injection rate (for example in Gas Lift Optimization, or with [GLIFTLIM](#)).

---

## Example

```
WALQCALC
' * '      DENO      / equates ALQ to oil surface density in all wells
PROD3     NONE      / except for PROD3 which has no special ALQ definition
/
```

## Sets oil API for oil injection wells

This keyword can be used to specify the oil API in the injection stream of each well. The keyword should only be used in runs with the API tracking option active (keyword [API](#) in the RUNSPEC section). If the WAPI keyword does not appear in the injection schedule, then the API of the block being injected into is assumed. Data should only appear for wells which are currently declared to be oil injection wells in [WCONINJE](#).

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. The corresponding value of the injected oil API gravity. This quantity can be a user defined argument (UDA), and can be set with keywords [UDQ](#) and [UDADIMS](#).

UNITS: °API

End data record with a slash (/).

End the set of records with a blank record, containing just a slash (/).

### Example

```
WAPI
OILINJ 42.0 /
/
```

## WARN

# Allow ECLIPSE warning messages

This keyword switches warning messages back on after being suppressed by the [NOWARN](#) keyword.

The keyword has no associated data.

This keyword is optional, and may only be used in runs with the Thermal option. See keyword [THERMAL](#).

The data comprises NTPVT (see keyword [TABDIMS](#)) records, each terminated by a slash (/). Each record consists of three items of data:

1. The reference temperature  $T_{ref}$   
 UNITS: K (METRIC), °R (FIELD), K (LAB), K (PVT-M)  
 DEFAULT: 293.15 K = 527.67 °R
2. The first thermal expansion coefficient  $c_{T1}$   
 UNITS: 1/K (METRIC), 1/°R (FIELD), 1/K (LAB), 1/K (PVT-M)  
 DEFAULT:  $3.0e-4 \text{ K}^{-1} = 1.67 \text{ °R}^{-1}$
3. The second thermal expansion coefficient  $c_{T2}$   
 UNITS: 1/K<sup>2</sup> (METRIC), 1/°R<sup>2</sup> (FIELD), 1/K<sup>2</sup> (LAB), 1/K<sup>2</sup> (PVT-M)  
 DEFAULT:  $3.0e-6 \text{ K}^{-2} = 9.26e-7 \text{ °R}^{-2}$

If this keyword is used the water formation volume factor  $B_w$  is defined by  

$$B_w(P, T) = B_w(P_{ref}) \cdot (1-X) \cdot (1 + c_{T1} \cdot (T-T_{ref}) + c_{T2} \cdot (T-T_{ref})^2)$$

where

$$X = C \cdot (P - P_{ref}) \text{ and}$$

$P_{ref}$ ,  $B_w(P_{ref})$  and  $C$  are defined by the [PVTW](#) keyword.

## Example

```
WATDENT
/
```

## WATER

### Run contains water

This indicates that the run contains water as an active phase, whose saturation can vary.

The keyword has no associated data.

	SCHEDULE

The data specified consists of a number of tables of water pressure data, each terminated with a slash (/). The number of tables should be equal to NTPVT (see item 2 of the [TABDIMS](#) keyword).

Each row of the table consists of 3 columns of data, and at least two rows of data should be entered.

Outside the range of specified pressures, values are linearly extrapolated.

1. The water phase pressure.

Values should increase down the column.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

2. The water formation volume factor

Values should decrease down the column.

UNITS:  $\text{mm}^3/\text{sm}^3$  (METRIC), rb/stb (FIELD), rcc/scc (LAB),  $\text{mm}^3/\text{sm}^3$  (PVT-M)

3. The water viscosity.

Values should be level or increasing down the column.

UNITS: cP (METRIC), cP (FIELD), cP (LAB), cP (PVT-M)

There must be the same number of entries in each column of a given table, and the number of rows should be less than or equal to NPPVT (item 4 of keyword [TABDIMS](#)).

Apart from the last or first rows, values in the second and third columns may be defaulted, and such values are linearly interpolated.

### Example

```

WATERTAB
3000 1.00341 0.52341
3900 1      0.56341 /

```

## WATVISCT Water viscosity as a function of temperature

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is optional and can be used with the blackoil temperature option or the compositional Thermal option.

If the temperature option is active (see keyword [TEMP](#)), and if the WATVISCT keyword is used, then the [VISCREF](#) keyword should be specified to supply the reference conditions for the water viscosity. If the Thermal option is active (see keyword [THERMAL](#)), VISCREF is only needed if a pressure dependence is required, as discussed below.

The data comprises NTPVT (see keyword [TABDIMS](#)) tables of water viscosity versus temperature, each terminated by a slash (/). Each table consists of 2 columns of data:

Column:

1. The temperature.

The values should increase monotonically down the column.

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

2. The corresponding water viscosity

UNITS: cP (METRIC), cP (FIELD), cP (LAB), cP (PVT-M)

There must be the same number of entries in each column of a given table. This number should not be less than 2 or greater than NPPVT (see keyword [TABDIMS](#)).

The values supplied for the water viscosity are assumed to be at the reference pressure given in the [VISCREF](#) keyword and at the reference salt concentration defined by item 2, record 1 of the [PVTWSALT](#) keyword, if the Brine option is active. The water viscosity at the prevailing temperature, pressure and optionally salt concentration is then calculated as follows:

$$\mu_w(T, P) = \mu_T(T) \frac{\mu_p(P)}{\mu_p(P_{ref})} \quad \text{Eq. 3.213}$$

or, if the brine option is active, as

$$\mu_w(T, P, c_s) = \mu_T(T) \frac{\mu_p(P, c_s)}{\mu_p(P_{ref}, c_{s,ref})} \quad \text{Eq. 3.214}$$

where

$\mu_T$  is the viscosity from the WATVISCT keyword.

$\mu_p$  is the viscosity from the [PVTW](#) or [PVTWSALT](#) keyword.

$P_{ref}$  is the reference pressure defined by the [VISCREF](#) keyword.

$c_{s,ref}$  is the reference salt concentration defined by item 2, record 1 of the [PVTWSALT](#) keyword.

In the Thermal [VISCREF](#) the values of water viscosity are assumed to be independent of pressure, unless the [VISCREF](#) keyword is used. In this case the water viscosity is defined by equation [3.213](#).

See also keyword [OILVISCT](#).

ECLIPSE 100

---

**Note:** ECLIPSE 100 linearly interpolates the reciprocal of the water viscosities between data points, rather than the values themselves.

---

ECLIPSE 300

---

**Note:** ECLIPSE 300 linearly interpolates the water viscosities directly between data points.

---

## Example

With  $NTPVT = 1$  and  $NPPVT \geq 3$ :

```
WATVISCT
  10  1
 100 0.6
 150 0.4  /
```

## WAVAILIM

## Requests availability limiting of injection

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword requests that the availability of injection fluids is to be taken into account when calculating injection rates. If the required injection target is greater than the amount of injection fluid available from the production system the injector goes onto availability control.

If the injection stream originates from a particular source group or well (named in item 3 of [GINJGAS](#), [WINJGAS](#), [GRUPINJE](#) or [WELLINJE](#) when item 2 is GV or WV), and the injection target exceeds the available gas from this source, the extra gas required is taken from the make-up gas stream if this is specified for the group or well with the injection target. If no make-up gas is specified, the behavior of the injection controls will depend on whether the keyword WAVAILIM is entered. Without this keyword, the injection target is honored by injecting more gas than is available, resulting in a negative excess rate in the gas accounting table. If the WAVAILIM keyword is entered, the injection rate is limited by the amount of gas available for injection from the source group or well. When the injection stream originates from a source group, the gas available for injection is its produced gas, minus its fuel and sales gas (unless specified otherwise in [WTAKEGAS](#)), plus its advance gas rate specified in [GADVANCE](#) (unless the 99A release default mixing tank treatment has been enabled by setting [item 30](#) in OPTIONS3 to 2). When the injection stream originates from a source well, the gas available for injection is its produced gas, plus its advance gas specified in [WADVANCE](#) (unless the 99A release default mixing tank treatment has been enabled by setting [item 30](#) in OPTIONS3 to 2).

If a limited source of gas is shared between two or more injection groups, the injection calculation may have to be iterated a number of times to match the groups' share of the available gas with their injection capability (see keyword [GCONTROL](#)).

The WAVAILIM keyword contain no items.

See also "[Group injection control options](#)" in the *ECLIPSE Technical Description*.

## WBHGLR

## Well limits on bottom hole gas liquid ratio

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword provides two facilities for limiting the bottom hole gas liquid ratio of a production well. The bottom hole GLR is defined as the ratio of free gas flow to liquid flow at bottom hole conditions, that is at the bottom hole pressure of the well (at the datum defined in item 5 of keyword [WELSPEC](#)). Facilities to restrict this quantity can be useful when there is a down hole pump, whose efficiency can be seriously reduced by the presence of free gas. Using this keyword, the quantity can be restricted by a well cutback limit and/or a well economic limit.

The well cutback limit is applied in exactly the same manner as the [WCUTBACK](#) keyword. If the well exceeds the cutback limit (item 2) at the end of the timestep, it will be set to operate at a reduced target rate of the control phase specified in item 5. The target rate of the control phase is set equal to the well's current flow rate of that phase, multiplied by the cutback factor specified in item 4. A cutback reversal limit may also be entered (item 3) to reverse the cutback process if the bottom hole GLR falls below this value. If the well is currently operating under rate control of the phase selected in item 5, the target rate of the phase is increased by dividing it by the cutback factor. Any user-defined limit on the control phase in item 5 is overwritten, so it is best to choose as the control phase a phase for which there are no user-defined limits.

The economic limit (item 6) is applied in exactly the same manner as the [WECON](#) keyword. If the bottom hole GLR exceeds the economic limit, the well is closed or worked over as specified in item 7.

The value of the bottom hole GLR can be written to the Summary file using the SUMMARY section mnemonic WBGLR.

The WBHGLR keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Upper limit bottom hole GLR for well rate cutback

A value of 0.0 or > 1.0E19 switches off this check.

UNITS:  $\text{rm}^3/\text{rm}^3$  (METRIC),  $\text{rb}/\text{rb}$  (FIELD),  $\text{rcc}/\text{rcc}$  (LAB),  $\text{rm}^3/\text{rm}^3$  (PVT-M)

DEFAULT: Infinity (1.0E20)

3. Lower limit bottom hole GLR for reversing the cutback process

A value of 0.0 or > 1.0E19 switches off this check.

UNITS:  $\text{rm}^3/\text{rm}^3$  (METRIC),  $\text{rb}/\text{rb}$  (FIELD),  $\text{rcc}/\text{rcc}$  (LAB),  $\text{rm}^3/\text{rm}^3$  (PVT-M)

DEFAULT: 0.0

4. Rate cutback factor

This is the ratio of the reduced flow rate to the current flow rate. It should be less than 1.0

The same rate cutback factor applies to both this keyword and the [WCUTBACK](#) keyword. If [WCUTBACK](#) has been entered previously, this item overwrites item 6 in that keyword. If [WCUTBACK](#) is entered subsequently, its item 6 overwrites this item.

UNITS: Fraction

DEFAULT: same as item 6 in the WCUTBACK keyword, if that has been entered previously, otherwise 1.0

5. Control phase, to which the reduced rate applies

OIL Reduced oil rate

WAT Reduced water rate

GAS Reduced gas rate

LIQ Reduced liquid rate

RESV Reduced reservoir fluid volume rate

COMB Reduced linearly combined rate (coefficients must be set with [LINCOM](#))

You are advised to choose a phase that does not have a user defined rate limit, as it would be overwritten whenever a cutback or cutback reversal occurs; see Note 3 in the documentation for keyword WCUTBACK.

The same control phase applies to both this keyword and the WCUTBACK keyword. If WCUTBACK has been entered previously, this item overwrites item 7 in that keyword. If WCUTBACK is entered subsequently, its item 7 overwrites this item.

DEFAULT: same as item 7 in the WCUTBACK keyword, if that has been entered previously, otherwise RESV

6. Maximum bottom hole GLR economic limit

A value of 0.0 or  $> 1.0E19$  switches off this check.

UNITS:  $\text{rm}^3/\text{rm}^3$  (METRIC),  $\text{rb}/\text{rb}$  (FIELD),  $\text{rcc}/\text{rcc}$  (LAB),  $\text{rm}^3/\text{rm}^3$  (PVT-M)

DEFAULT: Infinity (1.0E20)

7. Workover procedure on exceeding the bottom hole GLR economic limit

NONE Do nothing

CON Shut worst-offending connection

+CON Shut worst-offending connection and all below it

WELL Shut or stop well (item 9 in keyword [WELSPECS](#))

PLUG Plug back well (see keyword [WPLUG](#))

DEFAULT: same as item 7 in the [WECON](#) keyword, if this has been entered previously; otherwise NONE

8. Remove cutbacks when the well is worked over?

YES When the well is worked over after violating an economic limit (set in keywords [CECON](#) and [WECON](#) for example), any rate cutbacks performed on the well are completely reversed by removing the rate limit on the control phase specified in item 5.

NO Any cutbacks made to the well remains in force (unless reversed by application of cutback reversal limits).

The same instruction applies to both this keyword and the WCUTBACK keyword. If WCUTBACK has been entered previously, this item overwrites item 14 in that keyword. If WCUTBACK is entered subsequently, its item 14 overwrites this item.

DEFAULT: NO

End each data record with a slash (/).

End the set of records with a blank record, containing just a slash.

See also keywords [WCUTBACK](#), [WECON](#) and [WLIMTOL](#).

## Example

```
WBHGLR
Well  Cutback   Cutback   Cutback   Control   Economic   Workover
Name  Limit      Reversal  Factor    Phase     Limit      Procedure
WELL1 0.3         0.05      0.8       RESV      /
WELL2 4*
/
```

## WBOREVOL Sets volume for wellbore storage

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies an effective wellbore volume for individual wells, to enable ECLIPSE to model wellbore storage effects in well tests. ECLIPSE calculates the well solution variables (BHP, water fraction and gas fraction) by solving a material balance equation for each phase in each well:

production rate = inflow through connections - material accumulation in wellbore.

Normally, the accumulation term is made negligible by giving the wellbore a very small volume (1.0E-5 FT<sup>3</sup>). But the keyword WBOREVOL allows you to specify a larger volume, enabling ECLIPSE to model wellbore storage effects through the accumulation term. The keyword should be entered **before** the [WCONPROD](#) or [WELOPEN](#) keyword that opens or stops the well at the start of the test. Note that in order to calculate the BHP variation in a shut-in test, the well must be **stopped** rather than **shut**.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Effective wellbore volume

UNITS: m<sup>3</sup> (METRIC), ft<sup>3</sup> (FIELD), cc (LAB), m<sup>3</sup> (PVT-M)

DEFAULT: 1.0E-5, giving negligible storage effects.

3. Well BHP at start of test

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: Pressure in the grid block containing the topmost connection in the well. (This is a suitable value for the start of the flowing period, provided that the bottom hole datum depth has been defaulted in item 5 of keyword [WELSPECS](#). If the bottom hole datum is set at any other depth, you should either set the initial BHP here if it is known, or let the well reach its initial BHP by running it **stopped** for a while before the test.)

The setting of the initial BHP is ignored if the wellbore volume is 1.0E-5 or less, as this turns the wellbore storage facility off.

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

---

**Note:** This keyword must **not** be used for multisegment wells (see "[Multisegment wells](#)" in the *ECLIPSE Technical Description*). Their wellbore volumes are set when their segments are defined in keyword [WELSEGS](#).

---

### Example

```
WBOREVOL
-- well name    wellbore volume    initial pressure

## The effective wellbore volume

The effective wellbore volume can be determined from the dimensionless wellbore storage coefficient, as shown below.

The dimensionless wellbore storage coefficient,  $C_D$ , is defined as:

$$C_D = \frac{C}{2\pi\phi c_t h r_w^2} \quad \text{Eq. 3.215}$$

where

$C$  is the wellbore storage coefficient

$\pi$  is 3.14159

$\phi$  is the formation porosity

$c_t$  is the total compressibility of the system (fluid + rock)

$h$  is the formation thickness

$r_w$  is the wellbore radius.

The wellbore storage coefficient  $C$  is defined as the increase in the volume of fluid that the wellbore can store per unit increase in pressure,

$$V = \frac{dV}{dP} \quad \text{Eq. 3.216}$$

For storage due to fluid expansion in the wellbore,

$$C = c_w V_w \quad \text{Eq. 3.217}$$

where

$c_w$  is the compressibility of the fluid in the wellbore

$V_w$  is the effective volume of the wellbore.

Thus the effective wellbore volume is related to the dimensionless storage coefficient by:

$$V_w = \frac{2\pi\phi c_t h r_w^2 C_D}{c_w} \quad \text{Eq. 3.218}$$

## WCALVAL Sets the calorific value of gas at a well

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword WCALVAL specifies the calorific value of the gas produced from a particular well, for use with the gas calorific value control option (see "Gas calorific value control" in the *ECLIPSE Technical Description*). The energy production rate from that well is then equal to its gas rate multiplied by its calorific value. Well calorific values can be changed at any time by reentering the keyword.

If **no** tracer has been defined with the CALTRAC keyword to represent the calorific value of the gas in the reservoir, the gas producing wells must have their calorific values set individually with keyword WCALVAL. Any well **not** given a calorific value with keyword WCALVAL will have a zero calorific value.

If a calorific value tracer **has** been defined with keyword CALTRAC, each well's calorific value will be set equal to its produced concentration of the tracer, unless this is overridden by use of the WCALVAL keyword. WCALVAL may be used to override the tracer value for individual wells. A well may subsequently be switched back to using the tracer value by entering a negative value for the calorific value in item 2.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/). The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "Well name and well list template matching" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword WLIST.

2. Calorific value of gas from the well

A negative value causes the well to have its calorific value set according to the concentration of the tracer named in the CALTRAC keyword.

UNITS: kJ/sm<sup>3</sup> (METRIC), Btu/Mscf (FIELD), J/scc (LAB), kJ/sm<sup>3</sup> (PVT-M)

DEFAULT: -1.0

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

### Example

```
WCALVAL
'P*'      40000.0 /
PROD3     38500.0 /
PROD4     39300.0 /
/
```

## WCOL

## Coloring for WARP linear solver

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword controls the coloring method used within the WARP linear solver. This is initiated using the [WARP](#) keyword. Coloring is required when using the [PARALLEL](#) option. The presence of this keyword initiates the WARP linear solver. The keyword contains three items of data terminated with a slash (/).

1. The type of coloring.

Valid inputs are:

'XY' The partition is subdivided in the X and Y directions

'X' The partition is subdivided in the X direction

'Y' The partition is subdivided in the Y direction

' ' If left blank the coloring is chosen based on the partition splits, so if [NPROCX](#), [NPROCY](#) then 'Y' coloring is used, otherwise 'X' coloring is used. This is the DEFAULT.

2. Number of colors.

This item is only relevant if the number of processors is set greater than 1 in item 1 of the [PARALLEL](#) keyword. Otherwise, a value of 1 is assumed.

DEFAULT: 2 (if there is more than one processor)

3. LGR sub-grid treatment.

1 - The color of any LGR grid is inherited from the base grid. Portions of LGR grid of the same level of refinement and color are amalgamated into a sub-grid.

If the number of colors set in item 2 of this keyword is set to 1, then each level of LGR refinement represents a sub-grid.

2 - The color of any LGR grid is inherited from the base grid, and the portions of the base grid and LGR grid that have the same color are then amalgamated into the same sub-grid. This is the DEFAULT.

In this case the number of sub-grids is independent of the number, or levels, of LGRs. If the number of colors in item 2 of this keyword is set to 1, then only one sub-grid will result.

3 - Each LGR is colored using the type and number specified in items 1 and 2. No amalgamation of LGRs within or between levels is performed.

Many sub-grids can easily be generated with this method.

For further information see "[The ECLIPSE 300 WARP linear solver](#)" in the *ECLIPSE Technical Description*

## WCOMPRES Compresses internal well arrays

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword may be used to reduce to memory requirements of a simulation with a large number of wells, some of which have many connections, but most have relatively few connections. In such circumstances, internal well arrays holding connection data that are dimensioned to the maximum number of connections per well multiplied by the maximum number of wells (see items 1 and 2 of [WELLDIMS](#)) will be wasteful of memory. If this keyword is specified, these internal arrays will be dimensioned to the actual number of well connections in the simulation, which may be specified in item 1 below. Alternatively, if item 1 is defaulted, a pre-sweep of the `SCHEDULE` section keywords will be performed to estimate the number of well connections in the simulation. Both the actual and estimated number of connections are reported in the print file at the end of the simulation.

The keyword is followed by one record containing one item and must be terminated with a slash (/).

1. Number of well connections in the simulation.

DEFAULT: This quantity will be estimated by a pre-sweep of the Schedule section keywords that define wells and well connections.

**Note:** In some circumstances, the number of connections estimated by the pre-sweep or set by the user may be less than the actual number of connections required during the simulation. For example, this will happen if new connections are defined in a flexible restart run that are not present in the base run. (A pre-sweep of the restart data may not be reliable, and is thus banned, as some or all of the `SCHEDULE` section keywords may have been deleted before the timestepping keyword at the restart time.) In these circumstances, extra space for the internal well arrays will be automatically reallocated by increasing the number of connections in blocks of ten.

## WCONHIST **Observed rates for history matching production wells**

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used in place of [WCONPROD](#) to declare production wells as special history matching wells, and to enter their observed flow rates (and optionally their measured BHP and THP values). The equivalent keyword for defining history matching injection wells is [WCONINJH](#).

Wells can be declared as history matching wells during the history matching process, when their oil, water and gas production rates are known. ECLIPSE treats them differently from ordinary production wells, in the following ways:

- The observed oil, water and gas rates entered with this keyword can be written to the summary file, along with the water cut, GOR and THP for example, for comparison with the rates calculated during the simulation.
- The wells have a restricted set of control modes:

**ORAT** The well produces the observed oil rate. The other phases will be produced according to their mobility ratios.

**WRAT** The well produces the observed water rate. The other phases will be produced according to their mobility ratios.

**GRAT** The well produces the observed gas rate. The other phases will be produced according to their mobility ratios.

**LRAT** The well produces at a liquid rate equal to the sum of the observed oil and water rates. The calculated oil and water rates may differ from the values entered if the mobility ratios have not been fully matched.

**CRAT** The well produces at a combined rate equal to the linear combination of the observed oil, water and gas rates. The coefficients for the linear combination are defined with keyword [LINCOM](#).

**RESV** At each timestep, ECLIPSE calculates the reservoir fluid volume rate corresponding to the observed phase flow rates, using the reservoir pressure at the beginning of the timestep, and puts the well under RESV control to produce at that target. (The reservoir pressure used is either the average hydrocarbon pressure of the field, or the average hydrocarbon pressure of a specified fluids-in-place region, depending on the entry for item 13 in the keyword [WELSPECS](#).) The calculated oil, water and gas rates may differ from the values entered if the mobility ratios have not been fully matched.

*ECLIPSE 300 only*

**WGRA** The well produces the observed wet gas rate. The other phases will be produced according to their mobility ratios.

*ECLIPSE 300 only*

**NGL** The well produces the observed NGL rate. The other phases will be produced according to their mobility ratios.

**BHP** The well produces at the observed BHP.

The LRAT and RESV control modes are useful for making the well produce the correct amount of total fluid from the reservoir before the mobility ratios are fully matched. Thus the rate of pressure decline should be approximately correct.

- The phase flow rates entered here are not treated as upper limits. If the well's calculated water rate, for example, exceeds the observed value, the well does **not** automatically change control to WRAT. Apart from setting the rate target, the phase flow rates are only used for reporting in the SUMMARY file.
- For control modes other than BHP the BHP lower limit is automatically set to atmospheric pressure when the well is first declared a history matching well (the first time it appears in a WCONHIST keyword). This is to reduce the possibility of the well changing to BHP control before its productivity index has been properly matched. (Changing to BHP control at atmospheric pressure is a sign that the Kh or skin factor is very badly matched.) You can reset the BHP limit to any desired value with the keyword [WELTARG](#) after the first WCONHIST keyword in which the well appears. The well's BHP limit is not changed by subsequent WCONHIST keywords unless the BHP control mode is selected. There is an option (see keyword [WHISTCTL](#)) to make the run stop automatically if a history matching well changes to BHP control.

---

**CAUTION:**

With multisegment wells (keyword [WELSEGS](#)), you are recommended to use [WELTARG](#) after WCONHIST to set a BHP limit that is within the range of the PVT tables. If these tables are extrapolated to atmospheric pressure, it is quite possible that the fluid properties could become unphysical. The multisegment well model requires realistic fluid properties in order to converge. Note that the calculation of the well potential uses the BHP limit, even if the actual operating BHP of the well is far above this value.

- For BHP control mode the observed BHP is set as the target. If a subsequent WCONHIST keyword alters the control mode then the BHP target will be reset to atmospheric pressure.

The observed flow rates and pressures can be made to change with time by repeating the WCONHIST keyword at each timestep. A history matching well can be converted into a normal well (with the standard set of controls) simply by re-specifying it with the [WCONPROD](#) keyword.

The WCONHIST keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/). The set of records must end with a blank record, containing only a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Open/shut flag for the well

OPEN Well open for production

STOP Well stopped off above the formation

SHUT Well completely isolated from the formation

DEFAULT: OPEN

When the well is shut or stopped, set the observed flow rates to zero. If the flow rates are set to zero while the well is open the behavior depends on whether crossflow is permitted (item 10 in keyword [WELSPECS](#)). If crossflow is allowed the well behaves as if stopped (although its status is still reported

as OPEN). If crossflow is banned the well will be automatically shut (and its status is reported as SHUT).

### 3. Control mode

ORAT Controlled by the observed oil rate (item 4)

WRAT Controlled by the observed water rate (item 5)

GRAT Controlled by the observed gas rate (item 6)

LRAT Controlled by the observed liquid rate (oil + water)

CRAT Controlled by the observed linearly combined rate (see keyword [LINCOM](#))

RESV Controlled by the reservoir fluid volume rate calculated from the observed phase flow rates

BHP Controlled by the well bottom hole pressure (item 10)

*ECLIPSE 300 only*

WGRA Controlled by the observed wet gas rate (item 11)

*ECLIPSE 300 only*

NGL Controlled by the observed NGL rate (item 12)

The control mode may be overridden by earlier use of the [WHISTCTL](#) keyword.

### 4. Observed oil production rate

UNITS:  $\text{sm}^3/\text{day}$  (METRIC),  $\text{stb}/\text{day}$  (FIELD),  $\text{scc}/\text{hr}$  (LAB),  $\text{sm}^3/\text{day}$  (PVT-M )

DEFAULT: 0.0

### 5. Observed water production rate

UNITS:  $\text{sm}^3/\text{day}$  (METRIC),  $\text{stb}/\text{day}$  (FIELD),  $\text{scc}/\text{hr}$  (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

DEFAULT: 0.0

### 6. Observed gas production rate

UNITS:  $\text{sm}^3/\text{day}$  (METRIC),  $\text{Mscf}/\text{day}$  (FIELD),  $\text{scc}/\text{hr}$  (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

DEFAULT: 0.0

### 7. Production well VFP table number

(see keyword [VFPPROD](#))

Set this to zero if you do not require the THP to be calculated.

If set > 0, the well's THP is calculated and reported, but the lower limit check is disabled so that the well does not go on to THP control.

DEFAULT: Initially zero, subsequently no change from previous value

### 8. Artificial lift quantity, for use in calculating the THP

(see keyword [VFPPROD](#))

This should be defaulted if you do not require the THP to be calculated

UNITS: These depend on what the ALQ was meant to represent when the table was created. Refer to section "[Record 6:ALQ values](#)" in the description of keyword VFPPROD.

DEFAULT: Initially zero, subsequently no change from previous value

9. Observed tubing head pressure (THP)

Values entered here are only used for reporting purposes, to compare with the calculated THP. The observed THPs may be written to the SUMMARY file using the [SUMMARY](#) section keyword WTHPH. The well does **not** change to THP control if the calculated THP falls below this value.

Default this item if you have no observed THP value to enter.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: 0.0

10. Observed bottom hole pressure (BHP)

The observed BHPs may be written to the SUMMARY file using the SUMMARY section keyword WBHPH.

Default this item if you have no observed BHP value to enter.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: 0.0

*ECLIPSE 300 only*

11. Observed wet gas production rate

The observed wet gas production rate may be written to the Summary File using the SUMMARY section keyword WWGPRH.

UNITS: sm<sup>3</sup>/day (METRIC), Mscf/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day ( PVT-M)

DEFAULT: 0.0

*ECLIPSE 300 only*

12. Observed NGL production rate

The observed NGL production rate may be written to the Summary File using the SUMMARY section keyword WNLPRH.

UNITS: sm<sup>3</sup>/day (METRIC), stb/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day ( PVT-M)

DEFAULT: 0.0

End the data record with a slash (/).

End the set of records with a blank record, containing only a slash.

---

**Note:** If items 7 and 8 are defaulted, the VFP table number and ALQ value for the well keep their previous values. Their values are initially set to 0 and 0.0 respectively when the well is first declared a History Matching Well. If you want the THP to be calculated during the history match, set these quantities to the required values either in the well's first WCONHIST keyword or by subsequently using keyword [WELTARG](#), then subsequent WCONHIST keywords can have their items 7 and 8 defaulted. This saves having to re-specify these items continually in all WCONHIST keywords.

---

## Summary file output

The observed production rates and totals, phase ratios (water cut and GOR for example) and pressures (BHP, THP), of history matching wells can be written to the Summary file, along with their calculated values. The SUMMARY section keywords denoting observed values end with an H (such as WOPRH).

The observed values are set from the data entered in the WCONHIST keyword. Thus the user can construct a graph comparing, for example, the calculated water cut of a history matching well (WWCT) with its observed water cut (WWCTH). The observed rates are also accumulated over time (for example WOPTH), and these may be compared with the calculated cumulative totals (for example WOPTH).

The corresponding field and group keywords (for example FOPRH, GWPRH) refer to the sum of their subordinate well flows, with the flows of all history matching wells replaced with their historical rates specified in WCONHIST. Thus, for example, FWCT can be compared with FWCTH to determine how well the field water cut matches its observed value.

If a well is subsequently taken out of history matching mode, by re-specifying it with WCONPROD, the Summary file output is calculated as described below:

- The observed rates and ratios (for example, WOPRH, WWCTH) are set to zero, as there is no observed data input.
- Their cumulative totals are still incremented over time, using the well's calculated rates. Thus the difference between, for example, WOPTH and WOPTH at any time will reflect the cumulative difference between the observed and calculated rates integrated over the period in which the well was in history matching mode.
- The group historical rates (for example, GOPRH) are the sum of the observed rates of their subordinate history matching wells and the calculated rates of any wells that are not in history matching mode, adjusted by any efficiency factors. Thus the difference between, for example, GOPR and GOPRH reflects the difference between the observed rates and calculated rates of all its wells that are currently in history matching mode.
- The group historical cumulative totals (for example GOPTH) are the sum of the well cumulative historical totals (WOPTH), and are also equal to the group historical rates (GOPRH) integrated over time.

## Example

```

WCONHIST
-- well  open/   ctrl   oil   water  gas   VFP   ALQ   obs  obs

## WCONINJE Control data for injection wells

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The records may be terminated early with a slash (/), the remaining items taking default values. Default values can be specified before the slash by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Injector type

WATER Water injector

GAS Gas injector

*ECLIPSE 300* When running in compositional mode, the nature of the injected gas must also be specified with keyword [WINJGAS](#), unless the well is subordinate to a group with gas injection controls where the injection fluid is defined.

*ECLIPSE 300* An alternative gas injector type, HCGAS can be used. The difference between GAS and HCGAS injectors is described in "[Calculation of molar rates in ECLIPSE 300](#)"

*ECLIPSE 100* OIL Oil injector

*ECLIPSE 300* An alternative oil injector type, HCOIL must be used.

MULTI Multiphase injector

*ECLIPSE 100* Water and/or gas and/or oil injection.

*ECLIPSE 300* Water and/or gas injection. To inject oil and gas, use HCGAS or HCOIL, as described in "[Calculation of molar rates in ECLIPSE 300](#)"

This injects the preferred phase of the well (as specified with the keyword [WELSPECS](#)) plus the other phases for which non-zero surface volume proportions are specified in items 12 to 14.

*ECLIPSE 300* HCGAS Gas injector

When running in compositional mode, the nature of the injected gas must also be specified with keyword [WINJGAS](#).

An alternative gas injector type, GAS can be used. The difference between GAS and HCGAS injectors is described in "[Calculation of molar rates in ECLIPSE 300](#)"

*ECLIPSE 300* HCOIL Oil injector

When running in compositional mode, the nature of the injected oil must be specified with keyword [WINJOIL](#).

See "[Calculation of molar rates in ECLIPSE 300](#)"

*Thermal*            STEAM-    Steam and gas injector  
                         GAS

*Thermal*            STEAM-    Steam and oil injector  
                         OIL

*Thermal*            When running in thermal mode, the enthalpy of the injected fluid must be specified with keyword [WINJTEMP](#). If steam and water are injected, the injector type should be defined as [WATER](#) and the injection rate (item 5) should be set as the cold water equivalent (C.W.E.) rate. If steam, water and gas are injected, the injector type should be defined as [STEAM-GAS](#) and the injection rate (item 5) should be set as the cold water equivalent (C.W.E.) rate of the steam and water; the rate of gas injection can be specified using item 11. If steam, water and oil are injected, the injector type should be defined as [STEAM-OIL](#) and the injection rate (item 5) should be set as the cold water equivalent (C.W.E.) rate of the steam and water; the ratio of oil volume to steam volume (C.W.E.) can be specified using item 15.

### 3. Open/shut flag for the well

OPEN Well open for injection.

STOP Well stopped off above the formation.

SHUT Well completely isolated from the formation

*ECLIPSE 100 only*

AUTO Well initially SHUT, but is opened automatically as soon as constraints on drilling rate (keyword [WDRILTIM](#)), drilling rig availability (keyword [GRUPRIG](#)), and the maximum number of open wells per group (keyword [GECON](#) item 9) allow. If no such constraints are specified, the well opens immediately. Wells on AUTO are opened in the order in which they are first specified in keyword [WELSPECS](#), unless any belong to a group that already has its maximum number of open wells or has all its available drilling rigs already occupied.

DEFAULT: OPEN

### 4. Control mode

RATE Controlled by surface flow rate target (item 5)

RESV Controlled by reservoir volume rate target (item 6)

BHP Controlled by BHP target (item 7)

THP Controlled by THP target (item 8)

The control mode is not available with multiphase injectors.

GRUP The well is immediately under group control, to inject its share of a group or field target set with the keyword [GCONINJE](#).

### 5. Surface flow rate target or upper limit. User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

For a multiphase injector, this is the surface flow rate of the preferred phase of the well.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC), stb/day for oil or water (FIELD), Mscf/day for gas (FIELD), scc/hr (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

DEFAULT: No target or limit

6. Reservoir fluid volume rate target or upper limit. User defined arguments can be set with keywords UDQ and UDADIMS.

UNITS:  $\text{rm}^3/\text{day}$  (METRIC), rb/day (FIELD), rcc/hr (LAB),  $\text{rm}^3/\text{day}$  (PVT-M)

DEFAULT: No target or limit

7. BHP target or upper limit. User defined arguments can be set with keywords UDQ and UDADIMS.

It is recommended that this quantity should be set to a value not exceeding the highest pressure in the PVT tables, to ensure the tables are not extrapolated in the well. It is best not to default this quantity, as its value is used in calculating the well potential.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

*ECLIPSE 100*                    DEFAULT: 6803 atma, or 1.0E5 psia, or 6891 barsa

*ECLIPSE 300*                    DEFAULT: 1000 atma = 14695.9 psia = 1013.25 barsa

*Thermal*                        DEFAULT: 200 atma = 2939.1 psia = 202.65 barsa

*E300 CO2STORE*                DEFAULT: 592.15 atma=8702.18 psia =600 barsa

All defaults stated are accurate to 2 decimal places.

8. THP target or upper limit. User defined arguments can be set with keywords UDQ and UDADIMS.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: No target or limit

9. Injection well VFP table number

(See keyword [VFPINJ](#))

Set this to zero if no THP calculations are required and the limiting THP value has been defaulted.

DEFAULT: 0

*ECLIPSE 100 only*                This applies unless [item 92](#) of OPTIONS is greater than zero, in which case the default is initially zero, and subsequently no change from the previous value. This mimics the behavior of [WCONINJH](#) [item 7](#).

10. Vaporized oil concentration in the injected gas, or dissolved gas concentration in the injected oil.

This item is ignored for multiphase injectors.

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/Mscf for gas injectors (FIELD), Mscf/stb for oil injectors (FIELD), scc/scc (LAB)

DEFAULT: 0.0

- Thermal*                        11. Ratio of gas volume to steam volume (C.W.E.) for a STEAM-GAS injector. User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), Mscf/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: 0.0

*ECLIPSE 100 only*

12. Surface volume proportion of oil in a multiphase injector.

This must be greater than zero if the preferred phase of the multiphase injection well (set in the keyword [WELSPECS](#)) is oil.

UNITS: dimensionless

DEFAULT: 0.0

13. Surface volume proportion of water in a multiphase injector.

This must be greater than zero if the preferred phase of the multiphase injection well (set in the keyword [WELSPECS](#)) is water.

UNITS: dimensionless

DEFAULT: 0.0

14. Surface volume proportion of gas in a multiphase injector.

This must be greater than zero if the preferred phase of the multiphase injection well (set in the keyword [WELSPECS](#)) is gas.

UNITS: dimensionless

DEFAULT: 0.0

*Thermal*

15. Ratio of oil volume to steam volume (C.W.E.) for a STEAM-OIL injector (for use with steam-solvent injection).

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: 0.0

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

See also keyword [WELTARG](#), which can be used to reset selected control quantities individually.

## Calculation of molar rates in ECLIPSE 300

In compositional injection, volume rates are converted to molar rates (for the injector type settings, see item 2 of the [WCONINJE](#) keyword):

- For GAS and WATER injectors, a constant molar density is used. The gas molar density is determined from the ideal gas law. The water molar density is determined from the water gravity density specified by the [DENSITY](#) or [GRAVITY](#) keyword. The molar densities used in a simulation are output to the “Standard conditions” section of the report file.
- For HCGAS and HCOIL injectors, a flash at stock tank conditions ([STCOND](#)) is used to calculate the phase molar densities.
- For STEAM-GAS and STEAM-OIL injectors, a flash at stock tank conditions ([STCOND](#)) is also used to calculate the gas or oil molar densities. For back compatibility with pre-2012.1 versions of STEAM-GAS, set [item 276](#) in [OPTIONS3](#) to 1 to use a fixed gas molar density.

*Thermal*

The stock-tank flash used for HCGAS, HCOIL, STEAM-GAS and STEAM-OIL injectors may not produce a single phase fluid of the expected type. For example an HCGAS injection fluid may not flash to single phase gas. Therefore:

- If the flash produces a two-phase fluid, then both phases will be injected and the well will be controlled by the rate of the specified phase. This mechanism can be used to inject two-phase hydrocarbons.
- If the flash produces a single-phase fluid of the wrong type then a constant molar density will be used, determined from

$$\frac{n}{V} = \frac{P}{RTZ}$$

For HCGAS, a compressibility of  $Z = 1$  is used when the surface flash finds no gas, giving the same values as the GAS injector molar density. For HCOIL, a fixed compressibility of  $Z = 0.05$  is used when the surface flash finds no oil.

HCGAS allows different injection streams to have different molar densities. However it should not be used when reservoir gas is reinjected (see [WINJGAS](#)), since the injection fluid composition is not known in advance.

In black oil simulations, HCGAS and GAS are the same, and HCOIL is the equivalent to the ECLIPSE 100 OIL injector.

## Notes

- The surface proportions in items 12 to 14 are the ratio of the surface volumes of the various phases. Due to the different units used to specify surface volumes for liquids and gas at surface conditions in FIELD units, care must be taken when specifying the surface proportions of multiphase well involving gas. See Example 3 for an illustration.
- When specifying the preferred phase for a multiphase injector, it may help to speed up the convergence of the well model if you specify the phase for which the proportion is greatest as the preferred phase.
- If you have a large proportion of the non-preferred phases, you may have to increase the value of MXWSIT in [TUNING](#) keyword record 3 in order to allow the well model to converge. The simulator will give a message if this is the case.

*ECLIPSE 100 only*

## Examples

### Example 1

```

WCONINJE
INJ1 GAS OPEN RATE 500 1* 5000 1000 2 /
INJ2 WAT OPEN RESV 1* 1000 4000 /
INJ3 WAT OPEN RATE 700 1* 5000 /
/

```

### Example 2

This example shows a multiphase (oil, water and gas) injector, MI1, on which gas has previously been specified as the preferred phase. The units in this example are METRIC.

*ECLIPSE 100 only*

```
WCONINJE
MI1 MULTI OPEN RATE 16000 1* 500 4* 0.05 0.15 0.80 /
/
```

In this example, a gas rate target of 16,000 sm<sup>3</sup>/day has been specified, and the proportions of oil to water to gas is 0.05: 0.15: 0.80 (as specified items 12 to 14). Hence the injection fluid will consist of 16,000 sm<sup>3</sup>/day of gas, (16,000\*0.05/0.8 =) 1,000 sm<sup>3</sup>/day of oil and (16,000\*0.15/0.8 =) 3,000 sm<sup>3</sup>/day of water.

### Example 3

This example shows a multiphase (water and gas) injector, MI2, on which water has previously been specified as the preferred phase. The units in this example are FIELD.

```
WCONINJE
MI2 MULTI OPEN RATE 2000 1* 5000 5* 0.8 0.2 /
/
```

In this example, a water rate target of 2,000 stb/day has been specified, and the proportion of water to gas is 0.2: 0.8 (as specified items 13 and 14). Hence the injection fluid will consist of 2,000 stb/day of water and (2,000\*0.2/0.8 =500 stb/day =) 2.807 Mscf/day of gas.

## WCONINJH Observed rates for history matching injection wells

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used in place of [WCONINJE](#) to declare injection wells as special history matching wells, and to enter their observed flow rates (and optionally their measured BHP and THP values). The equivalent keyword for defining history matching production wells is [WCONHIST](#).

Wells can be declared as history matching wells during the history matching process, when their injection rates are known. During the simulation these wells are normally be constrained to operate at their observed injection rates, and their calculated BHP and/or THP values are compared against the measured values.

ECLIPSE treats history matching wells differently from ordinary injection wells, in the following ways:

- The observed injection rates entered with this keyword can be written to the Summary file, and also the measured BHP and THP values if they are entered here, for comparison with the rates and pressures calculated during the simulation.
- The set of control modes for the wells is restricted to RATE and BHP. For RATE control the BHP upper limit is automatically set to a large value when the well is first declared a history matching well (the first time it appears in a WCONINJH keyword) and when the control mode switches from BHP to RATE. For BHP control the observed BHP is used as the target. This is to reduce the possibility of the well changing to BHP control before its productivity index has been properly matched. (Changing to BHP control at a very high pressure is a sign that the Kh or skin factor is very badly matched.) You can reset the BHP limit to any desired value with the keyword [WELTARG](#) after the first WCONINJH keyword in which the well appears. The well's BHP limit is not changed by subsequent WCONINJH keywords. There is an option (see keyword [WHISTCTL](#)) to make the run stop automatically if a history matching well changes to BHP control.

---

**CAUTION:** With multisegment wells (keyword [WELSEGS](#)), you are recommended to use [WELTARG](#) after [WCONHIST](#) to set a BHP limit that is within the range of the PVT tables. If these tables are extrapolated to a very high pressure, it is quite possible that the fluid properties could become unphysical. The multisegment well model requires realistic fluid properties in order to converge. Note that the calculation of the well potential uses the BHP limit, even if the actual operating BHP of the well is far below this value.

---

The observed flow rates and pressures can be made to change with time by repeating the WCONINJH keyword at each timestep. A history matching well can be converted into a normal well (with the standard set of controls) simply by respecifying it with the WCONINJE keyword.

The WCONINJH keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/). The set of records must end with a blank record, containing only a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Injector type

WATER Water injector

GAS Gas injector

*ECLIPSE 300 only*

When running in compositional mode, the nature of the injected gas must also be specified with keyword [WINJGAS](#), unless the well is subordinate to a group with gas injection controls where the injection fluid is defined.

*ECLIPSE 100 only*

OIL Oil injector

MULTI Multiphase injector (oil and/or water and/or gas).

This injects the preferred phase of the well (as specified with the keyword [WEL SPECS](#)) plus the other phases for which non-zero surface volume proportions are specified in items 9 to 11.

### 3. Open/shut flag for the well

OPEN Well open for injection

STOP Well stopped off above the formation

SHUT Well completely isolated from the formation

DEFAULT: OPEN

When the well is shut or stopped, set the observed flow rate to zero. If the flow rates are set to zero while the well is open the behavior depends on whether crossflow is permitted (item 10 in keyword [WEL SPECS](#)). If crossflow is allowed the well behaves as if stopped (although its status is still reported as OPEN). If crossflow is banned the well will be automatically shut (and its status is reported as SHUT).

### 4. Observed injection rate (at surface conditions)

For a multiphase injector, this is the surface flow rate of the preferred phase of the well.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC), stb/day for oil or water (FIELD), Mscf/day for gas (FIELD), scc/hr (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

DEFAULT: 0.0

### 5. Observed bottom hole pressure (BHP)

Values entered here are only used for reporting purposes, to compare with the calculated BHP. The observed BHPs may be written to the Summary file using the [SUMMARY](#) section keyword WBHPH. The well does **not** change to BHP control if the calculated BHP rises above this value. (The actual BHP upper limit is set to a very high value when the well first appears in a WCONINJH keyword, but you can subsequently reset it to any desired value with the [WELTARG](#) keyword.)

Default this item if you have no observed BHP value to enter.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: 0.0

### 6. Observed tubing head pressure (THP)

Values entered here are only used for reporting purposes, to compare with the calculated THP. The observed THPs may be written to the Summary file using the [SUMMARY](#) section keyword WTHPH. The

well does **not** change to THP control if the calculated THP rises above this value. Default this item if you have no observed THP value to enter.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: 0.0

7. Injection well VFP table number

(see keyword [VFPINJ](#))

Set this to zero if you do not require the THP to be calculated.

If set > 0, the well's THP is calculated and reported, but the upper limit check is disabled so that the well does not go on to THP control.

DEFAULT: Initially zero, subsequently no change from previous value

*ECLIPSE 100 only* 8. Vaporized oil concentration in the injected gas, or dissolved gas concentration in the injected oil.

This item is ignored for multiphase injectors.

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/Mscf for gas injectors (FIELD), Mscf/stb for oil injectors (FIELD), scc/scc (LAB)

DEFAULT: 0.0

*ECLIPSE 100 only* 9. Surface volume proportion of oil in a multiphase injector.

This must be greater than zero if the preferred phase of the multiphase injection well (set in the keyword [WELSPECS](#)) is oil.

UNITS: dimensionless

DEFAULT: 0.0

10. Surface volume proportion of water in a multiphase injector.

This must be greater than zero if the preferred phase of the multiphase injection well (set in the keyword [WELSPECS](#)) is water.

UNITS: dimensionless

DEFAULT: 0.0

11. Surface volume proportion of gas in a multiphase injector.

This must be greater than zero if the preferred phase of the multiphase injection well (set in the keyword [WELSPECS](#)) is gas.

UNITS: dimensionless

DEFAULT: 0.0

12. Well control mode

RATE Well is controlled by injection rate

BHP Well is controlled by bottom hole pressure

DEFAULT: RATE

End the data record with a slash (/).

End the set of records with a blank record, containing only a slash.

## Notes

*ECLIPSE 300 only*

In multiphase compositional injection, all hydrocarbons are specified as gas regardless of their phase, and the actual liquid-vapor composition is determined via a flash calculation. Also with this simulator, oil injection is not available in black oil models. Hence the preferred phase for a multiphase injection well (specified in the `WELSPECS` keyword) cannot be set to `OIL`, and the ‘Surface volume proportion of oil in a multiphase injector’ (item 9) is ignored.

## Summary file output

There are equivalent facilities for writing injection well historical rates and pressures to the `SUMMARY` file as there are for production wells (see keyword `WCONHIST`).

The observed injection rates and their cumulative totals may be written to the `SUMMARY` file using the corresponding `SUMMARY` section keywords ending with an H (`WWIRH`, `WGIRH`, `WWITH`, `WGITH`). The observed BHP and THP values, if they are supplied here, may be written to the Summary file using the keywords `WBHPH` and `WTHPH` respectively.

The corresponding field and group keywords (for example `FWIRH`, `GGIRH`) refer to the sum of their subordinate injection wells’ observed, and their cumulative totals.

If a well is subsequently taken out of history matching mode, by re-specifying it with `WCONINJE`, the Summary file output is calculated as described below:

- The observed rates and ratios (for example, `WWIRH`, `WWCTH`) are set to zero, as there is no observed data input.
- Their cumulative totals are still incremented over time, using the well’s calculated rates. Thus the difference between, for example, `WWITH` and `WWIT` at any time will reflect the cumulative difference between the observed and calculated rates integrated over the period in which the well was in history matching mode.
- The group historical rates (for example, `GWIRH`) are the sum of the observed rates of their subordinate history matching wells and the calculated rates of any wells that are not in history matching mode, adjusted by any efficiency factors. Thus the difference between, for example, `GWIR` and `GWIRH` reflects the difference between the observed rates and calculated rates of all its wells that are currently in history matching mode.
- The group historical cumulative totals (for example `GWITH`) are the sum of the well cumulative historical totals (`WWITH`), and are also equal to the group historical rates (`GWIRH`) integrated over time.

## Example

```

WCONINJH
-- well   well   open/   inj   obs   obs   VFP   Rs/Rv
-- name   type   shut   rate  BHP   THP   tab
  WINJ    WAT    OPEN   2410 /
  GINJ    GAS    OPEN   3970 3676 2852  2 /
/

```

## Other

See the examples in the [WCONINJE](#) keyword for an illustration of how to specify the oil, water and gas surface volume proportions for multiphase injectors (WCONINJH items 9-11).

## WCONINJP Control data for pattern flood injection wells

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used to specify a well that injects at a reservoir volume rate defined by the production of the wells that surround it. An example of this type of control would be to specify a well that injects at a rate equal to the sum of one quarter of the voidage from each of the four neighboring producers in a five spot pattern.

The keyword can only be used on one injection well at a time, so it must be specified more than once if there is more than one injection well under this type of control.

The keyword is followed by a data record that specifies the injection well and then a number of data records specifying the production wells in the surrounding pattern that each make a contribution to defining the injection well's rate. Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing just a slash.

The data items in each record are:

### Record 1

This record defines control data for the injection well. It is similar to the [WCONINJE](#) keyword except that the injection rate is not specified; this rate is calculated at each timestep from the produced voidage of the surrounding pattern of wells that are defined in subsequent records of this keyword.

The record may be terminated early with a slash (/), the remaining items taking default values. Default values can be specified before the slash by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

1. Name of the pattern flood injection well
2. Injector type

WATER Water injector

GAS Gas injector

*ECLIPSE 300*

When running in compositional mode, the nature of the injected gas must also be specified with keyword [WINJGAS](#).

*ECLIPSE 100 only*

OIL Oil injector

MULTI Multiphase injector (oil and/or water and/or gas).

This injects the preferred phase of the well (as specified with the keyword [WELSPECS](#)) plus the other phases for which non-zero surface volume proportions are specified in items 9 to 11.

3. Open/shut flag for the well

OPEN Well open for injection.

STOP Well stopped off above the formation.

SHUT Well completely isolated from the formation

DEFAULT: OPEN

4. BHP upper limit

It is recommended that this quantity should be set to a value not exceeding the highest pressure in the PVT tables, to ensure the tables are not extrapolated in the well. It is best not to default this quantity, as its value is used in calculating the well potential.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

*ECLIPSE 100*                    DEFAULT: 6804 atma, or 1.0E5 psia, or 6895 barsa

*ECLIPSE 300*                    DEFAULT: 1000 atma = 14700 psia = 1013 barsa

*Thermal*                        DEFAULT: 200 atma = 2940 psia = 202.6 barsa

*E 300 CO2STORE*                DEFAULT: 592.15 atma=8702 psia =600 barsa

5. THP upper limit

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: No limit

6. Injection well VFP table number

(See keyword [VFPINJ](#))

Set this to zero if no THP calculations are required and the limiting THP value has been defaulted.

DEFAULT: 0

*ECLIPSE 100 only*    7. Vaporized oil concentration in the injected gas, or dissolved gas concentration in the injected oil

This item is ignored for multiphase injectors.

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/Mscf for gas injectors (FIELD), Mscf/stb for oil injectors (FIELD), scc/scc (LAB)

DEFAULT: 0.0

8. Injection voidage rate target multiplier

This multiplies the calculated voidage rate target for the pattern flood injector.

DEFAULT: 1.0

*ECLIPSE 100 only*    9. Surface volume proportion of oil in a multiphase injector.

This must be greater than zero if the preferred phase of the multiphase injection well (set in the keyword [WELSPECS](#)) is oil.

UNITS: dimensionless

DEFAULT: 0.0

10. Surface volume proportion of water in a multiphase injector.

This must be greater than zero if the preferred phase of the multiphase injection well (set in the keyword [WELSPECS](#)) is water.

UNITS: dimensionless

DEFAULT: 0.0

11. Surface volume proportion of gas in a multiphase injector.

This must be greater than zero if the preferred phase of the multiphase injection well (set in the keyword `WEL SPECS`) is gas.

UNITS: dimensionless

DEFAULT: 0.0

End data record with a slash (/).

## Each subsequent record

The subsequent records each define a production well and the fraction of its reservoir volume rate that contributes to the overall rate for the injection well specified in record 1.

1. Production well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword `WLIST`.

2. The production rate fraction for the well(s) in item 1 of this record

This fraction multiplies the well's reservoir volume rate (or part thereof, see item 3 below). This product, when added to those from all the other contributing producers, defines the flow rate for the injection well specified in record 1.

DEFAULT: The fraction will be updated at the beginning of each timestep on the basis of the number of injectors assigned to replace the voidage of each producer. A producer's fractions will thus change if one of its associated injectors is shut (or opened), with the current set of open injectors effectively automatically compensating to ensure the producer's voidage is still replaced

3. Fluid-in-place region number

If this is specified, then the voidage rate contribution from this well is restricted to the sum of the voidage flows from connections to grid cells that fall within this fluid-in-place region. Note that connection voidage rates are calculated at the reference pressures of the appropriate fluid-in-place regions; these pressures may differ from the reference pressure used to calculate the well's overall voidage rate. (See [item 88](#) in `OPTIONS3` or [item 85](#) in `OPTIONS`.)

DEFAULT: 0

End data record with a slash (/).

## Notes

- A pattern flood injection well is automatically set as unavailable for higher level group control.
- If an injector has previously been defined as a pattern flood injector and is then re-specified using this keyword without any associated production wells, it will be switched back to being a normal injector. This switch may also be achieved by re-specifying the control mode of the well using the `WCONINJE` keyword.
- The control mode of a pattern flood injector is reported as 'PFVR' in the print file.
- Although there is no limit to the number of producers that may contribute to the overall rate of a pattern flood injector, the voidage from a particular producer cannot be split between more than ten pattern flood injectors.

*ECLIPSE 300 only*

- In multiphase compositional injection, all hydrocarbons are specified as gas regardless of their phase, and the actual liquid-vapor composition is determined via a flash calculation. Also with this simulator, oil injection is not available in black oil models. Hence the preferred phase for a multiphase injection well (specified in the [WELSPECS](#) keyword) cannot be set to OIL, and the ‘Surface volume proportion of oil in a multiphase injector’ (item 9) is ignored.

## Example

The water injection well INJW replaces a quarter of the reservoir voidage of each of its four surrounding producers. This is effectively its share of the production voidage in a repeated five spot pattern.

```
WCONINJP
INJW WAT 1* 5000 /
PRD1 /
PRD2 /
PRD3 /
PRD4 /
/
```

## Other

See the examples in the [WCONINJE](#) keyword for an illustration of how to specify the oil, water and gas surface volume proportions for multiphase injectors (WCONINJP record 1, items 9-11).

## WCONPROD Control data for production wells

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The records may be terminated early with a slash (/). The remaining items will assume their default values. Default values can be specified before the slash by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records must end with a blank record, containing only a slash (/).

### 1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

### 2. Open/shut flag for the well

OPEN Well open for production

STOP Well stopped off above the formation

SHUT Well completely isolated from the formation

*ECLIPSE 100 only*

AUTO Well initially SHUT, but is opened automatically as soon as constraints on drilling rate (keyword [WDRILTIM](#)), drilling rig availability (keyword [GRUPRIG](#)), and the maximum number of open wells per group (keyword [GECON](#) item 9) allow. If no such constraints are specified, the well will open immediately. Wells on AUTO are opened in the order in which they are first specified in keyword [WELSPECS](#), unless any belong to a group that already has its maximum number of open wells or has all its available drilling rigs already occupied.

It is preferable to shut or stop the well rather than give it a zero flow rate target. In particular, a zero flow rate target applied to a well with a THP limit may cause hunting between control modes. Furthermore, ECLIPSE 300 interprets a zero rate limit (applied to any item that is not the control mode's target) as a defaulted, hence inactive, limit.

DEFAULT: OPEN

### 3. Control mode

ORAT Controlled by oil rate target (item 4)

WRAT Controlled by water rate target (item 5)

GRAT Controlled by gas rate target (item 6)

LRAT Controlled by liquid rate target (item 7)

CRAT Controlled by linearly combined rate target (item 19)

RESV Controlled by reservoir fluid volume rate target (item 8)

BHP Controlled by BHP target (item 9)

	THP	Controlled by THP target (item 10)
	WGRA	Controlled by wet gas rate target (item 13)
ECLIPSE 300 only	TMRA	Controlled by total molar rate target (item 14)
ECLIPSE 300 only	STRA	Controlled by steam rate target (item 15) (available only with the Thermal option)
ECLIPSE 300 only	SATP	Controlled by water saturation pressure (item 16) (available only with the Thermal option)
ECLIPSE 300 only	SATT	Controlled by water saturation temperature (item 17) (available only with the Thermal option)
ECLIPSE 300 only	CVAL	Controlled by calorific rate target (item 18). Molar calorific values must be specified with the <b>CALVAL</b> keyword before this control mode may be used.
ECLIPSE 300 only	NGL	Controlled by NGL rate target (item 20).
	GRUP	The well is immediately under group control, to produce its share of a group or field target rate set with keyword <b>GCONPROD</b> .
	DEFAULT:	' ' (Undefined)
ECLIPSE 100		The control mode can be left defaulted if the well is shut/stopped and is not placed in the drilling queue.
	4.	Oil rate target or upper limit. This quantity can be a user defined argument (UDA), and can be set with keywords <b>UDQ</b> and <b>UDADIMS</b> .  UNITS: sm <sup>3</sup> /day (METRIC), stb/day (FIELD), scc/hr (LAB), sm <sup>3</sup> /day (PVT-M)  DEFAULT: No target or limit
	5.	Water rate target or upper limit. This quantity can be a user defined argument (UDA), and can be set with keywords <b>UDQ</b> and <b>UDADIMS</b> .  UNITS: sm <sup>3</sup> /day (METRIC), stb/day (FIELD), scc/hr (LAB), sm <sup>3</sup> /day (PVT-M)  DEFAULT: No target or limit
	6.	Gas rate target or upper limit. This quantity can be a user defined argument (UDA), and can be set with keywords <b>UDQ</b> and <b>UDADIMS</b> .
ECLIPSE 300		In compositional mode, the gas rate of a well is defined by passing the produced well hydrocarbon through a copy of the separator to which the well is assigned, or by a flash to standard conditions if no separator has been defined.  UNITS: sm <sup>3</sup> /day (METRIC), Mscf/day (FIELD), scc/hr (LAB), sm <sup>3</sup> /day (PVT-M)  DEFAULT: No target or limit
	7.	Liquid rate target or upper limit. This quantity can be a user defined argument (UDA), and can be set with keywords <b>UDQ</b> and <b>UDADIMS</b> .  UNITS: sm <sup>3</sup> /day (METRIC), stb/day (FIELD), scc/hr (LAB), sm <sup>3</sup> /day (PVT-M)  DEFAULT: No target or limit

8. Reservoir fluid volume rate target or upper limit. This quantity can be a user defined argument (UDA), and can be set with keywords UDQ and UDADIMS.

The reservoir fluid volume rate is the volume of the fluids produced when measured at the average hydrocarbon pressure in the field, or the average pressure in a nominated fluid-in-place region if item 13 is set in [WELSPECS](#).

UNITS:  $\text{rm}^3/\text{day}$  (METRIC),  $\text{rb}/\text{day}$  (FIELD),  $\text{rcc}/\text{hr}$  (LAB),  $\text{rm}^3/\text{day}$  (PVT-M)

DEFAULT: No target or limit

9. BHP target or lower limit. This quantity can be a user defined argument (UDA), and can be set with keywords UDQ and UDADIMS.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

ECLIPSE 100      DEFAULT: 1 atma = 14.70 psia

ECLIPSE 300      DEFAULT: 100 atma = 1469.59 psia

If the control mode in item 3 is put to BHP, then this item cannot be defaulted. It is recommended that this quantity should be set to a value not less than the lowest pressure in the PVT tables, to ensure the tables are not extrapolated in the well. It is best not to default this quantity, as its value is used in calculating the well potential. Further, if a well approaches the default BHP, calculated THP values will become negative in ECLIPSE 100.

10. THP target or lower limit. This quantity can be a user defined argument (UDA), and can be set with keywords UDQ and UDADIMS.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: 0.0

ECLIPSE 100      A THP limit of zero will prevent the well switching to THP control, whatever the value of its calculated THP. But its THP is still calculated, provided that it has a positive VFP table number in item 11.

11. Production well VFP table number (see keyword [VFPPROD](#))

Set this to zero if no THP calculations are required and the limiting THP value has been set to zero.

DEFAULT: 0

12. Artificial lift quantity, for use in THP calculations (see keyword [VFPPROD](#))

UNITS: These depend on what the ALQ was meant to represent when the table was created. Refer to section "[Record 6:ALQ values](#)" in the description of keyword [VFPPROD](#).

DEFAULT: 0.0

ECLIPSE 300 only      13. Wet gas production rate target or upper limit

Wet gas rate is related to the hydrocarbon moles produced using a unity Z-factor at surface conditions.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC),  $\text{Mscf}/\text{day}$  (FIELD),  $\text{scc}/\text{hr}$  (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

DEFAULT: No target or limit

ECLIPSE 300 only      14. Total molar rate target or upper limit. (Note that the total molar rate includes water.)

UNITS:  $\text{kg-M}/\text{day}$  (METRIC),  $\text{lb-M}/\text{day}$  (FIELD),  $\text{gm-M}/\text{hr}$  (LAB),  $\text{kg-M}/\text{day}$  (PVT-M)

- DEFAULT: No target or limit
- ECLIPSE 300 only* 15. Steam production rate target or upper limit, Cold Water Equivalent. This quantity can be a user defined argument (UDA), and can be set with keywords UDQ and UDADIMS. (available only with the Thermal option)
- UNITS: sm<sup>3</sup>/day (METRIC), stb/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)
- DEFAULT: No target or limit
- ECLIPSE 300 only* 16. The pressure offset  $\Delta P$  for saturation pressure control. This quantity can be a user defined argument (UDA), and can be set with keywords UDQ and UDADIMS. (Available only with the Thermal option.)
- The bottom hole pressure is constrained by  $BHP \geq P_{sat} + \Delta P$  where  $P_{sat}$  is the maximum saturated water pressure in all the producing completion cells. The pressure offset can be output using the WPOFF summary keyword.
- UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)
- ECLIPSE 300 only* 17. The temperature offset  $\Delta T$  for saturation temperature control. This quantity can be a user defined argument (UDA), and can be set with keywords UDQ and UDADIMS (available only with the Thermal option).
- The bottom hole pressure is constrained by  $BHP \geq P_{sat}(T + \Delta T)$  where  $T$  is the maximum temperature in all the producing completion cells. The temperature offset can be output using the WTOFF summary keyword.
- UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)
- ECLIPSE 300 only* 18. Calorific rate target or upper limit
- UNITS: kJ/day (METRIC), Btu/day (FIELD), J/hr (LAB), kJ/day (PVT-M)
- DEFAULT: No target or limit
19. Linearly combined rate target or upper limit. Linear combination coefficients must be set with keyword LINCOM. This quantity can be a user defined argument (UDA), and can be set with keywords UDQ and UDADIMS.
- UNITS: determined by keyword LCUNIT
- DEFAULT: No target or limit
- ECLIPSE 300 only* 20. NGL rate target or upper limit. This quantity can be a user defined argument (UDA), and can be set with keywords UDQ and UDADIMS.
- UNITS: sm<sup>3</sup>/day (METRIC), stb/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)
- DEFAULT: No target or limit

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

See also keyword WELTARG, which can be used to reset selected control quantities individually.

## WCUTBACK Well cutback limits (for producers and injectors)

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

Default values can be specified by null repeat counts of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Water cut upper limit for well rate cutback (producers only)

A value of 0.0 switches off this limit

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: No limit

3. Gas-oil ratio upper limit for well rate cutback (producers only)

A value of 0.0 switches off this limit

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), Mscf/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: No limit

4. Gas-liquid ratio upper limit for well rate cutback (producers only)

A value of 0.0 switches off this limit

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), Mscf/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: No limit

5. Water-gas ratio upper limit for well rate cutback (producers only)

A value of 0.0 switches off this limit

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/Mscf (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: No limit

6. Rate cutback factor (fraction)

This is the ratio of the reduced flow rate to the current flow rate. It should be less than 1.0

*ECLIPSE 100*

The same rate cutback factor applies to both this keyword and the [WBHGLR](#) keyword. If WBHGLR has been entered previously, this item overwrites item 4 in that keyword. If WBHGLR is entered subsequently, its item 4 overwrites this item.

*ECLIPSE 100*

DEFAULT: same as item 4 in the WBHGLR keyword if that has been entered previously; otherwise 1.0.

7. Control phase, to which the reduced rate applies

OIL Reduced oil rate  
 WAT Reduced water rate  
 GAS Reduced gas rate  
 LIQ Reduced liquid rate  
 RESV Reduced reservoir fluid volume rate  
 COMB Reduced linearly combined rate (coefficients must be set with [LINCOM](#))

ECLIPSE 300 only

WGAS Reduced wet gas rate

ECLIPSE 300 only

NGL Reduced NGL rate

You are advised to choose a phase that does not have a user defined rate limit, as it would be overwritten whenever a cutback or cutback reversal occurs; see Note 3 below.

ECLIPSE 100

The same control phase applies to both this keyword and the [WBHGLR](#) keyword. If [WBHGLR](#) has been entered previously this item overwrites item 5 in that keyword. If [WBHGLR](#) is entered subsequently its item 5 overwrites this item.

ECLIPSE 100

DEFAULT: same as item 5 in the [WBHGLR](#) keyword if that has been entered previously; otherwise, no default is allowed.

8. Grid block pressure limit for well rate cutback

(Applied to any block containing an open connection to the well)

A value of 0.0 or  $> 1.0E19$  switches off this limit.

This is treated as a lower limit for production wells, and an upper limit for injection wells.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: 0.0

9. Grid block pressure limit for reversing the cutback process

(Applied to any block containing an open connection to the well.)

A value of 0.0 or  $> 1.0E19$  switches off this limit.

This is treated as an upper limit for production wells, and a lower limit for injection wells.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: 0.0

10. Water cut lower limit for reversing the cutback process (producers only)

A value of 0.0 switches off this limit.

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: 0.0

11. Gas-oil ratio lower limit for reversing the cutback process (producers only)

A value of 0.0 switches off this limit.

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), Mscf/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: 0.0

12. Gas-liquid ratio lower limit for reversing the cutback process (producers only)

A value of 0.0 switches off this limit.

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), Mscf/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: 0.0

13. Water-gas ratio lower limit for reversing the cutback process (producers only)

A value of 0.0 switches off this limit.

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/Mscf (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: 0.0

14. Remove cutbacks when the well is worked over?

YES When the well is worked over after violating an economic limit (set in keywords [CECON](#) and [WECON](#) for example), any cutbacks performed on the well are completely reversed by removing the rate limit on the control phase specified in item 7.

NO Any cutbacks made to the well remain in force (unless reversed by the application of cutback reversal limits).

ECLIPSE 100

The instruction applies to both this keyword and the [WBHGLR](#) keyword. If [WBHGLR](#) has been entered previously, this item overwrites item 8 in that keyword. If [WBHGLR](#) is entered subsequently, its item 8 overwrites this item.

DEFAULT: NO

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

## Notes

- Whenever the well violates one of the cutback limits given in items 2 to 5 and 8, it is set to operate at a reduced target rate of the phase specified in item 7. Its control mode will automatically change to the mode corresponding to item 7 (if it is not already under that mode of control). The target rate of the control phase is set equal to the well's current flow rate of that phase, multiplied by the cutback factor specified in item 6.
- Whenever the well violates one of the cutback reversal limits given in items 9 to 13, **and** if the well is currently operating under rate control of the phase selected in item 7, the target rate of the phase is increased by dividing it by the factor specified in item 6. This essentially reverses the cutback process.
- The well's target rate of the phase selected in item 7 is reset each time one of the limits is violated. Any initially user-defined rate limit for the phase is 'forgotten'. Thus a series of cutback reversals could increase the rate target for that phase beyond its initial limit. This can be avoided by choosing a phase in item 7 for which there is no user-defined limit. For example, if the well has rate limits defined directly for just the oil and water phases, a suitable control phase would be [LIQ](#) or [RES](#). The well

changes to this control mode when it is cut back. During cutback reversals this limit is progressively increased, but the original oil and water limits remain intact and are not exceeded.

4. The keyword can be applied to both producers and injectors. The limits in items 2 to 5 and items 10 to 13 refer to production wells only. The pressure limits in items 8 and 9 can be applied to both production and injection wells.

See also keyword [WLIMTOL](#).

## Example

```
WCUTBACK  
'P*' 0.6 3* 0.9 LIQ 3000 /  
WELL2 1* 3.0 2* 0.9 RESV 3* 2.0 /  
/
```

## WCUTBACK Tracer cutback limits for production wells

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

WCUTBACK is followed by any number of records, described below, each record terminated by a slash (/). A record may be terminated early at any item; the remaining items assume their default values. Default values can be specified before the slash by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted. There are two types of record; one describes the connection and the second lists the tracers and their limits.

The set of records must end with a blank record, containing only a slash (/).

### Records for the connection

Records of the first kind can contain some or all of the following items:

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Rate cutback factor (fraction)

This is the ratio of the reduced flow rate to the current flow rate. It should be less than 1.0.

The same rate cutback factor applies to both this keyword and the [WBHGLR](#) / [WCUTBACK](#) keyword. If [WBHGLR](#) or [WCUTBACK](#) has been entered previously, this item overwrites item 4 in [WBHGLR](#) or item 6 in [WCUTBACK](#). If [WBHGLR](#) or [WCUTBACK](#) is entered subsequently, item 4 of [WBHGLR](#) or item 6 of [WCUTBACK](#) overwrites this item.

DEFAULT: same as item 4 in the [WBHGLR](#) keyword or item 6 in the [WCUTBACK](#) keyword, if entered previously; otherwise 1.0.

3. Control phase, to which the reduced rate applies

OIL Reduced oil rate

WAT Reduced water rate

GAS Reduced gas rate

LIQ Reduced liquid rate

RESV Reduced reservoir fluid volume rate

COMB Reduced linearly combined rate (coefficients must be set with [LINCOM](#))

4. Remove cutbacks when the well is worked over?

YES When the well is worked over after violating an economic limit (set in keywords [CECON](#) and [WECON](#) for example), any cutbacks performed on the well are completely reversed by removing the rate limit on the control phase specified in item 7.

NO Any cutbacks made to the well remain in force, unless reversed by application of cutback reversal limits.

End the record with a slash (/)

## Subsequent records for the tracers

There can follow a maximum of three subsequent records for each well. These records have some or all of the following items.

1. Tracer name (Use PLY for a polymer and BRI for brine)
2. Total tracer rate upper limit for well rate cutback  
DEFAULT: No limit
3. Total tracer rate lower limit for well rate cutback reversal  
DEFAULT: No limit
4. Total tracer concentration upper limit for well rate cutback (not available for partitioned tracers)  
DEFAULT: No limit
5. Total tracer concentration lower limit for well rate cutback reversal (not available for partitioned tracers)  
DEFAULT: No limit

End the record with a slash (/).

End the data for this well with a blank line containing just a slash (/).

Note that this means that the keyword will end with two blank lines containing just slashes.

## Notes

1. No units are given for the tracer rates. The rates are those of the carrier flow.
2. Since the tracers are solved after the main reservoir simulation if it is subsequently discovered that a limit is violated, the timestep is always repeated with the action enforced from the start of the timestep. Even with this it may be that the 'action' lags the violation by a timestep.
3. Whenever the well violates one of the cutback limits given in items 2 to 5 of record 2, it is set to operate at a reduced target rate of the phase specified in item 3 of record 1. Its control mode will automatically change to the mode corresponding to item 3 (if it is not already under that mode of control). The target rate of the control phase is set equal to the well's current flow rate of that phase, multiplied by the cutback factor specified in item 2.
4. Whenever the well violates one of the cutback reversal limits, **and** if the well is currently operating under rate control of the phase selected in item 3 of record 1, the target rate of the phase is increased by dividing it by the factor specified in item 2 of record 1. This essentially reverses the cutback process.
5. The well's target rate of the phase selected in item 3 of record 1 is reset each time one of the limits is violated. Any initially user-defined rate limit for the phase is 'forgotten'. Thus a series of cutback reversals could increase the rate target for that phase beyond its initial limit. This can be avoided by choosing a phase in item 3 of record 1 for which there is no user-defined limit. For example, if the well has rate limits defined directly for just the oil and water phases, a suitable control phase would be LIQ or RESV. The well changes to this control mode when it is cut back. During cutback reversals this limit is progressively increased, but the original oil and water limits remain intact and are not exceeded.
6. This keyword must end with two lines containing only slashes. See the example.

## Example

```
WCUTBACT
  PROD1  0.8 WAT /

```

## WCYCLE

## Automatic cycling of wells on and off

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword provides a means of automatically cycling wells on and off for specified intervals of time. The facility can be used, for example, to simulate a WAG process, where the injection well is represented by separate water and gas injectors that are cycled on and off alternately.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template.

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. On-period - The well is turned off at the beginning of the first timestep that starts after the specified on-period has elapsed since it was last turned on.

A zero or negative value prevents the well being turned on again by automatic cycling.

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

DEFAULT: 0.0

3. Off-period - If the well was turned off by automatic cycling, it is turned on again at the beginning of the first timestep that starts after the specified off-period has elapsed since it was turned off.

If the well was closed for any other reason (for example manually or due to an economic limit), it remains closed until action is taken to open it again. Once opened again, it resumes cycling.

A zero or negative value prevents the well being turned off again by automatic cycling.

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

DEFAULT: 0.0

4. Start-up time - The well's efficiency factor is steadily ramped up over the specified start-up time when it is turned on by automatic cycling. During each timestep after reopening, its efficiency factor is multiplied by the quantity

$$(T - T_o) / \text{Start-up Time} \quad \text{Eq. 3.219}$$

where

T is the time at the end of the timestep

T<sub>o</sub> is the time the well was turned on for as long as  $T - T_o < \text{Start-up Time}$ .

Thus if the start-up time is large compared to the timestep size, the well will be brought on gradually, avoiding the timestep convergence difficulties sometimes observed when a high-rate well is suddenly opened.

The start-up time also applies to wells turned on by periodic testing (see keyword [WTEST](#)).

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

DEFAULT: 0.0, which gives an instantaneous start-up.

5. Maximum length of the timestep in which the well is turned on by automatic cycling. The value specified here overrides the normal maximum step length (see keyword [TUNING](#)) during the timestep in which the well is turned on by automatic cycling. This provides a means of cutting back the timestep when a well is turned on, to avoid the convergence difficulties sometimes observed when a high-rate well is suddenly opened.

A zero or negative value applies no restriction on the timestep size, other than the normal maximum step length.

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

DEFAULT: 0.0 (no timestep restriction on start-up)

6. Should the timesteps be controlled to coincide exactly with the on/off cycling times of this well?

YES The timesteps coincide with this well's on/off cycling times, and the well therefore cycles with exactly the specified periods. (If there are several wells cycling on and off at different times, this could slow the run down by imposing small timesteps.)

NO The timesteps does not automatically coincide with this well's on/off cycling times. The well cycles at the beginning of the next timestep that starts after the specified period has elapsed. The well's on/off periods may therefore be longer than the values specified, unless they coincide with reporting times.

DEFAULT: NO

End the data record with a slash (/).

End the set of records with a blank record containing just a slash.

## Example

To initiate a WAG injection scheme, injecting water for 60 day periods and gas for 40 day periods, starting with water, with a 10 day maximum timestep at each changeover:

Set the cycle periods:

```
WCYCLE
-- well   on      off      startup  max t/s   control
-- name   period  period  time     on startup timesteps?
      INJW   60.0   40.0   1*      10.0     YES      /
      INJG   40.0   60.0   1*      10.0     YES      /
/
```

Start with the water injector open and the gas injector shut:

```
WELOPEN
      INJW   OPEN  /
      INJG   SHUT  /
/
```

Advance to the start of the first gas injection period and open the gas injector. It will start cycling:

```
TSTEP
60.0 /
WELOPEN
      INJG   OPEN  /
/
```

## WDFAC

## Sets well D-factor (flow-dependent skin for gas)

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template.

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. D-factor for the well(s).

UNITS: day/sm<sup>3</sup> (METRIC), day/Mscf (FIELD), hr/scc (LAB), day/sm<sup>3</sup> (PVT-M)

DEFAULT: 0.0

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

The D-factors for wells not specified with this keyword are defaulted to zero, unless they are set in keyword [COMPDAT](#) or [COMPDATL](#).

---

**Note:** For ECLIPSE 100, if the [VDFLOW](#) or the [VDFLOWR](#) keyword has been specified and has been applied to the well connections by setting [item 218](#) of the [OPTIONS](#) keyword to 2, this will be superseded by the calculation due to the WDFAC keyword.

---

## Converting the well D-factor into the connection D-factors

The D-factor is normally obtained from measurements on the well, and is multiplied by the well's free gas flow rate to give the non-Darcy flow addition to the skin factor:

$$S \rightarrow S + D_w |Q_{fg}| \quad \text{Eq. 3.220}$$

Within the simulator, however, it is treated as a quantity associated with each well connection rather than the well as a whole, and it is multiplied by the connection's free gas flow rate to give the local non-Darcy skin contribution:

$$S \rightarrow S + D(j) |q_{fg}(j)| \quad \text{Eq. 3.221}$$

If the well has more than one connection, the connections' D-factors must be scaled to apply to the connection flows instead of the well flow, in order to give the same addition to the skin factor. ECLIPSE performs the scaling automatically, when the well D-factor is specified. The scaling calculation assumes the free gas flow rate in each connection is proportional to the connection transmissibility factor. It aims to give each connection the same non-Darcy skin, by setting the D-factors in inverse proportion to the connection transmissibility factor:

$$D(j) = D_w \frac{\sum T_w(i)}{T_w(j)} \quad \text{Eq. 3.222}$$

where

$T_{w,j}$  represents the transmissibility factor for the connection  $j$ , and

$\sum_i T_{w,i}$  represents the sum of the transmissibility factors of the well's currently open connections.

Note that the scaling is performed according to the number of connections open at the time WDFAC is entered. It is assumed that the D-factor entered has been measured at this time, while the well has its current number of open connections. The scaling does not of course change the D-factor if the well has only one open connection. If you wish to examine the resulting connection D-factors, request a printout of the Schedule section keyword data, and the D-factors are printed in the table of well connection data.

If subsequently one or more connections in the well are closed, the well's D-factor changes. However, the D-factors of the remaining connections should not be affected. There is therefore no need to specify the well's D-factor again, because the connection D-factors by default retain their original scaled values.

If you wish to enter the connection D-factors directly, bypassing the scaling calculation, they may be entered **with a negative sign** in item 12 of keyword `COMPDAT` or item 13 of keyword `COMPDATL`.

See also "[The flow-dependent skin factor](#)" in the *ECLIPSE Technical Description* for further discussion on the treatment of flow-dependent skin.

ECLIPSE 300

---

**Note:** If non-Darcy Forchheimer effects for gas flow have been enabled via item 4 of the `VELDEP` keyword, then a D-factor for each production well connection will be calculated. These calculated, Forchheimer parameter based D-Factors will override those set in this keyword. See "[Forchheimer parameter based well D-factors](#)" in the *ECLIPSE Technical Description* for further details.

---

## Example

```

WDFAC
-- well    well
-- name    D-factor
   PROD1  1.5E-3  /
   PROD2  1.2E-3  /
/

```

## WDFACCOR D-factor correlation (flow-dependent skin factor for gas)

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword defines an expression for connection D-factors that is based on a correlation for the coefficient of inertial resistance, usually known as  $\beta$ , in Forchheimer's flow equation as described below. The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/). The set of records must end with a blank record, containing only a slash (/).

- Well name, well name template, well list or well list template.  
A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).
- Coefficient A in the D-factor correlation  
DEFAULT: 0.0
- Power B of a connected grid block permeability in the D-factor correlation  
DEFAULT: 0.0
- Power C of a connected grid block porosity in the D-factor correlation  
DEFAULT: 0.0

For each connection in the well, a D-factor will be calculated based on the permeability and porosity of the connected grid block together with the fluid properties of the wellbore. These D-Factors are recalculated each time a [COMPDAT](#) or [COMPDATL](#) or [WDFAC](#) or WDFACCOR is found in the schedule.

The calculated D-factor may be written to the summary file using the keyword [CDFAC](#).

---

**Note:** For ECLIPSE 100, if the [VDFLOW](#) or the [VDFLOWR](#) keyword has been specified and has been applied to the well connections by setting [item 218](#) of the [OPTIONS](#) keyword to 2, this will be superseded by the calculation due to the [WDFACORR](#) keyword.

---

### The D-factor correlation

Following [Dake \[Ref. 30\]](#), the expression for the non-Darcy flow D-factor used here is:

$$D = A \cdot K_e^B \cdot \varphi^C \cdot \frac{K_e}{h} \cdot \frac{1}{r_w} \cdot \frac{\gamma_g}{\mu_g} \quad \text{Eq. 3.223}$$

where

$A$ ,  $B$ ,  $C$  are supplied by this keyword

$K_e$  is the effective permeability of the connected grid block. For a vertical well the permeability used here is the geometric mean of the x- and y-direction permeabilities,  $K_e = (k_x k_y)^{1/2}$ .

$\varphi$  is the porosity of the connected grid block

$h$  length of the connection

- $r_w$  wellbore radius
- $\gamma_g$  relative density of produced or injected gas at surface conditions with respect to air at standard temperature and pressure
- $\mu_g$  gas viscosity at bottom hole pressure

ECLIPSE 300

Note that  $\gamma_g$  and  $\mu_g$  vary with time and thus so will the calculated D-factor.

ECLIPSE 100

Note that  $\mu_g$  varies with time and thus so will the calculated D-factor.

See also "The flow-dependent skin factor" in the *ECLIPSE Technical Description* for further discussion on the treatment of flow-dependent skin.

### The coefficient of inertial resistance

The expression for the non-Darcy D-factor can be written as

$$D = \alpha \cdot \beta \cdot \frac{Ke}{h} \cdot \frac{1}{r_w} \cdot \frac{\gamma_g}{\mu_g} \tag{Eq. 3.224}$$

where  $\beta$  is the coefficient of inertial resistance, given by

$$\beta = const \cdot K_e^B \cdot \phi^C \tag{Eq. 3.225}$$

$\beta$  has Forchheimer units. A laboratory determined relationship for  $\beta$  can be obtained by using a  $const = 883.90$  (as converted from Dake),  $B = -1.1045$  and  $C = 0$  (from Dake).

$\alpha$  is a constant, the value of which depends on the units system, as shown in the see the following table.

	Metric	Field	Lab	PVT-Metric
Unit	day / sm <sup>3</sup>	day / Mscf	hr / scf	day / sm <sup>3</sup>
$\alpha$	2.24460 x 10 <sup>-10</sup>	6.83352x10 <sup>-8</sup>	5.41375 x 10 <sup>-11</sup>	2.25533 x 10 <sup>-10</sup>

Table 3.51: Unit-dependent constant for the Forchheimer parameter-dependent skin-factor

Thus Dake's formula (in field units) can be specified by entering  $A = 6.04e - 5$ ,  $B = -1.1045$  and  $C = 0$ .

### Example

```

WDFACCOR
-- well Coeff      Power  Power
-- name   A        B      C
   PROD1 6.04e-5 -1.1045 0.0 /   Dake's formula values (field units)
/
    
```

## WDRILPRI Puts wells into the prioritized drilling queue

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used to put wells into the prioritized drilling queue and to define their drilling priority values and drilling unit numbers. The drilling priority values set here will override the values calculated using the drilling priority equation (see keyword [DRILPRI](#)).

The wells are opened in decreasing order of their drilling priority when they are needed to maintain a group rate target under group control by guide rate ([GCONPROD](#), [GCONINJE](#), [GCONSALE](#)) or when needed to maintain a group's production potential ([GDRILPOT](#)). If a group (including the field) cannot meet its production target, the production well with the highest drilling priority that is subordinate to that group, and not subordinate to any other group under the same mode of production control, are opened automatically. If a group cannot meet its injection target, the injection well with the highest drilling priority that is subordinate to that group, and not subordinate to any other group under injection control for the same phase, will be opened automatically.

Well opening may be delayed by constraints on the rate of drilling new wells (see keyword [WDRILTIM](#)), the availability of drilling rigs (keyword [GRUPRIG](#)) and, in ECLIPSE 100, on the maximum number of open wells in any group (item 9 of keyword [GECON](#)). If a well cannot currently be drilled because of any of these constraints, wells with lower drilling priority in the queue are examined in decreasing priority order to see if there is another suitable well that can be drilled instead.

An alternative to the prioritized drilling queue is the sequential drilling queue, from which wells are opened in the sequence in which they are placed in the queue. Wells are placed in the sequential drilling queue using the keyword [QDRILL](#). Only one type of drilling queue may exist at any given time in the run; the two types of queue cannot operate together.

### ECLIPSE 100

The drilling queue facility should not be confused with the automatic opening option ('AUTO' in item 2 of keyword [WCONPROD](#) and item 3 of keyword [WCONINJE](#) for example). They are two completely separate facilities. Wells in the drilling queue are opened only when needed to maintain group production and injection targets. Wells on 'AUTO' are opened as soon as allowed by constraints on drilling rate and number of open wells per group, irrespective of group flow rates.

The WDRILPRI keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template .

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Drilling priority value for the well(s).

If the priority is zero the well is removed from the drilling queue.

If the priority is greater than zero, the well's drilling priority remains fixed at this value.

If the priority is negative, the well's drilling priority is calculated at specified intervals (see keyword [DRILPRI](#)) from its potential rates. For producers, it is calculated from the priority equation defined with keyword [DRILPRI](#). For injectors the drilling priority is set equal to their injection potentials.

DEFAULT: Negative

Priority values do not have any units.

ECLIPSE 100 only

### 3. Drilling unit number

If set > 0 all wells with this particular drilling unit number is drilled at the same time. Also their drilling priorities (either calculated or user-specified) are added together when the drilling queue is scanned for the highest priority value, so that the most productive unit overall is selected if the well priorities reflect their production potentials. This facility allows, for example, wells in the same locality to be drilled consecutively once it has been decided to send a drilling rig there.

Once a unit has been selected for drilling, the drilling process for **all** its wells begins immediately. The drilling rig is logged as busy for the sum of the wells' drilling times (keyword [WDRILTIM](#) item 2). However, all the wells begin flowing immediately unless they are flagged as closed while being drilled ([WDRILTIM](#) item 3). In that case each well is given a zero efficiency factor until its drilling process is finished, and each well is drilled consecutively in the order in which they were first declared with the [WELSPECS](#) keyword. If more than one rig is available, the drilling process is shared between them.

DEFAULT: 0

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

---

**Note:** The drilling queue is **not** used for opening wells belonging to groups under prioritization group control (keyword [GCONPRI](#)), as the prioritization algorithm itself handles the opening and closing of these wells. Drilling priorities should not be confused with well priorities set with keywords [PRIORITY](#) and [WELPRI](#).

---

See also keywords [DRILPRI](#), [WDRILRES](#), [WELSOMIN](#), [PRORDER](#) and [QDRILL](#).

## Example

```
WDRILPRI
'PROD*' -1.0 /
PROD1 1000.0 /
/
```

## WDRILRES Prevents two wells being drilled in the same block

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

After this keyword is used, any well in the drilling queue (keyword [QDRILL](#) or [WDRILPRI](#)) or on automatic opening (AUTO in keyword [WCONPROD](#) for example) will be prevented from opening if it is completed in the same grid block as a well that is already open. It is then removed from the drilling queue or automatic opening queue.

With this facility it is effectively possible to allocate a well to the first group that is able to support it, subject to its maximum allowed number of open wells set in keyword [GECON](#). You must define a different well for each group, completed in the same location, and place them in the drilling queue or under automatic opening. These wells in fact all represent the same physical well. Thus when one well is opened the remaining wells must be left shut.

This keyword does not prevent wells being opened manually, for example, with keyword [WELOPEN](#).

The keyword has no associated data.

## WDRILTIM

## Controls on the automatic drilling of new wells

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The records may be terminated at any item after item 1. The remaining items will assume their default values.

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template.

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

If [QDRILL](#) is entered here, followed by the slash terminator, the option to prevent repeated premature opening of wells in the drilling queue will be invoked (see "[Wells in the drilling queue](#)").

2. Time taken to drill the well

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

DEFAULT: 0.0

This item limits the rate at which new wells can be opened either:

*ECLIPSE 100 only*

- automatically (AUTO in keywords [WCONPROD](#), [WCONINJE](#), [WCONINJ](#), [WELOPEN](#)),
- or from the drilling queue (keyword [QDRILL](#) or [WDRILPRI](#)),
- or on the closure of another well (item 9 in keyword [WECON](#)).

A well with a non-zero drilling time requires a drilling rig. It will not be drilled if all the rigs available to the well are occupied up to the end of the timestep. When a drilling rig allocated to any superior group becomes free, the well's drilling operation will occupy the rig for the specified time. Rig availability has no effect on wells being opened manually (for example with keywords [WELOPEN](#) or [WCONPROD](#)). Drilling rigs are allocated to groups with the keyword [GRUPRIG](#).

3. Closure of well during drilling and workovers

**YES** The well is treated as shut during automatic drilling and workovers, by temporarily adjusting its efficiency factor (see keyword [WEFAC](#)) for the timesteps in which these processes occur. Its flows are then not included in the group totals and cumulative totals while it is being drilled or worked over. The closure time for workovers is set in keyword [WORKLIM](#) (it defaults to zero if [WORKLIM](#) is not entered). This does not affect wells being opened or recompleted 'manually'.

**NO** The well starts flowing at the beginning of the timestep in which its drilling operation starts, and is not shut during workovers.

Drilling is prevented if all the drilling rigs available to the well are occupied up to the end of the timestep. Otherwise the well will be opened at the beginning of the timestep.

DEFAULT: NO

*ECLIPSE 100 only*

4. Compartment number for the well (a positive integer or zero).

If set positive, all wells in that compartment will be temporarily shut while any well in the compartment is drilled or worked over automatically. The temporary closure is performed by reducing the wells' efficiency factors for the timesteps in which an automatic drilling or workover occurs. Wells being opened or recompleted 'manually' will have no effect.

A positive number may be supplied only if item 3 is set to YES.

DEFAULT: 0

(temporary closure is not performed in compartment number 0)

End the data record with a slash (/).

End the set of records with a blank record containing just a slash.

## Wells in the drilling queue

If the controls in items 3 and 4 are applied to wells in the drilling queue, they may cause wells to be drilled sooner than is really necessary. If a group cannot meet its flow target, a well from the drilling queue is opened. But if the well is treated as shut during the drilling process, its full benefit is not realized until the timestep after drilling has been completed. Its contribution during the timestep in which it is drilled may therefore not be sufficient to enable the group to reach its target, and a second well from the drilling queue may be opened (provided that there is still some free drilling rig time left in the timestep). For ECLIPSE 100, this effect is even more likely to occur if other wells in the same compartment are shut during the drilling process. The loss of flow from these wells during the drilling process can be greater than the extra contribution from the new well in the timestep in which it is drilled. Thus the immediate effect of drilling a new well could be a net reduction in flow rate, and the drilling queue is scanned again if there is still some free drilling rig time left in the timestep.

There is an optional switch to prevent the early drilling of additional wells in the drilling queue. It is triggered by including an extra record in this keyword, having `QDRILL` in item 1 in place of a well name, followed by the slash terminator:

```
QDRILL /
```

If any other item in this record is set to a non-default value, the record is treated as a standard one referring to a well called `QDRILL`. If all other items in the `QDRILL` record are defaulted, the switch preventing repeated drillings is set ON for the rest of the simulation (including any restarts). The switch prevents the drilling queue being scanned during timesteps in which a drilling operation of non-zero duration is already taking place (including drilling operations started in a previous timestep) on the same type of well (producer and water injector for example) subordinate to the group requesting the drilling. Thus the decision on whether to scan the drilling queue to open an additional well is taken only after any wells of the same type and subordinate to the same group requesting the drilling are fully on stream.

ECLIPSE 100

If the opening of new wells from the drilling queue is one of the Group Production Rule actions specified in keyword `PRORDER`, do not use the `QDRILL` switch in keyword `WDRILTIM`. Instead, it is better to set item 1 in the second record of keyword `PRORDER` to NO, as this restricts all the production rule actions and not just drilling.

## Example

```
WDRILTIM
-- well   drilling   close while   compartment
-- name   time       drilling?     number
  'W1*'   30 /
  'W2*'   25         YES           1 /
```

QDRILL /  
/

## WECON

## Economic limit data for production wells

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The records may be terminated at any item after item 1. The remaining items will assume their default values. Default values can be specified before the slash by null repeat counts of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template.

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Minimum oil production rate. User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

If the oil production rate falls below the specified minimum, the well is shut or stopped (see item 9 in keyword [WELSPECS](#)).

However, if the well has any connections left on automatic opening (see item 6 of keyword [COMPDAT](#)) and which meet the minimum oil saturation requirements (if imposed with keyword [WELSOMIN](#)), one of these is opened instead, as soon as a workover rig is available.

If item 10 is POTN, the minimum rate limit is applied to the well's oil production potential instead of its actual rate.

A zero or negative value switches off this limit.

UNITS: sm<sup>3</sup>/day (METRIC), stb/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: 0.0

3. Minimum gas production rate. User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

If the gas production rate falls below the specified minimum, the well is shut or stopped (see item 9 in keyword [WELSPECS](#)).

However, if the well has any connections left on automatic opening (see item 6 of keyword [COMPDAT](#)) and which meet the minimum oil saturation requirements (if imposed with keyword [WELSOMIN](#)), one of these is opened instead, as soon as a workover rig is available.

If item 10 is POTN, the minimum rate limit is applied to the well's gas production potential instead of its actual rate.

ECLIPSE 100

ECLIPSE 100

ECLIPSE 300

If, in compositional mode, a well is controlled by gas volume rate, surface volumes are obtained by  $(Q_g^m RT_{\text{ref}}) / P_{\text{ref}}$ , where  $Q_g^m$  is the molar gas rate,  $R$  the gas constant,  $P_{\text{ref}}$  the standard pressure and  $T_{\text{ref}}$  the standard temperature.

UNITS: sm<sup>3</sup>/day (METRIC), Mscf/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: 0.0

4. Maximum water cut. User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

The water cut is the ratio of water to total liquid (oil + water) surface volume production rates.

A value of 0.0 switches off this limit.

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: No limit

5. Maximum gas-oil ratio. User defined arguments can be set with keywords UDQ and UDADIMS.

A negative or zero value switches off this limit.

ECLIPSE 100

If a negative value is specified (- X), the well is not closed or worked over on violation of its water cut limit (item 4), or a group water cut limit (GECON) or a group water or liquid rate limit (GCONPROD), if the well has a gas-liquid ratio greater than the positive value X. This option is intended for wells that produce mainly gas and mainly oil at different stages of their life. The option allows the well to have a high water cut while it is a gas producer.

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), Mscf/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: No limit

6. Maximum water-gas ratio. User defined arguments can be set with keywords UDQ and UDADIMS.

A value of 0.0 switches off this limit.

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/Mscf (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: No limit

7. Workover procedure on exceeding water cut, GOR, WGR or GLR limit

NONE No action to be taken

CON Shut worst-offending connection

+CON Shut worst-offending connection and all those below it. (See keyword COMPORD)

(In ECLIPSE 300, CON+ is interpreted as +CON for back-compatibility)

WELL Shut or stop the well (item 9 in keyword WEL SPECS)

ECLIPSE 100

PLUG Plug back the well (see keyword WPLUG)

DEFAULT: NONE

8. End run flag

YES The run stops at the next report time if the well is shut or stopped for any reason after being opened

NO The run continues regardless

DEFAULT: NO

9. Name of well to be opened when this well is shut (the follow-on well)

If a well name is entered here, the named well is opened when the well specified in item 1 is closed automatically for any reason (for example on violating an economic limit). The named well must be fully specified as a SHUT producer or injector. Manual closure of the well in item 1 (for example using WCONPROD or WELOPEN) does not cause the named well to be opened.

This option can be used, for example, to open an injector when a producer closes after becoming uneconomic. If the injector has the same completions as the producer, the effect is equivalent to converting the producer into an injector, although in this case they is regarded as two separate wells.

If the well to be opened is given a non-zero drilling time in keyword `WDRILTIM`, the opening is subject to constraints on drilling rig availability (see keyword `GRUPRIG`).

DEFAULT: '

10. Quantity to which the minimum economic limits in items 2, 3, 14 and 16 will be applied

**RATE** The limits are applied to the well's actual flow rate. The minimum rate checks are bypassed for wells whose rate target is currently cut back under prioritization (`GCONPRI`), to prevent them being closed while temporarily flowing with a small target rate. For wells subordinate to groups under guide rate control (`GCONPROD`), the minimum rate limits will be applied unless the group has a zero production rate target.

**POTN** The limits are applied to the well's production potential (that is the rate that the well could immediately achieve if all rate limits were removed, honoring only its BHP and THP limits, and any drawdown limit if requested in `WELDRAW` - see "Well potentials" in the *ECLIPSE Technical Description*). Thus if the well's production rate was cut back to meet a group rate target, this does not trigger the minimum economic limit check. Wells under prioritization (`GCONPRI`) have their potentials checked against the minimum economic limits, even if they are not currently selected to flow, and are permanently closed if the potential is too small.

DEFAULT: RATE

11. Secondary maximum water cut limit.

If this value is set  $> 0.0$  (and  $< 1.0$ ), a secondary water cut limit is applied to the well. The application of this limit depends on the action selected in item 12. The application associated with the actions `LAST` and `RED` are described in item 12. For all other actions, the secondary limit is applied as described below.

If the well has been subjected to a number of workovers due to the violation of the primary water cut limit (item 4), it is shut in when its last remaining connection is closed in a workover. However, if the well has a secondary water cut limit set, it will be reopened at the beginning of the next timestep and the secondary water cut limit will replace the primary water cut limit in the economic limit tests. Also, all its connections that were closed in the previous workovers are reopened. The connections may be closed again in subsequent workovers whenever the well exceeds the new water cut limit, depending on the workover action chosen in item 12.

Thus, the well can be kept within its primary water cut limit for as long as possible by closing its worst offending connections. But when its last connection exceeds the primary water cut limit, the whole well is given a second life for as long as it able to produce within the secondary water cut limit. Obviously, the secondary water cut limit should be set to a value significantly greater than the primary limit in item 4.

The workover procedure in item 7 should be set to `CON`, `+CON` or `PLUG`.

UNITS:  $\text{sm}^3/\text{sm}^3$  (`METRIC`), `stb/stb` (`FIELD`), `scc/scc` (`LAB`),  $\text{sm}^3/\text{sm}^3$  (`PVT-M`)

DEFAULT: 0.0 (No secondary water cut limit)

12. Workover action on exceeding the secondary water cut limit defined in item 11

`NONE` Do nothing

- CON Shut worst-offending connection
- +CON Shut worst-offending connection and all those below it (see keyword [COMPORD](#))
- WELL Shut or stop the well (item 9 in keyword [WELSPECS](#))
- ECLIPSE 100* PLUG Plug back the well (see keyword [WPLUG](#))
- LAST The secondary water-cut is applied only to the last open connection in the well. (Connections on automatic opening class as open in this context.) This action differs from the ones above in that, when the well has only one connection left open and it begins to exceed its primary water-cut limit again, the well remains open until it exceeds its secondary water-cut limit but the other connections closed in previous workovers will **not** be reopened.
- ECLIPSE 100* RED The well is worked over each time it violates its primary water-cut limit, as normal. But each workover attempts to close sufficient connections to reduce the well's water-cut to below the specified secondary limit. Clearly, in this case, the secondary value should be **less** than the primary value. Assuming the well can be worked over to achieve this secondary value, it is not worked over again until the primary value is again violated. This option has the effect of requiring fewer workovers but closing more connections per workover.
- DEFAULT: The same action as defined in item 7
13. Maximum gas-liquid ratio
- The workover procedure on exceeding this limit is defined in item 7.
- A value of 0.0 switches off this limit.
- UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), Mscf/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)
- DEFAULT: No limit
14. Minimum liquid production rate
- If the liquid production rate falls below the specified minimum, the well is shut or stopped (see item 9 in keyword [WELSPECS](#)).
- If item 10 is POTN, the minimum rate limit is applied to the well's liquid production potential instead of its actual rate.
- A zero or negative value switches off this limit.
- UNITS:  $\text{sm}^3/\text{day}$  (METRIC), stb/day (FIELD), scc/hr (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)
- DEFAULT: 0.0
- ECLIPSE 300 only* 15. Maximum temperature
- (available only with the Thermal option; keyword [THERMAL](#) in the RUNSPEC section.)
- The well is shut if this temperature is exceeded.
- UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)
16. Minimum reservoir fluid production rate
- If the reservoir fluid production rate falls below the specified minimum, the well is shut or stopped (see item 9 in keyword [WELSPECS](#)).

If item 10 is POTN, the minimum rate limit is applied to the well's reservoir fluid production potential instead of its actual rate.

A zero or negative value switches off this limit.

UNITS:  $\text{m}^3/\text{day}$  (METRIC),  $\text{rb}/\text{day}$  (FIELD),  $\text{rcc}/\text{hr}$  (LAB),  $\text{m}^3/\text{day}$  (PVT-M)

DEFAULT: 0.0

End data record with a slash (/).

Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Component index

An integer between 1 and the value set in keyword [COMPS](#).

3. Maximum mole fraction of the component specified by item 2 in the produced wellstream. This quantity can be a user defined argument (UDA), and can be set with keywords [UDQ](#) and [UDADIMS](#).

A value of 1.0 switches off this limit.

4. Workover procedure on exceeding the mole fraction limit

NONE No action to be taken

CON Shut worst-offending connection

+CON Shut worst-offending connection and all those below it (see keyword [COMPORD](#))

WELL Shut or stop the well (item 9 in keyword [WELSPECS](#))

DEFAULT: NONE

5. End run flag

YES The run stops at the next report time if the well is shut or stopped for any reason after being opened

NO The run continues regardless

DEFAULT: NO

See also keywords [COMPLUMP](#) and [WLIMTOL](#)

## WECONINJ Economic limit data for injection wells

x	ECLIPSE 100
	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The records may be terminated at any item after item 1. The remaining items assume their default values. Default values can be specified before the slash by null repeat counts of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Minimum economic injection rate.

If the injection rate falls below the specified minimum, the well is shut or stopped (see item 9 in keyword [WEL SPECS](#)). This rate applies to the phase specified in item 2 of the keyword [WCONINJ](#) or [WCONINJE](#).

If item 3 below is POTN, the minimum rate limit is applied to the well's oil/water/gas injection potential instead of its actual rate.

A zero or negative value switches off this limit.

UNITS: As appropriate for item 2 of [WCONINJ](#)/[WCONINJE](#)

DEFAULT: 0.0

3. Quantity to which the minimum economic limits in item 2 will be applied.

**RATE** The limits apply to the well's actual injection rate. For wells under group control ([GCONINJE](#)), the minimum rate limit will be applied unless the group has a zero injection rate target.

**POTN** The limit applies to the well's injection potential (that is the rate that the well could immediately achieve if all rate limits were removed, honoring only its BHP and THP limits - see "[Well potentials](#)" in the *ECLIPSE Technical Description*). Thus if the well's injection rate was cut back to meet a group rate target, this will not trigger the minimum economic limit check.

DEFAULT: RATE

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

See also keyword [WLIMTOL](#).

### Example

```
WECONINJ
INJ1 500 RATE /
```

INJ2 800 POTN /  
/

## Tracer economic limits for production wells

WECONT is used to set tracer economic limits for production wells, including polymer and brine.

WECONT is followed by any number of records, described below, each record terminated by a slash (/). A record may be terminated early at any item; the remaining items assume their default values. Default values can be specified before the slash by a null repeat count of the form  $n^*$ , where  $n$  is the number of consecutive items to be defaulted. There are two types of record; one describes the connection and the second lists the tracers and their limits.

The set of records must end with a blank record, containing only a slash (/).

### Records for the connection

Records of the first kind can contain some or all of the following items:

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Workover procedure when a limit is violated

NONE No action to be taken

CON Shut worst-offending connection

+CON Shut worst-offending connection and all those below it(see keyword [COMPORD](#))

WELL Shut or stop the well (item 9 in keyword [WELSPECS](#))

PLUG Plug back the well (see keyword [WPLUG](#))

DEFAULT: NONE

3. End run flag

YES The run stops at the next report time if the well is shut or stopped for any reason after being opened

NO The run continues regardless

DEFAULT: NO

4. Name of well to be opened when this well is shut (the follow-on well)

If a well name is entered here, the named well is opened when the well specified in item 1 is closed automatically for any reason (for example on violating an economic limit). The named well must be fully specified as a SHUT producer or injector. Manual closure of the well in item 1 (for example using [WCONPROD](#) or [WELOPEN](#)) does not cause the named well to be opened.

This option can be used, for example, to open an injector when a producer closes after becoming uneconomic. If the injector has the same completions as the producer, the effect is equivalent to converting the producer into an injector, although in this case they are regarded as two separate wells.

If the well to be opened is given a non-zero drilling time in keyword [WDRILTIM](#), the opening is subject to constraints on drilling rig availability (see keyword [GRUPRIG](#)).

DEFAULT: ' ' (no follow-on well)

End the record with a slash (/).

## Records for the tracers

A maximum of three subsequent records can follow, for each well. These records have some or all of the following items.

1. Tracer name (Use PLY for a polymer and BRI for brine)

2. Maximum total tracer rate

DEFAULT: No limit

3. Maximum total tracer concentration (not available for partitioned tracers)

DEFAULT: No limit

The following are only available for two-phase tracers

4. Maximum free tracer rate

DEFAULT: No limit

5. Maximum free tracer concentration

DEFAULT: No limit

6. Maximum solution tracer rate

DEFAULT: No limit

7. Maximum solution tracer concentration

DEFAULT: No limit.

End the record with a slash (/).

End the data for this well with a blank line containing just a slash(/).

Note that this means that the keyword will end with two blank lines containing just slashes.

## Notes

- No units are given for the tracer rates. The rates are those of the carrier flow.
- Since the tracers are solved after the main reservoir simulation if it is subsequently discovered that a limit is violated, the timestep is always repeated with the action being enforced from the start of the timestep. Even with this it may be that the 'action' lags the violation by a timestep.
- If the limit is on tracer concentration it is possible for the 'action' to lag the apparent violation by 2 timesteps. This is because the concentration is a derived quantity, and in deriving the value at the well ECLIPSE uses the latest available information. This may result in a value (slightly) different from the one calculated, and reported later, from the tracer calculation. If this is problematic it may be worth considering using [ACTION](#) keywords to replace the keyword entirely or to use [ACTION](#) keywords to reduce the timestep in the run-up to the limit being violated.
- This keyword needs to end with two lines containing only slashes. See the examples.

## Sets well efficiency factors (for downtime)

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Efficiency factor for the well(s)

This is the fractional time for which the well is operational. For example, if the well is 'down' for 10 percent of the time, its efficiency factor will be 0.9.

The efficiency factor must be greater than zero.

DEFAULT: 1.0

3. **Extended Network option only** Should a well's efficiency factor be included when calculating the branch flows and pressure losses in the extended network option? (See "[Well and group efficiency factors](#)" in the *ECLIPSE Technical Description*).

YES The extended network branch pressure losses is calculated using the well's time-averaged flow rate (that is the well rate multiplied by its efficiency factor).

NO The extended network branch pressure losses is calculated using the well's maximum flow (that is the well rate **not** multiplied by its efficiency factor).

This flag applies only to the extended network model (constructed with keywords [BRANPROP](#) and [NODEPROP](#)). If the Standard Network Model is being run ([GRUPNET](#), [GNETINJE](#)), the time-averaged well flows are always used to calculate the branch pressure losses.

DEFAULT: YES

---

**CAUTION:** Do not select the NO option in item 3 if group rate constraints are to be handled by automatic chokes (if [NODEPROP](#) item 3 is YES for any network node). The constraints are then applied to the flow in the network (the sum of the wells' maximum flow rates), which are inconsistent with the group flows (which are always the sum of the subordinate wells' time averaged flows).

---

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

The efficiency factors for wells not specified with this keyword are defaulted to 1.0.

### Treatment of downtime

Each well is solved at its full flowing conditions, and the well rates and pressures given in the well reports describe the state of the flowing well. However, the flow rates are multiplied by the well's efficiency factor when:

- The well rates are summed to give the group flow rates,

- The well rates are multiplied by the timestep and added to the cumulative flows,
- The connection flows are applied as source/sink terms in the reservoir material balance equations.

This essentially treats the wells as going down individually for random short intervals within each timestep, rather than all going down simultaneously. (If all the wells in a group are brought down together for regular maintenance, then the efficiency factor should be applied to the group with keyword `GEFAC`, currently available in ECLIPSE 100 only.) The group and field flows represent the average flow rates over the period. For example, if the efficiency factors are all 0.5, the well's individual flow rates sum to twice the group rate, but only half of them are flowing at any given instant on average.

If a group flow target is applied (for example with `GCONPROD`), this is interpreted as the target average flow rate of the group with the wells flowing intermittently according to their efficiency factors. The effect of the wells' downtime is to make the wells flow proportionately more while they are operating. For example, consider a group with a target oil rate of 10,000 stb/day to be divided equally between its 10 wells. If all wells had zero downtime, each would produce 1,000 stb/day. However, if they all have an efficiency factor of 0.8, each well must produce 1,250 stb/day while it is flowing to make up the group's target rate, provided that the wells' flowing conditions at this rate do not violate any of their operating limits.

#### ECLIPSE 100

If wells are receiving gas lift, their lift gas injection rates are multiplied by their efficiency factors when summing the group lift gas supply rates. The group lift gas supply rates are needed if there are restrictions on the total lift gas supply (that is, if using the `GLIFTLIM` keyword or the ECLIPSE 100 gas lift optimization facility).

When the standard network option is in use, the network pressure losses are calculated at the group average flow rates (that is the sum of the well rates multiplied by their efficiency factors). However, the extended network model, in which the network structure can be different from the group hierarchy, offers more flexibility (see "[Well and group efficiency factors](#)" in the *ECLIPSE Technical Description*). If `WEFAC` keyword item 3 is set to `NO` for each well, the pressure losses in the extended network are calculated using the maximum flows instead (that is the sum of the well rates **not** multiplied by their efficiency factors). The branch flows are then of course be different from the reported flows of the corresponding groups, which are their time-averaged rates.

An efficiency factor will still be applied to a well whose status is currently set to `STOP`. This includes flow across the well bore if the crossflow model is active. As the well efficiency factor assumes that the well is solved at operating conditions and that there is zero flow across the well during downtime, `WEFAC` is inappropriate for modeling downtime of wells with crossflow. To model crossflow accurately during downtime it is advised that the well's status is defined explicitly by manually opening and shutting the well for the appropriate time rather than using `WEFAC`.

### Example

```

WEFAC
' P * '    0.9 /
PROD2     0.8 /

```

## WELCNTL

**Resets a well control mode and operating target**

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to reset the control mode and target value for a well, without having to re-specify all the other quantities required by the control keywords [WCONPROD](#) or [WCONINJE](#). These other quantities are left unchanged, including the open/shut status of the well. The well control data must initially have been fully specified using [WCONPROD](#), [WCONINJE](#), [WCONHIST](#) or [WCONINJH](#).

This keyword is similar to the [WELTARG](#) keyword, but it also allows the control mode to be changed, not just an operating target or limit. Changing the control mode in this way, particularly when using a defaulted item 3, can be useful when switching from history matching mode to predictive mode during a simulation.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Definition of the new control mode for the well

ORAT Oil rate

WRAT Water rate

GRAT Gas rate

LRAT Liquid rate

CRAT Linearly combined rate (coefficients must be set with [LINCOM](#))

RESV Reservoir fluid volume rate

BHP Bottom hole pressure

THP Tubing head pressure (A non-zero VFP table number must first have been set)

*ECLIPSE 300 only*

WGRA Wet gas rate

*ECLIPSE 300 only*

NGL NGL rate

*ECLIPSE 300 only*

CVAL Calorific production rate

*ECLIPSE 300 only*

REIN Reinjection fraction

*ECLIPSE 300 only*

STRA Steam rate (Available only with the Thermal option)

*ECLIPSE 300 only*

SATP Saturation pressure offset (Available only with the Thermal option)

*ECLIPSE 300 only*

SATT Saturation temperature offset (Available only with the Thermal option)

3. New value of the operating target for this control mode.

UNITS: The units depend upon the quantity chosen. The appropriate units are listed in the specification for keywords [WCONPROD](#) and [WCONINJE](#).

DEFAULT: A defaulted value results in ECLIPSE using the corresponding flowing value for the well at the end of the previous timestep as the target for the control in item 2.

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

See also keyword [WELTARG](#).

---

**Note:** One of the primary purposes of this keyword is to make the transition from history matching mode to prediction mode easier to specify. However, if this keyword is used to change the control mode of a well which was previously specified using [WCONHIST](#) or [WCONINJH](#), then the old historical **target** (for example, oil rate) will still be present as a **limit**. This limit may interfere with the new control mode specified with the [WELCNTL](#) keyword, and cause the well to switch back to the old control mode. In order to avoid this, remove the old limit by using the [WELTARG](#) keyword to set this limit to a large value (1.0E+8 for example).

---

## Example

```
WELCNTL
  PROD1  ORAT  1500  /
  PROD2  BHP   /
  /
```

## WELDEBUG Controls on debug output for individual wells

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used control debug output for individual wells.

**Note:** This output is primarily intended as an aid to program development and debugging, and it should not be requested for normal program runs.

The keyword is followed by any number of lines, each containing the following data and each terminated with a slash (/). The last line must be followed by a line containing only a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Debug output control.

This is a 4-figure integer:

The 1<sup>st</sup> figure controls debug from well flow and property calculations.

The 2<sup>nd</sup> figure controls debug from connection flow calculations.

The 3<sup>rd</sup> figure controls debug from calculations involving VFP tables.

The 4<sup>th</sup> figure controls debug from well terms in the solver.

This should be either 0, 1 or 2. If a 4-figure integer is read, only the first figure is regarded as significant.

A value of 1 or more turns the relevant debug output switch on. Higher integers result in greater quantities of debug output. A value of zero turns the debug output off.

*ECLIPSE 100*

*ECLIPSE 300*

*ECLIPSE 300*

*ECLIPSE 300*

This keyword is ignored if [DEBUG3](#) (11) is set to either 1 or 2, in which case debug is output for all wells.

In parallel, a [DEBUG3](#) keyword, possibly empty, must be present in the [RUNSPEC](#) section for the debug output files to be created properly for each task.

### Example

```
WELDEBUG
  PROD1 2120 /
  PROD2 1001 /
/
```

## WELDRAW

## Sets maximum allowable drawdown for production wells

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to set the maximum drawdown allowed for each production well. At each timestep, the maximum drawdown  $D_{max}$  is converted into a maximum production rate  $Q_{max}$  of a selected phase, either liquid (oil + water) or gas, using the relationship

$$Q_{max} = D_{max} \sum_j [T_{wj} M_j] \quad \text{Eq. 3.226}$$

where the term

$$\sum_j [T_{wj} M_j]$$

denotes the product of the connection transmissibility factor  $T_w$  and the phase's mobility  $M$  in the connection, summed over all open connections in the well.

This relationship effectively defines the drawdown as

$$D = P_{av} - P_w \quad \text{Eq. 3.227}$$

where

$P_w$  is the well's bottom hole pressure, and

$P_{av}$  is a PI-weighted average of the pressures  $P$  in the grid blocks containing the well's open connections, given by

$$P_{av} = \frac{\sum_j \{T_{wj} M_j [P_j - H_{wj}]\}}{\sum_j [T_{wj} M_{wj}]} \quad \text{Eq. 3.228}$$

$H_{wj}$  is the hydrostatic wellbore pressure head between the connection  $j$  and the well's bottom hole pressure reference depth.

For a more detailed definition of these terms, see "[Well inflow performance](#)" in the *ECLIPSE Technical Description*.

As an alternative to limiting the PI-weighted average of the drawdowns within the grid blocks containing the well's open connections, it is also possible to apply the limit to the **maximum** drawdown within the set of grid blocks containing open connections to the well. This option would be particularly useful for wells completed in two or more layers with poor vertical communication and disparate pressures. The choice is determined by item 5 of the keyword. If this item is set to MAX, ECLIPSE calculates the minimum allowed BHP as

$$P_{w,\min} = \text{Max}_j (P_j - H_{wj} - D_{max}) \quad \text{Eq. 3.229}$$

which it converts into a maximum production rate using the current fluid mobilities,

$$Q_{max} = \sum_j \{T_{wj} M_j [P_j - H_{wj} - P_{w,\min}]\} \quad \text{Eq. 3.230}$$

When a well's production rate is being constrained by its drawdown limit, the well will be on liquid or gas rate control (depending on the phase selected), producing at the rate of  $Q_{max}$  given above. If you have set a

specific rate limit for the selected phase (using keyword `WCONPROD` or `WELTARG`), the flow rate is the minimum of  $Q_{\max}$  and the user-specified limit.

Since  $Q_{\max}$  depends on the mobility of the selected phase, which can change at each Newton iteration of a timestep, a well constrained by its drawdown limit could have a different flow rate target at each iteration. This may slow down the convergence rate of the Newton iterations. Therefore  $Q_{\max}$  is updated only during the first `NUPCOL` iterations of each timestep, just like the target rates of wells under group control (see keyword `NUPCOL`). For any remaining iterations,  $Q_{\max}$  is left unchanged, which may cause the actual drawdown to drift slightly away from the limit. Normally this drift will be negligible provided that the phase's mobility does not change too much during a single timestep. Obviously the selected phase should be the dominant one for the well, that is, liquid for oil wells and gas for gas wells.

Drawdown control can be used in combination with group control and other well constraints.

The keyword `WELDRAW` is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword `WLIST`.

2. Maximum allowable drawdown for the well(s). This is a user defined argument that can be set with keywords `UDQ` and `UDADIMS`.

UNITS: bars (`METRIC`), psi (`FIELD`), atm (`LAB`), atm (`PVT-M`)

3. Phase selected for rate limit.

LIQ For oil wells (unless fully gassed out)

GAS For gas wells (unless fully watered out)

At each timestep, the drawdown limit will be converted into a maximum production rate limit for this phase, using the current value of the phase's mobility in each connection.

DEFAULT: GAS if the well's preferred phase (`WELSPECS` item 6) is gas, LIQ in all other cases.

4. Do you wish the drawdown limit to be taken into account when calculating the well's production potential?

YES The well's production potential depends on its BHP, THP and drawdown limits

NO The well's production potential depends only on its BHP and THP limits.

Production potentials may be output in the well reports (`WELSPECS` item 7) and the `SUMMARY` file (`WOPP` for example). ECLIPSE uses them to calculate well guide rates or priorities for group control. See "[Well potentials](#)" in the *ECLIPSE Technical Description*.

DEFAULT: NO

5. Do you wish to limit the PI-weighted average of the drawdowns within the grid blocks containing the well's connections, or the maximum drawdown within the set of connection grid blocks?

AVG Limit the PI-weighted average drawdown, according to equations 3.226 to 3.228

MAX Limit the maximum drawdown, according to equations 3.229 and 3.230

DEFAULT: AVG

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

## Example

```

## WELLCF

## Specifies behavior of wells with conductive fracture

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The WELLCF keyword should be used to modify the default behavior of wells intersected by conductive fractures modeled using the single medium conductive fracture formulation (see "Dual porosity" in the *ECLIPSE Technical Description* for further information). The SCFDIMS keyword must be present in the RUNSPEC section.

The keyword is followed by a number of records, each record describing the behavior required when a particular well is intersected by one or more fractures. The record fields are:

1. Name Name of the well concerned
2. CUT, NOCUT Whether or not the well is intersected by fractures
3. CCF\_MULT CCF Multiplier to apply (whether CUT or NOCUT)
4. IC I-coordinate of the connection to apply the multiplier to
5. JC J-coordinate of the connection to apply the multiplier to
6. KC K-coordinate of the connection to apply the multiplier to
7. IC1 Completion start index to apply multiplier to
8. IC2 Completion end index to apply multiplier to

Each record should be terminated by a slash (/), and the total keyword data terminated by one final slash.

The CUT / NOCUT item must be entered; it has no default. If NOCUT is specified, then the saturation table index for that block will revert to that originally specified, and the well CCF modified so as to remove most of the effect of the single medium conductive fractures feature.

The CCF multiplier given is applied to the well completions specified, regardless of the value of the CUT / NOCUT item. It has a default of unity.

The well block specifications may be given as either single block entries {I,J,K}, one per line of data entry corresponding to a particular connection, or as a completion index range (IC1-IC2). Both methods may be defaulted with zero values, in which case all connected blocks are affected by the CUT / NOCUT item and the CCF\_MULT given. If both methods are employed at the same time, then the connections chosen will satisfy both criteria.

**Note:** The WELLCF keyword behaves similarly to the WPIMULT keyword in that if a well completion is specified again, using COMPDAT, then in order to keep the required CCF multiplier, the WELLCF keyword and data must be re-specified. Also, multiple WELLCF keywords will result in cumulative multipliers on the CCF.

### Example

```
WELLCF
'P1' CUT 1.0 5* /
/
```

## WELLCOMP Specifies a well completion

Specifies the position and properties of one or more well completions. This must be entered after the [WELLSPEC](#) keyword defining the appropriate well.

This keyword is retained for back-compatibility; you are encouraged to use keyword [COMPDAT](#) instead, which is compatible with both simulators.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash, the remaining items taking default values. Defaults can also be specified by a null repeat count of the form N\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. The I-index of the completion. If set to 0, or defaulted, this takes the value specified in [WELLSPEC](#).
3. The J-index of the completion. If set to 0, or defaulted, this takes the value specified in [WELLSPEC](#).
4. The smaller K-index of the completions

DEFAULT: 1

5. The higher K-index of the completions

DEFAULT: 1

6. The saturation table for well mobilities.

If set to 0, or defaulted, the cell saturation table number is used - that is, the value specified with [SATNUM](#).

7. The well bore diameter.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: 1 ft = 0.3048 m

8. The completion connection factor.

If this is not entered a default value is calculated using the Peaceman formula discussed in "[The connection transmissibility factor](#)" in the *ECLIPSE Technical Description*.

If a value > 0.0 is entered, the completion connection factor is set to this value. The value will also be used to calculate either the connection's effective Kh or the denominator term  $\ln(r_o/r_w) + S$  according to the following rules:

- If the Kh value in item 11 is defaulted or set negative, the Kh value is calculated from the connection transmissibility factor and the denominator term. The denominator term is calculated from the grid block dimensions, as described in the "[Well inflow performance](#)" in the *ECLIPSE Technical Description*.

- If the Kh value is set > 0.0, the denominator term is calculated from the connection transmissibility factor and the given Kh value, instead of the well bore radius and the grid block dimensions.
- If the Kh value is set = 0.0, it is replaced by the effective Kh of the grid block, then used to calculate the denominator term in the same way as if it had been set > 0.0.

The denominator term is used when calculating the well's productivity/injectivity index and when calculating the effects of a D-factor (see "[Well inflow performance](#)" in the *ECLIPSE Technical Description*). Thus, when the connection factor is set to a positive value, the results of these calculations depend on the setting of the Kh value in item 11.

---

**Note:** If a positive value is entered for the connection transmissibility factor, this should include the effect of any skin entered in item 11, but exclude the effect of any D-factor. The effect of a D-factor is modeled separately by adjusting the mobility (see "[The flow-dependent skin factor](#)" in the *ECLIPSE Technical Description*).

---

UNITS: cP.rm<sup>3</sup>/day/bars (METRIC), cP.rb/day/psi (FIELD), cP.rcc/hr/atm (LAB), cP.rm<sup>3</sup>/day/atm (PVT-M)

9. The skin factor

DEFAULT: 0

10. The saturation table for imbibition (when Hysteresis option used).

If set to 0, or defaulted, the cell imbibition table number will be used. This is the value specified with [IMBNUM](#).

11. Well Kh (permeability x thickness) value.

If defaulted, values of  $Kh_{net}$  are taken from cells in which the well is completed.

If a positive value for the connection transmissibility factor is entered in item 8, the calculation of the denominator term depends on whether the Kh value is set or defaulted. See item 8.

This quantity is required for calculating the connection transmissibility factor (if a default or zero value was supplied for item 8). It is ignored if not required.

UNITS: mD.m (METRIC), mD.ft (FIELD), mD.cm (LAB), mD.m (PVT-M)

DEFAULT: Negative

12. Direction in which the well penetrates the grid block.

This should be one of:

X The well penetrates the grid block in the X direction

Y The well penetrates the grid block in the Y direction

Z The well penetrates the grid block in the Z direction

FX The well is assumed completed in a fracture in the x-direction

FY The well is assumed completed in a fracture in the y-direction

This item is used in calculating the transmissibility factor of the connection if it was not supplied in item 8. In Cartesian grids the Peaceman formula is used, taking the components of permeability and grid block dimensions appropriate to the direction of penetration (see "[The connection transmissibility factor](#)" in the *ECLIPSE Technical Description*). Note that the formula assumes that the well completely penetrates a rectangular block through its center in a direction perpendicular to two of its faces.

In radial grids, only penetration in the Z direction is allowed.

If a value other than Z is specified, [HWELLS](#) must be included in the RUNSPEC section If FX or FY is specified, [FWELLS](#) must be included in the RUNSPEC section

DEFAULT: z

See also "[Hysteresis](#)" in the *ECLIPSE Technical Description*

## Examples

### Example 1

Well P11 is completed in cells (1,1,3) and (1,1,4), with a diameter of 0.5 and well I5 in cell (7,7,1), with a diameter of 0.3ft. Both use the first saturation function table.

```
WELLCOMP
P11 1 1 3 4 1 0.5 /
I5 7 7 1 1 1 0.3 /
/
```

### Example 2

In some cases it may be necessary to assign data values to each completion of a well individually, in which case a separate line of data should be entered for each line. Suppose that from flow meter analysis the Kh values of layers 3, 4 and 5 are 73, 94 and 35 respectively. The well is completed vertically in location (8,8), with a 0.5 ft diameter.

```
WELLCOMP
PRI 8 8 3 3 1* 0.5 3* 73 / --Layer 3
PRI 8 8 4 4 1* 0.5 3* 94 / --Layer 4
PRI 8 8 5 5 1* 0.5 3* 35 / --Layer 5
/
```

### Example 3

The completions of a given well need not share the same I,J values, so that a well may be deviated out of a column. For example, a well completed in layers 1 to 4 of column (5,18) and layers 7 to 10 of column (6,18) might have:

```
WELLCOMP
WW1 5 18 1 4 1* 0.4 /
WW1 6 18 7 10 1* 0.5 /
/
```

## WELLGR

## Specifies well guide rates

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies the user guide rate for a well.

This keyword is retained for back-compatibility; you are encouraged to use keyword [WGRUPCON](#) instead, which is compatible with both simulators.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash, the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. Well name, well name template, well list or well list template .

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. A character specifying whether the well is available for group control.

Y Well is available for control by a parent group

N Well is not available for control by a parent group

DEFAULT: Y

3. The guide rate value.
4. The type of guide rate being specified.

This must be one of the following:

OIL Oil production guide rate

WAT Water production guide rate

GAS Gas production guide rate

LIQ Liquid production guide rate

COM Linearly combined production guide rate (coefficients must be set with [LINCOM](#))

WG Wet gas production guide rate

VP Voidage production guide rate

IG Gas surface volume injection guide rate

IW Water surface volume injection guide rate

VG Gas voidage injection guide rate

VW	Water voidage injection guide rate
VI	Injection voidage guide rate (sets VG and VW)
RV	Reservoir voidage guide rate (sets VP, VG and VW)
INJ	Injection guide rate (sets IG and IW)
NONE	No guide rate specified, use potentials
ALL	Set all guide rates

Only the first two characters are significant.

By default, guide rates are set to the potential production or injection values of a group. These are normalized when used to distribute a group target over the sons of a group. In general, it is best to either specify all the guide rates for the sons of a group, (to specify the required distribution of targets explicitly), or to allow the default potential guide rates to be used.

It is usual to set one production guide rate (one of OI, WA, GA, LI, WG, VP), one water injection guide rate (one of IG, VG) and one gas injection guide rate (one of IW, VW). The others in each of these three classes are set using flow ratios from the value specified. The ALL option, VI, RV and INJ options allow several guide to be set explicitly.

## Example

```
WELLGR
Z45 Y 100.0 INJ /
/
```

## See also

## WELLINJE **Specifies well injection targets**

	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies the injection control data for a well. Both the nature of the fluid to be injected, and the target and limiting rates at which injection is to occur are defined.

This keyword is retained for back-compatibility; you are encouraged to use keyword [WCONINJE](#) instead, which is compatible with both simulators, unless you wish to use the Thermal Option items which are not available with [WCONINJE](#).

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash (/), the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. A character string specifying the fluid to be injected.

In black oil mode this may only be [WAT](#) or [GAS](#). In compositional mode, the nature of the injected fluid (that is, the mole fraction of each component) must be known. This may be defined in one of the following ways:

- the injection stream has a user specified composition, defined with the [WELLSTRE](#), [WINJMIX](#) or [WINJORD](#) keyword
- the injection stream is taken from the production of a named well or group.

The fluid string must be one of the following:

[WAT](#) Water.

[GAS](#) Gas may be selected in either a black oil or a compositional run.

In a compositional run the composition of the injected gas is set to that of the field separator gas. However, it is generally better to specify the injected gas composition more precisely.

From 2007.1, in a compositional run, [GAS](#) is internally converted to [GV](#) (for the field separator) which has better reinjection and gas accounting behavior. [item 113](#) of [OPTIONS3](#) can be used to recover the pre-2007.1 behavior.

[ST](#) Implies that the molar composition of the injected fluid has been defined using the [WELLSTRE](#) keyword.

[MIX](#) Implies that the molar composition of the injected fluid has been defined as a mixture using either the [WINJMIX](#) or [WINJORD](#) keywords.

[WV](#) Implies that the injected fluid is to be taken from the vapor production of a nominated well.

GV Implies that the composition of the injected fluid is to be taken from the vapor production of a nominated group.

The injection fluid string may only be defaulted if the well is injecting gas under group control, in which case the injection stream is that defined for the group.

3. A character string is required if the composition of the injection fluid was specified using the ST, MIX, WV or GV methods.

In these cases this item is a character string specifying the name of the wellstream, mixture, well or group that defines or supplies the injection stream.

4. A character string specifying the method used to control the rate at which fluid is injected.

This must be one of the following:

WAT Inject a target water volume rate set in item 6

GAS Inject a target gas volume rate set in item 7

BHP Maintain a target BHP set in item 8

THP Maintain a target THP set in item 9

RV Inject the fluid at a target reservoir volume rate set in item 10

WG Inject the fluid at a target wet gas volume rate set in item 11

RE Reinjection or voidage replacement control, at a fraction set in item 12

TM Inject the fluid at a target total molar rate set in item 20

CW Continuous water/gas injection

GR Specifies that the well is under group control.

The character string determines the constraint to be used as an initial target for injection; other constraints entered are interpreted as limits.

---

**Note:** To achieve multi-component injection, use STREAM for the injection fluid and CW for the control method. This requires WELLSTRE to specify the mole fractions of the hydrocarbon gas components. Water vapor and liquid enthalpies are calculated with the quality and temperature as specified in items 21 and 22. Hydrocarbon gas enthalpies are calculated with the temperature and pressure in items 22 and 23 (pressure defaults to the water vapor pressure if unspecified). Water and hydrocarbon gas volume rates are specified with the following items 6 and 7.

---

5. The target/limit oil volume rate.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC), stb/day (FIELD), scc/hr (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

6. The target/limit water volume rate.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC), stb/day (FIELD), scc/hr (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

7. The target/limit gas volume rate.

UNITS: sm<sup>3</sup>/day (METRIC), Mscf/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

8. The target/limit bottom hole pressure.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

9. The target/limit tubing head pressure.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

10. The target/limit reservoir volume rate.

UNITS: rm<sup>3</sup>/day (METRIC), rb/day (FIELD), rcc/hr (LAB), rm<sup>3</sup>/day (PVT-M)

11. The target/limit wet gas volume rate.

The wet gas volume injected is related to the moles injected using a unity Z-factor at standard conditions.

UNITS: sm<sup>3</sup>/day (METRIC), Mscf/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

12. The target/limit reinjection fraction or voidage replacement fraction.

If item 18 is set to S, item 12 is interpreted as a reinjection fraction. When this is a target, the well will attempt to inject the fluid specified in item 2 at a surface rate equal to the reinjection fraction multiplied by the water or available produced gas rate of the group or well named in item 14. The available gas rate of a group for reinjection is by default equal to the group's gas production rate plus the rate of any advanced gas associated with the group (keyword [GADVANCE](#)) minus its fuel rate (keyword [GRUPFUEL](#)) minus its sales target (keyword [GRUPSALE](#)); however, the ordering of this definition can be altered using keyword [WTAKEGAS](#). In the case of a reinjection fluid defined by a stream or mixture, the specified fraction of the available surface gas production rate is applied as a wet gas reinjection rate target.

If item 18 is set to R, item 12 is interpreted as a voidage replacement fraction. When this is a target, the well attempts to inject the fluid specified in item 2 at a reservoir volume rate equal to the voidage replacement fraction multiplied by the total reservoir volume production rate of the group or well named in item 14.

A make-up gas stream may be specified in item 17, which is mixed with the injection stream if the target gas injection rate exceeds the available gas rate.

DEFAULT: 1.0 if item 4 is RE 0.0 otherwise

13. The type of production used to define the rate under reinjection or voidage replacement control.

This is required for reinjection or voidage replacement control. It may be one of the following:

W Implies the reinjection or voidage replacement depends on the production of the **well** named in item 14.

G Implies the reinjection or voidage replacement depends on the production of the **group** named in item 14.

DEFAULT: W if item 2 is WV

DEFAULT: G if item 2 is GV

14. The name of the production well or group that controls the reinjection or voidage replacement rate.

This is required for reinjection or voidage replacement control. If item 13 is W it should be the name of a production well. If item 13 is G it should be the name of a group.

If this name is not specified, it defaults to the fluid composition source name (item 3) for injection fluids WV or GV in item 2.

15. Gas rate to be subtracted from the reinjection rate target.

This is only relevant when reinjecting a fraction of a named well's production. The well in item 1 then attempts to inject at a rate equal to the reinjection fraction multiplied by the production rate of the well in item 14, minus the rate in item 15.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC), Mscf/day (FIELD), scc/hr (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

16. The VFP table number for the well.

The injection well VFP table must be supplied with the keyword `VFPINJ`.

This is only required if a THP target or limit is set.

17. The mnemonic for a wellstream to be used as make-up gas

This is only required if make-up gas is to be used when the injected gas rate exceeds the advance and/or available produced gas from the source group or well.

18. The way in which reinjection or voidage replacement fraction in item 12 is to be interpreted.

S Reinject a fraction of **surface** volume production (that is, reinjection)

R Replace a fraction of **reservoir** volume production (that is, voidage replacement)

DEFAULT: S

19. The stage of the separator that defines the fluid composition for injection

The vapor from any stage of the separator may act as a source of injection fluid. The default value of 0 results in the use of the vapor from the whole separator as the injection fluid.

Note that the choice of separator stage also affects the available produced gas supply rate from the source group or well (item 3) if the source is GV or WV (item 2), and also that of the control group or well (item 14) for reinjection.

DEFAULT: 0

20. The target or limit total molar rate.

UNITS: kg-M/day (METRIC), lb-M/day (FIELD), gm-M/hr (LAB), kg-M/day (PVT-M)

21. The steam quality of the injected fluid.

(available only with the Thermal option).

If specified, the steam quality must be between 0 and 1. If specified, either the temperature or the pressure must also be specified, but not the specific enthalpy rate.

22. The temperature of the injected fluid.

(available only with the Thermal option or the Temperature option).

If specified, either the steam quality or the pressure must also be specified, but not the specific enthalpy rate.

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

**Note:** To maintain a constant injection well temperature with a specified pressure, the pressure should approximately match the well's current BHP. If the pressure is specified to be lower than the current BHP, for example, then the injection energy and hence the actual well temperature is lower than that required. If the completion block temperature is to be maintained at a constant value, then the specified pressure should be approximately that of the region around the well. In this case, the reported well temperature may be lower than the completion block temperature because the reported well temperature is calculated at the well's BHP.

23. The pressure of the injected fluid.

(available only with the Thermal option or the Temperature option).

If specified, then one of (steam quality, temperature, specific enthalpy rate) must also be specified.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

24. The specific enthalpy rate of the injected fluid.

(available only with the Thermal option).

If specified, the pressure must also be specified and neither the steam quality nor temperature may be specified.

UNITS: kJ/kg-M (METRIC), Btu/lb-M (FIELD), J/gm-M (LAB), kJ/kg-M (PVT-M)

## Notes

See notes [number 2](#), [number 3](#) and [number 4](#) in the [GRUPINJE](#) keyword documentation.

## Examples

### Example 1

Water is to be injected by the well at a bottom hole pressure of 4020 psia.

```
WELLINJE
WELLX Water ' ' Bhp 3* 4020 /
/
```

### Example 2

The hydrocarbon defined by wellstream MixC is to be injected at a wet gas rate of 100 Mscf per day:

```
WELLINJE
WZ-2 Stream MixC WG 6* 100 /
/
```

### Example 3

Well I injects all vapor from group G, minus sales gas of 1500 Mscf/day.

```
WELLINJE
I GVapour G Reinj 7* 1.0 GVapour G 1500 /
/
```

### Example 4

Wells I1 and I2 both inject under the control of group GR1. This group supplies the rate targets and the nature of the fluid to be injected:

```
WELSPECS
I1 GR1 ... /
/
WELLINJE
I1 2* GR /
I2 2* GR /
/
```

### Example 5

Well I is to inject the mixture SOLVENT, previously defined using a [WELLSTRE](#) keyword, at a rate of 150000 m<sup>3</sup>/day:

```
WELLINJE
I Stream SOLVENT Gas 2* 150000 /
/
```

## WELLKBHP Specify K-index of cell used to define BHP reference depth

This keyword is used to specify the K index in the grid of the completion cell used to define the BHP reference depth. It will overwrite the depth entered in keyword [WELSPECS](#) with the center depth of the grid block containing the first defined completion of the well in a specified layer. The well must first have a completion defined in the layer.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash, the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. The K index (layer number, counting from top) used to define the bottom hole pressure reference depth.

### Example

```
WELLKBHP
W24 4 /
/
```

This keyword specifies the production targets for a well.

The keyword is retained for back-compatibility; you are encouraged to use keyword [WCONPROD](#) instead, which is compatible with both simulators.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash, the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. A character string defining the method of controlling the well.

This must be one of the following:

OIL	Oil volume rate
WAT	Water volume rate
GAS	Gas volume rate
LIQ	Liquid volume rate
COM	Linearly combined volume rate (coefficients must be set with <a href="#">LINCOM</a> )
BHP	Bottom hole pressure control
THP	Tubing head pressure control
RV	Reservoir voidage rate
WG	Wet gas rate
TM	Total molar rate
ST	Steam rate (available only with the Thermal option)
SATP	Water saturation pressure control (available only with the Thermal option)
SATT	Water saturation temperature control (available only with the Thermal option)
GROUP	Specifies that the well is under group control

Only the first two characters are significant.

3. The target oil volume rate.  
UNITS: sm<sup>3</sup>/day (METRIC), stb/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)
4. The target water volume rate.  
UNITS: sm<sup>3</sup>/day (METRIC), stb/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)
5. The target gas volume rate.  
UNITS: sm<sup>3</sup>/day (METRIC), Mscf/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)
6. The target liquid (oil+water) volume rate.  
UNITS: sm<sup>3</sup>/day (METRIC), stb/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)
7. The target or limiting bottom hole pressure.  
UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)
8. The target tubing head pressure.  
UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)
9. The target or limit reservoir volume rate  
Volume rate is the reservoir volume of the fluids produced or injected when at the well reference pressure. The reference pressure is usually the average hydrocarbon pressure in the field. However, this may be set to the average pressure in a nominated fluid-in-place region using item 13 in [WEL SPECS](#).  
UNITS: rm<sup>3</sup>/day (METRIC), rb/day (FIELD), rcc/hr (LAB), rm<sup>3</sup>/day (PVT-M)
10. The target wet gas volume rate.  
The volume of wet gas is required. Given a number of moles, this can be obtained as  $V = nRT / P$ , where  $T$  and  $P$  are standard pressure and temperature,  $R$  is the gas constant,  $V$  is the volume rate and  $n$  is the molar rate. See "[Units](#)" in *ECLIPSE Technical Description* for further details.  
If group control is specified, the well target need not be specified.  
UNITS: sm<sup>3</sup>/day (METRIC), Mscf/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)
11. The VFP table index for this well.  
Only required if a THP target or limit is to be specified.
12. Artificial lift quantity, for use in THP calculations.  
See keyword [VFPPROD](#).  
UNITS: These depend on what the ALQ was meant to represent when the table was created. Refer to section "[Record 6:ALQ values](#)" in the description of keyword [VFPPROD](#).  
DEFAULT: 0.0
13. The target or limit total molar rate.  
UNITS: kg-M/day (METRIC), lb-M/day (FIELD), gm-M/hr (LAB), kg-M/day (PVT-M)
14. The target or limit steam rate, Cold Water Equivalent, (available only with the Thermal option).  
UNITS: sm<sup>3</sup>/day (METRIC), stb/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

15. The pressure offset  $\Delta P$  for saturation pressure control, (available only with the Thermal option). The bottom hole pressure is constrained by  $BHP \geq P_{sat} + \Delta P$  where  $P_{sat}$  is the maximum saturated water pressure in all the producing completion cells.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

16. The temperature offset  $\Delta T$  for saturation pressure control, (available only with the Thermal option). The bottom hole pressure is constrained by  $BHP \geq P_{sat}(T + \Delta T)$  where  $T$  is the maximum temperature in all the producing completion cells.

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

17. The target/limit linearly combined rate

UNITS: determined by keyword [LCUNIT](#)

## Examples

### Example 1

The well is set to a target oil volume rate of 1000 stb/day, with a bottom hole pressure limit of 4511 psia.

```
WELLPROD
P Oil 1000.0 3* 4511.0 /
/
```

### Example 2

The well is placed under group control, but with a minimum bottom hole pressure limit of 400 psia.

```
WELLPROD
P GR 4* 400 /
/
```

	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword requests a Sand Management Advisor (SMA) calculation of all connection critical drawdowns, and that appropriate action be taken if the completion drawdown exceeds a percentage of this critical drawdown. This keyword with its calculation is not available commercially.

A license for Schlumberger staff to run WELLSMA can be obtained by contacting ECLIPSE support.

## WELLSPEC Introduces a new well

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword introduces a new well, specifying the name and position of the well head, the BHP reference depth and the separator used.

The keyword is retained for back-compatibility; you are encouraged to use keyword [WELLSPECS](#) instead, which is compatible with both simulators.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash, the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. The name of the well.

A character string of up to 8 letters. This must be specified and non-blank.

2. The name of the group to which the well belongs.

DEFAULT: FIELD

3. The I-index of the header.

4. The J-index of the header

5. The bottom hole pressure reference depth.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

If this quantity is defaulted, the reference depth is set equal to the center depth of the grid block containing the topmost connection in the well

6. The name of the separator to which the well is connected.

A separator need only be nominated in the compositional case for production wells. The separator nominated must have been previously defined using the [SEPCOND](#) keyword.

---

**Note:** If a separator is not specified here or with [WSEPCOND](#), and the well can trace its parentage to a group which has a default separator specified (see [SEPCOND](#)), then this will be used. If this is not the case, the separator conditions specified with [FIELDSEP](#) are used. If [FIELDSEP](#) is not entered, a single flash to standard conditions is used.

---

7. Fluids-in-place number to obtain reservoir conditions used in calculating a well's voidage rate. This is only required if the crossflow well model is being used.

If 0 is entered, the average hydrocarbon conditions in the field are used.

If a negative value is entered, the region number is set equal to the fluids-in place region number of the lowest grid block in which the well is completed.

If a positive value is entered, this is interpreted as the required fluids-in-place region number. A warning message is printed if the well is not completed in a grid block within that region.

DEFAULT: 0

## Example

Well P, in group G, is located in cell I=2,J=2, with a BHP reference depth of 8345 ft, and feeds separator SepA1.

```
WELLSPEC  
P G 2 2 8345 SepA1 /  
/
```

## WELLSTRE Set composition of injection stream

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

When, in a compositional or thermal run, oil or gas is injected via a stream, this keyword may be used to specify the composition of the injected stream.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash, the remaining items taking default values of 0.0. Defaults can also be specified by a null repeat count of the form  $n^*$ , where  $n$  is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. The name of the well stream.

The maximum number of wellstreams allowed is governed by item 6 of keyword [WELLDIMS](#).

2.  $x_1$ , the mole fraction of the first component. User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

3.  $x_2$ , the mole fraction of the second component. User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

...

...

...

- $N_c + 1$   $x_{N_c}$ , the mole fraction of the  $N_c$ <sup>th</sup> component. User defined arguments can be set with keywords [UDQ](#) and [UDADIMS](#).

$N_c$  mole fractions should be specified, where  $N_c$  is the number of components in the run. The values are checked using the condition that the sum of the mole fractions must be 1.0.

Once the gas wellstream is defined, it may be used in the [WINJGAS](#) or [GINJGAS](#) keyword, for example, to specify an injected composition, or used to define a make-up gas.

Once an oil wellstream is defined, it may be used in the [WINJOIL](#) keyword, for example, to specify an injected composition.

### Example

```
WELLSTRE
'MixB' 0.5 0.3 0.1 0.05 0.05 /
/
```

## WELLSTRW Set composition of injection water stream

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword may be used to specify the composition of an injected water stream when using the multi-component water model, or when using any of the [CO2STORE](#), [GASWAT](#) or [GASSOL](#) options.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash, the remaining items taking default values of 0.0. Defaults can also be specified by a null repeat count of the form  $n^*$ , where  $n$  is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. The name of the well stream.

The maximum number of wellstreams allowed is governed by item 6 of keyword [WELLDIMS](#).

2.  $x_1$ , the mole fraction of the first component.
3.  $x_2$ , the mole fraction of the second component.

...

...

...

$N_w + 1$   $x_{N_w}$ , the mole fraction of the  $N_w^{\text{th}}$  component.

$N_w$  mole fractions should be specified, where  $N_w$  is the number of components in the run.

---

**Note:** If [GASSOL](#) is present, NCMPHW components and water are present in the aqueous phase; hence  $N_w$  is the number of components in the aqueous phase NCMPHW followed by the water fraction. If [CO2STORE](#) or [GASWAT](#) is present  $N_w$  is the number of allowed components in the [CO2STORE](#) or [GASWAT](#) run.

---

The values are checked using the condition that the sum of the mole fractions must be 1.0.

Once the wellstream is defined, it may be used in the [WINJW](#) keyword to specify an injected composition.

See "[Water components](#)" in the *ECLIPSE Technical Description* for further details of the water component option.

### Example

```

WELLSTRW
  Fresh 1.0 0.0/
  Brine 0.0 1.0/
/

```

## WELLTARG **Change well target or limit**

WELLTARG is an alias for [WELTARG](#).

x	<b>ECLIPSE 300</b>
x	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The data consists of tables of well names and the temperature cutback table number to be used for that well.

Each table is terminated by a slash (/).

Each table consists of 2 columns of data.

Column:

1. The well name.

This well name should already have been specified.

2. The corresponding cutback table number.

A table number of zero means that no cutback is performed for this well.

The table number supplied should be less than or equal to the number of well cutback tables in the run, specified with the [TCBDIMS](#) keyword in the RUNSPEC section.

DEFAULT: 0

This keyword can be repeated at a later timestep to assign different tables to each well.

See also the keywords [WELLTCBT](#) and [WELLTCBC](#).

### Example

```

-- well P1 uses TCB table 2
-- well P2 uses TCB table 1
WELLTCB
  P1 2 /
  P2 1 /
/

```

## WELLTCBC Well temperature cutback critical temperature

	<b>ECLIPSE 100</b>
x	<b>ECLIPSE 300</b>
x	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword defines a temperature that is used as a threshold temperature by the [WELLTCB](#) keyword. The current value of the well temperature cutback will remain unchanged until the well temperature goes beyond the limit given in [WELLTCBT](#) by more than this threshold value.

The purpose of this keyword is to try to prevent repeated changes in the well cutback value. These can arise if the well temperature is on the borderline between two cutback values.

Argument:

1. The well name.

This well name should already have been specified.

2. The critical or threshold temperature.

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

### Example

```
WELLTCBC
P1 5 /
```

## WELLTCBT Well temperature cutback table

	<b>ECLIPSE 100</b>
x	<b>ECLIPSE 300</b>
x	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The data consists of tables of temperature cutback factors.

Each table is terminated by a slash (/).

Each table consists of 2 columns of data.

Column:

1. The temperature.

Values should be greater than 0 and should increase monotonically down the column.

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

2. The corresponding cutback factor.

Values should be between 0 and 1 and should decrease down the column. The first value in the column should be 1.

The number of tables supplied should be equal to the number of well cutback tables in the run, specified with the [TCBDIMS](#) keyword in the RUNSPEC section or defaulted to 1.

The number of rows should be less than or equal to the maximum number of rows of data specified with TCBDIMS.

The cutback factor is used to multiply the maximum or target oil rate, gas rate, water rate, liquid rate, voidage rate, and hydrocarbon rate for each well specified in the [WELLTCB](#) keyword.

The cutback factor to be used for the next timestep is not interpolated between the values specified in the tables. The cutback factor specified at a particular temperature is applied until the next highest temperature is reached. In the example below, for the first table, a factor of 1 (that is no cutback) applies for all temperatures up to 140, then a factor of 0.95 applies between 140 and 210, then a factor of 0.85 from 210 to 500, then a factor of 0.4 for any temperature above 500.

---

**Note:** These tables are not stored in the Restart files. However, a well that is linked to a table in the base run (using [WELLTCB](#)) is still linked to the table in the restart run. Therefore, the tables should be redefined in the restart run.

---

### Example

```

-- 2TCB tables
WELLTCBT
126 1
140 .95
210 .85
500 .4
/
135 1
300 .6
600 .3
/

```

## WELLWAG Specifies WAG well injection targets

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies a WAG (water and gas) injection mode for a well. A [WCONINJE](#) keyword must previously have been entered to define the injection fluids, the required targets and limits for example. The initial injection mode may be set to water or gas; it is overruled by the WELLWAG mode.

Note that if the injection rates are re-specified with another [WCONINJE](#) keyword, the WELLWAG data must be entered again (otherwise the well returns to normal single phase injection). This need not be done if [WELTARG](#) is used to change the rates.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash, the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. A character string specifying the type of WAG cycle.

Must be one of:

T Time

M Months

Y Years

DEFAULT: T

3. The first fluid to be injected in the WAG sequence.

This may be W or G.

4. The injection period for the fluid identified in item 3.

5. This item identifies the second fluid to be injected.

At present only water and gas cycling is supported, and this defaults to G if item 3 is W, and to W if item 3 is G.

6. The injection period for the fluid identified in item 5.

7. Injection well VFP table number for the first fluid to be injected.

(See keyword [VFPINJ](#))

Set this to zero if no THP calculations are required and the limiting THP value has been defaulted.

DEFAULT: Value previously set for this well.

8. Injection well VFP table number for the second fluid to be injected.

(See keyword `VFPINJ`.)

Set this to zero if no THP calculations are required and the limiting THP value has been defaulted.

DEFAULT: Value previously set for this well.

9. Control mode for first fluid to be injected.

RATE Control by surface flow rate target (item 5 of keyword `WCONINJE` or keyword `WELTARG`)

BHP Control by BHP target

THP Control by THP target

DEFAULT: RATE

10. Control mode for second fluid to be injected.

RATE Control by surface flow rate target (item 5 of keyword `WCONINJE` or keyword `WELTARG`)

BHP Control by BHP target

THP Control by THP target

DEFAULT: RATE

11. BHP target or upper limit for first fluid to be injected

UNITS: barsa (`METRIC`), psia (`FIELD`), atma (`LAB`), atma (`PVT-M`)

DEFAULT: Value previously set by keyword `WCONINJE` or keyword `WELTARG`

12. BHP target or upper limit for second fluid to be injected

UNITS: barsa (`METRIC`), psia (`FIELD`), atma (`LAB`), atma (`PVT-M`)

DEFAULT: Value previously set by keyword `WCONINJE` or keyword `WELTARG`

13. THP target or upper limit for first fluid to be injected

UNITS: barsa (`METRIC`), psia (`FIELD`), atma (`LAB`), atma (`PVT-M`)

DEFAULT: Value previously set by keyword `WCONINJE` or keyword `WELTARG`

14. THP target or upper limit for second fluid to be injected

UNITS: barsa (`METRIC`), psia (`FIELD`), atma (`LAB`), atma (`PVT-M`)

DEFAULT: Value previously set by keyword `WCONINJE` or keyword `WELTARG`

## Examples

### Example 1

Inject gas with composition defined by wellstream `Stream` at a rate of 30000 Mscf/day, and water at a rate of 45000 stb/day, with a bottom hole pressure limit of 4500 psia, alternating with a 91.25 day period, starting with water injection.

```

## WELMOVEL Moves a well into an LGR at a restart

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

WELMOVEL allows a well which was specified in the global grid to be moved into a local grid. This keyword is intended for situations where you wish to add a local grid around a preexisting well at a restart. (that is, the well existed in the global grid in the initial base run but is to be placed in a new local grid at the restart). If this keyword is used then all the previously specified connection data for the well are deleted. The connection data for these wells must then be re-specified using the keyword [COMPDATL](#). All the well properties such as group membership, rates and cumulative totals are however preserved.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The records may be terminated early with a slash (/); the remaining items assume their default values.

The set of records must end with a blank record, containing only a slash (/).

1. Well name (Up to 8 characters)
2. Name of the local refined grid in which the well is located  
If the well is completed in an amalgamation of local grids (see keyword [AMALGAM](#)), the name of any local grid in the amalgamation may be used here.
3. I - location of well head, in the coordinate system of the local grid
4. J - location of well head, in the coordinate system of the local grid

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

---

**Note:** The cumulative totals for wells is not the same as the sum of the cumulative totals for all the connections after this keyword is used, as the well totals contain the cumulative totals for the connections that were deleted by the use of this keyword.

---

---

**Note:** This keyword was intended to provide additional functionality for the Near Wellbore Modeling tool and should only be used with caution when the data set has not been generated by this product. The keyword should be placed before the first occurrence of any [COMPDAT](#) or [COMPDATL](#) keywords in the SCHEDULE section of a restart run.

---

### Example

```

WELMOVEL
PROD1  LGR1  6 8 /
PROD2  LGR2  5 9 /
/

```

## WELOPEN Shuts or reopens wells or well connections

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to shut or reopen wells or well connections, without having to specify the rest of the well control data or connection data. To shut or reopen a well, leave items 3 - 7 defaulted. To shut or reopen individual well connections, enter their I,J,K location in items 3 - 5, or enter their completion number in items 6 and 7. Completion numbers are set in keyword [COMPLUMP](#).

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The records may be terminated after item 1 or item 2. The remaining items assume their default values.

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Open/shut flag for the well or connections

OPEN Well or connections open to flow

SHUT Well or connections completely isolated from formation

STOP Well stopped off above formation. (If the record applies to a connection, it has the same effect as SHUT.)

*ECLIPSE 100 only*

AUTO Well or connections initially SHUT but open automatically. (See keyword [WCONPROD](#) item 2 for an explanation of AUTO applying to wells, and keyword [COMPDAT](#) item 6 for connections).

POPEN The well opens only if it is "priority-closed", that is temporarily closed under Prioritization control (see "[Prioritization - an alternative to guide rate control](#)" in the *ECLIPSE Technical Description*). The well remains closed if it has been closed for any other reason. This may be useful when changing the group control method from Prioritization to Guide Rate control.

DEFAULT: OPEN

3. I - location of connecting grid block(s)

DEFAULT: Negative

4. J - location of connecting grid block(s)

DEFAULT: Negative

5. K - location of connecting grid block(s)

DEFAULT: Negative

6. Number of first completion in range

DEFAULT: Negative

7. Number of last completion in range

DEFAULT: Negative

If items 3 - 7 are all defaulted, the Open/Shut/Stop command applies to the well, leaving the connections unchanged. An attempt to open a well with no connections open results in an error condition.

If any of items 3 - 7 are set zero or positive, the command applies to the eligible connections of the well, leaving the status of the well itself unchanged. The eligible connections are those with I,J,K locations matching the specified location indices in items 3 - 5 and a completion number in the range specified by items 6 - 7. A zero or negative value for a location index (I, J or K) matches any value of that location index. Similarly a zero or negative value for a completion range lower/upper end point indicates that there is no lower/upper bound on the completion numbers.

To open a well **and** one or more of its connections requires two records, one to operate on the well and the other to operate on the connections.

End the data record with a slash (/).

End the set of records with a blank record containing just a slash.

---

**Note:** If this keyword is used to shut a well during a history matching simulation, the actual production or injection rates are set to zero from this point in time, but all historical well rates remain unaltered. If the well was actually shut at this point in time, then the [WCONHIST](#) or [WCONINJH](#) keywords should be used to shut the well and thus zero the historical well rates.

---

## Example

```

WELOPEN
' * '          / opens all shut or stopped wells in the field
PROD3  SHUT / shuts well PROD3, if it is open
' * '          OPEN 0 0 3 / opens all well connections in layer 3
PROD4  OPEN 0 0 0 / opens all connections of well PROD4
PROD5  SHUT 0 0 4 / shuts connection(s) to layer 4 in well PROD5
PROD6  SHUT 0 0 0 4 6/ shuts connection in completions 4, 5 and 6 in PROD6
/

```

## WELOPENL Shuts or reopens wells or well connections within local grids

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to shut or reopen wells or well connections in local grids, without having to specify the rest of the well control data or connection data. The connections must first have been defined with the keyword [COMPDATL](#). WELOPENL performs the same role as [WELOPEN](#) does, but the name of the local grid containing the connections specified in the record should be entered in item 2 of WELOPENL.

To shut or reopen a well, leave items 4- 8 defaulted. Well connections can be shut or reopened either according to their I,J,K location (items 4 - 6) or according to their completion number (items 7 and 8). Completion numbers are set in keyword [COMPLMPL](#).

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The records may be terminated after item 1 or item 2. The remaining items will assume their default values.

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template.

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Name of local grid containing the connections to be opened or closed

If this item is defaulted or set to a blank string, the local grid name will be set to the well's local grid named in keyword [WELSPECL](#). (In ECLIPSE 100, the local grid name should not be defaulted if the local grid is amalgamated, unless items 4-8 have been defaulted.)

The local grid name may also be defaulted if the connection locations in items 4, 5 and 6 are all defaulted, as the action in item 3 then applies to the well itself (or to specific completions within it if items 7 and 8 are set, and ECLIPSE 100 already knows which local grid they belong to).

*ECLIPSE 100*

If items 4 - 8 are all defaulted but a local grid name is specified here, the action in item 3 will be performed on any wells named in item 1 that have connections in the named local grid (or any other local grids amalgamated with it).

DEFAULT: ''

3. Open/shut flag for the well or connections

OPEN Well or connections open to flow

SHUT Well or connections completely isolated from formation

STOP Well stopped off above formation, allowing crossflow through the well bore if two or more connections are open (If the record applies to a connection, it has the same effect as SHUT).

*ECLIPSE 100 only*

AUTO Well or connections initially SHUT but open automatically. (See keyword [WCONPROD](#) item 2 for an explanation of AUTO applying to wells, and keyword [COMPDAT](#) item 6 for connections).

POPN The well opens only if it is "priority-closed", that is temporarily closed under Prioritization control (see "[Prioritization - an alternative to guide rate control](#)" in the *ECLIPSE Technical*

*Description*). The well remains closed if it has been closed for any other reason. This may be useful when changing the group control method from Prioritization to Guide Rate control.

DEFAULT: OPEN

4. I - location of connecting grid block(s)

DEFAULT: Negative

5. J - location of connecting grid block(s)

DEFAULT: Negative

6. K - location of connecting grid block(s)

DEFAULT: Negative

7. Number of first completion in range

DEFAULT: Negative

8. Number of last completion in range

DEFAULT: Negative

If items 4 - 8 are all defaulted, the Open/Shut/Stop command applies to the well, leaving the connections unchanged. An attempt to open a well with no connections open will result in an error condition.

If any of items 4 - 8 are set zero or positive, the command applies to the eligible connections of the well, leaving the status of the well itself unchanged. The eligible connections are those with I,J,K locations matching the specified location indices in items 4 - 6 and a completion number in the range specified by items 7 - 8. A zero or negative value for a location index (I, J or K) matches any value of that location index. Similarly a zero or negative value for a completion range lower/upper end-point indicates that there is no lower/upper bound on the completion numbers.

To open a well **and** one or more of its connections requires two records, one to operate on the well and the other to operate on the connections.

End the data record with a slash (/).

End the set of records with a blank record containing just a slash.

ECLIPSE 100

**Note:** The local grid name in item 2 is required only when the keyword has to operate on connections within amalgamated local grids. In all other cases it can be defaulted. But if it is specified in these other cases, it restricts the keyword's operation to wells having connections in the named local grid (or any other local grid amalgamated with it). Whenever item 2 is defaulted, keyword **WELOPEN** may be used instead of **WELOPENL** with the same effect.

## Example

```
WELOPENL
-- Open all shut or stopped wells whose names begin with P in the field
'P*' /
-- Shut well PROD3, if it is open
PROD3 1* SHUT /
-- Shut all wells having connections in local grid CARF1
-- (and any other local grids amalgamated with it)
'*' CARF1 SHUT /
-- Open all well connections in layer 3 of local grid CARF2
'*' CARF2 OPEN 0 0 3 /
```

```
-- Open all connections in local grid CARF3 for well PROD4
PROD4 CARF3 OPEN 0 0 0 /
-- Shut all connections in local grid CARF4 for well PROD4
PROD4 CARF4 SHUT 0 0 0 /
-- Shut connections in layer 4 of local grid CARF2 for well PROD5
PROD5 CARF2 SHUT 0 0 4 /
-- Shut connection in completions 4, 5 and 6 in well PROD6
PROD6 1* SHUT 0 0 0 4 6/
/
```

## WELPI

## Sets well productivity/injectivity index values

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to set the productivity/injectivity index (PI) value of one or more wells to a specified value. The well connection properties must be defined in the usual manner, with keyword [COMPDAT](#), but the connection transmissibility factors are adjusted proportionately so that the calculated PI of the well equals the specified value. The PI is calculated using the phase and drainage radius defined in items 6 and 7 of keyword [WELSPECS](#). The definition of the PI and its relationship to the well's connection transmissibility factors is discussed in "[The productivity index](#)" in the *ECLIPSE Technical Description*. Note that the calculation is not suitable for application to horizontal wells.

The adjustment of the connection factors is performed at the time the [WELPI](#) keyword is entered, using the current grid block solution. If the fluid mobilities in the grid blocks subsequently change, the well's actual PI also changes.

The P.I. value should not be set for gas wells which have a D-factor or use a special inflow equation (item 8 in [WELSPECS](#)). In these circumstances the gas phase P.I. vary with the well's BHP.

## ECLIPSE 300

Under some circumstances the P. set for a newly opened gas injector are not exact due to the composition of the injected gas not being accurately known during the calculation.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Steady-state productivity/injectivity index value of the well(s)

UNITS:  $\text{sm}^3/\text{day}/\text{bars}$  (METRIC),  $\text{stb}/\text{day}/\text{psi}$  or  $\text{Mscf}/\text{day}/\text{psi}$  (FIELD),  $\text{scc}/\text{hr}/\text{atm}$  (LAB),  $\text{sm}^3/\text{day}/\text{atm}$  (PVT-M)

This item must be supplied and cannot be defaulted.

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

---

**Note:** When the [WELPI](#) keyword is read, the connections that are currently defined for the well will have their connection factors scaled to give the well the specified PI at the current grid block conditions. If at a later time new connections are introduced, the connection factors are not scaled again unless [WELPI](#) is reentered, and so the PI of the well changes. Moreover, if an existing connection is later re-specified with [COMPDAT](#), its connection factor is reset from the [COMPDAT](#) data, overwriting its earlier scaled value. Consequently, care should be taken when changing the connection data after entering [WELPI](#).

---

**CAUTION:** Keywords [WELPI](#) and [WPIMULT](#) should not both be used on the same well at the same time, unless there is an intervening [TIME](#), [TSTEP](#) or [DATES](#) keyword.

---

## Example

```
WELPI  
PROD1 10.2 /  
PROD2 14.3 /  
/
```

# WELPRI

## Sets well priority numbers

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to set the priority numbers for one or more production wells. The priority numbers set here will override the values calculated using the priority equation (see keyword [PRIORITY](#)). If the keyword is not used, the priority numbers for all wells will be calculated from the priority equation.

The keyword [PRIORITY](#) must be used before using this keyword.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. First priority number for the well(s)

If the priority number is greater than zero, this number overrides the value calculated from the first priority equation.

If the number is negative, the well priority number is calculated from the first priority equation.

The number must not be zero.

DEFAULT: Negative

Priority numbers do not have any units.

ECLIPSE 300

---

**Note:** Currently, ECLIPSE 300 has a single priority equation, and well priorities cannot be scaled.

---

ECLIPSE 100 only

3. First priority scaling factor.

The well's first priority number (either set in item 2 or calculated from the first priority equation) is multiplied by the number specified here.

DEFAULT: 1.0

ECLIPSE 100 only

4. Second priority number for the well(s)

If the priority number is greater than zero, this number overrides the value calculated from the second priority equation.

If the number is negative, the well's second priority number is calculated from the second priority equation.

The number must not be zero.

This item must be defaulted if a second priority equation has not been defined.

DEFAULT: Negative

Priority numbers do not have any units.

ECLIPSE 100 only

5. Second priority scaling factor.

The well's second priority number (either set in item 4 or calculated from the second priority equation) is multiplied by the number specified here.

DEFAULT: 1.0

This item must be defaulted if a second priority equation has not been defined.

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

## Example

```
WELPRI
'PROD*' -1.0 /
PROD4 1* 2.0 1* 2.0 / (ECLIPSE 100 only)
PROD5 100 1* 100 / (ECLIPSE 100 only)
/
```

## WELSEGS

## Defines the segment structure of a multisegment well

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used to designate a well to be a multisegment well, and to define the segment structure of the well. The well must previously have been introduced with the [WELSPECS](#) keyword (or [WELSPECL](#) if the well is situated in a local grid refinement).

The keyword can only be used on one well at a time, so it must be specified more than once if there is more than one multisegment well.

The WELSEGS keyword may be re-entered for a particular well later in the run, if you wish to change its segment structure (for example to add a new branch). Only the new or modified segments need to be entered; the properties of all the other segments are retained. But if the segment structure is changed, you should then reenter the [COMPSEGS](#) (or [COMPSEGL](#)) data to reallocate the grid block connections to the new segments.

Multisegment wells are described in detail in "[Multisegment wells](#)" in the *ECLIPSE Technical Description*.

The keyword is followed by a number of data records to describe the segment properties and geometry of the (possibly multibranch) well. Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing just a slash.

The data items in each record are:

### Record 1

The first record identifies the well, sets some general flags, and sets the properties of its top segment, the one nearest the wellhead. This segment is labeled segment number 1.

1. Name of the well
2. Depth of the nodal point of the top segment

ECLIPSE takes this value to be the BHP reference depth of the well. BHP reference depth data entered elsewhere are ignored for multisegment wells.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

This item must be entered the first time each multisegment well is defined in WELSEGS. On subsequent entries of WELSEGS it may be defaulted to keep its original value. The depth should not normally be changed during the simulation.

3. Length down the tubing to the nodal point of the top segment

This item fixes the position of the top segment's node (the BHP reference point) relative to the 'zero tubing length reference point', from which all the tubing length values are measured. There are no pressure losses calculated across this segment, as the multisegment well model does not calculate pressure losses above the nodal point of the top segment. (Pressure losses between the BHP reference depth and the tubing head should normally be handled by VFP tables in the usual way.)

A zero value entered here implies that tubing lengths are measured from the BHP reference point in the top segment.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: 0.0 (the first time a multisegment well is declared), no change (on any subsequent entries).

## 4. Effective wellbore volume of the top segment

This quantity is used to calculate wellbore storage effects in the top segment.

UNITS: m<sup>3</sup> (METRIC), ft<sup>3</sup> (FIELD), cc (LAB), m<sup>3</sup> (PVT-M)

DEFAULT: 1.0E-5, giving negligible storage effects (the first time a multisegment well is declared), no change (on any subsequent entries).

## 5. Type of tubing length and depth information entered in the subsequent records of this keyword

INC The length and depth values entered in items 5 and 6 of the subsequent records refer to the incremental changes of these quantities along each segment.

ABS The length and depth values entered in items 5 and 6 of the subsequent records refer to the absolute values of the tubing length and depth at the segment nodes.

DEFAULT: There is no default; this item **must** be set.

## 6. Components of the pressure drop to be included in the calculation for each of the well's segments:

HFA Hydrostatic + friction + acceleration

HF- Hydrostatic + friction

H- Hydrostatic only. This item must be contained within quotes.

For segments whose friction+hydrostatic pressure drops are obtained from a VFP table (item 5 in keyword [WSEGTABL](#) set to FH), the total pressure drop is treated as friction; the hydrostatic component is not separated out. If HFA is selected here, the acceleration pressure drop is calculated separately using a homogeneous flow model and added to the pressure drop interpolated from the VFP table. In this case, ideally the VFP table should not contain the acceleration pressure loss, as it is then accounted twice; but this component of the pressure loss is generally very small. (See "[Pressure drop components](#)" in the *ECLIPSE Technical Description*.) If this well contains flow control devices specified with keywords [WSEGAICD](#), [WSEGSICD](#), [WSEGLABY](#) or [WSEGVALV](#), or looped flow paths specified with keyword [WSEGLINK](#), then this item must be set so that friction is included.

DEFAULT: HFA

## 7. Default Multiphase flow model for the well's segments

HO Homogeneous flow; the phases all flow with the same velocity.

DF A Drift Flux Model, which allows for slip between the phases. The slip is a combination of profile slip (a velocity ratio) and local slip (a relative vertical velocity). At low flow rates the local slip can cause countercurrent flow, where the heavy and light phases flow in opposite directions. (See "[The drift flux slip model](#)" in the *ECLIPSE Technical Description*.)

The first time each segment is defined with [WELSEGS](#), its multiphase flow model is set according to the above choice. The keyword [WSEGFMOD](#) may subsequently be used to change the flow model for specific segments or reset the model's parameters for specific segments.

If [WELSEGS](#) is entered again for the same well, this item does **not** affect the flow model for segments that have been defined in an earlier entry. The exception to this is when HO is entered; any segments that use the drift flux model change to homogeneous flow.

---

**Note:** DF must be selected here if **any** of the well's segments are to use the Drift Flux Model. The top segment (segment 1) always uses the Homogeneous Flow Model; there are no pressure losses calculated along this segment.

---

Individual segments may also be designated to have their pressure drops determined from VFP tables instead of a built-in Flow Model (see keyword [WSEGTABL](#)).

DEFAULT: HO

8. X coordinate of the nodal point of the top segment, relative to the origin of the grid

The X and Y coordinates of the segment nodes are stored on the restart or graphics files to enable graphics applications to produce plots of the well trajectory. The data is not used for any other purpose and may be left defaulted if trajectory plots are not required.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: 0.0 (the first time a multisegment well is declared), no change (on any subsequent entries).

9. Y coordinate of the nodal point of the top segment, relative to the origin of the grid

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: 0.0 (the first time a multisegment well is declared), no change (on any subsequent entries).

- Thermal Option only* 10. Cross-sectional area of the pipe wall used in thermal conductivity calculation

(see note 3).

UNITS: m<sup>2</sup> (METRIC), ft<sup>2</sup> (FIELD), cm<sup>2</sup> (LAB), m<sup>2</sup> (PVT-M)

DEFAULT: 0.0

- Thermal Option only* 11. Volumetric heat capacity of the pipe wall.

UNITS: kJ/m<sup>3</sup>/K (METRIC), Btu/ft<sup>3</sup>/°R (FIELD), J/cc/K (LAB), kJ/m<sup>3</sup>/K (PVT-M)

DEFAULT: 0.0

- Thermal Option only* 12. Thermal conductivity of the pipe wall.

UNITS: kJ/m/day/K (METRIC), Btu/ft/day/°R (FIELD), J/cm/hr/K (LAB), kJ/m/day/K (PVT-M)

DEFAULT: 0.0

End the data record with a slash (/).

## Each subsequent record

The subsequent records define the properties of all the well's segments except for the top segment. The segments must be numbered between 2 and NSEGMX (entered in the RUNSPEC section keyword [WSEGDIMS](#)). Segments may be entered in any order, and neighboring segments need not be numbered consecutively; ECLIPSE reorders them internally. A contiguous set of segments having the same properties can be entered together in a single record as a range. The segments within a range must have consecutively increasing numbers.

1. Segment number at the start of the range (nearest the top segment)

- An integer between 2 and NSEGMX.
2. Segment number at the far end of the range  
An integer between 2 and NSEGMX, not less than item 1.  
The remaining items in this record set the properties of the segments in this range. To enter properties for a single segment, set items 1 and 2 equal.
  3. The branch number  
An integer between 1 and NLBRMX (set in the RUNSPEC section in keyword [WSEGDIMS](#)).  
Segments situated on the main stem must have a branch number of 1. Lateral branches should be numbered between 2 and NLBRMX. Lateral branches may also have subordinate branches; in this case each branch must have a higher branch number than its parent branch.
  4. Number of the segment to which the segment at the start of the range (item 1) is joined, that is its neighbor in the direction of the wellhead. This is its **outlet segment**; the convention being that production flows are positive.  
A node that is a branch point in a multilateral well can be the outlet segment of two or more segments on different branches.
  5. If item 5 of Record 1 is INC:  
The length of each segment in the range, that is the distance between its nodal point and that of its neighbor in the direction of the wellhead.  
Or, if item 5 of Record 1 is ABS:  
The length down the tubing (from the zero tubing length reference point) at the nodal point of the **last** segment in the range. ECLIPSE divides the length between this point and the node of the range's outlet segment (item 4) into n equal lengths, where n is the number of segments in this range.  
UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)
  6. If item 5 of Record 1 is INC:  
Depth change along each segment in the range, that is the depth of its nodal point minus the depth of its outlet segment's nodal point.  
Or, if item 5 of Record 1 is ABS:  
The depth of the nodal point of the **last** segment in the range. ECLIPSE calculates the depths of any other segments in this range by interpolating between this depth and the depth of the range's outlet segment (item 4), linearly according to their length down the tubing.  
UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)
  7. Tubing internal diameter (or the equivalent diameter for annular cross-sections)  
UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)
  8. The effective absolute roughness of the tubing.  
This quantity is used to calculate the Fanning friction factor.  
UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)
  9. Cross-sectional area for fluid flow

UNITS: m<sup>2</sup> (METRIC), ft<sup>2</sup> (FIELD), cm<sup>2</sup> (LAB), m<sup>2</sup> (PVT-M)

DEFAULT:  $\pi(D^2/4)$

10. Volume of the segment

UNITS: m<sup>3</sup> (METRIC), ft<sup>3</sup> (FIELD), cc (LAB), m<sup>3</sup> (PVT-M)

DEFAULT:  $A \cdot L$

11. If item 5 of Record 1 is INC:

The length of each segment in the range projected onto the X-axis, that is the X coordinate of its nodal point minus that of its neighbor in the direction of the wellhead.

Or, if item 5 of Record 1 is ABS:

X coordinate of the nodal point of the **last** segment in the range, relative to the origin of the grid. ECLIPSE calculates the X coordinates of any other segments in this range by interpolating between this value and the X coordinate of the range's outlet segment (item 4), linearly according to their length down the tubing.

The X and Y coordinates of the segment nodes are stored on the restart or graphics files to enable graphics applications to produce plots of the well trajectory. The data is not used for any other purpose and may be left defaulted if trajectory plots are not required.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: 0.0

12. If item 5 of Record 1 is INC:

The length of each segment in the range projected onto the Y-axis, that is the Y coordinate of its nodal point minus that of its neighbor in the direction of the wellhead.

Or, If item 5 of Record 1 is ABS:

Y coordinate of the nodal point of the **last** segment in the range, relative to the origin of the grid. ECLIPSE calculates the Y coordinates of any other segments in this range by interpolating between this value and the Y coordinate of the range's outlet segment (item 4), linearly according to their length down the tubing.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: 0.0

13. Cross-sectional area of the pipe wall used in thermal conductivity calculation (see note 3). For tubing with circular cross-sections the area can be calculated using the formula  $A = \pi \cdot (r_o^2 - r_i^2)$  where  $r_o$  is the outer radius of and  $r_i$  is the inner radius. (ECLIPSE 300 thermal option only.)

UNITS: m<sup>2</sup> (METRIC), ft<sup>2</sup> (FIELD), cm<sup>2</sup> (LAB), m<sup>2</sup> (PVT-M)

DEFAULT: item 10 of Record 1

14. Volumetric heat capacity of the pipe wall (ECLIPSE 300 thermal option only).

UNITS: kJ/m<sup>3</sup>/K (METRIC), Btu/ft<sup>3</sup>/°R (FIELD), J/cc/K (LAB), kJ/m<sup>3</sup>/K (PVT-M)

DEFAULT: item 11 of Record 1

15. Thermal conductivity of the pipe wall (ECLIPSE 300 thermal option only).

UNITS: kJ/m/day/K (METRIC), Btu/ft/day/°R (FIELD), J/cm/hr/K (LAB), kJ/m/day/K (PVT-M)

DEFAULT: item 12 of Record 1

End the data record with a slash (/).

End the set of data records with a slash.

## Notes

1. Multisegment well data can be complicated to enter. It is advisable to check your data by examining the output in the Print file.

ECLIPSE 100

The output is generated by entering the argument WELSPECS in the RPTSCHEM keyword.

ECLIPSE 300

The output is generated by RPTPRINT keyword switches 6 and 7. This allows WELL and COMPLETION reports to be written which in turn prints out new segment and new completion data in addition to a multisegment well report.

2. Multisegment wells must use the average density calculation for the hydrostatic head (item 12 of keyword WELSPECS is automatically be set to AVG).
3. In thermal simulations (Thermal option), heat can be conducted both across and along the pipe wall. Conduction across the pipe wall (between the well and the formation, or between inner tubing and outer annulus segments) is governed by the WSEGHEAT keyword. Conduction along the pipe wall, between each segment and its outlet segment, is determined by the cross-sectional area of the pipe wall material (item 13) and its thermal conductivity (item 15). Since the top segment has no outlet segment, its thermal conductivity (item 12 of record 1) is used purely as a default value for the other segments.

Heat can also be stored in the pipe wall. The amount of energy that it stored within the pipe wall of each segment depends on the volume of the pipe wall material and its heat capacity. The volume of pipe wall material is equal to the segment length multiplied by the pipe wall cross-sectional area (item 13). The heat capacity is defined in item 14. The corresponding data items for the top segment (items 10 and 11 of record 1) govern the heat storage in that segment and also act as default values for the other segments.

## Examples

### Example 1

To define multilateral well with a main stem and three horizontal lateral branches:

```

WELSEGS
-- Name      Dep 1   Tlen 1   Vol 1   Len&Dep   PresDrop   FlowModel
   PROD     7010     0.0     1*      INC      HF-      /
-- First    Last    Branch  Outlet   Length   Depth     Diam     Rough   Area   Vol
-- Seg      Seg    Num     Seg      Change
-- Main Stem

## Example 2

ECLIPSE 100

To change its segments to use the drift flux slip model at a later stage in the run, it is necessary to reset the well's default slip model to DF and then use [WSEGFMOD](#) to change its segments to use the drift flux model:

```
WELSEGS
-- Name      Dep 1   Tlen 1   Vol 1   Len&Dep   PresDrop   FlowModel
   PROD      3*                INC        HF-        DF /
/
WSEGFMOD
-- Well      Segments      Flow   Local   Prof   Prof   Prof
-- Name      From  To      Model  Slip   A     B     v mult
   PROD      2    27      DF    /
/
```

## WELSOMIN **Minimum oil saturation for automatic opening**

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword should be followed by a single real number which represents the minimum oil saturation in a grid block necessary to allow a well connection to be opened automatically in it. The number must be followed by a slash (/).

A connection on automatic opening (see item 6 of keyword [COMPDAT](#)) is not opened during a workover if the grid block has an oil saturation below this value. If a well is opened from the drilling queue (keyword [QDRILL](#) or [WDRILPRI](#)) or on automatic opening (see item 2 in keyword [WCONPROD](#)), any connection in a grid block with an oil saturation below this value is not opened, but will be placed under automatic opening instead.

If the [COMPLUMP](#) keyword is used to lump connections together into completions, the minimum oil saturation value applies to the average oil saturation in the grid blocks connecting with a completion, weighted in proportion to their connection transmissibility factors. If this average saturation exceeds the minimum value, all the connections in the completion are opened. If this average saturation is less than the minimum value, none of the connections in the completion are allowed to open.

This limit does not prevent connections being opened manually (for example using keyword [COMPDAT](#)).

If this keyword is omitted, automatic opening of connections takes place regardless of the grid block oil saturation.

### Example

```
WELSOMIN
0.2 /
```

## WELSPECL **General specification data for wells in local grids**

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

WELSPECL must be used in place of [WELSPECS](#) to set the general specification data for wells in local refined grids. The keyword data is similar to that for [WELSPECS](#), except there is an additional item at position 3 which gives the name of the local grid refinement in which the well is located. The connection data for these wells must be specified using the keyword [COMPDATL](#) instead of [COMPDAT](#).

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The records may be terminated early with a slash (/); the remaining items assume their default values. Default values can be specified before the slash by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records must end with a blank record, containing only a slash (/).

1. Well name  
(Up to 8 characters)
2. Name of the group to which the well belongs  
(Up to 8 characters)

*ECLIPSE 100*

The name `FIELD` cannot be used as a group name here. Also, node-groups defined with keyword [GRUPTREE](#) cannot contain wells.

A well can be reassigned to a different group during the simulation, if required, by reentering its WELSPECL data with the new group name.

*ECLIPSE 300*

DEFAULT: `FIELD`

3. Name of the local refined grid in which the well is located

*ECLIPSE 100*

If the well is completed in an amalgamation of local grids (see keyword [AMALGAM](#)), the name of any local grid in the amalgamation may be used here. Only one record is needed per well, even for wells which are completed in more than one local grid.

4. I - location of well head, in the coordinate system of the local grid
5. J - location of well head, in the coordinate system of the local grid

For horizontal wells, items 4 and 5 define the location of the heel of the well, which ECLIPSE may use to determine the order of the connections (see the [COMPORD](#) keyword). If all connections are vertical, items 4 and 5 are for reporting purposes only; the well can still connect with grid blocks having different I- and J- locations. See keyword [COMPDATL](#).

6. Reference depth for bottom hole pressure

This should be situated in the vicinity of the perforations. A recommended location is the top-most perforation of the well.

If this quantity is defaulted or given a negative value, the reference depth is set equal to the center depth of the grid block containing the top-most connection in the well.

In multisegment wells (See "[Multisegment wells](#)" in the *ECLIPSE Technical Description*) the bottom hole reference depth is set equal to the depth of the well's top segment node entered in record 1 of keyword [WELSEGS](#).

UNITS: m (`METRIC`), ft (`FIELD`), cm (`LAB`), m (`PVT-M`)

## 7. Preferred phase for the well

OIL The well is primarily an oil well

WATER The well is primarily a water well

GAS The well is primarily a gas well

LIQ May be used to output the oil + water phase P.I.

This information is used to define the productivity/injectivity index of the well, or its potential flow rate (see item 8). It can also be used in the group/field production rate control option (see item 7 in keyword [GCONPROD](#)).

## 8. Drainage radius for productivity/injectivity index calculation

The instantaneous productivity/injectivity index is printed in the well reports. It is calculated from a steady-state relationship, which is described in "[The productivity index](#)" in the *ECLIPSE Technical Description*.

If a zero value is specified, the pressure equivalent radius of the (local) grid blocks containing the well connections is used. The productivity/injectivity index is then equal to the sum over the connections of the product of the connection factor and the local mobility of the preferred phase specified in item 7.

*ECLIPSE 100*

If a negative value is specified, the well's potential flow rate of the preferred phase is printed in the well reports instead of the productivity/injectivity index. The well's potential rate is the flow rate it would achieve in the absence of any rate constraint, limited only by its BHP and/or THP constraint, at the current grid block conditions - see "[Well potentials](#)" in the *ECLIPSE Technical Description*.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: 0.0

## 9. Flag for use of a special inflow equation to model the flow of gas between the completed grid blocks and the well completions

STD or NO The standard inflow equation is used

*ECLIPSE 100 only*

R-G or YES The Russell-Goodrich equation

*ECLIPSE 100 only*

P-P The dry gas pseudo-pressure equation

(This option is not available in gas condensate runs.)

GPP The generalized pseudo-pressure equation

(This option may be used by gas condensate producers. See also keyword [PICOND](#).)

The Russell-Goodrich and dry gas pseudo-pressure equations just alter the free gas mobility to take account of its pressure dependence between the grid block pressure and the connection pressure. The generalized pseudo-pressure equation alters both the gas and oil mobilities, and takes account also of the effects of condensate dropout. See "[The phase mobilities](#)" in the *ECLIPSE Technical Description* for a description of these options.

*ECLIPSE 300 only*

The generalized pseudo-pressure method may be activated in ECLIPSE 300 for all wells by entering the keyword [PSEUPRES](#) early in the SCHEDULE section. This will override item 9 above.

DEFAULT: STD

10. Instructions for automatic shut-in

STOP Stop well above formation (allowing crossflow)

SHUT Isolate well from the formation

The well can be automatically shut or stopped if a well or group economic limit, or a group flow limit, is violated.

DEFAULT: SHUT

11. Crossflow ability flag

YES Crossflow allowed in the well

NO Crossflow not allowed; the connections act as one-way valves, preventing flow if there is a reverse drawdown

DEFAULT: YES

12. Pressure table number for wellbore fluid properties

(This governs the calculation of wellbore hydrostatic head at formation level, and the relation between surface rates and reservoir fluid volume rate.)

*ECLIPSE 100 only*

If a zero value is entered, the pressure table number is set equal to the PVT region number of the lowest grid block in which the well is completed.

*ECLIPSE 300 only*

If a zero value is entered, the pressure table number is set equal to the PVT region number of first grid block in which the well is completed.

DEFAULT: 0

13. Type of density calculation for the wellbore hydrostatic head

SEG Segmented density calculation.

The flowing mixture density is calculated between each adjacent pair of connections, and depends on the relative quantities of the phases flowing in these particular sections of the wellbore. This calculation is more accurate than the other choice if different mixtures of fluids enter the well through each connection, but it is treated **explicitly** in the numerical scheme.

AVG Averaged density calculation.

The flowing mixture density is treated as uniform throughout the wellbore at formation level, and depends on the total inflow rates of each phase and the well's bottom hole pressure. This calculation is performed **implicitly** in the numerical scheme.

It is usually best to use SEG, for its greater accuracy, and change to AVG only if the explicit calculation causes stability problems.

The hydrostatic heads calculated using segmented densities in the wellbore are damped to reduce the likelihood of stability problems by combining values from the previous timestep with those of the current timestep in a weighted average.

*ECLIPSE 100*

- The damping is only applied to stopped wells or wells with a zero rate target, and the weighting used in the damping is calculated internally.

*ECLIPSE 300*

- The damping is applied to both open and stopped wells, and the weighting used in the damping can be adjusted using [item 44](#) in the `OPTIONS3` keyword.

---

**CAUTION:** An error in the damping algorithm was fixed in the 2010.1 version of the simulators. This may change simulation results. To revert to the previous behavior, use [item 145](#) in the `OPTIONS` keyword in ECLIPSE 100, and [item 213](#) of the `OPTIONS3` keyword in ECLIPSE 300.

---

This item is ignored for multisegment wells (see "[Multisegment wells](#)" in the *ECLIPSE Technical Description*). In these wells the average mixture density is calculated implicitly within each segment.

DEFAULT: SEG

ECLIPSE 300

The default density calculation may be changed using [item 65](#) in the `OPTIONS3` keyword

14. Fluids-in-place region number supplying the reservoir conditions used in calculating the well's reservoir fluid volume rate.

(The reservoir fluid volume rate is based on the volume that the produced or injected mixture would occupy at the average conditions - hydrocarbon pressure,  $R_s$ ,  $R_v$  - within the specified fluids-in-place region.)

If a zero value is entered, the average hydrocarbon conditions in the **global** grid system is used.

If a negative value is entered, the region number is set equal to the fluids-in-place region number of the lowest grid block in which the well is completed.

If a positive value is entered, this is interpreted as the required fluids-in-place region number. A warning message is printed if the well is not completed in a grid block within that region.

DEFAULT: 0

15. Reserved for use by FrontSim.
16. Reserved for use by FrontSim.

ECLIPSE 300

17. Specify the type of well model:

STD The standard well model.

HMIW High mobility injection wells. An average completion pressure is considered, this is to overcome convergence problems when the completion mobilities in the injection wells are high. See "[High mobility injection wells](#)" in the *ECLIPSE Technical Description*.

DEFAULT: STD

ECLIPSE 100

18. Polymer mixing table number for wellbore fluid properties.

This determines how polymer affects wellbore fluid viscosity for friction wells and multisegment wells. It has no effect for standard wells and no effect if `POLYMER` has not been activated.

If a zero value is entered, the polymer mixing table number is set equal to the `PLMIXNUM` table number of the lowest grid block in which the well is completed.

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

ECLIPSE 300

**Note:** Remember to specify the well separator conditions with `WSEPCOND` when using `WELSPECL`.

ECLIPSE 100

**Note:** In a parallel run, if an LGR is switched off, a well cannot be defined within an LGR.

## Examples

## WELSPECS General specification data for wells

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword introduces a new well, defining its name, the position of the wellhead, its bottom hole reference depth and other specification data.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The records may be terminated early with a slash (/); the remaining items will assume their default values. Default values can also be specified before the slash by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records must end with a blank record, containing only a slash (/).

1. Well name  
(Up to 8 characters)
2. Name of the group to which the well belongs  
(Up to 8 characters)

*ECLIPSE 100*

The name `FIELD` cannot be used as a group name here. Also, node-groups defined with keyword `GRUPTREE` cannot contain wells. **It is strongly recommended that this item is not defaulted in ECLIPSE 100.**

A well can be re-assigned to a different group during the simulation, if required, by re-entering its WELSPECS data with the new group name.

*ECLIPSE 300*

DEFAULT: `FIELD`

3. I - location of well head or heel
4. J - location of well head or heel

For horizontal wells, items 3 and 4 define the location of the heel of the well, which ECLIPSE may use to determine the order of the connections (see the `COMPORD` keyword). If all connections are vertical, items 3 and 4 are used for reporting purposes only; the well can still connect with grid blocks having different I- and J- locations.

5. Reference depth for bottom hole pressure

This should be situated in the vicinity of the perforations. A recommended location is the topmost perforation of the well.

In multisegment wells the bottom hole reference depth is set equal to the depth of the well's top segment node entered in record 1 of keyword `WELSEGS`.

DEFAULT: If this quantity is defaulted or given a negative value, the reference depth is set equal to the center depth of the grid block containing the first connection in the well as defined by `COMPORD`.

*ECLIPSE 100*

If the grid has one or more cells above sea level, then a negative value is taken as a reference depth.

UNITS: m (`METRIC`), ft (`FIELD`), cm (`LAB`), m (`PVT-M`)

6. Preferred phase for the well
  - OIL The well is primarily an oil well
  - WATER The well is primarily a water well

GAS The well is primarily a gas well

LIQ May be used to output the oil + water phase P.I.

This information is used to determine the worst offending well or connection for closure when a group production rate limit is exceeded in [GCONPROD](#) (see item 7) and [GCONPRI](#) (see item 3).

ECLIPSE 100

This information is also used to define the productivity/injectivity index of the well, or its potential flow rate (see item 7).

7. Drainage radius for productivity/injectivity index calculation.

The instantaneous productivity/injectivity index is printed in the well reports. It is calculated from a steady-state relationship, which is described in "[The productivity index](#)" in the *ECLIPSE Technical Description*.

If a zero value is specified, the pressure equivalent radius of the grid blocks containing the well connections is used. The productivity/injectivity index is then equal to the sum over the connections of the product of the connection factor and the local mobility of the preferred phase specified in item 6.

ECLIPSE 100

If a negative value is specified, the well's potential flow rate of the preferred phase is printed in the well reports instead of the productivity/injectivity index. The well's potential rate is the flow rate it would achieve in the absence of any rate constraint, limited only by its BHP and/or THP constraint, at the current grid block conditions - see "[Well potentials](#)" in the *ECLIPSE Technical Description*. (When running the Gas Field Operations Model, the well's gas delivery capacity is printed instead, for a production well.)

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: 0.0

8. Flag for use of a special inflow equation to model the flow of gas between the completed grid blocks and the well completions

STD or NO The standard inflow equation will be used

ECLIPSE 100 only

R-G or YES The Russell-Goodrich equation

ECLIPSE 100 only

P-P The dry gas pseudo-pressure equation  
(This option is not available in gas condensate runs.)

GPP The generalized pseudo-pressure equation.  
(This option may be used by gas condensate producers. See also keyword [PICOND](#).)

The Russell-Goodrich and dry gas pseudo-pressure equations just alter the free gas mobility to take account of its pressure dependence between the grid block pressure and the connection pressure. The generalized pseudo-pressure equation alters both the gas and oil mobilities, and takes account also of the effects of condensate dropout. See "[Special inflow equations](#)" in the *ECLIPSE Technical Description* for a description of these options.

ECLIPSE 300 only

The generalized pseudo-pressure method may be activated in ECLIPSE 300 for all wells by entering the keyword [PSEUPRES](#) early in the SCHEDULE section. This will override item 8 above.

DEFAULT: STD

9. Instructions for automatic shut-in

STOP Stop well above formation (allowing crossflow)

SHUT Isolate well from the formation.

The well can be automatically shut or stopped if a well or group economic limit, or a group flow limit, is violated.

DEFAULT: SHUT

10. Crossflow ability flag

YES Crossflow allowed in the well

NO Crossflow not allowed; the connections act as one-way valves, preventing flow if there is a reverse drawdown

DEFAULT: YES

11. Pressure table number for wellbore fluid properties

(This governs the calculation of wellbore hydrostatic head at formation level, and the relation between surface rates and reservoir fluid volume rate)

*ECLIPSE 100 only*

If a zero value is entered, the pressure table number is set equal to the PVT region number of the lowest grid block in which the well is completed.

*ECLIPSE 300 only*

If a zero value is entered, the pressure table number is set equal to the PVT region number of first grid block in which the well is completed.

DEFAULT: 0

12. Type of density calculation for the wellbore hydrostatic head

SEG Segmented density calculation.

The flowing mixture density is calculated between each adjacent pair of connections, and depends on the relative quantities of the phases flowing in these particular sections of the wellbore. This calculation is more accurate than the other choice if different mixtures of fluids enter the well through each connection, but it is treated **explicitly** in the numerical scheme.

AVG Averaged density calculation.

The flowing mixture density is treated as uniform throughout the wellbore at formation level, and depends on the total inflow rates of each phase and the well's bottom hole pressure. This calculation is performed **implicitly** in the numerical scheme.

It is usually best to use SE, for its greater accuracy, and change to AVG only if the explicit calculation causes stability problems.

The hydrostatic heads calculated using segmented densities in the wellbore are damped to reduce the likelihood of stability problems by combining values from the previous timestep with those of the current timestep in a weighted average.

*ECLIPSE 100*

- The damping is only applied to stopped wells or wells with a zero rate target, and the weighting used in the damping is calculated internally.

*ECLIPSE 300*

- The damping is applied to both open and stopped wells, and the weighting used in the damping can be adjusted using [item 44](#) in the `OPTIONS3` keyword.

---

**Note:** An error in the damping algorithm has been identified and fixed in the 2010.1 version of the simulators. This fix has not been made to the default behavior as it may change simulation results. To use the correct damping, use [item 145](#) in the `OPTIONS` keyword in ECLIPSE 100, and [item 213](#) of the `OPTIONS3` keyword in ECLIPSE 300.

---

This item is ignored for multisegment wells (see "[Multisegment wells](#)" in the *ECLIPSE Technical Description*). In these wells the average mixture density is calculated implicitly within each segment.

DEFAULT: `SEG`

ECLIPSE 300

The default density calculation may be changed using [item 65](#) in the `OPTIONS3` keyword

13. Fluids-in-place region number supplying the reservoir conditions used in calculating the well's reservoir fluid volume rate.

(The reservoir fluid volume rate is based on the volume that the produced or injected mixture would occupy at the average conditions - hydrocarbon pressure,  $R_s$ ,  $R_v$  - within the specified fluids-in-place region).

If a zero value is entered, the average hydrocarbon conditions in the field is used.

If a negative value is entered, the region number is set equal to the fluids-in-place region number of the lowest grid block in which the well is completed.

If a positive value is entered, it is interpreted as the required fluids-in-place region number. A warning message is printed if the well is not completed in a grid block within that region.

DEFAULT: `0`

14. Reserved for use by FrontSim.
15. Reserved for use by FrontSim.

ECLIPSE 300

16. Specify the type of well model:

`STD` The standard well model.

`HMIW` High mobility injection wells. An average completion pressure is considered, this is to overcome convergence problems when the completion mobilities in the injection wells are high. See "[High mobility injection wells](#)" in the *ECLIPSE Technical Description*

DEFAULT: `STD`

ECLIPSE 100

17. Polymer mixing table number for wellbore fluid properties.

This determines how polymer affects wellbore fluid viscosity for friction wells and multisegment wells. It has no effect for standard wells and no effect if `POLYMER` has not been activated.

If a zero value is entered, the polymer mixing table number is set equal to the `PLMIXNUM` table number of the lowest grid block in which the well is completed.

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

ECLIPSE 300

**Note:** Remember to specify the well separator conditions with `WSEPCOND` when using `WELSPECS`.

## Examples

### Example 1

## WELTARG Resets a well operating target or limit

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to reset a target or limit value for a well, without having to re-specify all the other quantities required by the control keywords [WCONPROD](#) or [WCONINJE](#). These other quantities are left unchanged, including the open/shut status of the well. The well control data must initially have been fully specified using [WCONPROD](#) or [WCONINJE](#).

If the well has been declared a history matching well (see keywords [WCONHIST](#) and [WCONINJH](#)) the [WELTARG](#) keyword may be used to modify its BHP limit, VFP table number, and artificial lift quantity. The other quantities should not be modified with this keyword.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Definition of the control or constraint quantity to be changed

ORAT Oil rate

WRAT Water rate

GRAT Gas rate

LRAT Liquid rate

CRAT Linearly combined rate (coefficients must be set with [LINCOM](#))

RESV Reservoir fluid volume rate

BHP Bottom hole pressure

THP Tubing head pressure (A non-zero VFP table number must first have been set)

VFP VFP table number

LIFT Artificial lift quantity (A non-zero VFP table number must first have been set)

GUID Guide rate (For group controlled wells)

*ECLIPSE 300 only*

WGRA Wet gas rate

*ECLIPSE 300 only*

NGL NGL rate

*ECLIPSE 300 only*

CVAL Calorific production rate

*ECLIPSE 300 only*

REIN ReInjection fraction

*ECLIPSE 300 only*

STRA Steam rate (Available only with the Thermal option)

*ECLIPSE 300 only*      SATP Saturation pressure offset. (Available only with the Thermal option)

*ECLIPSE 300 only*      SATT Saturation temperature offset (Available only with the Thermal option)

3. New value of this quantity.

UNITS: The units depend upon the quantity chosen. The appropriate units are listed in the specification for keywords [WCONPROD](#) and [WCONINJE](#).

DEFAULT: If the quantity in item 2 is VFP, LIFT or GUID, then the value here may not be defaulted. For all other quantities, a defaulted value here will result in ECLIPSE using the corresponding flowing value for the well at the end of the previous timestep as the target or limit for the control or constraint in item 2.

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

See also keyword [WTMULT](#).

## Example

```
WELTARG
PROD1  ORAT  1500 /
PROD2  BHP   3000 /
/
```

## WFOAM

## Sets foam concentration for injection wells

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used to specify the concentration of foam in the injection stream of each well, when the Foam Model is enabled. If the WFOAM keyword does not appear in the injection schedule, then concentration values of zero are assumed.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/). The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. The concentration of foam in the injection stream for the well. This quantity can be a user defined argument (UDA), and can be set with keywords [UDQ](#) and [UDADIMS](#).

If item 1 of [FOAMOPTS](#) is set to 'GAS', then the well should be a gas injector, and the concentration units are:

UNITS: kg/sm<sup>3</sup> (METRIC), lb/Mscf (FIELD), gm/scc (LAB)

If item 1 of [FOAMOPTS](#) is set to 'WATER', then the well should be a water injector and the concentration units are:

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB)

End data record with a slash (/).

End the set of records with a blank record, containing just a slash (/).

See also keyword [WCONINJE](#).

## WFRICSEG **Converts friction well WFRICTN data into a multisegment well**

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword may be used to define both the segment structure and the connection locations of a multisegment well, using the data from the [WFRICTN](#) keyword. It replaces both the [WELSEGS](#) keyword and the [COMPSEGS](#) keyword. It thus provides an easy way of converting a friction well into a multisegment well, simply by changing the keyword name to WFRICSEG. (See "[Converting friction wells to multisegment wells](#)" in the *ECLIPSE Technical Description*.)

Friction wells that are situated in local grids and use the [WFRICTNL](#) keyword should be converted by changing the keyword to [WFRICSGL](#).

Note that friction wells and multisegment wells cannot coexist in the same run. **All** the friction wells must be converted if this facility is used. Also the [FRICTION](#) keyword must be removed from the RUNSPEC section, replacing it with the [WSEGDIMS](#) keyword with appropriate dimensions.

ECLIPSE creates the segment structure such that there is one segment per grid block connection, plus an additional segment at the well's bottom hole reference point. The segments are distributed so that the nodal point of each segment is located at the center of the corresponding grid block connection. The segment lengths are set equal to the tubing length between adjacent connections. The depths of the segment nodes are set equal to the center depths of the connecting grid blocks, as there is no data in WFRICTN that defines the depth trajectory of the well bore. ECLIPSE outputs the resulting WELSEGS and COMPSEGS data to the Print file in the appropriate keyword format. The keyword data may then be copied, if desired, to replace the WFRICSEG keyword in the data file where it can be edited for additional flexibility. It is advisable to readjust the segment depths to correspond to the actual well trajectory, as setting them equal to the grid block center depths produces spurious undulations if the grid is not aligned with the well.

When the WFRICTN data represents a multilateral well, ECLIPSE creates the branches and numbers them. However, ECLIPSE is unable to recognize whether the original main stem continues past a branch junction. Instead, **two** new branches are created at each branch junction, one of these being the continuation of the main stem. It is important to allow for this when setting the maximum number of branches in WSEGDIMS. For example, a well consisting of a main stem and a single lateral branch will be converted to have three branches: the upper part of the main stem, the lateral branch and the section of the main stem below the branch junction. You can reduce the number of branches, if desired, by copying the output WELSEGS and COMPSEGS data and editing it to renumber all the main stem sections as branch 1 (don't forget to edit the branch numbers in COMPSEGS accordingly).

The WFRICSEG keyword data items are identical to those of the WFRICTN keyword.

## WFRICSGL **Converts friction well WFRICTNL data into a multisegment well**

	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword may be used to define both the segment structure and the connection locations of a multisegment well situated in a local grid (or an amalgamated set of local grids), using the data from the [WFRICTNL](#) keyword. It replaces both the [WELSEGS](#) keyword and the [COMPSEGL](#) keyword. It thus provides an easy way of converting a friction well into a multisegment well, simply by changing the keyword name to WFRICSGL. (See "[Converting friction wells to multisegment wells](#)" in the *ECLIPSE Technical Description*.)

Note that friction wells and multisegment wells cannot coexist in the same run. **All** the friction wells must be converted if this facility is used. Also the [FRICTION](#) keyword must be removed from the RUNSPEC section, replacing it with the [WSEGDIMS](#) keyword with appropriate dimensions.

ECLIPSE creates the segment structure such that there is one segment per local grid block connection, plus an additional segment at the well's bottom hole reference point. The segments are distributed so that the nodal point of each segment is located at the center of the corresponding grid block connection. The segment lengths are set equal to the tubing length between adjacent connections. The depths of the segment nodes are set equal to the center depths of the connecting grid blocks, as there is no data in WFRICTNL that defines the depth trajectory of the well bore. ECLIPSE outputs the resulting WELSEGS and COMPSEGL data to the Print file in the appropriate keyword format. The keyword data may then be copied, if desired, to replace the WFRICSGL keyword in the data file where it can be edited for additional flexibility. It is advisable to readjust the segment depths to correspond to the actual well trajectory, as setting them equal to the grid block center depths produces spurious undulations if the grid is not aligned with the well.

When the WFRICTNL data represents a multilateral well, ECLIPSE creates the branches and numbers them. However, ECLIPSE is unable to recognize whether the original main stem continues past a branch junction. Instead, **two** new branches are created at each branch junction, one of these being the continuation of the main stem. It is important to allow for this when setting the maximum number of branches in WSEGDIMS. For example, a well consisting of a main stem and a single lateral branch will be converted to have three branches: the upper part of the main stem, the lateral branch and the section of the main stem below the branch junction. You can reduce the number of branches, if desired, by copying the output WELSEGS and COMPSEGL data and editing it to renumber all the main stem sections as branch 1 (don't forget to edit the branch numbers in COMPSEGL accordingly).

The WFRICSGL keyword data items are identical to those of the WFRICTNL keyword.

## WFRICTN

## Designates a well as a friction well

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used to designate a well to be a friction well, for which the frictional pressure losses between the connections and the well's bottom hole reference point are calculated and included in the connection head terms. This facility is primarily intended for use with horizontal and multilateral wells, in which frictional pressure losses may be significant over the horizontal section of the wellbore and in the branches. (See "[Wellbore friction option](#)" in the *ECLIPSE Technical Description*.)

This keyword can only be used on one well at a time, so the keyword must be specified more than once if there is more than one friction well. If the keyword is repeated for a particular well (for example to add a new branch or new connections), the data for the **entire** well must be supplied each time the keyword is used.

If the well is completed in one or more local grids that have been amalgamated (see "[Local grid refinement and coarsening](#)" in the *ECLIPSE Technical Description*), the keyword `WFRICTNL` must be used instead of `WFRICTN`. Either keyword may be used for wells completed in single unamalgamated local grids.

The keyword is followed by a number of data records to describe the properties and geometry of the (possibly multibranch) well. Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing just a slash.

The data items in each record are:

### Record 1

The first record identifies the well and sets the tubing diameter, roughness and flow scaling factor, which are used in the friction pressure loss calculation.

1. Name of the well
2. Tubing internal diameter

This quantity is used for calculating the frictional pressure drop between the connections and the well's bottom hole reference point. It need not be the same as the wellbore diameter set in `COMPDAT` item 9, which is used to calculate the connection transmissibility factors.

Different internal diameters may be set for individual connections, with item 8 in subsequent records.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

3. The effective absolute roughness of the tubing

This quantity is used to calculate the Fanning friction factor.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

4. Flow scaling factor (dimensionless)

The volumetric flow rate in the wellbore is multiplied by the scaling factor when the friction pressure drop is calculated. This quantity is useful if the well is being simulated in a half or quarter grid, taking advantage of symmetry. In this case, the well's flow rate will only be a half or quarter of the true flow rate. The scaling factor can then be used to multiply the connection flow rates by 2 or 4, so that the true flow rate is used in the friction calculation.

DEFAULT: 1.0

End the data record with a slash (/).

## Each subsequent record

The subsequent records set the start and end of each connection's perforations in terms of distance along the tubing from the well's bottom hole reference point. These distances are required by the frictional pressure drop calculation, which treats each connection's flow as entering the tubing half way between the start and end of the perforations in the grid block. The bottom hole reference point should be downstream for a producer (upstream for an injector) of all the perforations. A suitable position is at the start of the perforations (the end nearest the wellhead). The order in which these records are entered is used to determine the structure of the well (see "[Multilateral wells](#)" in the *ECLIPSE Technical Description*). For standard horizontal wells, the connections should be entered in order of increasing distance from the bottom hole reference point, that is from the heel out to the toe.

The connections may either be specified individually, or in one or more "ranges". A range is a contiguous row or column of grid blocks that are fully penetrated by the well. The well is assumed to penetrate a range perpendicularly through the center of each grid block in the specified direction. The distance along the tubing to the start and end of each connection in the range is determined by summing the DX, DY or DZ thicknesses of the grid blocks in the range. All connections in the well must have their tubing distances set, either individually or within a range, working from the connection nearest the well's bottom hole reference point out to the furthest connection of the well.

For a standard horizontal well, each connection should be referenced by this keyword just once, either individually or as part of a range. For multilateral wells, the topology of the branches is defined by referencing specific connections again at each branch point. If a connection is referenced again in WFRICTN after its first entry, either singly or as the **first** connection of a range, then it is taken to indicate that the subsequent connections form a branch that joins the well at this location. The connections in this branch should be ordered from the join out towards its toe. The properties of branch point connections are defined by items 4 - 8 of the record in which they are first referenced; these items are ignored when a connection is referenced again. All connections must of course have been defined initially in keyword [COMPDAT](#). Note that there must therefore be a connection defined at each branch point. However, if the well is not actually perforated within these grid blocks the connection should be declared as SHUT in keyword [COMPDAT](#). The maximum number of branches emanating from any one connection must be entered in keyword [FRICTION](#) in the RUNSPEC section. See "[Multilateral wells](#)" in the *ECLIPSE Technical Description* for further details and examples.

1. I - location of the individual connection, or the connection at the **start** of the range (nearest the well's bottom hole reference point)
2. J - location of the individual connection, or the connection at the **start** of the range (nearest the well's bottom hole reference point)
3. K - location of the individual connection, or the connection at the **start** of the range (nearest the well's bottom hole reference point)
4. Distance down the tubing from the well's bottom hole reference point to the **start** of the perforations in **this grid block**

This item must not be negative.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: Zero, for the first of these records, or the distance to the end of the previous connection or range, for subsequent records

5. Distance down the tubing from the well's bottom hole reference point to the **end** of the perforations in **this grid block**

This item, if set, must be greater than item 4.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: Value of item 4 + thickness of the grid block in the direction of penetration

6. Direction of penetration through the grid block or the range:

X or I for horizontal penetration in the x-direction

Y or J for horizontal penetration in the y-direction

Z or K for vertical penetration

This item is used for calculating the distance to the end of the perforations in the connection (or the connections in the range), where it defines which component of the grid block size to add (DX, DY or DZ). The item must be set if item 5 is defaulted, or if a range is specified in item 7. Otherwise it may be defaulted as it is not required.

7. Grid block I, J, or K coordinate at the **end** of the range, depending on the direction of penetration set in item 6. (For example the I-coordinate of the grid block at the end of the range, if the well penetrates in the I-direction.)

This may be greater than, or less than, the corresponding grid block coordinate in item 1, 2 or 3, depending on whether the well penetrates out towards the positive or negative I, J or K direction.

If this item is set, the tubing lengths are calculated for all the well's connections that lie within the range. Should the range pass through an inactive grid block ECLIPSE prints a warning message and assume a zero thickness for that cell. If this is not appropriate, the range should be split and the thickness of the inactive grid block accounted for by explicitly defining the tubing lengths in items 4 and 5.

If this item is defaulted, this record sets the tubing lengths for the single connection identified by items 1, 2 and 3.

8. Tubing internal diameter for this connection, or range of connections.

A value entered here is used instead of the value entered in item 2 of "Record 1". This allows, for example, branches in multilateral wells to have different diameters.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: The value entered in item 2 of Record 1.

End the data record with a slash (/).

End the set of data records with a slash.

## Notes

- Friction wells must use the segmented density calculation for the hydrostatic head (SEG in item 12 of keyword [WELSPECS](#)).
- Multilateral well data can be complicated to enter. It is advisable to check your data by examining the output generated by [RPTSCHED](#) keyword switch 14 (mnemonic [WELSPECS](#)).
- Friction wells must not have connections in coarsened grid cells.

## Examples

A well called HORIZ with 6 connections.

### Example 1

This example sets the tubing lengths manually for each connection of the well 'HORIZ'

```
WFRICTN
-- Name      Diam  Roughness  Scalefac
   HORIZ     0.25  1.0E-3    1.0 /
-- I J K  Tlen1  Tlen2   Dirn   RangeEnd  Diam
   3 5 6    0.0  100.0 /
   4 5 6   100.0 200.0 /
   5 5 6   200.0 400.0 /
   6 5 6   400.0 600.0 /
   7 5 6   600.0 700.0 /
   8 5 6   700.0 800.0 /
/
```

### Example 2

This example sets the tubing lengths for the same set of well connections grouped into a single range. The well is assumed to penetrate fully the grid blocks I=3-8, J=5, K=6, with the connection at I=3 nearest the wellhead

```
WFRICTN
-- Name      Diam  Roughness  Scalefac
   HORIZ     0.25  1.0E-3    1.0 /
-- I J K  Tlen1  Tlen2   Dirn   RangeEnd  Diam
   3 5 6    0.0    1*    I      8 /
/
```

### Example 3

This example defines a simple multilateral well, having a horizontal main stem (3-8, 5, 6) based on the previous example and a single perpendicular side-branch (5, 5-1, 6) of smaller diameter, joining the main stem at (5, 5, 6). Note that the branch point connection (5, 5, 6) is referenced twice: firstly as part of the main stem range, and secondly as the start of the side-branch range. The properties of the connection are taken from the first reference (that is, I-direction penetration and a diameter of 0.25).

```
WFRICTN
-- Name      Diam  Roughness  Scalefac
   MULTI     0.25  1.0E-3    1.0 /
-- I J K  Tlen1  Tlen2   Dirn   RangeEnd  Diam
   3 5 6    0.0    1*    I      8      / main stem (3-8, 5, 6)
   5 5 6    2*          J      1      0.19 / side branch (5, 5-1, 6)
/
```

Or, equivalently,

```
WFRICTN
-- Name      Diam  Roughness  Scalefac
   MULTI     0.25  1.0E-3    1.0 /
-- I J K  Tlen1  Tlen2   Dirn   RangeEnd  Diameter
   3 5 6    0.0    1*    I      8      / main stem (3-8, 5, 6)
   5 5 6          / branch-point (5, 5, 6)
   5 4 6    2*          J      1      0.19 / side branch (5, 4-1, 6)
/
```

## WFRICTNL Designates a well in a local grid as a friction well

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used to designate a well in a local grid to be a friction well for the Wellbore Friction option (see "[Wellbore friction option](#)" in the *ECLIPSE Technical Description*). WFRICTNL performs the same role as does [WFRICTN](#), but the local grid name should be specified to allow for wells completed in amalgamated local grids (see keyword [AMALGAM](#)).

The frictional pressure losses between the connections and the well's bottom hole reference point are calculated and included in the connection head terms. This facility is primarily intended for use with horizontal and multilateral wells, in which frictional pressure losses may be significant over the horizontal section of the wellbore and in the branches.

This keyword can only be used on one well at a time, so the keyword must be specified more than once if there is more than one friction well. If the keyword is repeated for a particular well (for example to add a new branch or new connections), the data for the **entire** well must be supplied each time the keyword is used.

The keyword is followed by a number of data records to describe the properties and geometry of the (possibly multibranch) well. Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing just a slash.

The data items in each record are:

### Record 1

The first record identifies the well and sets the tubing diameter, roughness and flow scaling factor, which are used in the friction pressure loss calculation.

1. Name of the well
2. Tubing internal diameter

This quantity is used for calculating the frictional pressure drop between the connections and the well's bottom hole reference point. It need not be the same as the wellbore diameter set in [COMPDATL](#), which is used to calculate the connection transmissibility factors.

Different internal diameters may be set for individual connections, with item 9 in subsequent records.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

3. The effective absolute roughness of the tubing

This quantity is used to calculate the Fanning friction factor.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

4. Flow scaling factor (dimensionless)

The volumetric flow rate in the wellbore is multiplied by the scaling factor when the friction pressure drop is calculated. This quantity is useful if the well is being simulated in a half or quarter grid, taking advantage of symmetry. In this case, the well's flow rate will only be a half or quarter of the true flow rate. The scaling factor can then be used to multiply the connection flow rates by 2 or 4, so that the true flow rate is used in the friction calculation.

DEFAULT: 1.0

End the data record with a slash (/).

## Each subsequent record

The subsequent records set the name of the local grid and also the start and end of each connection's perforations in terms of distance along the tubing from the well's bottom hole reference point. These distances are required by the frictional pressure drop calculation, which treats each connection's flow as entering the tubing half way between the start and end of the perforations in the grid block. The bottom hole reference point should be downstream for a producer (upstream for an injector) of all the perforations. A suitable position is at the start of the perforations (the end nearest the wellhead). The order in which these records are entered is used to determine the structure of the well (see "Multilateral wells" in the *ECLIPSE Technical Description*). For standard horizontal wells, the connections should be entered in order of increasing distance from the bottom hole reference point, that is from the heel out to the toe.

The connections may either be specified individually, or in one or more ranges. A range is a contiguous row or column of grid blocks that are fully penetrated by the well. The well is assumed to penetrate a range perpendicularly through the center of each grid block in the specified direction. The distance along the tubing to the start and end of each connection in the range is determined by summing the DX, DY or DZ thicknesses of the grid blocks in the range. All connections in the well must have their tubing distances set, either individually or within a range, working from the connection nearest the well's bottom hole reference point out to the furthest connection of the well.

For a standard horizontal well, each connection should be referenced by this keyword just once, either individually or as part of a range. For multilateral wells, the topology of the branches is defined by referencing specific connections again at each branch point. If a connection is referenced again in WFRICTNL after its first entry, either singly or as the **first** connection of a range, then it is taken to indicate that the subsequent connections form a branch that joins the well at this location. The connections in this branch should be ordered from the join out towards its toe. The properties of branch point connections are defined by items 5 - 9 of the record in which they are first referenced; these items are ignored when a connection is referenced again. All connections must of course have been defined initially in keyword [COMPDATL](#). Note that there must therefore be a connection defined at each branch point. However, if the well is not actually perforated within these grid blocks the connection should be declared as SHUT in keyword [COMPDATL](#). The maximum number of branches emanating from any one connection must be entered in keyword [FRICTION](#) in the RUNSPEC section. See "Multilateral wells" in the *ECLIPSE Technical Description* for further details and examples.

1. Name of local grid containing the connections or range specified in this record.

If the local grid containing the well is not amalgamated (using keyword [AMALGAM](#)), this item may be defaulted or set to a blank string. The local grid name then defaults to the well's local grid named in keyword [WELSPECL](#).

The connection locations in items 2, 3, 4 and 8 refer to their coordinates within this local grid.

2. I - location of the individual connection, or the connection at the **start** of the range (nearest the well's bottom hole reference point)
3. J - location of the individual connection, or the connection at the **start** of the range (nearest the well's bottom hole reference point)
4. K - location of the individual connection, or the connection at the **start** of the range (nearest the well's bottom hole reference point)
5. Distance down the tubing from the well's bottom hole reference point to the **start** of the perforations in this grid block.

This item must not be negative.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: Zero, for the first of these records, or distance to the end of the previous connection or range, for subsequent records

6. Distance down the tubing from the well's bottom hole reference point to the **end** of the perforations in **this grid block**

This item, if set, must be greater than item 5.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: value of item 5 + thickness of the grid block in the direction of penetration

7. Direction of penetration through the grid block or the range:

X or I for horizontal penetration in the x-direction

Y or J for horizontal penetration in the y-direction

Z or K for vertical penetration

This item is used for calculating the distance to the end of the perforations in the connection (or the connections in the range), where it defines which component of the grid block size to add (DX, DY or DZ). The item must be set if item 6 is defaulted, or if a range is specified in item 8. Otherwise it may be defaulted as it is not required.

8. Grid block I, J, or K coordinate at the **end** of the range, depending on the direction of penetration set in item 7. (For example the I-coordinate of the grid block at the end of the range, if the well penetrates in the I-direction.)

This may be greater than, or less than, the corresponding grid block coordinate in item 2, 3 or 4, depending on whether the well penetrates out towards the +ve or -ve I, J or K direction.

If this item is set, the tubing lengths are calculated for all the well's connections that lie within the range. Should the range pass through an inactive grid block ECLIPSE prints a warning message and assume a zero thickness for that cell. If this is not appropriate, the range should be split and the thickness of the inactive grid block accounted for by explicitly defining the tubing lengths in items 5 and 6.

If this item is defaulted, this record will set the tubing lengths for the single connection identified by items 2, 3 and 4.

A range cannot span more than one local grid.

9. Tubing internal diameter for this connection, or range of connections.

A value entered here will be used instead of the value entered in item 2 of Record 1. This allows, for example, branches in multilateral wells to have different diameters.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: The value entered in item 2 of Record 1

End the data record with a slash (/).

End the set of data records with a slash.

## Notes

- Friction wells must use the segmented density calculation for the hydrostatic head (SEG in item 13 of keyword [WELSPECL](#))

- It is still possible to use keyword `WFRICTN` for wells completed in a single, non-amalgamated local grid.
- Multilateral well data can be complicated to enter. It is advisable to check your data by examining the output generated by `RPTSCHED` keyword switch 14 (mnemonic `WELSPECS`).
- Friction wells must not have connections in coarsened grid cells.

## Examples

A well called `HORIZ` with 6 connections in two amalgamated local grids.

### Example 1

This example sets the tubing lengths manually for each connection of the well `HORIZ` which is completed in local grids `WEST` and `EAST`.

```

WFRICTNL
-- Name      Diam      Roughness      Scalefac
  HORIZ      0.25      1.0E-3        1.0 /
-- Local Grid - I J K  Tlen1  Tlen2  Dirn  RangeEnd  Diam
  WEST      3 5 6  0.0    100.0  /
  WEST      4 5 6  100.0  200.0  /
  WEST      5 5 6  200.0  400.0  /
  EAST      1 5 3  400.0  600.0  /
  EAST      2 5 3  600.0  700.0  /
  EAST      3 5 3  700.0  800.0  /
/

```

### Example 2

This example sets the tubing lengths for the same set of well connections grouped into two ranges, one for each local grid `WEST` and `EAST`. The well is assumed to penetrate fully the grid blocks `I=3-5, J=5, K=6` in grid `WEST` and `I=1-3, J=5, K=3` in grid `EAST`. The connection at `I=3` in grid `WEST` is nearest the wellhead.

```

WFRICTNL
-- Name      Diam      Roughness      Scalefac
  HORIZ      0.25      1.0E-3        1.0 /
-- Local Grid - I J K  Tlen1  Tlen2  Dirn  RangeEnd  Diam
  WEST      3 5 6  0.0    1*    I    5 /
  EAST      1 5 3  1*    1*    I    3 /
/

```

The examples of multilateral wells are similarly analogous to those in the `WFRICTN` keyword in the wellbore friction option, and you are referred there for this feature. The only difference, as above, is the need to specify the name of the local grid.

## WGASPROD Special gas producers for sales gas control

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to declare one or more production wells to be special gas producers, which are opened from the drilling queue in preference to other wells when the sales gas production rate falls below the minimum limit (see item 4 of keyword [GCONSALE](#)).

The wells must first be declared as shut producers and given any other operating constraints with keyword [WCONPROD](#), and placed in the drilling queue in the required order with keyword [QDRILL](#). The wells should be placed under [GRAT](#) control and given a nominal gas rate in item 6 of keyword [WCONPROD](#). The nominal gas rate is overridden when the wells are opened from the drilling queue, as their gas rate targets are set automatically at multiples of the incremental rate set in item 2 below.

The purpose of special gas producers is to ensure sufficient gas to meet sales gas requirements independently of any oil production target. You must ensure these wells are completed in a region of the field that provides a suitably high GOR. Special gas producers are opened from the drilling queue only when the sales gas rate has fallen below the minimum requirement, and are not opened as part of normal group production control. They are automatically made unavailable for group control (equivalent to specifying [NO](#) in item 2 of keyword [WGRUPCON](#)), so that their production will not be reduced if a superior group comes under oil rate control. Any limit on the minimum oil saturation necessary for a well to be opened (set with keyword [WELSOMIN](#)) is ignored for these wells.

The keyword is followed by any number of records, each containing the following items of data and terminated with a slash (/).

The set of records must end with a blank record, containing only a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Incremental gas production rate

The well's target gas production rate is increased by this amount each time the sales gas rate of a superior group falls below the minimum limit, until either it reaches the maximum number of increments set in item 3 or it becomes constrained by another limit set in [WCONPROD](#).

This item must be set to a number greater than zero.

UNITS:  $\text{sm}^3/\text{day}$  ([METRIC](#)),  $\text{Mscf}/\text{day}$  ([FIELD](#)),  $\text{scc}/\text{hr}$  ([LAB](#)),  $\text{sm}^3/\text{day}$  ([PVT-M](#))

3. Maximum permitted number of increments

Once this number of increments have been applied to the well, no more increments can be applied and the drilling queue is searched for another special gas producer to open. Thus, the eventual gas production rate is limited to the incremental rate times the maximum number of increments.

A zero value turns the well back to an ordinary producer.

### Example

Define the wells as shut producers and give them any other operating constraints. Place them under gas rate control with a nominal rate limit:

```
WCONPROD
'GASWEL*' SHUT GRAT 2* 1.0 2* 3000 /
/
```

Place the special gas producers in the drilling queue along with any other wells:

```
QDRILL
PROD4 PROD5 PROD6 GASWEL1 GASWEL2 /
```

Declare the wells as special gas producers and set their incremental rates and maximum number of increments:

```
WGASPROD
GASWEL1 3000 4 /
GASWEL2 4000 2 /
/
```

## WGMEM

x	SCHEDULE

This keyword is used to write out ECLIPSE 300 Geomechanics data along specified well surveys at specified times of a simulation. Data to be written includes survey properties, mechanical properties such as Young's modulus, Poisson's ratio, Biot's constant, Initial Cohesion, and stresses, pressures as well as wellbore phase flow rates with time.

This keyword is only available to Schlumberger engineers and can only be accessed if the SMA license is obtained.

## WGORPEN Sets data for GOR penalty option

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The GOR penalty option provides a means of controlling the oil production rate target of individual wells for each month, as a function of their previous month's average gas-oil ratio. The option is specifically intended to model a production regulation imposed by regulatory bodies in certain countries.

When this facility is activated for individual wells with the WGORPEN keyword, the wells' oil production rate target/limit for each calendar month is automatically set to be

$$\text{Oil Rate} = \frac{(\text{Base GOR}) \cdot (\text{Maximum Rate Limit})}{\text{Average GOR over previous month}} \quad \text{Eq. 3.231}$$

subject to the condition that it does not exceed the maximum rate limit. The base GOR and the maximum rate limit are parameters you enter.

While this facility is in use, the timesteps are automatically restricted to end at the end of each calendar month (although reports will only be printed at the report times entered with [DATES](#), [TIME](#) or [TSTEP](#)). At the end of each month, the average gas-oil ratio of each well's production over the month is determined. At the beginning of the next timestep, the oil production rate target/limit for the new month is set according to the formula above, for each well using the facility.

The calculated oil rate target/limit overwrites any value for this quantity that may have been set previously with keyword [WCONPROD](#) or [WELTARG](#). The well is still able to switch to other modes of control if necessary, and group control may also be applied in the usual way. The facility can be applied to just a subset of the production wells, if desired. Any wells using this facility must previously have been declared as producers with keyword [WCONPROD](#). If the wells are placed under oil rate control in [WCONPROD](#), an oil rate target/limit must still be specified in that keyword, but it is overwritten at the start of the next timestep.

The GOR penalty option can subsequently be turned off for individual wells by giving them a zero or negative Base GOR. Unless a new oil rate limit is specified with [WCONPROD](#) or [WELTARG](#), it remains at the value last calculated. If no producers are using the facility, the timesteps are no longer restricted to terminate at the end of each calendar month.

The WGORPEN keyword should normally be applied at the beginning of a month. If it is entered part way through a month, the average GOR for that month (which is used to calculate the next month's oil rate) reflects the production between the time of the keyword entry and the end of the month.

The keyword is followed by any number of records, each containing some or all of the following items of data and terminated with a slash (/).

The set of records must end with a blank record, containing only a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Base GOR

A zero or negative value turns the GOR Penalty option off for the specified well(s).

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC),  $\text{Mscf}/\text{stb}$  (FIELD),  $\text{scc}/\text{scc}$  (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

3. Maximum Rate Limit

UNITS:  $\text{sm}^3/\text{day}$  (METRIC),  $\text{stb}/\text{day}$  (FIELD),  $\text{scc}/\text{hr}$  (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

## 4. Initial average GOR

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), Mscf/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

The value entered here is used to calculate the first month's oil rate target.

This item may be defaulted. Its default value is set as follows:

- If the GOR penalty option is already in use, the previous month's average GOR for each well will already have been calculated. It is left unchanged.
- If the GOR penalty option has just been turned on, the average GOR has not been calculated. It is therefore set equal to the well's GOR at the previous timestep. If the well has just been opened, the average GOR defaults to the Base GOR set in item 2.

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

## Example

```

WGORPEN
-- well name   base GOR   MRL   Initial average GOR
   PROD1      2.0      1000   /
   PROD2      1.8      1000   /
/

```

## WGRUPCON Sets well guide rates for group control

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Is the well available for group control?

**YES** The well is automatically placed under group control if a rate target is imposed on its group, or on a higher level group to which it connects, or on the field.

**NO** The well is prevented from coming under group control - it flows according to its own target or limits.

DEFAULT: YES

3. Guide rate

(A dimensionless number governing the well's share of the group's target rate)

The target rates of the wells under group control are set in proportion to their guide rates, to meet the group or field production target. If the guide rate phase (see item 4) differs from the phase under control, the guide rate is translated into a guide rate for the controlled phase using the well's flow rates at the beginning of each timestep.

If a zero or negative guide rate is specified, the well's guide rate is set at the beginning of each timestep from the general formula specified with keyword [GUIDERAT](#). If a general formula has not been specified, or for injection wells (for which there is no general formula), the well's guide rate is set equal to its production or injection potential (that is the flow rate the well would instantaneously achieve in the absence of any rate constraints; see "[Well potentials](#)" in the *ECLIPSE Technical Description*). When the well's guide rate is set to its potential, the change in guide rate between timesteps is subject to limits defined in the keyword [DGRDT](#) for ECLIPSE 300.

DEFAULT: Negative

4. Phase to which the well's guide rate applies:

**OIL** Guide rate applies to water phase

**WAT** Guide rate applies to oil phase

**GAS** Guide rate applies to gas phase

**LIQ** Guide rate applies to liquid phase (for production wells only)

**COMB** Guide rate applies to linearly combined phase (coefficients must be set with [LINCOM](#)) (for production wells only)

*ECLIPSE 300 only*

**CVAL** Guide rate applies to the calorific production rate (for production wells only)

ECLIPSE 300 only

RAT Guide rate applies to the surface flow rate of the phase that the well is injecting (for injectors only)

RES Guide rate applies to the reservoir fluid volume rate

This item can be defaulted if the well's guide rate has been defaulted or given a negative value.

DEFAULT: ' ' = undefined

#### 5. Guide rate scaling factor

The well's guide rate (either set in item 3 or calculated from its potentials) is multiplied by the number specified here.

DEFAULT: 1.0

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

---

**Note:** This keyword is required only if well guide rates have to be set specifically or require a scaling factor, or if certain wells are to be prevented from coming under group control. If the keyword is not used, all wells are available for group control if required, and their guide rates are set from the formula specified with keyword `GUIDERAT` (if present), or set equal to their potentials (if keyword `GUIDERAT` is not present).

---

## WH2NUM

## Two-phase WAG hysteresis saturation function region numbers

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
x	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

The WH2NUM saturation function region number specifies which set of water saturation functions (input using [SWOF](#), [SWFN](#) and related keywords in the PROPS section) should be used for the two-phase water relative permeabilities associated with the WAG hysteresis option specified via the [WAGHYSTR](#) keyword.

The keyword should be followed by one integer for every grid block in the current input box specifying the saturation function region to which it belongs. The region number should not be less than 1 or greater than NTSFUN (see keyword [TABDIMS](#)). The data must be terminated by a slash (/).

Grid blocks are ordered with the X axis index cycling fastest, followed by the Y and Z axis indices. Repeat counts may be used for repeated values (for example 115\*2). Note that spaces must not be inserted on either side of the asterisk.

This keyword is optional if the [WAGHYSTR](#) keyword has been specified. If omitted, the region numbers will default to those assigned to the [SATNUM](#) keyword. If specified, for grid blocks where the region number specified by WH2NUM is different to that specified by SATNUM, the WAG hysteresis two-phase water relative permeability functions will be taken from the WH2NUM table for saturation regions for which WAG hysteresis has been applied to the water phase.

For more information on the saturation keywords, see the [SWFN](#) and [SWOF](#) keywords in the PROPS section. The WAG hysteresis models are described in more detail under "[Hysteresis in WAG floods](#)" in the *ECLIPSE Technical Description*

### Example

With NTSFUN=2 specified in keyword [TABDIMS](#); NDIVIX=8, NDIVIY=6 and NDIVIZ=5 specified in RUNSPEC keyword [DIMENS](#); and no input BOX set:

```
WH2NUM
144*1 96*2 /

## WHISTCTL Control mode instructions for history matching wells

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword contains instructions that influence the control of all history matching wells (see keywords [WCONHIST](#) and [WCONINJH](#)).

The first item enables you to override the history matching production well control modes, set in all subsequent [WCONHIST](#) keywords, with a single specified control mode. In the initial stages of history matching, the production wells may be on RESV control so that they produce the correct amount of total reservoir voidage before the water cut and gas oil ratio have been matched. But when these ratios have been matched, you may wish to rerun the simulation with the wells producing their observed oil rates. Instead of having to work through all the [WCONHIST](#) keywords changing RESV to ORAT, you may just enter the [WHISTCTL](#) keyword once before the first [WCONHIST](#) keyword.

The second item can be used to instruct ECLIPSE to stop the run if any history matching well has changed to BHP control at the end of the report step. By default, the BHP lower limit of each history matching production well is automatically set to atmospheric pressure when it is first declared in [WCONHIST](#). Similarly, the BHP upper limit for history matching injection wells is initialized to a very high value when they are first declared in [WCONINJH](#). Thus if a well violates this limit and changes to BHP control, it is a sign that the Kh or skin factor is very badly matched. You can set the BHP limit to a more reasonable value to make the test more sensitive, using the keyword [WELTARG](#) placed after the first [WCONHIST](#) (or [WCONINJH](#)) keyword in which the well appears.

The [WHISTCTL](#) keyword is followed by a single record containing the following items, terminated with a slash (/).

1. The overriding production well control mode to be applied to all wells specified in subsequent [WCONHIST](#) keywords:

ORAT Wells are controlled by the observed oil rate

WRAT Wells are controlled by the observed water rate

GRAT Wells are controlled by the observed gas rate

LRAT Wells are controlled by the observed liquid rate (oil + water)

CRAT Wells are controlled by the observed linearly combined rate (coefficients must be set with [LINCOM](#))

*ECLIPSE 300 only*

NGL Wells are controlled by the observed NGL rate

RESV Wells are controlled by the reservoir fluid volume rate calculated from the observed phase flow rates

BHP Wells are controlled by bottom hole pressure

NONE No control mode override is applied; the control modes specified in subsequent [WCONHIST](#) keywords will be honored

DEFAULT: NONE, giving no control mode override

---

**Note:** This keyword will only change the control mode of a well when the well is named in a subsequent WCONHIST keyword. It has no effect on previous WCONHIST keywords.

---

2. Flag to terminate the run if any history matching well has changed to BHP control:

YES Terminate the run

NO Continue the simulation with the well on BHP control

DEFAULT: NO

---

**Note:** The run only terminates if a well switches to BHP control; if the user sets one or more wells to BHP control with WHISTCTL or WCONHIST the simulation will continue.

---

## Examples

### Example 1

To change the control mode of all history matching production wells to produce the observed amount of oil:

```
WHISTCTL  
ORAT /
```

### Example 2

To terminate the run if a history matching well changes to BHP control (applying no control mode override):

```
WHISTCTL  
1* YES /
```

## WHTEMP

## Specifies data for tubing head temperature (THT) calculations

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used to specify the VFP table reference number for tubing head temperature calculations or to set the constant tubing head temperature value. This option is supported only for production wells and not for injection wells. Tubing head temperature values for a well may be examined using the summary keyword WTHHT.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

The well(s) must previously have been declared as a producer.

2. Production well VFP table number

This number should refer to a production VFP table that contains Tubing Head Temperatures in the body of the table (see keyword [VFPPROD](#)).

Each production VFP table must have a unique table number irrespective of whether the body of the table holds pressures or temperatures.

A well must have both a pressure VFP table and a temperature VFP table specified for a Tubing Head Temperature to be calculated from a VFP table.

3. The constant tubing head temperature

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

Either item 2 or item 3 of this keyword should be specified, but not both.

End each data record with a slash (/).

End the set of records with a blank record, containing just a slash (/).

### Example

```

WHTEMP
PA1  1* 40.0 /
PA2  1 /
PA3  2 1*/
/

```

## WI

## Enter overall water composition

The data consists of a single composition for each reservoir equation of state region. See "[Water components](#)" in the *ECLIPSE Technical Description* for further details of the water component option.

### Example

For two water components

```
WI  
1.0 0.0  
/
```

## WINJEDET

## Make-up of a lumped component in terms of its detailed components for an injection well

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies the make-up of the fluid to be injected at a well in terms of the detailed components in a lumped simulation. Lumped simulations are enabled with the [LUMPDIMS](#) keyword in the `RUNSPEC` section; further details can be found in "[Delumping and lumping](#)" in the *ECLIPSE Technical Description*.

**CAUTION:** The order of the entries in the tables is very important and should match exactly the order in which the lumpings and detailed components were entered in the `LUMPING` keyword.

The data comprises a well name, followed by a fraction for each detailed component for each lumping. The fraction represents the proportion of the mole fraction of the carrier component to be associated with that tracer/detailed component. For each lumped phase the fractions must add up to 1.

Each entry must be terminated with a slash (/).

1. Well name
2. The fraction of the first lumped component to be associated with the first detailed component of this lumping.
3. The fraction of the first lumped component to be associated with the second detailed component of the lumping.

...

...

...

- n The fraction of the second lumped component to be associated with the first detailed component of this lumping

...

...

item 2 and each subsequent item can be a user defined argument (UDA), and can be set with keywords [UDQ](#) and [UDADIMS](#). Care should be taken to ensure that the detailed components for each lumped component will sum to one. If they do not sum to one they will be normalized, which may give unintended results.

The keyword must be terminated with a slash (/)

### Example

For the example in the [LUMPING](#) keyword:

```

WINJEDET
IN18 0.5 0.5
      0.25 0.25 0.5 /
INEAST 0.0 1.0
       0.0 0.5 0.5 /
/

```

## WINJGAS

## Specify the nature of injection gas

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies the nature of the gas to be injected by a gas injection well. This should be used if [WCONINJE](#) is used instead of [WELLINJE](#) to specify control data for gas injection wells in compositional models. However, it is not necessary to use WINJGAS for wells subordinate to a group having gas injection controls for which the nature of its injected gas is defined (keyword [GINJGAS](#)); this will ensure that the injection stream will be that defined for the group. If a gas injection well under group control has its own fluid set, then this fluid, and not that defined for the group, will be injected at a rate controlled by the group.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash, the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. Well name, well name template, well list or well list template.

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. A character string specifying the nature of the fluid to be injected.

**GAS** The composition of the injected gas is set to that of the field separator gas. However, it is generally better to specify the injected gas composition more precisely.

From 2007.1, GAS is internally converted to GV (for the field separator) which has better reinjection and gas accounting behavior. [OPTIONS3](#) item 113 can be used to recover the pre-2007.1 behavior.

**STREAM** The molar composition of the injected fluid is defined using the [WELLSTRE](#) keyword. The name of the stream must be entered in item 3.

**MIX** The molar composition of the injected fluid is defined as a mixture using either keyword [WINJMIX](#) or [WINJORD](#). The name of the mixture must be entered in item 3.

**GV** The injected fluid is taken from the vapor production of a nominated group. The name of the group must be entered in item 3.

**WV** The injected fluid is taken from the vapor production of a nominated well. The name of the well must be entered in item 3.

**GRUP** The injected fluid is that defined for a superior group.

DEFAULT: GRUP

Only the first two characters are significant.

3. A character string is required if the composition of the injection fluid was specified using STREAM, MIX, GV or WV in item 2.

In these cases this item is a character string specifying the name of the well stream, mixture, group or well that defines or supplies the injection stream.

The available gas supply from a source group (or well) may be augmented by advance gas defined in keyword [GADVANCE](#) (or [WADVANCE](#)). Gas used for fuel ([GRUPFUEL](#)) and sales ([GRUPSALE](#)) is by default subtracted from a source group's available gas supply for reinjection, but keyword [WTAKEGAS](#) may be used to alter the priorities for reinjection, fuel and sales.

4. The mnemonic for a well stream to be used as make-up gas.

This is only required if make-up gas is to be used to make up the injection target of the well named in item 1, if insufficient injection gas is available from the source defined in items 2 and 3.

If make-up gas is used, the injection calculation may have to be iterated to match the injection gas composition with the injection rate (see keyword [GCONTROL](#)).

5. The stage of the separator that defines the fluid composition for injection

The vapor from any stage of the separator may act as a source of injection fluid. The default value of 0 results in the use of the vapor from the whole separator as the injection fluid.

Note that the choice of separator stage also affects the available produced gas supply rate from the source group or well (item 3) if the source is GV or WV (item 2).

DEFAULT: 0

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

See also keyword [WAVAILIM](#).

## Notes

- For accurate group gas accounting, there is a limitation that reinjection control and any sales gas or fuel gas requirements must all be specified for the same group, usually the FIELD group, and not split across the group hierarchy. This limitation only applies if the injection gas contains group vapor, with the vapor taken from a separator stage (that is not from the whole separator).
- When the fluid composition is taken from the produced vapor from another well or group of wells (item 2 set to WV or GV), then it is possible that the composition will be undefined, for example when the producing well or group is shut. In this case, for compositional fluids, the injection composition will be set to be 100% component 1.

## Example

All injection wells are to use the vapor produced by the FIELD group.

```

WINJGAS
'I*' GV Field /
/

```

## WINJMIX

## Specifies an injection mixture by fraction

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

WINJMIX specifies a number of fluid sources to be used to define an injection stream. The contribution of each fluid to the mixed injection stream is defined by a mixing fraction.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/). Each record defines a single fluid in a mixture.

The records can be terminated early with a slash, the remaining items taking default values. Defaults can also be specified by a null repeat count of the form  $n^*$ , where  $n$  is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. The name of the mixture.

The maximum number of mixtures is set in [WELLDIMS](#) item 7 and is defaulted to 5.

2. The mixture contribution index of the fluid defined below.

The maximum number of mixture fluids is set in [WELLDIMS](#) item 9 and is defaulted to 3. The contribution index must be an integer between 1 and this number.

Note that the calculation of the injection mixture is not dependent on the order in which the mixture sources are specified.

3. The fraction of this fluid in the mixture.

This fraction multiplies the molar composition of this fluid in the mixture.

4. The nature of this fluid.

The fluid type must be one of the following:

**GAS** The composition of the fluid is set to that of the field separator gas. However, it is generally better to specify the injected gas composition more precisely.

From 2007.1, **GAS** is internally converted to **GV** (for the field separator) which has better reinjection and gas accounting behavior. [item 113](#) in [OPTIONS3](#) can be used to recover the pre-2007.1 behavior.

**STREAM** The molar composition of the fluid is defined using the [WELLSTRE](#) keyword. The name of the stream must be entered in item 5.

**GV** The fluid is taken from the vapor production of a nominated group. The name of the group must be entered in item 5.

**WV** The fluid is taken from the vapor production of a nominated well. The name of the well must be entered in item 5.

Only the first two characters are significant.

5. A character string is required if the fluid was specified as **STREAM**, **WV** or **GV**.

In these cases this item specifies the name of the wellstream, well or group that defines the fluid's composition.

6. The stage of the separator that defines the fluid composition.

The vapor from any stage of the separator may act as a source of injection fluid. The default value of 0 results in the use of the vapor from the whole separator as the injection fluid.

Note that the choice of separator stage also affects the available produced gas supply rate from the source group or well (item 5) if the source is GV or WV (item 4).

DEFAULT: 0

## Notes

- If the WINJMIX keyword contains only well or group vapor sources and the WAVAAILIM keyword is present, the injection rate of the mixture is limited to the sum of the well and group vapor production. However, availability does not extend to items within the mixture; if a mixture fraction is set that requires a well or group to provide more vapor than it produces, then that well or group over-injects and a negative excess will be set in the gas accounting tables. Essentially, WINJMIX provides a mixture whose composition is independent of the injection rate. If you wish to honor the availability of individual items within the mixture, WINJORD should be used instead.
- Prior to 2008.1 if a mixture contained a well or group vapor item and this well or group had advanced gas associated with it, then the advanced gas was combined with the available produced gas of that well or group. The advanced gas and the available produced gas were treated as one item in the mixture; note that the advanced gas was **not** used before the produced gas in this case, regardless of the setting of [item 30](#) in OPTIONS3 item 30. From 2008.1 this behavior was altered so that advanced gas is injected before the mixture gas in the same manner as other reinjection sources. The pre-2008.1 behavior may be recovered using [item 139](#) of OPTIONS3.
- If a stream is present as an item in the mixture, this effectively has an infinite supply and thus the availability of the mixture is infinite. The well injection fraction table (if present) will show values that do not sum to unity; the difference is accounted for by the stream item in the mixture. Note that the composition of the mixture is independent of the injection rate, and that the availability of individual GV or WV items also present in the mixture are not honored, which could therefore over inject and show a negative excess in the gas accounting tables. This situation is handled better using WINJORD instead.
- For accurate group gas accounting, there is a limitation that reinjection control and any sales gas or fuel gas requirements must all be specified for the same group, usually the FIELD group, and not split across the group hierarchy. This limitation only applies if the injection mixture contains a group vapor item, with the vapor taken from a separator stage (that is not from the whole separator).

## Example

```

## WINJMULT

## Pressure-dependent injectivity multipliers

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword may be used to provide multipliers to the injectivity index of injection wells that vary with the wells' BHP or the pressure in the wellbore adjacent to the individual connections. The injectivity multipliers could be used to take approximate account of hydraulic fracturing at water injection wells.

Each time the well flows are calculated, the fluid mobility at each connection in the well is multiplied by a factor:

$$1.0 + a(P_w - P_f) \text{ when } P_w > P_f \text{ or} \quad \text{Eq. 3.232}$$

$$1.0 \text{ when } P_w < P_f \quad \text{Eq. 3.233}$$

where

$a$  is the multiplier gradient set in item 3

$P_w$  is the instantaneous value of the well's bottom hole pressure or the wellbore pressure adjacent to the individual connections (see item 4)

$P_f$  is the fracturing pressure set in item 2.

The injectivity multipliers may be either reversible or irreversible, depending on the setting of item 4. If the irreversible option is selected, the multipliers do not decrease if the well pressure subsequently decreases.

The multipliers act on the fluid mobilities and thus increase the injectivity index of the well. The reported values of the connection transmissibility factor remain unaltered.

The multipliers are only applied to injection wells. If any production wells are specified here, their productivity index is not altered.

Wells with pressure-dependent injectivity multipliers cannot also have a D-factor (flow-dependent skin). Also, do not set their injectivity index using keyword [WELPI](#), because this calculation is based on the original fluid mobilities at each connection in the well. The well's PI would only be correctly set to the user supplied value if fracturing had yet to occur.

## ECLIPSE 300

This keyword has not been implemented within the Multisegment Well Model.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Fracturing pressure ( $P_f$ )

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

This can be defaulted only when item 3 is defaulted.

3. Multiplier gradient ( $a$ )

UNITS: 1/bars (METRIC), 1/psi (FIELD), 1/atm (LAB), 1/atm (PVT-M)

DEFAULT: 0.0

#### 4. Mode of operation

**WREV** All connections in the well have the same injectivity multiplier, which is determined by the well's BHP. items 5 - 7 are ignored. The increase in injectivity is reversed if the BHP subsequently declines.

**CREV** The injectivity multiplier applies to the set of connections defined by items 5 - 7, and is determined by the wellbore pressure adjacent to each connection. The increase in injectivity is reversed for **all** connections in the well if the wellbore pressure subsequently declines.

**CIRR** The injectivity multiplier applies to the set of connections defined by items 5 - 7, and is determined by the wellbore pressure adjacent to each connection. The increase in injectivity is **irreversible** for **all** connections in the well; each connection continues using its maximum attained injectivity multiplier if the wellbore pressure declines.

DEFAULT: WREV

#### 5. I - location of connecting grid block(s)

DEFAULT: Negative (allows any I-location)

#### 6. J - location of connecting grid block(s)

DEFAULT: Negative (allows any J-location)

#### 7. K - location of connecting grid block(s)

DEFAULT: Negative (allows any K-location)

If items 5 - 7 are all defaulted, or item 4 set to WREV, the injectivity multiplier will be applied to all connections in the well.

If any of items 5 - 7 are set positive, and item 4 is **not** set to WREV, the injectivity multiplier applies only to a subset of the connections in the well. The connections in the subset are those with I,J,K locations matching the specified location indices in items 5 - 7. A zero or negative value for a location index (I, J or K) matches any value of that location index.

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

## Example

Injection wells IW1 and IW2 use the default WREV mode, in that all their connections have the same injectivity multiplier, which depends on the well's BHP and is reversible if the BHP declines. For injection well IW3, the connections in layers 3 and 4 have their own separate injectivity multiplier parameters and the increase in injectivity index in this well is irreversible.

```

WINJMULT
IW1 5000 0.0052 /
IW2 4800 0.013 /
IW3 4600 0.0045 CIRR 0 0 3 /
IW3 4700 0.0042 CIRR 0 0 4 /
/

```

## WINJOIL

## Specify the nature of injection oil

## WINJORD

## Specifies an injection mixture by order

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

WINJORD specifies a number of fluid sources to be used to define an injection stream. It specifies an ordering of the fluids. These are taken in the specified order subject to their availability.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/). Each record defines a single fluid in the mixture.

The records can be terminated early with a slash, the remaining items taking default values. Defaults can also be specified by a null repeat count of the form  $n^*$ , where  $n$  is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. The name of the mixture.

The maximum number of mixtures is set in [WELLDIMS](#) item 7 and is defaulted to 5.

2. The mixture contribution index of the fluid defined below.

The maximum number of mixture fluids is set in [WELLDIMS](#) item 9 and is defaulted to 3. The contribution index must be an integer between 1 and this number.

The fluids will be taken in increasing order of their contribution index, from 1 to  $n$ .

3. The nature of this fluid.

The fluid type must be one of the following:

**GAS** The composition of the fluid is set to that of the field separator gas. However, it is generally better to specify the injected gas composition more precisely.

From 2007.1, **GAS** is internally converted to **GV** (for the field separator) which has better reinjection and gas accounting behavior. [item 113](#) of [OPTIONS3](#) can be used to recover the pre-2007.1 behavior.

**STREAM** The molar composition of the fluid has been defined using the [WELLSTRE](#) keyword. The name of the stream must be entered in item 4.

**GV** The fluid is to be taken from the vapor production of a nominated group. The name of the group must be entered in item 4.

**WV** The fluid is to be taken from the vapor production of a nominated well. The name of the well must be entered in item 4.

Only the first two characters are significant.

4. A character string is required if the fluid was specified as **STREAM**, **WV** or **GV**.

In these cases this item specifies the name of the wellstream, well or group that defines the fluid's composition.

5. The stage of the separator that defines the fluid composition.

The vapor from any stage of the separator may act as a source of injection fluid. The default value of 0 results in the use of the vapor from the whole separator as the injection fluid.

Note that the choice of separator stage also affects the available produced gas supply rate from the source group or well (item 4) if the source is **GV** or **WV** (item 3).

DEFAULT: 0

## Notes

- If a mixture contains a well or group vapor item and this well or group has advanced gas associated with it, then the advanced gas is combined with the available produced gas of that well or group. The advanced gas and the available produced gas are treated as one item in the mixture. Note that the advanced gas is **not** used before the produced gas in this case, regardless of the setting [item 30](#) in `OPTIONS3` keyword.
- If a stream is present as an item in the mixture, this effectively has an infinite supply and thus the availability of the mixture is infinite. The well injection fraction table (if present) shows values that do not sum to unity; the difference is accounted for by the stream item in the mixture. Note that, because of the infinite availability of a stream, no item entered after a stream is used.
- The composition of the injected gas in general varies with the injection rate, and thus the injection calculation may have to be iterated to match the injection gas composition with the injection rate (see keyword `GCONTROL`).
- For accurate group gas accounting, there is a limitation that reinjection control and any sales gas or fuel gas requirements must all be specified for the same group, usually the `FIELD` group, and not split across the group hierarchy. This limitation only applies if the injection mixture contains a group vapor item, with the vapor taken from a separator stage (that is not from the whole separator).

## Example

## WINJTEMP The nature of injection fluid

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can only be used with the [THERMAL](#) option or the [TEMP](#) option.

WINJTEMP specifies the nature of the water, gas or steam gas to be injected by a well. The well control must have already been defined using the [WCONINJE](#) keyword. The pair of keywords [WCONINJE](#) and [WINJTEMP](#) are an alternative to using the [WELLINJE](#) keyword.

In thermal simulations, where an energy equation is solved, the specific enthalpy of the injected fluid must be specified. This can be done directly, by specifying the enthalpy at a given pressure (using items 4 and 5). This is not straightforward since the fluid enthalpy is not easy for the user to calculate. Alternative data can therefore be specified, allowing the simulator to calculate the enthalpy. This can be done by specifying the temperature at a given pressure (using items 3 and 4). However, if a mixture of water and steam is being injected (that is the pressure is the water saturation pressure) then the pressure and temperature do not specify the enthalpy uniquely. This is because different proportions of steam and water can exist at the saturation pressure and temperature. In this case the steam quality should be specified, as well as either the temperature (items 2 and 3) or the pressure (items 2 and 4). For further information regarding the calculation of the enthalpy of the injected fluid see "[Water, steam and gas injection](#)" and "[Energies and enthalpies](#)" in the *ECLIPSE Technical Description*.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated by a slash(/).

The records can be terminated early using the slash (/) character, the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. Well name, well name template, well list or well list template.

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

This item is always required and the wells referenced must have already been defined by this point in the [SCHEDULE](#) section.

*Thermal only*

2. The steam quality of the injected fluid. This quantity can be a user defined argument (UDA), and can be set with keywords [UDQ](#) and [UDADIMS](#).

If specified, the steam quality must be between 0 and 1. Also, either the temperature or the pressure must be specified, but not the specific enthalpy rate.

For water injectors or 100% gas injectors, the steam quality should not be used. For these injectors, specify the pressure and temperature (or pressure and enthalpy) instead.

3. The temperature of the injected fluid. This quantity can be a user defined argument (UDA), and can be set with keywords [UDQ](#) and [UDADIMS](#).

*Thermal only*

This quantity is used to define the specific enthalpy of the injected fluid. The actual temperature of the fluid at a particular point along the wellbore will depend on the pressure at that point. If the pressure in the wellbore changes over time, the temperature will therefore also change over time. See "[Temperature at the bottom hole pressure](#)" in the *ECLIPSE Technical Description* for further information.

If specified, either the steam quality or the pressure must also be specified, but not the specific enthalpy rate.

UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)

4. The pressure of the injected fluid. This quantity can be a user defined argument (UDA), and can be set with keywords UDQ and UDADIMS.

If specified, then one of steam quality, temperature, or specific enthalpy rate must also be specified.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

*Thermal only*

5. The specific enthalpy of the injected fluid. This quantity can be a user defined argument (UDA), and can be set with keywords UDQ and UDADIMS.

If specified, the pressure must also be specified. If specified, neither the steam quality nor the temperature may be specified.

UNITS: kJ/kg-M (METRIC), Btu/lb-M (FIELD), J/gm-M (LAB), kJ/kg-M (PVT-M)

---

**Note:** For 2012.1, the enthalpy calculation was improved. To revert this new calculation to pre-2012.1 behavior, set [item 276](#) in OPTIONS3 to 1.

---

## Example

```

WINJTEMP
--      SQ   T(C) P(BAR)
WELL1 0.7   200   1* / STEAM-WATER
WELL2 0.7   1*    15 / STEAM-WATER
WELL3 1*    20    15 / WATER
WELL4 1*    250   15 / STEAM
/

```

## Specify the nature of injection water

This keyword specifies the nature of the water to be injected by a water injection well, and is activated within the multi-component water model and options [CO2STORE](#), [GASWAT](#) and [GASSOL](#).

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash, the remaining items taking default values. Defaults can also be specified by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. A character string specifying the nature of the fluid to be injected.

**STREAM** The molar composition of the injected fluid is defined using the [WELLSTRW](#) keyword. The name of the stream must be entered in item 3.

DEFAULT: STREAM

Only the first two characters are significant.

3. A character string is required specifying the name of the well stream that defines the injection stream.

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

See "[Water components](#)" in the *ECLIPSE Technical Description* for further details of the water component option.

### Example

```
WINJW
'I*' STREAM Brine/
/
```

## WINJWAT

### The nature of injection water

This keyword can only be used with the THERMAL option (keyword [THERMAL](#) in the RUNSPEC section).

WINJWAT is an alias for [WINJTEMP](#).

## WLIFT

## Automatic retubing and THP or lift switching data

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword supplies data for the automatic retubing and THP or lift switching option. If a well's production rate falls below the value set in item 2, or if its water cut exceeds the value set in item 7, or if its gas-liquid ratio exceeds the value set in item 9, or if the well dies under THP control, then one of three operations is performed:

- If a THP value has been set in item 8, the well switches to this new THP limit in decrements defined by item 11. This can be regarded as switching the well into a lower pressure separator to increase its productivity. Obviously, to have the desired effect, the new THP limit must be lower than the well's original THP limit. If a decrement is set in item 11 the THP switching is performed in stages; each time THP switching is triggered the THP is reduced by the specified decrement, until the final THP value set in item 8 is reached.
- If a VFP table number has been set in item 4, the well switches to this table. This can be regarded as a retubing operation, if the new table has been calculated with a different tubing diameter from the original table.
- If an artificial lift quantity has been set in item 5, the well uses this new lift quantity to interpolate the VFP table. The new ALQ will be reached in increments defined in item 10. This can be regarded as switching on (or uprating) artificial lift in the well. If an increment is set in item 10 the lift switching is performed in stages; each time lift switching is triggered the ALQ will be increased by the specified increment, until the final ALQ value set in item 5 is reached. If an efficiency factor has been set in item 6, the well uses this new value in place of its original value when the lift switching (or its first increment) has taken place, to allow for an increase in downtime resulting from the lift system. The switching of artificial lift can be made subject to constraints on the number of wells using lift, and the sum of their ALQs, by using the keyword [GLIFTLIM](#). (Alternatively, the new ALQ value in item 5 could be lower than the well's original value, as long as it is still above 0.0, if artificial lift is to be reduced when the well's formation GLR increases beyond the limit set in item 9.)
- If positive values are specified for two or more of items 8, 4 and 5, a multistage process will result. A switching operation is performed each time the well's production rate, water cut or GLR violates a limit set in item 2, 7 or 9. The operations are performed in the following order:
  - Switch to the lower THP limit (for example change to a lower pressure separator)
  - Switch to the second VFP table (for example perform a retubing operation)
  - Switch to the new artificial lift quantity (for example turn on lift).

---

**Note:** The order of the above actions can be overridden if the [PRORDER](#) keyword is used. By setting item 2 in record 2 of keyword [PRORDER](#) to 'YES', the order given above is replaced by the order given in the first record of [PRORDER](#).

---

The switching operations are performed at the end of the timestep in which the minimum rate or maximum water cut or GLR limit is violated. But if a limit tolerance fraction has been set with keyword [WLIMTOL](#), the timestep is recalculated if the limit is violated by more than this fraction.

The [WLIFT](#) keyword may also be used to enter secondary values of the THP, the VFP table number and the ALQ to be activated by the group production rules (see actions [THP](#), [RETUBE](#) and [LIFT](#) in the [PRORDER](#) keyword, and "[Group production rules](#)" in the *ECLIPSE Technical Description*). Switching is performed when required to keep the well's group (or a superior group) producing at its target rate set in keyword [GCONPROD](#). THP or lift switching is performed in stages if increments are set in items 11 or 10. The order in which the different switching operations occur in these circumstances depends upon the order

in which the actions are listed in the PRORDER keyword. If you wish the switching process to be activated only by the Group Production Rules or if the well dies under THP control, and not by the rate, water cut or GLR of the well itself, then you must default the rate, water cut and GLR limits in items 2, 7 and 9 of this keyword.

The WLIFT keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The records may be terminated at any item after item 1. The remaining items assume their default values. Default values can be specified before the slash by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Well production rate below which the switching operations are triggered

A zero or negative value implies that the switching operations are not triggered by a low well production rate. Default this item if you require the switching operations to be triggered only by the group production rules (keyword PRORDER) or if the well dies under THP control.

UNITS: sm<sup>3</sup>/day (METRIC), stb/day for OIL or LIQUID, or Mscf/day for GAS (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: 0.0

3. Phase to which the production rate limit in item 2 refers

OIL, LIQUID, or GAS

(The word may be abbreviated; only the first character is significant)

DEFAULT: OIL

4. New VFP table number for retubing

When retubing is performed this will replace the table number previously specified with keyword [WCONPROD](#).

DEFAULT: 0

No retubing operation is performed if a default, zero or negative value is entered.

5. New artificial lift quantity for lift switching

When lift switching is performed this replaces the artificial lift quantity previously specified with keyword [WCONPROD](#) or [WELTARG](#). The lift switching is performed in stages if an incremental value is set in item 10.

UNITS: These depend on what the ALQ was meant to represent when the table was created. Refer to section "[Record 6:ALQ values](#)" in the description of keyword [VFPPROD](#).

DEFAULT: 0.0

No lift switching operation is performed if a default, zero or negative value is entered.

## 6. New well efficiency factor after lift switching

When lift switching is performed this will replace the efficiency factor previously specified with keyword `WEFAC`, for example to account for any increase in downtime resulting from the lift system. If lift switching is performed in stages, the new efficiency factor takes effect when the first ALQ increment is applied.

DEFAULT: 0.0

A zero or negative value leaves the original efficiency factor unchanged.

## 7. Well water cut value above which the switching operations are triggered

A zero or negative value implies that the switching operations are not triggered by a high well water cut. Default this item if you require the switching operations to be triggered only by the group production rules (keyword `PRORDER`) or if the well dies under THP control.

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), stb/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: 0.0

## 8. New THP limit

When THP switching is performed, this replaces the THP limit previously specified with keyword `WCONPROD` or `WELTARG`. The THP switching is performed in stages if an incremental value is set in item 11.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: 0.0

No THP switching operation is performed if a default or zero value is entered.

---

**Note:** Switching to a lower THP limit has no effect if the well's group is part of a network (see "[Network option](#)" in the *ECLIPSE Technical Description*), as the wells' THP limits are set by their group's nodal pressure in the network.

---

## 9. Well gas-liquid ratio value above which the switching operations are triggered

A zero or negative value implies that the switching operations are not triggered by a high GLR. Default this item if you require the switching operations to be triggered only by the group production rules (keyword `PRORDER`) or if the well dies under THP control.

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), Mscf/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: 0.0

## 10. Increment to be added to (or subtracted from) the well's ALQ value at each lift switching event

Each time lift switching is triggered for the well, its ALQ is changed by the specified increment, until the final ALQ value set in item 5 is reached.

UNITS: These depend on what the ALQ was meant to represent when the table was created. Refer to section "[Record 6:ALQ values](#)" in the description of keyword `VFPPROD`.

DEFAULT: 1.0E20 (infinity, that is ECLIPSE will switch to the secondary value in item 5 in a single operation.)

## 11. Decrement to be subtracted from the well's THP value at each THP switching event (entered as a positive number)

Each time THP switching is triggered for the well, its THP is decreased by subtracting the specified decrement, until the final THP value set in item 8 is reached.

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

DEFAULT: 1.0E20 (infinity, that is ECLIPSE will switch to the secondary value in item 8 in a single operation.)

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

Switching operations will not be performed on a well whose rate target is currently cut back under prioritization, to prevent these happening prematurely while the well is temporarily flowing with a small rate target.

See also keywords [GLIFTLIM](#), [WLIMTOL](#) and [PRORDER](#).

## Example

Well PROD1 is given an artificial lift quantity of 5.0 and an efficiency factor of 0.8 when its water cut first exceeds 0.5.

Well PROD2 has its VFP table number changed to 3 the first time its liquid production rate falls below 500, and on the second time it is given artificial lift as PROD1.

Well PROD3 has its THP limit reduced to 60, in steps of 20, whenever its liquid production rate falls below 500. When the THP limit has been reduced to 60, its VFP table number is changed to 4 the next time its liquid rate falls below 500.

```

WLIFT
--well  min  flow  new VFP  new  new      max  new  max  ALQ  THP
--name  flow  phase  tab no   ALQ  efffac  WCT  THP  GLR  incr  decr
  PROD1 1*   1*    0    5.0  0.8    0.5  /
  PROD2 500  LIQ    3    5.0  0.8    /
  PROD3 500  LIQ    4    1*   1*    1*  60  1*  1*  20/
/

```

## WLIFTOPT Gas lift optimization data for wells

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The WLIFTOPT keyword must be used to tell ECLIPSE which wells should have their lift gas injection rates calculated by the optimization facility; and to set their maximum and minimum lift gas injection rates and weighting factors. The LIFTOPT keyword must be entered before WLIFTOPT, to activate the Gas Lift Optimization facility.

See "Gas lift optimization" in the *ECLIPSE Technical Description* for further details.

The keyword is followed by any number of records, each containing between two and seven items of data and terminated with a slash (/). The set of records must end with a blank record, containing only a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "Well name and well list template matching" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword `WLIST`.

2. Is the well's lift gas injection rate to be calculated by the optimization facility?

YES The well's lift gas injection rate is calculated by the optimization facility.

NO The well's lift gas injection rate remains fixed at a value that can be set either in item 3 of this keyword, or in item 12 of keyword `WCONPROD`, or with keyword `WELTARG`.

3. Maximum rate of lift gas injection for the well

To prevent extrapolation of the VFP tables, any value entered here must not exceed the largest ALQ value in the well's VFP table.

If item 2 is NO, then item 3 is regarded as the fixed lift gas injection rate for the well. If item 3 is defaulted, the lift gas rate remains unchanged at its current value.

UNITS: sm<sup>3</sup>/day (METRIC), Mscf/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: The largest ALQ value in the well's VFP table (if item 2 is YES).  
Remain unchanged (if item 2 is NO).

4. Weighting factor for preferential allocation of lift gas  $\alpha_w$

Each increment of lift gas supply is allocated to the well that currently has the largest weighted incremental gradient which is calculated according to the formula  $\alpha_w \cdot \Delta Q_o / (\Delta Q_{gli} + \alpha_g \cdot \Delta Q_g)$  where  $\alpha_w$  is the weighting factor for the preferential allocation of lift gas,  $\Delta Q_o$  and  $\Delta Q_g$  are the increments in oil and gas rate respectively for a gas lift increment of  $\Delta Q_{gli}$  and  $\alpha_g$  is the incremental gas rate weighting factor defined by item 6 below. Further lift gas increments are not allocated to the well if its weighted incremental gradient is less than the minimum economic gradient set in item 2 of keyword `LIFTOPT`.

This item is ignored if item 2 is NO.

DEFAULT: 1.0

5. Minimum rate of lift gas injection for the well

If a positive value is specified, the well is allocated at least that amount of lift gas, unless the well is unable to flow with that rate of lift gas injection, or unless the well can already meet one of its own rate limits before receiving its minimum lift gas rate.

If a negative value is specified, the well is allocated at least enough lift gas to enable it to flow, provided that it can flow at a lift gas injection rate within the maximum set in item 3. The magnitude of the negative value is not important.

If there is not enough lift gas available to satisfy all the wells' minimum requirements, the wells are allocated their minimum requirements in decreasing order of their weighting factor (item 4).

If the well belongs to a group (including the FIELD) having a production rate target that can be achieved without any gas lift, by default no lift gas is allocated to the well, regardless of any minimum requirement. However, if the well is given a weighting factor greater than 1.0 (item 4), the well receives its minimum lift gas requirement even if the group could achieve its production rate target without any gas lift, unless the well can flow at one of its own rate limits without its full minimum amount of lift gas.

This item will be ignored if item 2 is NO.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC), Mscf/day (FIELD), scc/hr (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

DEFAULT: 0.0

6. Incremental gas rate weighting factor  $\alpha_g$

The incremental gradient is calculated according to the formula  $\alpha_w \cdot \Delta Q_o / (\Delta Q_{gli} + \alpha_g \cdot \Delta Q_g)$  where  $\alpha_w$  is the weighting factor for the preferential allocation of lift gas defined by item 4 above,  $\Delta Q_o$  and  $\Delta Q_g$  are the increments in oil and gas rate respectively for a gas lift increment of  $\Delta Q_{gli}$  and  $\alpha_g$  is the incremental gas rate weighting factor. If this value is greater than zero, the incremental gas rate will influence the calculation of the incremental gradient and may be used to discourage the allocation of lift gas to wells which produce more gas.

This item is ignored if item 2 is NO.

DEFAULT: 0.0

7. Allocate additional lift gas when a group gas target has been achieved but the oil rate limit has not been reached?

By default, unless an overriding minimum lift gas has been defined in item 5 above, during the gas lift optimization process a well which would potentially cause a group gas target to be exceeded, if allocated further lift gas, will be constrained from receiving more lift gas.

If this item is defined to be YES this constraint is removed for a group which is on gas target control and subject to an oil rate limit. This provides a mechanism for continuing gas lift optimization to increase the oil rate, up to the oil rate limit, after a group gas rate target has been achieved. Following the completion of the gas lift optimization calculations, however, any potential improvement in the oil rate of an individual well which has been achieved in this manner may be lost at the expense of additional lift gas if the well production is reduced subsequently to comply with the group constraints.

This item is ignored if item 2 is NO.

YES The well can receive further lift gas.

NO The well cannot receive further lift gas.

DEFAULT: NO

End the data record with a slash (/).

End the set of records with a blank record containing just a slash (/).

## Example

```
.....  
WLIFTOPT  
-- well      optimize    max lift    weighting  min lift  
-- name      gas lift?    gas rate   factor      gas rate  
--           SM3/DAY    SM3/DAY  
  'PA*'      YES  
  'PB*'      YES          1*          1.01       -1.0       / keep these flowing  
  PC1        NO          0.0  
  PC2        NO          5E4                          / no gas lift  
  /                          / fixed gas lift  
.....
```

## WLIMTOL

## Tolerance fraction for economic and other limits

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword should be followed by a single real number that represents the tolerance fraction, terminated with a slash (/).

The tolerance fraction applies to the following limits:

- Connection, well, group and field economic limits (see keywords [CECON](#), [WECON](#), [GECON](#) and [WECONINJ](#)),
- Group/field maximum rate limits resulting in well workovers or closures (see keyword [GCONPROD](#) and [GCONPRI](#)),
- Well and group cutback limits (see keywords [WCUTBACK](#) and [GCUTBACK](#)).

ECLIPSE 100:

- Automatic retubing and lift switching limits (see keyword [WLIFT](#)),
- Maximum THP design limits (see keyword [WTHPMAX](#)),
- Bottom hole GLR limits (see keyword [WBHGLR](#)).

ECLIPSE 100

**Note:** In particular this keyword does not apply to the keywords [CECONT](#), [WECONT](#), [GECONT](#), [WCUTBACT](#) and [GCUTBACT](#) which always repeat the timestep.

If one of these limits is violated during a timestep, the remedial action is taken at the end of the timestep. Thus the limit is broken for one timestep before the action is taken. However, if the limit is broken by more than the tolerance fraction multiplied by the limiting value, the timestep is recalculated after the remedial action has been taken. In this case, the action takes effect from the beginning of the timestep during which the limit would otherwise have been violated.

Note, however, that the timestep is repeated only once; if a limit is still violated at the end of the repeated timestep another remedial action is taken but the timestep is not repeated again.

If the keyword is not used, the tolerance fraction is set to infinity (1.0E20), and the timestep is not recalculated for any limit violation.

ECLIPSE 100

See also keyword [GCONTOL](#), regarding the tolerance applied to group control targets.

### Example

```
WLIMTOL
0.2 /
```

## WLIST

## Sets up lists of well names, for use in other well keywords

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword WLIST may be used to construct and maintain well lists, which are lists of well names. Well lists whose names begin with an asterisk (\*) may be entered wherever a well name root can be entered in the SCHEDULE section well keywords, as an alternative method of specifying several wells at once.

Each list should have a unique name, consisting of up to eight characters. The first character must be an asterisk and the second character must be a letter. Each list may contain any number of well names. Up to 50 well names may be added to a list in a single data record. Lists containing more than 50 well names may be constructed by appending well names to the list in subsequent data records. Wells may be added to, deleted from or moved between lists at any time in the simulation. A well may belong to more than one list at a time, up to a maximum as set in item 11 of WELLDIMS.

In ECLIPSE 100, well lists are also used by keyword WLISTARG to set individual operating targets or limits for several wells in a single data record. The WLIST keyword supersedes the old WLISTNAM keyword, which is retained for back compatibility. WLISTNAM must still be used to operate on old-style list names (beginning with a letter), but these lists are not recognized in any keyword other than WLISTARG.

Well lists may be used in the ACTIONX keyword to define a grouping of wells, whose combined rates, totals or ratios can form part of a triggering condition in this keyword.

Combined rates, totals and ratios for all the wells in a well list may also be written to the summary file using an appropriate group summary mnemonic followed by the well list name (see Table 2.28).

ECLIPSE 300

---

**Note:** Well list totals are the cumulative total of wells currently on the list. If a well is removed from the list then its contribution the total will also be removed. Similarly, if a well is added to the list then the full well total will be included, not the total from the time at which the well was added.

---

The WLIST keyword should be followed by any number of data records, terminating with a blank record containing just a slash (/). Each data record consists of the following items, and is terminated with a slash. The data items are:

1. The well list name.

This should consist of up to 8 characters, enclosed in quotes. The first character of the list name must be an asterisk and the second character must be a letter.

2. The operation.

This must be one of:

**NEW** Starts a fresh list having the specified name. If a list with that name already exists, all well names are first removed from it. The following well names are then placed on the list.

**ADD** Appends the following well names to the list.

**MOV** Moves the following wells from whatever list they are currently a member of to the list named in item 1, appending them to the end of this list.

**DEL** Removes the following well names from the list named in item 1.

- 3- 52 A list of up to 50 well names.

The wells must previously have been declared with the WELSPECS keyword.

Well name roots (enclosed in quotes and ending with an asterisk) may also be used here. When a well name root is encountered, all currently declared wells whose names match the name root will be processed. The wells are added to the list in the order in which they were first declared in the simulation.

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

## Example

This example first creates a fresh well list \*LIST1 containing 8 wells, opens these wells, adds 3 more wells (already open) to the list, then resets their oil rate target/limit. In addition, 4 wells are moved to \*LIST2 and are shut.

```

.....
WLIST
-- List      Oper      Well

## WLISTARG Resets operating targets/limits for a list of wells

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to reset a control or constraint value for a list of wells that has previously been set up with the keyword [WLIST](#) (or [WLISTNAM](#)). The operation of the [WLISTARG](#) keyword is similar to [WELTARG](#), except that several wells can have their targets or limits reset to different values in a single data record. This allows the data to be presented in a more compact form than the alternative keyword [WELTARG](#), which requires a separate line of data for each separate value. The facility is useful when simulating production history, where the target rates of all the wells have to be reset regularly.

Before [WLISTARG](#) can be used on a list of wells, the control data of each well must initially have been fully specified using [WCONPROD](#) or [WCONINJE](#). If a well has been declared a history matching well (see keywords [WCONHIST](#) and [WCONINJH](#)) the [WLISTARG](#) keyword may be used to modify its BHP limit, VFP table number, and artificial lift quantity; the other quantities should **not** be modified with this keyword.

The [WLISTARG](#) keyword is followed by any number of data records, each containing the following items of data, and each terminated with a slash (/). The set of records must end with a blank record, containing only a slash.

1. The well list name (enclosed in quotes)

The well list must previously have been set up with the keyword [WLIST](#) (or [WLISTNAM](#)).

2. Definition of the control or constraint quantity to be changed

ORAT Oil rate

WRAT Water rate

GRAT Gas rate

LRAT Liquid rate

CRAT Linearly combined rate (coefficients must be set with [LINCOM](#))

RESV Reservoir fluid volume rate

BHP Bottom hole pressure

THP Tubing head pressure (A non-zero VFP table number must first have been set)

VFP VFP table number

LIFT Artificial lift quantity (A non-zero VFP table number must first have been set)

GUID Guide rate (For group controlled wells)

*ECLIPSE 300 only*

WGRA Wet gas rate

*ECLIPSE 300 only*

CVAL Calorific production rate

*ECLIPSE 300 only*

REIN ReInjection fraction

*ECLIPSE 300 only*

STRA Steam rate (Available only with the Thermal option)

*ECLIPSE 300 only*      SATP Saturation pressure offset (Available only with the Thermal option)

*ECLIPSE 300 only*      SATT Saturation temperature offset (Available only with the Thermal option)

3. 4,... New value of this quantity, for each well in the well list

The first value applies to the first well in the list, the second value applies to the second well in the list, and so on.

UNITS: The units depend upon the quantity chosen. The appropriate units are listed in the specification for keywords [WCONPROD](#) and [WCONINJE](#).

DEFAULT: If the quantity in item 2 is VFP, LIFT or GUID, then the values here may not be defaulted. For all other quantities, a defaulted value here will result in ECLIPSE using the corresponding flowing value for the well at the end of the previous timestep as the target or limit for the control or constraint in item 2.

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

## Example

This example resets the oil rate target for the 8 wells on the list \* PRLST1, and resets the water rate target for the 4 wells on the list \* INLST1.

```

WLISTARG
-- List      Control  Value for
-- Name      Quantity  each well.....
 '*PRLST1'  ORAT      1500 2110 1930 1320 1670 1460 1290 1830 /
 '*INLST1'  WRAT      3240 2970 2850 2740 /
/

```

## WLISTDYN Sets up a dynamic lists of well names

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword **WLISTDYN** may be used set up a dynamic well list. This list differs from a static, user-defined well list (see keyword **WLIST**) in that membership of the list is automatically reset at the end of each timestep. The membership is determined by a condition on a well type quantity. For example, the list might be made up of all the wells in a particular group that have a water cut greater than 0.7. Membership may also be defined as, for example, the 3 wells with the highest water cut belonging to a particular group.

Well lists whose names begin with an asterisk (\*) may be entered wherever a well name root can be entered in the **SCHEDULE** section well keywords. Well lists may also be used in the **ACTIONX** keyword to define a grouping of wells, whose combined rates, totals or ratios can form part of a triggering condition in this keyword. Combined rates, totals and ratios for all the wells in a well list may also be written to the summary file using an appropriate group summary mnemonic followed by the well list name (see "[Well and group flow quantities](#)").

The maximum number of dynamic well lists in a simulation is limited by item 12 of the **WELLDIMS** keyword. A well may belong to more than one list at a time, up to a maximum number as set in item 11 of **WELLDIMS**.

The **WLISTDYN** keyword should be followed by any number of data records, terminating with a blank record containing just a slash (/). Each data record consists of the following items, and is terminated with a slash. The data items are:

1. The well list name. This should consist of up to 8 characters, enclosed in quotes. The first character of the list name must be an asterisk and the second character must be a letter.
2. Group name or group name root

A group name root, enclosed in quotes and ending with an asterisk (\*), can be used to refer to several groups in one record.

All the wells that belong to this group (or these groups) will be considered for membership of this dynamic well list. Note that wells which can be hierarchically traced to this group through intermediate groups will not be considered for membership of the dynamic well list.

3. Well mnemonic. This is the defining quantity for list membership.

If the mnemonic refers to a production type quantity, then only production wells from the group defined in item 2 will be considered for membership of the list. Similarly if the mnemonic refers to an injection type quantity, only injection wells will be considered.

The mnemonic must be one of:

WOPR Well oil production rate

WOPT Well oil production total

WOIR Well oil injection rate

WOIT Well oil injection total

WWPR Well water production rate

WWPT Well water production total

WWIR Well water injection rate

WWIT Well water injection total  
WGPR Well gas production rate  
WGPT Well gas production total  
WGIR Well gas injection rate  
WGIT Well gas injection total  
WLPR Well liquid production rate  
WLPT Well liquid production total  
WVPR Well voidage production rate  
WVPT Well voidage production total  
WVIR Well voidage injection rate  
WVIT Well voidage injection total  
WGOR Well gas oil ratio  
WWCT Well water cut  
WWGR Well water gas ratio  
WBHP Well bottom hole pressure (production type quantity)  
WTHP Well tubing head pressure (production type quantity)

4. The operator for the membership condition. This must be one of:

'>' (Greater than)

'<' (Less than)

'Highest'

'Lowest'

5. The value for the membership condition.

If the operator in item 4 is greater than or less than, then the unit of this value depends upon the quantity selected in item 3.

If the operator in item 4 is highest or lowest, then this value is the number of wells selected from the top or bottom of a list ordered by the well quantity in item 3.

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

## Notes

- The automatic updating of a dynamic well list at the end of every timestep may be disabled by setting item 2 of this keyword to 'OFF' and leaving items 3 to 5 blank. The contents of this well list then become static. To reverse this action, set item 2 to 'ON' (and leave items 3 to 5 blank).
- If a dynamic well list name is entered in item 1 of a **WLIST** keyword, then it becomes a static list and is no longer updated at the end of each timestep. Its contents are effectively frozen at this point and may be altered by the operations of the **WLIST** keyword. Similarly, if a static well list name is entered in item 1 of this keyword, then the list is emptied and henceforth is defined by the membership condition in this keyword.
- The contents of all dynamic well lists are reported in the .PRT file at each report time.

## Examples

### Example 1

In this example a dynamic well list (\*HIGHGOR) is created that contains all the wells that currently have a GOR exceeding 100 Mscf/stb. The **ACTIONX** keyword checks whether the combined oil production rate of all the wells in this well list falls below 50 stb/day. (Note that the condition on there being some oil production ensures that the action is not triggered for a list of empty wells.) When this is true, all the wells in this list are shut and the dynamic well list is disabled. This action is only performed once.

```

WLISTDYN
 '*HIGHGOR' '*' WGOR > 100 /
/

ACTIONX
ACT1 1 /
GOPR '*HIGHGOR' > 0 AND /
GOPR '*HIGHGOR' < 50 /
/
WELOPEN
 '*HIGHGOR' SHUT /
/
WLISTDYN
 '*HIGHGOR' OFF /
/
ENDACTIO

```

### Example 2

In this example a dynamic well list (\*HIGHWCT) is created that contains the 3 wells from group GRP1 that currently have the highest water cut. These 3 wells then have their oil rate target reduced by 5%. The simulation is then advanced (and the dynamic well list automatically updated) and again the 3 highest water cut wells have their oil rate reduced by 5%.

```

WLISTDYN
 '*HIGHWCT' 'GRP1' 'WWCT' 'HIGHEST' 3 /
/
WTMULT
 '*HIGHWCT' ORAT 0.95 /
/
TSTEP
100.0 /
WTMULT
 '*HIGHWCT' ORAT 0.95 /
/
TSTEP
100.0 /

```

## WLISTNAM Sets up lists of well names, for use in WLISTARG

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The WLISTNAM keyword has been superseded by the [WLIST](#) keyword, which offers a better set of facilities for managing well lists. WLISTNAM is retained for back compatibility, and it must still be used to operate on any old-style list names (beginning with a letter), but these lists are **not** recognized in any keyword other than [WLISTARG](#).

The keyword may be used to construct and maintain well lists, which are lists of well names. Well lists whose names begin with an asterisk (\*) may be entered wherever a well name root can be entered in the SCHEDULE section well keywords, as an alternative method of specifying several wells at once. Well lists are also used by keyword WLISTARG to set individual operating targets or limits for several wells in a single data record.

Each list should have a unique name, consisting of up to eight characters. The first character should be an asterisk and the second character must be a letter. Alternatively, pre-2000A style list names (beginning with a letter) are allowed, but these lists are **not** recognized by any keyword other than WLISTARG. Each list may contain any number of well names. Up to 50 well names may be added to a list in a single data record. Lists containing more than 50 well names may be constructed by appending well names to the list in subsequent data records. Wells may be added to, deleted from or moved between lists at any time in the simulation. A well may belong to more than one list at a time, up to a maximum as set in item 11 of [WELLDIMS](#).

The WLISTNAM keyword should be followed by any number of data records, terminating with a blank record containing just a slash (/). Each data record consists of the following items, and is terminated with a slash. The data items are

1 The well list name.

This should consist of up to 8 characters. The first character of the list name should be an asterisk (\*) and the second character should be a letter. Alternatively, pre-2000A style list names (beginning with a letter) are allowed, but these lists are **not** recognized by any keyword other than WLISTARG.

If a well list with this name has already been declared, the well names entered in items 2 - 51 of this record are appended to the end of the list.

2 - A list of up to 50 well names.

51

The wells must previously have been declared with the [WELSPECS](#) keyword.

Well name roots (ending with an asterisk) may also be used here. When a well name root is encountered, all currently declared wells whose names match the name root are processed. Wells are added to the list in the order in which they were first declared in the simulation.

If the first well name (item 2) is a default (1\*) or a blank (' '), all wells already on the list are first deleted from it, before any more wells are added. Thus the list is started anew, beginning with the well name in item 3.

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

### Example

This example first adds 8 wells to the well list \* PRLST1. It then deletes any existing wells from the list \* INLST1 and starts it afresh with 4 wells:

```
WLISTNAM
-- List      Well
-- Name      Names.....
  '*PRLST1'  PR5  WEL63  VV6  TS53  PR22  VV12  TS7  TS19 /
  '*INLST1'  1*   IW2   IW3  IW4  IW6 /
/
```

## WMF

## Specifies cell initial total water composition explicitly

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies the initial total water composition values for each cell. The keyword should be followed by  $N_x \cdot N_y \cdot N_z \cdot N_w$  values in normal order, with the X index changing fastest.

This keyword is normally used to specify the initial solution explicitly, as an alternative to equilibration using [EQUIL](#). Explicit initialization is expected if the [PRESSURE](#) keyword is present. The syntax follows that of [XMF](#) and [YMF](#).

WMF values that do not sum to 1.0 are normalized provided the error is less than 10%. An error greater than 10% is flagged as a data error.

See "[Water components](#)" in the *ECLIPSE Technical Description* for further details of the water component option.

### Example

```
WMF
324*1.0
324*0.0
/
```

## WMFVD

## Total water composition with respect to depth tables

The data comprises a table of total composition with respect to depth data for each equilibration region. Each table consists of  $N_w + 1$  columns of data, and is terminated with a slash (/).

Column:

1. Depth values.

The values should increase monotonically down the column.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

- 2 to  $N_w + 1$  The corresponding values of  $z_i$ , the total phase mole fractions. The  $N_w$  mole fractions specified must add up to unity, and the program checks that this is the case.

For depth values outside the interval specified, constant value extrapolation is performed. If the composition is independent of depth, only a single row is required.

The default maximum number of rows per table is 50; this may be reset using the third item in keyword [EQLDIMS](#). The number of equilibration regions is entered using the first item in keyword [EQLDIMS](#).

See "[Water components](#)" in the *ECLIPSE Technical Description* for further details of the water component option.

### Example

In this case a constant composition with respect to depth for 2 equilibration regions, with 3 water components:

```

WMFVD
1000.0 1.0 0.0 0.0
2000.0 0.0 1.0 0.0 /
1000.0 1.0 0.0 0.0
2000.0 0.0 0.0 1.0 /

```

## WNETCTRL Selects well THP or rate limits to be set by network

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used when running the network option (see "[Network option](#)" in the *ECLIPSE Technical Description*), to select the well control quantity that is held constant after the network has been balanced and until the next balancing calculation. Normally this quantity is the well THP limit, which is fixed equal to its group's nodal pressure in the network (plus any fixed pressure drop specified in keyword [WNETDP](#)). By default, this will be the network control quantity for all the wells if the WNETCTRL keyword is absent.

Consider, for example, the gas flow rate selected as the control quantity. The network will be balanced as usual by setting the wells' THP limits from their group's nodal pressure. However, any wells constrained by the network (that is that are under THP control in the balanced network) will have their gas flow rate limit fixed at its current value until the next network balancing calculation, and their THP limit removed. Any gas flow rate limit set by the user will still be honored, if ever that becomes the acting constraint.

It is expected that the default control quantity of THP will be the most suitable one for most simulations. Circumstances where it may be worth considering the flow rate as a control quantity are high-permeability fields with a low drawdown at the wells, which are coupled to a network in which the pressure losses are strongly sensitive to the flow rate. This may be the case in high-permeability gas reservoirs with compressors in the network. Keeping the well THP fixed until the next balancing calculation would generate large errors in the well flow rate if the change in reservoir pressure over the timestep is a significant fraction of the drawdown.

In general, this keyword should only be used if problems arise with THP as the control quantity; for example if large network balancing errors are reported at the end of the timestep. If large network balancing errors are reported, first check the [NETBALAN](#) keyword to ensure the convergence criteria are suitable and that the network is being balanced at every timestep. If this is so, then try setting a negative balancing interval to make ECLIPSE balance the network in each of the first [NUPCOL](#) Newton iterations of the timestep. If problems persist, or if the Newton iteration convergence is badly affected, then try selecting the flow rate to be the network control quantity.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/). The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Control quantity to remain fixed after each network balancing calculation when the well is limited by the network

THP    Tubing head pressure

LRAT    Liquid rate (Production wells only)

GRAT    Gas rate

WRAT    Water rate (Water injection wells only)

DEFAULT: THP

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

## Example

```
WNETCTRL  
'PROD*' THP /  
'GINJ*' GRAT /  
/
```

## WNETDP

## Fixed pressure drops between network node and THP

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used when running the network option (see "[Network option](#)" in the *ECLIPSE Technical Description*), to apply an additional fixed pressure drop between a well's tubing head and its group's corresponding node in the network. Normally the wells' THP limits are set equal to their group's nodal pressure at each network balancing calculation. But if a fixed pressure drop is specified with this keyword for a well, the well's THP is set as follows:

- for a production well in a production network:  
well THP = group's nodal pressure + fixed pressure drop for well
- for an injection well in an injection network:  
well THP = group's nodal pressure - fixed pressure drop for well.

The keyword can also be used to isolate individual wells from the effects of the network. If the fixed pressure drop is set to a value greater than or equal to 1.0E10, the well's THP limit remains unchanged by the network balancing calculation and is not set equal to its group's nodal pressure. The well's flow, however, is still added to the network flows.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Fixed pressure drop between the well and its group's network node

A value greater than or equal to 1.0E10 causes the well's THP limit to become independent of its group's nodal pressure. It remains constant unless changed manually in, for example, keyword [WCONPROD](#).

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

DEFAULT: 0.0

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

### Example

```
WNETDP
PROD1  20.0 /
PROD2  30.0 /

## WORKLIM

## Time taken for each automatic workover

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword should be followed by a single real number that represents the time taken to do each workover, followed by a slash (/). This imposes a limit on the number of well workovers that can be performed by a single workover rig in a given timestep. The limit is equal to the timestep size divided by the time taken for each workover. In ECLIPSE 100, a workover refers to the automatic closure, plug-back or opening of a well connection resulting from instructions specified in keywords [WECON](#), [CECON](#), [GECON](#), [GCONPROD](#), [GCONPRI](#), [GCONSALE](#), [PRORDER](#) and [WORKTHP](#). In ECLIPSE 300, a workover currently refers only to the automatic closure of a well connection as a result of an economic or rate limit being broken or a [WORKTHP](#) event. Connection changes performed manually (for example using [COMPDAT](#)) are not affected.

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

When several workovers need to be performed at any one time, they are performed in the following order of priority:

1. Workovers arising when a well cannot produce at its THP limit
2. Workovers arising from connection economic limit violations
3. Workovers arising from well economic limit violations
4. Workovers arising from group economic limit violations
5. Workovers arising from group flow limit violations
6. Workovers arising from field economic limit violations
7. Workovers arising from field flow limit violations.

Within each category, workovers are performed in decreasing order of fractional violation (for example actual GOR / limiting GOR).

If this keyword is absent the workover duration is defaulted to zero, and there is no limit on the rate of doing workovers.

Wells that are being worked over may be temporarily closed by setting item 3 in the keyword [WDRILTIM](#) to 'YES'.

See also the keyword [GRUPRIG](#) which assigns workover rigs to groups.

### Example

```
WORKLIM
5.0 /
```

## WORKTHP

## Workover procedure if well dies under THP control

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword may be used to instruct ECLIPSE to perform a workover if a well is unable to produce at its THP limit, to reduce its water cut. The workover closes the connection that had the highest water cut, and optionally any connections below it, or plugs back the bottom of the perforations. The workover is performed at the end of the timestep in which the well dies, and the well is revived at the beginning of the next timestep to see if it can produce at the reduced water cut. If the well still cannot produce, workovers are performed at the end of each timestep until all the connections are closed.

If the economic limit tolerance fraction has been set less than 1.0 in keyword [WLIMTOL](#), the timestep will be repeated after the workover has been performed. If connections are lumped together into completions (see keyword [COMPLUMP](#)), the workover closes all connections in the worst-offending completion (and optionally all below). If, in ECLIPSE 100, the well has any connections in its automatic opening queue (see item 6 of keyword [COMPDAT](#)) and which meet the minimum oil saturation requirement (if imposed with keyword [WELSOMIN](#)), one of these is opened if any connection is closed during a workover. See also keywords [WORKLIM](#) and [GRUPRIG](#) for limiting the rate at which workovers can be performed.

The WORKTHP keyword is followed by any number of records, each containing the following two items of data, and each terminated with a slash (/). The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Workover procedure if the well is unable to produce at its THP limit

NONE No workover, let the well die

CON Shut connection with highest water cut

+CON Shut connection with highest water cut, and all below it (see keyword [COMPORD](#))

*ECLIPSE 100 only*

PLUG Plug back the well (see keyword [WPLUG](#))

## WPAVE

## Well block average pressure controls

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword controls the calculation of well block average pressures. These averages represent the average pressure of the grid blocks containing connections to a given well, and optionally their adjacent and diagonal neighbors also, weighted according to either the connection transmissibility factors or the grid block pore volumes. WPAVE controls the averaging method for all wells in the simulation. Alternatively, pressure averaging controls for individual wells can be specified using the [WWPAVE](#) keyword. WPAVE overwrites any current controls specified by the WWPAVE keyword.

The average pressures can be written to the Summary file using the SUMMARY section keywords WBP, WBP4, WBP5 and WBP9. Well PIs based on these average pressures can also be written to the Summary file using the SUMMARY section keywords WPI1, WPI4, WPI5 and WPI9 (see "[SUMMARY section](#)").

The averages pertain to a Cartesian grid and should not be used in a radial grid. The averages are used for reporting purposes only, and will not affect any other results.

The keyword should be followed by a line containing the following items of data, terminated by a slash (/):

1. F1, the weighting factor between the inner block and the outer ring of neighboring blocks, in the connection factor weighted average.

If the value lies between 0.0 and 1.0, the average is calculated by equation 3.236. The value 1.0 gives total weighting to the inner blocks, containing the well connections. The value 0.0 gives total weighting to the 4 or 8 blocks neighboring each inner block.

A value of  $F1 < 0.0$  is used to indicate that the pressure of the inner block and its outer ring of neighboring blocks should be averaged according to their pore volumes. The average block pressure for each connection is calculated by equation 3.237.

DEFAULT: 0.5

---

**Note:** For one-block averages (WBP) F1 is effectively 1.0, whatever the value entered here.

---

2. F2, the weighting factor between the connection factor weighted average and the pore volume weighted average, used by equation 3.234.

The value should lie between 0.0 and 1.0. The value 1.0 gives a purely connection factor weighted average, and 0.0 gives a purely pore volume weighted average.

DEFAULT: 1.0

3. Depth correction flag

This flag controls how the grid block pressures are corrected to the well's bottom hole reference depth (see item 5 in keyword [WELSPCECS](#)), or to an alternative reference depth if specified in keyword [WPAVEDEP](#), by applying a hydrostatic head between each grid block center and the well's reference depth.

WELL The hydrostatic head is calculated using the density of the fluid in the wellbore at the well connections.

RES The hydrostatic head is calculated using a representative density for the fluid in the reservoir. This density is calculated by averaging over fluid density for all the grid blocks associated with the well's connections. The average over phases is weighted by the phase saturation, and the average over grid blocks is weighted by pore volume. Whether the averaging is performed

over all grid blocks with declared connections to the well or only those with currently open connections is determined by item 4.

NONE Grid block pressures are not depth corrected.

DEFAULT: WELL

---

**Note:** The wellbore fluid density is set to zero whenever the well is shut. Thus if WELL is selected there is a discontinuity in the reported pressure average when the well's status changes between shut and open/stopped.

---

#### 4. Well connection flag

OPEN Only grid blocks associated with currently open connections are included in the averaging calculation.

ALL Grid blocks associated with all currently defined connections (whether open or closed) are included in the averaging calculation.

DEFAULT: OPEN

---

**Note:** If OPEN is selected there is a discontinuity in the reported pressure average whenever new connections are opened or existing ones are closed. This may be avoided by selecting ALL and defining all the well's connections at the start of the run (whether initially open or closed).

---

If this keyword is not present, all items assume their default values, giving a connection factor weighted average, evenly weighted between the inner blocks and the outer ring of neighbors. The depth correction uses the wellbore density and only grid blocks associated with currently open well connections are included in the average.

---

**Note:** In dual porosity runs the wells are completed in the fracture system. A WBPn average reports the average pressure in the surrounding fracture cells.

---

## Examples

### Example 1

To give a connection factor weighted average, with increased weighting to the outer blocks:

```
WPAVE
0.2 1.0 /
```

### Example 2

To give a purely pore volume weighted average over **all** the blocks containing open or closed well connections and their neighbors:

```
WPAVE
1* 0.0 1* ALL /
```

### Example 3

To give a connection factor weighted average, where the pressure for each connection is the pore volume weighted average of pressures in the connection block and its outer ring of neighbors. The grid block pressures are not depth corrected:

```
WPAVE
-1.0 1.0 NONE /
```

### Calculation of well block average pressures

The well block average pressure  $\bar{P}_w$  for a given well is a weighted combination of the connection factor weighted average pressure  $\bar{P}_{w,cf}$  and the pore volume weighted average pressure  $\bar{P}_{w,pv}$

$$\bar{P}_w = F2\bar{P}_{w,cf} + (1-F2)\bar{P}_{w,pv} \quad \text{Eq. 3.234}$$

### Connection factor weighted average

This is the average over connections of the average block pressure  $\bar{P}_k$  at each (open or declared, depending on item 4) connection  $k$ , weighted according to the connection transmissibility factors  $T_k$

$$\bar{P}_{w,cf} = \frac{\sum_k T_k \bar{P}_k}{\sum_k T_k} \quad \text{Eq. 3.235}$$

When  $F1 \geq 0$ , the average block pressure for each connection  $k$  is the weighted average of the inner block pressure  $P_{i,k}$  (that is the block containing the connection) and the average of the pressures in the 4 or 8 blocks surrounding it  $P_{o,k}$

$$\bar{P}_k = F1P_{i,k} + (1-F1)\frac{\sum_{o,k} P_{o,k}}{N_{o,k}} \quad \text{Eq. 3.236}$$

when  $F1 \geq 0$

When  $F1 < 0$ , the average block pressure for each connection  $k$  is the average of the pressures in the inner block  $P_{i,k}$  and in each of the 4 or 8 blocks surrounding it  $P_{o,k}$ , weighted according to their pore volumes  $V_{i,k}$  and  $V_{o,k}$

$$\bar{P}_k = \frac{V_{i,k}P_{i,k} + \sum_{o,k} V_{o,k}P_{o,k}}{V_{i,k} + \sum_{o,k} V_{o,k}} \quad \text{Eq. 3.237}$$

when  $F1 < 0$

The pressure in each individual grid block  $P_{i,k}$  or  $P_{o,k}$  is corrected to the well's bottom hole reference depth according to the option selected in item 3, or to an alternative reference depth if specified in keyword [WPAVEDEP](#).

The number of surrounding blocks  $N_{o,k}$  is 4 for four-block and five-block averages (WBP4, WBP5) and 8 for nine-block averages (WBP9). The configuration is shown in figure 3.18. Four- and five-block averages use the four immediate neighbors (n) of the connecting grid block. Nine-block averages use in addition the four diagonal neighbors (d). The inner block is ignored in four-block averages (WBP4). The number of neighbors is smaller if the well is situated on the edge of the grid or adjacent to an inactive cell. The

neighbors are selected in the plane perpendicular to the direction of penetration of the connection (see item 13 of keyword `COMPDAT`). Thus for horizontal wells, the neighbors are in a vertical plane.

### Pore volume weighted average

This is simply the average depth-corrected pressure  $P_j$  in the selected set of grid blocks  $j$ , weighted by their pore volumes  $V_j$

$$\bar{P}_{w, pv} = \frac{\sum_j V_j P_j}{\sum_j V_j} \quad \text{Eq. 3.238}$$

The set of grid blocks  $j$  is selected from the blocks containing (open or declared, depending on item 4) connections of the well (i), their four immediate neighbors (n), and their four diagonal neighbors (d), in a similar manner to that described above for the other averaging scheme. One-block averages (WBP) just use the inner blocks (i). Four-block averages (WBP4) just use the immediate neighbors (n). Five-block averages (WBP5) use both (i) and (n). Nine-block averages (WBP9) use (i), (n) and (d).

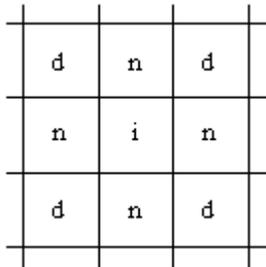

Figure 3.18. Grid block configuration in well block average pressure calculations

## WPAVEDEP Reference depth for well block average pressure calculation

x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword may be used to modify the reference depth for the calculation of well block average pressures (see keyword [WPAVE](#)) for output to the Summary file. By default, the grid block pressures are corrected to the well's bottom hole reference depth (see item 5 in keyword [WELSPECS](#)) by applying a hydrostatic head. The [WPAVEDEP](#) keyword enables the use of an alternative reference depth, which is used solely for this calculation.

The depth correction is calculated using either the fluid density in the well bore at the depth of the well connections, or the fluid density in the grid blocks associated with the well's connections, as requested in item 3 of keyword [WPAVE](#).

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. The reference depth for the calculation of well block average pressures.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: Use the well's bottom hole reference depth

End data record with a slash (/).

End the set of records with a blank record, containing just a slash (/).

## WPIMULT

## Multiplies well connection factors by a given value

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to multiply the connection transmissibility factors of selected well connections by a specified value. To multiply the transmissibility factors of **all** the connections in a well, leave items 3 - 7 defaulted. To multiply the transmissibility factors of a subset of connections in a well, you can identify the subset by their I,J,K location (items 3 - 5). A subset of connections can also be identified by their completion number (items 6 and 7). Completion numbers are set in keyword [COMPLUMP](#).

The WPIMULT keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template.

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Multiplier to act on the well's connection transmissibility factors and Kh values.

The value must be greater than 1.0E-10

DEFAULT: 1.0

3. I - location of connecting grid block(s)

DEFAULT: Negative (allows any I-location)

4. J - location of connecting grid block(s)

DEFAULT: Negative (allows any J-location)

5. K - location of connecting grid block(s)

DEFAULT: Negative (allows any K-location)

6. Number of first completion in range

DEFAULT: Negative; allows any completion number up to item 7 (if set)

7. Number of last completion in range

DEFAULT: Negative; allows any completion number from item 6 (if set)

If items 3 - 7 are all defaulted, the connection factor multiplier applies to all connections in the well.

If any of items 3 - 7 are set positive, the multiplying factor applies only to a subset of the connections in the well. The connections in the subset are those with I,J,K locations matching the specified location indices in items 3 - 5 and a completion number in the range specified by items 6 - 7. A zero or negative value for a location index (I, J or K) matches any value of that location index. Similarly a zero or negative value for a completion range lower/upper end-point indicates that there is no lower/upper bound on the completion numbers.

## Notes

- When WPIMULT is read, the connection factors of the chosen set of connections are immediately multiplied by the specified factor. If the COMPDAT keyword is subsequently used to reset any of their connection data, this causes the connection factors to be reset. If the multiplier is still required, WPIMULT must be entered again after COMPDAT.
- If WPIMULT is used more than once on the same set of well connections, without resetting the connection factors with an intermediate COMPDAT keyword, its effect is cumulative if there are intervening timestepping keywords - that is, the multiplying factor is applied to the chosen set of connections each time the keyword is entered.
- If the keyword applies to **all** the connections in a well (that is, the connection and completion items are defaulted) and it is used more than once, its effect will only be cumulative if at least one timestepping keyword falls between the WPIMULT (WPIMULTL) keyword repeats. If this is not the case and several keywords are defined for all the connections in a particular well before a timestepping keyword, only the last defined multiplier will be applied to the connection factors before the simulation is advanced.
- Keywords WELPI and WPIMULT should not both be used on the same well at the same time, that is without an intervening TIME, TSTEP or DATES keyword.

---

**Note:** This keyword can be used with OPTIONS3 (item 43) to avoid an error message being generated when a local grid well is referred to.

---

## Example

```
WPIMULT
PROD1 1.3 /(all connections in the well PROD1)
PROD2 0.82 1* 1* 5 /(all connections of well PROD2 in layer 5)
PROD3 0.6 1* 1* 1* 7 7 / (all connections of PROD3 in completion number 7)
/
```

## WPIMULTL **Multiplies well connection factors by a given value within local grids**

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to multiply the connection transmissibility factors of selected local grid well connections by a specified value. To multiply the transmissibility factors of **all** the connections in a well, leave items 3 - 8 defaulted. To multiply the transmissibility factors of a subset of connections in a well, you can identify the subset by their local grid name and I,J,K location (items 3 - 6). A subset of connections can also be identified by their completion number (items 7 and 8). Completion numbers are set in keyword [COMPLMPL](#).

WPIMULTL performs the same role as [WPIMULT](#), but the name of the local grid containing the connections specified in the record should be entered in item 3 of WPIMULTL. This keyword should be used when the well is completed in a local grid.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Multiplier to act on the well's connection transmissibility factors and Kh values

The value must be greater than 1.0E-10

DEFAULT: 1.0

3. Name of local grid containing the connections in items 4 - 6

If this item is defaulted or set to a blank string, the local grid name is set to the well's local grid named in keyword [WELSPECL](#). (In ECLIPSE 100, the local grid name should not be defaulted if the local grid is amalgamated.)

The local grid name may also be defaulted if the connection locations in items 4, 5 and 6 are all defaulted. The multiplier in item 2 then applies to all the connections in the well (or to specific completions within it if items 7 and 8 are set).

DEFAULT: ''

4. I - location of connecting grid block(s)

DEFAULT: Negative (allows any I-location)

5. J - location of connecting grid block(s)

DEFAULT: Negative (allows any J-location)

6. K - location of connecting grid block(s)

DEFAULT: Negative (allows any K-location)

7. Number of first completion in range

DEFAULT: Negative; allows any completion number up to item 8 (if set)

## 8. Number of last completion in range

DEFAULT: Negative; allows any completion number from item 7 (if set)

If items 4 - 8 are all defaulted, the connection factor multiplier is applied to all connections in the well (or all connections in the specified local grid if a local grid name is entered in item 3).

If any of items 4 - 8 are set positive, the multiplying factor applies only to a subset of the connections in the well or local grid. The connections in the subset are those with I,J,K locations matching the specified location indices in items 4 - 6 in the local grid named in item 3, and with a completion number in the range specified by items 7 - 8. A zero or negative value for a location index (I, J or K) matches any value of that location index. Similarly a zero or negative value for a completion range lower/upper end-point indicates that there is no lower/upper bound on the completion numbers.

## Notes

- When WPIMULT(L) (WPIMULTL) is read, the connection factors of the chosen set of connections are immediately multiplied by the specified factor. If the COMPDAT (COMPDATL) keyword is subsequently used to reset any of their connection data, this causes the connection factors to be reset. If the multiplier is still required, WPIMULT (WPIMULTL) must be entered again after COMPDAT(COMPDATL).
- If WPIMULT(WPIMULTL) is used more than once on the same well, without resetting the connection factors with an intermediate COMPDAT(L) keyword, its effect is cumulative - the multiplying factor is applied to the chosen set of connections each time the keyword is entered.
- If the keyword applies to **all** the connections in a well (that is, the connection and completion items are defaulted) and it is used more than once, its effect will only be cumulative if at least one timestepping keyword falls between the WPIMULT(WPIMULTL) keyword repeats. If this is not the case and several keywords are defined for all the connections in a particular well before a timestepping keyword, only the last defined multiplier will be applied to the connection factors before the simulation is advanced.
- Keywords WELPI and WPIMULT(WPIMULTL) should not both be used on the same well at the same time, without an intervening TIME, TSTEP or DATES keyword.

## Example

```

WPIMULTL
PROD1 1.3 / (all connections in the well PROD1)
PROD2 0.82 LGR2 / (all connections that the well PROD2 has in LGR 'LGR2')
PROD3 0.98 4* 5 8 / (applies to completions 5,6,7 and 8 of well PROD3)
PROD4 0.5 LGREAST 2* 3 / (all connections in layer 3 of LGR 'LGREAST')
PROD5 0.75 LGRWEST 3 19 7 / (Only applies to connection (3,19,7) of LGR 'LGRWEST')
/

```

## Assigns PI multiplier tables to wells

This keyword may be used to assign PI multiplier tables to individual wells. These tables scale the well's connection factors according to the maximum water cut it has so far achieved, and are input with the [PIMULTAB](#) keyword.

The WPITAB keyword is followed by any number of lines, each containing the following data and each terminated with a slash (/). The last line must be followed by a line containing only a slash.

1. Well name, well name template, well list or well list template.

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. PI multiplier table number.

An integer no greater than NTPIMT (see keyword [PIMTDIMS](#) in the RUNSPEC section).

A value of 0, or a negative value, will mean that no PI multiplier table will be assigned to that well.

DEFAULT: 0

See also keyword [WPIMULT](#), which may be used to multiply well PIs by a constant factor. Alternatively, keyword [WSCTAB](#) and its associated keywords may be used to modify the PI dynamically according to a scale deposition model. WPITAB and WSCTAB must not both be used on the same well.

### Example

```

WPITAB
  'P*' 2 /
  PROD2 1 /
  PROD3 0 /
/

```

## WPLUG

## Sets well plug-back lengths

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword must be used to set the plug-back lengths for all wells that may be subject to automatic plug-backs (requested in keywords [WECON](#), [GECON](#), [GCONPROD](#), [GCONPRI](#), [GCONSALE](#), [WECONT](#), [GECONT](#) and [WORKTHP](#)).

When a well is subject to an automatic plug-back a specified length of perforations is closed, starting from the top or bottom of the open connections in the well, or the top or bottom of the open connections in the worst offending completion, depending on the entry in item 4. The decision on whether to start from the top or the bottom depends on the reason for the plug-back; plug-backs to reduce the gas fraction starts from the top while those intended to reduce the water fraction will start from the bottom. A plug-back will not necessarily close an entire connection. A connection is only closed when there is no length of perforations remaining open in the grid block.

A plug-back will alter the depth of the top or bottom of the open perforations, thus affecting the ratio of fluids produced by the well. The initial top and bottom depths of the perforated length may be set in keyword [COMPVE](#), or defaulted to the center depths of the top and bottom grid block faces to give full penetration of the grid block. If item 10 in [COMPVE](#) is set to YES, the skin factor and transmissibility factor of the connection will also be recalculated after each plug-back, to reflect the reduced length of open perforations.

When plug-backs occur in runs that do **not** use the Vertical Equilibrium option, the new perforation depths are automatically converted into scaled saturation table endpoints, which are then treated as if they had been entered with the [COMPRP](#) keyword. The conversion is performed by assuming a VE-type segregation of phases within the grid block (see "[Representing the effects of partial penetration](#)"). There is a restriction on using plug-backs in non-VE runs that are fast restarts (see keyword [RESTART](#)). The required grid block geometry data is only stored on the SAVE file if the base run contained the keyword [COMPVE](#). So if you wish to use plug-backs during a subsequent fast restart, you should include keyword [COMPVE](#) in your base run, followed by just a slash if you do not need to set any partial penetration data at that time. The restriction does not apply to flexible restarts, as the required data are generated from the GRID section.

The WPLUG keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Length of perforation closed each time there is a plug-back from the top (for example for high GOR)

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

This item must be set to a value greater than zero.

3. Length of perforation closed each time there is a plug-back from the bottom (for example for high water cut)

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

This item must be set to a value greater than zero.

4. Perform plug-backs from the top/bottom of the well or the worst offending completion?

WELL Plug-backs to be performed from the top/bottom of the open connections in the well.

COMP Plug-backs to be performed from the top/bottom of the worst offending completion.  
(Connections are lumped into completions with keyword COMPLUMP.)

DEFAULT: WELL

Only the first letter is significant.

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

## Example

```
WPLUG  
'P*' 5.0 5.0 /  
PROD2 2.0 3.0 COMP /  
/
```

## WPOLYMER Sets polymer/salt concentrations for injection wells

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used to specify the concentration of polymer and salt in the injection stream of each well. If the WPOLYMER keyword does not appear in the injection schedule, then concentration values of zero are assumed. Data should only appear for wells which are currently declared to be water injection wells.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template.

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. The concentration of polymer in the injection stream for the well. This quantity can be a user defined argument (UDA), and can be set with keywords [UDQ](#) and [UDADIMS](#).

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB), kg/sm<sup>3</sup> (PVT-M)

3. The concentration of salt in the injection stream for the well. This quantity can be a user defined argument (UDA), and can be set with keywords [UDQ](#) and [UDADIMS](#).

If the salt-sensitivity option is not activated (using keyword [BRINE](#) in the RUNSPEC section), then the salt concentration entry is ignored.

UNITS: kg/sm<sup>3</sup> (METRIC), lb/stb (FIELD), gm/scc (LAB), kg/sm<sup>3</sup> (PVT-M)

4. The group whose produced polymer concentration should be used for the polymer concentration of the injection stream for the well.

If no group specified the concentration in item 2 will be used

5. The group whose produced salt concentration should be used for the salt concentration of the injection stream for the well.

If no group specified the concentration in item 3 will be used

End data record with a slash (/).

End the set of records with a blank record, containing just a slash (/).

### Example

```

WPOLYMER
INJ1  0.3  1.0  /
INJ2  0.0  0.0  /
INJ3  0.3  1.0  /
/

```

## WPOLYRED Sets polymer/water mixture viscosity in wells

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used to specify the viscosity reduction factor,  $\alpha$ , for polymer/water mixtures in wells. If this value is set to 1.0, the water phase viscosity in the well is calculated using the mixture viscosity set out in the [Treatment of fluid viscosities in the well](#) in the *ECLIPSE Technical Description*. If the viscosity reduction factor is set to zero, the pure water viscosity is used. A value between 0.0 and 1.0 gives an interpolated viscosity between these two values.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template.

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. The polymer viscosity reduction factor.

UNITS: dimensionless

DEFAULT: 1.0

End data record with a slash (/).

End the set of records with a blank record, containing just a slash (/).

### Example

```

WPOLYRED
  INJ1  0.3  /
  INJ2  0.0  /
  INJ3  0.3  /

```

## WPOTCALC Control calculation of shut and stopped well potentials

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword controls whether shut and stopped well potentials are always calculated, or only when necessary. By default, since 2007.1, these calculations are always performed.

If you do not require these potentials, then the calculation can be turned off. An example of a situation where the calculation of shut and stopped well potentials is not required is when a stopped well is segmented all the way to the surface (for example to look at the phase segregation process after the well is stopped). Such a well cannot operate at a constant THP and so the shut well potential calculation will not converge.

Shut and stopped well calculations are necessary in the following situations:

- When the well is in a priority drilling queue (see [WDRILPRI](#)) or when the prioritization option is used (see [PRIORITY](#)).
- When any group, well or connection requests a potential summary vector, for example using the FOPP keyword in the [SUMMARY](#) section.
- When an action uses a potential (see [ACTIONX](#)).

The calculation of shut and stopped well potentials will be performed regardless of the WPOTCALC setting in these necessary situations.

The keyword is followed by one item of data, terminated with a slash (/).

1. Flag indicating whether well potential calculations should be forced for all wells, regardless of whether they are shut or stopped.

NO Shut and stopped well potentials are not calculated unless necessary.

YES Shut and stopped well potentials are always calculated.

(The word may be abbreviated; only the first character is significant)

DEFAULT: YES

End the data record with a slash (/).

**Note:** Turning off the additional calculations of well potentials using this keyword is equivalent to specifying the [item 101](#) in [OPTIONS](#) to a non-zero multiple of 3.

### Example

```
WPOTCALC
NO /
```

## WREGROUP Automatic regrouping of wells

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to transfer wells automatically from one group to another, depending on the value of a chosen quantity such as the well's water cut or oil production rate. Some examples of where this may be useful are given below:

- There are two separate production streams, one for wells cutting significant amounts of water and one for wells with very low water cut. Wells are transferred from one stream to the other depending on their water cut.
- Wells can be classified as either high pressure wells or low pressure wells, depending on the calculated values of their tubing head pressure when they are flowing at a controlled rate.
- In runs using the Network option, wells can be moved from a high pressure network node to a low pressure network node to boost their production, once their original flow rate falls below a specified value.

Two limits are provided, an upper one and a lower one, so that the transfer between groups can be either one way or reversible. The limit values need not be the same for each direction, so that a reversible transfer may have a degree of hysteresis. The transfers take place at the start of the next timestep after a limit has been passed. The transfers take place instantaneously with no loss of production, and there is no restriction on the rate at which transfers can be performed.

ECLIPSE 100 only

---

**Note:** Further wells are not transferred into a group if they would exceed the maximum number of open wells in the group or a superior group, set in item 9 of keyword [GECON](#).

---

**Note:** If setting the well dimensioning data manually in the RUNSPEC section keyword [WELLDIMS](#), the value of NWGMAX (the maximum number of wells in any one group) must allow for all possible transfers.

---

The WREGROUP keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The records may be terminated at any item after item 1. The remaining items will assume their default values. Default values can be specified before the slash by a null repeat count of the form n\*, where n is the number of consecutive items to be defaulted.

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Name of the quantity on which the switching will be decided

WCT Water cut

GOR Gas-oil ratio

WGR Water-gas ratio

ORAT Oil rate

GRAT Gas rate

THP Tubing head pressure

' ' No regrouping for this well

DEFAULT: ' '

- Name of the group into which the well should be moved when its specified quantity **exceeds** the value in item 4

DEFAULT: The group in which the well was placed using the [WELSPECS](#) keyword

- Value of the quantity specified in item 2 **above** which the well is moved into the group specified in item 3

The value must not be less than the value of item 6

DEFAULT: Infinity ( $1.0E20$ ), which prevents switching on this condition

- Name of the group into which the well should be moved when its specified quantity **falls below** the value in item 6

DEFAULT: The group in which the well was placed using the [WELSPECS](#) keyword

- Value of the quantity specified in item 2 **below** which the well is moved into the group specified in item 5

The value must not be greater than the value of item 4

DEFAULT: 0.0, which prevents switching on this condition

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

## Example

In this example all wells whose names start with PROD are moved into group WET when their water cut exceeds 0.2, and are moved back to their original group if their water cut subsequently falls below 0.1. That is except for well PROD3, which stays in the group specified in [WELSPECS](#) regardless of its water cut.

```

WREGROUP
'PROD*' WCT WET 0.2 1* 0.1 /
PROD3 /
/

```

## WRFT

## Request output to RFT file

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword initiates output of well RFT data to the RFT file. The data consists of the pressure, saturation and depth values for each grid block in which a well has a connection. The keyword is retained for back compatibility; however, you are encouraged to use keyword [WRFTPLT](#), which provides a more comprehensive set of options for writing well RFT and PLT data to the RFT file.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/). The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template.

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

End the data record with a slash (/).

End the set of records with a blank record, containing only a slash (/).

If the keyword is entered without any data records (that is followed only by a blank record), well RFT data will subsequently be output whenever a well is first opened. If the keyword contains data records referring to well names, then in addition the RFT data for those wells are output at that time in the simulation.

## Examples

## Example 1

Request RFT data output for any well when it is first opened.

```
WRFT
/
```

## Example 2

Request current RFT data output for specified wells, plus output when any well is subsequently opened.

```
WRFT
PROD1 /
'A*' /
/
```

## WRFTPLT

## Requests output of well RFT, PLT and segment data to the RFT file

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The keyword initiates output of well data to the RFT file. The well must previously have been introduced in the SCHEDULE section. This file contains data for one or more wells describing fluid conditions in the wellbore or the connecting grid blocks at selected times in the run. There are three categories of data that may be written to this file:

RFT data for grid blocks containing connections to the well:

- Depth
- Pressure
- Water and gas saturations
- Polymer and brine concentrations

PLT data for each connection in the well:

- Depth
- Pressure
- Oil, water, gas, polymer and brine flows
- Polymer and brine concentrations
- Tubing flows at each connection (the total upstream flow rates at both surface conditions and local wellbore conditions)
- Connection transmissibility factor and Kh
- Length down the tubing to the connection (ECLIPSE 100 friction wells and multisegment wells only)
- segment number containing the connection and its branch number (multisegment wells only)

Segment data for the multisegment well model (see "[Multisegment wells](#)" in the *ECLIPSE Technical Description*)

- Depth
- Tubing length
- Pressure
- Oil, water, gas, polymer and brine flow rates
- Oil, water and gas velocities
- Oil, water and gas holdup fractions
- Polymer and brine concentrations
- Oil, water, gas and polymer/water mixture viscosities
- Saturation pressure if SPSAT is present in summary section (ECLIPSE 300 only)
- Temperature (ECLIPSE 300 THERMAL only)
- Steam quality (ECLIPSE 300 THERMAL only)
- Enthalpy flow rate (ECLIPSE 300 THERMAL only)

- Energy density (ECLIPSE 300 THERMAL only)
- Information required to construct multilateral well structures including branch data and pointers to the neighboring downstream segment
- Setting (fraction open) of ICD on segment
- Base strength of ICD on segment

River data (ECLIPSE 100 only)

- Reach length
- Flux
- Area
- Reach water depth
- Exchange flux with aquifer
- Froude number
- Information required to construct river structures including branch data, branch name and pointers to the neighboring downstream reach

The RFT file can be read by GRAF. Alternatively it may be examined visually if written as formatted output (see keyword [FMTOUT](#)). Unformatted RFT files can be converted to formatted files by using the CONVERT utility. See "[File handling in ECLIPSE](#)" in the *ECLIPSE Technical Description*. A detailed list of the contents of the file can be found in the *ECLIPSE File Formats Reference Manual*.

The connection ordering of the relevant RFT and PLT data is controlled by keyword [COMPORD](#) for standard wells, and always follows the TRACK method for multisegment and friction wells.

The WRFPTPLT keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/). The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

Note that this well name, well name template, well list or well list template must have already been defined in the SCHEDULE section.

2. Output RFT data?

YES            Output the current RFT data for the well(s) at this time, describing conditions in the grid blocks containing well connections.

REPT           Output the current RFT data for the well(s) at this time and at all subsequent report times.

*ECLIPSE 100 only*

TIMESTEP    Output the current RFT data for the well(s) at this time and at all subsequent timesteps.

FOPN Output the current RFT data for the well(s) at this time if they are open. If any of the wells named in item 1 are not yet open, output their RFT data subsequently when they are first opened.

NO Do not output RFT data for the well(s).

DEFAULT: NO

### 3. Output PLT data?

YES Output the current PLT data for the well(s) at this time, describing the flows through the well connections.

REPT Output the current PLT data for the well(s) at this time and at all subsequent report times, while they are open or stopped.

*ECLIPSE 100 only*

TIMESTEP Output the current PLT data for the well(s) at this time and at all subsequent timesteps.

NO Do not output PLT data for the well(s).

DEFAULT: NO

### 4. Output segment or river data?

The data is output only for multisegment wells or rivers (see "[Multisegment wells](#)" in the *ECLIPSE Technical Description*). No output will be generated for other types of well

YES Output the current segment data for the well(s) or river(s) at this time, describing flows through each well segment.

REPT Output the current segment data for the well(s) or river(s) at this time and at all subsequent report times, while they are open or stopped.

*ECLIPSE 100 only*

TIMESTEP Output the current segment data for the well(s) or river(s) at this time and at all subsequent timesteps.

NO Do not output segment data or river(s) for the well(s).

DEFAULT: NO

End the data record with a slash (/).

End the set of records with a blank record, containing only a slash (/).

The automatic output of data at subsequent times can be cancelled by reentering WRFTPLT with the NO option selected.

---

**Note:** In ECLIPSE 300, WRFTPLT will not output RFT or PLT data at time zero as the simulation has yet to start.

---

## Examples

### Example 1

Request RFT data output for any currently declared well now (if open) or when it is subsequently first opened.

```

WRFPTPLT
--Well      RFT      PLT      Segment
--Name      Data      Data      Data
  'A*'      FOPN      /
/

```

### Example 2

Request current PLT data output for specified wells, now and at subsequent report times.

```

WRFPTPLT
--Well      RFT      PLT      Segment
--Name      Data      Data      Data
  PROD1      NO      REPT      /
  'A*'      NO      REPT      /
/

```

### Example 3

Request reach data output for specified river, now and at subsequent report times.

```

## WSALT

## Sets salt concentrations for injection wells

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used to specify the concentration of salt in the injection stream of each well. The keyword should only be used in runs with the brine option active (keyword [BRINE](#) in the RUNSPEC section). In runs with the polymer option active (keyword [POLYMER](#) in the RUNSPEC section) the keyword [WPOLYMER](#) should be used instead of WSALT. If neither of the WSALT or WPOLYMER keywords appear in the injection schedule, then concentration values of zero are assumed. Data should only appear for wells which are currently declared to be water injection wells.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1 Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2 to [N+1] The concentration of salt in the injection stream for the well.

In the standard brine model, there is a single salt component. In this case, item 2 contains a single value which is the salt concentration of the injection stream. This quantity can be a user defined argument (UDA), and can be set with keywords [UDQ](#) and [UDADIMS](#).

*ECLIPSE 100 only*

When the multi-component brine model (keyword [BRINE](#) in conjunction with keyword [ECLMC](#)) is active, the [BRINE](#) keyword has N entries which specify all of the salt components in the brine mixture. In this case, items 2 to [N+1] of the WSALT keyword contain entries for each of these salt components in the injection stream. Any or all of the concentrations can be user defined arguments (UDA), and can be set with keywords [UDQ](#) and [UDADIMS](#).

UNITS: kg/sm<sup>3</sup> ([METRIC](#)), lb/stb ([FIELD](#)), gm/scc ([LAB](#)), kg/sm<sup>3</sup> ([PVT-M](#))

*ECLIPSE 100 only*

[N+2] The group's salt concentration to be used for the injection stream

This item specifies the group whose produced salt concentration should be used for the salt concentration of the injection stream for the well.

If no group is specified, the concentrations in items 2 to [N+1] will be used.

---

**Note:** When using group reinjection the concentration used by the well will lag the group's concentration by one timestep.

---

---

**Note:** Group reinjection is not available in the Multi-Component Brine model.

---

End data record with a slash (/).

End the set of records with a blank record, containing just a slash (/).

## WSCCLEAN Multiplies deposited well scale by a given value

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to reduce the amount of scale deposited around well connections after a scale cleanup operation. The rate at which scale is deposited around well connections and how the currently deposited scale alters the productivity index of the connections is controlled by tables defined in the [SCDPTAB](#) and [SCDATAB](#) keywords; these tables are assigned to wells using the [WSCTAB](#) keyword. To change the deposited scale of **all** the connections in a well, leave items 3 - 7 defaulted. To change the deposited scale of a subset of connections in a well, you can identify the subset by their I,J,K location (items 3 - 5). A subset of connections can also be identified by their completion number (items 6 and 7). Completion numbers are set in keyword [COMPLUMP](#).

The WSCCLEAN keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

- Well name, well name template, well list or well list template
 

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).
- Multiplier to act on the amount of currently deposited scale around well connections
 

The value must not be negative and should be less than 1.0 for a cleanup operation

DEFAULT: 1.0
- I - location of connecting grid block(s)
 

DEFAULT: Negative (allows any I-location)
- J - location of connecting grid block(s)
 

DEFAULT: Negative (allows any J-location)
- K - location of connecting grid block(s)
 

DEFAULT: Negative (allows any K-location)
- Number of first completion in range
 

DEFAULT: Negative; allows any completion number up to item 7 (if set)
- Number of last completion in range
 

DEFAULT: Negative; allows any completion number from item 6 (if set)

If items 3 - 7 are all defaulted, the multiplier applies to all connections in the well.

If any of items 3 - 7 are set positive, the multiplying factor applies only to a subset of the connections in the well. The connections in the subset are those with I,J,K locations matching the specified location indices in items 3 - 5 and a completion number in the range specified by items 6 - 7. A zero or negative value for a location index (I, J or K) matches any value of that location index. Similarly a zero or negative value for a completion range lower/upper end-point indicates that there is no lower/upper bound on the completion numbers.

## Notes

- The total amount of scale deposited around a connection, the scale deposited per unit perforated length, and resulting PI reduction factor can each be written to the Summary file using the SUMMARY section keywords CDSM, CDSML and CDSF.
- When WSCCLEAN is read, the deposited scale of the well's connections (or a chosen set thereof) is immediately multiplied by the factor specified in this keyword. At the beginning of the next timestep, these reduced scale depositions are used to recalculate connection PI reduction factors that apply throughout the timestep. At the end of this timestep, the reported scale deposition is the sum of the reduced scale deposition at the beginning of the timestep and the scale deposited during the timestep.
- This keyword can be used with OPTIONS3 (item 43) to avoid an error message being generated when a local grid well is referred to.

## Example

```
WSCCLEAN
PROD1 0.9 /(all connections in the well PROD1)
PROD2 0.82 1* 1* 5 /(all connections of well PROD2 in layer 5)
PROD3 0.6 1* 1* 1* 7 7 / (all connections of PROD3 in completion number 7)
/
```

## WSCLENL Multiplies deposited well scale by a given value within local grids

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to reduce the amount of scale deposited around well connections after a scale cleanup operation. The rate at which scale is deposited around well connections and how the currently deposited scale alters the productivity index of the connections is controlled by tables defined in the [SCDPTAB](#) and [SCDATAB](#) keywords; these tables are assigned to wells using the [WSCTAB](#) keyword. To change the deposited scale of **all** the connections in a well, leave items 3 - 8 defaulted. To change the deposited scale of a subset of connections in a well, you can identify the subset by their local grid name and their I,J,K location (items 4 - 6). A subset of connections can also be identified by their completion number (items 7 and 8). Completion numbers are set in keyword [COMPLMPL](#).

WSCLENL performs the same role as [WSCCLEAN](#), but the name of the local grid containing the connections specified in the record should be entered in item 3 of WSCLENL. This keyword should be used when the well is completed in a local grid.

The WSCLENL keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Multiplier to act on the amount of currently deposited scale around well connections

The value must not be negative and should be less than 1.0 for a cleanup operation

DEFAULT: 1.0

3. Name of local grid containing the connections in items 4 - 6

If this item is defaulted or set to a blank string, the local grid name is set to the well's local grid named in keyword [WELSPECL](#). (In ECLIPSE 100, the local grid name should not be defaulted if the local grid is amalgamated.)

The local grid name may also be defaulted if the connection locations in items 4, 5 and 6 are all defaulted. The multiplier in item 2 then applies to all the connections in the well (or to specific completions within it if items 7 and 8 are set).

DEFAULT: ''

4. I - location of connecting grid block(s)

DEFAULT: Negative (allows any I-location)

5. J - location of connecting grid block(s)

DEFAULT: Negative (allows any J-location)

6. K - location of connecting grid block(s)

DEFAULT: Negative (allows any K-location)

7. Number of first completion in range

DEFAULT: Negative; allows any completion number up to item 8 (if set)

#### 8. Number of last completion in range

DEFAULT: Negative; allows any completion number from item 7 (if set)

If items 4 - 8 are all defaulted, the multiplier applies to all connections in the well.

If any of items 4 - 8 are set positive, the multiplying factor applies only to a subset of the connections in the well. The connections in the subset are those with I,J,K locations matching the specified location indices in items 4 - 6 in the local grid named in item 3, and a completion number in the range specified by items 7 - 8. A zero or negative value for a location index (I, J or K) matches any value of that location index. Similarly a zero or negative value for a completion range lower/upper end-point indicates that there is no lower/upper bound on the completion numbers.

## Notes

- The total amount of scale deposited around a connection, the scale deposited per unit perforated length, and resulting PI reduction factor can each be written to the Summary file using the SUMMARY section keywords CDSM, CDSML and CDSF.
- When WSCLENL is read, the deposited scale of the well's connections (or a chosen set thereof) is immediately multiplied by the factor specified in this keyword. At the beginning of the next timestep, these reduced scale depositions are used to recalculate connection PI reduction factors that apply throughout the timestep. At the end of this timestep, the reported scale deposition is the sum of the reduced scale deposition at the beginning of the timestep and the scale deposited during the timestep.

## Example

```

WSCLENL
PROD1 0.2 / (all connections in the well PROD1)
PROD2 0.82 LGR2 / (all connections that the well PROD2 has in LGR 'LGR2')
PROD3 0.98 4* 5 8 / (applies to completions 5,6,7 and 8 of well PROD3)
PROD4 0.5 LGREAST 2* 3 / (all connections in layer 3 of LGR 'LGREAST')
PROD5 0.75 LGRWEST 3 19 7 / (Only applies to connection (3,19,7) of LGR 'LGRWEST')
/

```

## WSCTAB

## Assigns scale deposition and damage tables to wells

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword may be used to assign scale deposition and scale damage tables to individual wells. These tables control the rate at which scale is deposited around well connections and how the currently deposited scale alters the productivity index of the connections. They are input with the [SCDPTAB](#), [SCDATAB](#) and [SCDATABG](#) keywords. The rate of scale deposition depends on the fraction of sea water present in the produced water, and a water phase tracer must accordingly be nominated to represent the sea water fraction, using keyword [SCDPTRAC](#).

The total amount of scale deposited around a connection, the scale deposited per unit perforated length, and resulting PI reduction factor can each be written to the Summary file using the SUMMARY section keywords CDSM, CDSML and CDSF.

Scale deposition is applied at both injecting and producing completions unless [item 108](#) in OPTIONS is set in ECLIPSE 100 or [item 129](#) in OPTIONS3 is set in ECLIPSE 300.

The WSCTAB keyword is followed by any number of records, each containing the following data items and each terminated with a slash (/).

The set of records must be followed by a blank record, containing only a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Scale deposition table number

An integer not exceeding NTSCDP (see keyword [SCDPDIMS](#) in the RUNSPEC section).

Scale deposition tables must be input with keyword [SCDPTAB](#).

A value of 0, or a negative value, means that no scale deposition table will be assigned to that well and thus no further scale is deposited around its connections.

DEFAULT: 0

3. Scale damage table number

An integer not exceeding NTSCDA (see keyword [SCDPDIMS](#) in the RUNSPEC section).

Scale damage tables must be input with keyword [SCDATAB](#).

A value of 0, or a negative value, means that no scale damage table is assigned to that well and thus the well performance is unaltered by the currently deposited scale.

DEFAULT: 0

4. **ECLIPSE 300 only for PROPFLOW:** Scale damage table number for proppant flowback

An integer not exceeding NTSCDG (see keyword [SCDPDIMS](#) in the RUNSPEC section).

Scale damage tables must be input with keyword [SCDATABG](#).

A value of 0, or a negative value, means that no scale damage table is assigned to that well and thus the well performance is unaltered by the currently deposited scale.

DEFAULT: 0

5. **ECLIPSE 100 only for karst aquifers:** Scale dissolution table number

An integer not exceeding NTSCDE (see keyword [SCDPDIMS](#) in the RUNSPEC section).

Scale dissolution tables must be input with keyword [SCDETAB](#).

A value of 0, or a negative value, means that no scale damage table is assigned to that well and thus the well performance is unaltered by the currently deposited scale.

DEFAULT: 0

See also keyword [WPIMULT](#), which may be used to multiply well PIs by a constant factor. Alternatively, keyword [WPITAB](#) and its associated keyword [PIMULTAB](#) may be used to modify a well's PI dynamically according to the maximum water cut it has achieved. [WSCTAB](#) and [WPITAB](#) must not both be used on the same well.

## Example

```
WSCTAB
' P*'  1  1  3  /
PROD2  1  2  1  /
/
```

## WSEGAICD Defines segments to represent an autonomous inflow control device

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword designates specific well segments to represent an autonomous inflow control device (ICD) in a multisegment well (see "Multisegment wells" in the *ECLIPSE Technical Description*). This type of device is used to control the inflow profile along a horizontal well or branch by imposing an additional pressure drop between the sand face and the tubing.

The pressure drop across the device varies with the density and viscosity of the reservoir fluid flowing through the device according to the following equation:

$$\delta P = \left( \frac{\rho_{mix}}{\rho_{cal}} \right) \cdot \left( \frac{\mu_{cal}}{\mu_{mix}} \right)^y \cdot \rho_{mix} \cdot K \cdot q^2 \quad \text{Eq. 3.239}$$

where

$x$  is the volume flow rate exponent (set in item 13)

$y$  is the viscosity function exponent (set in item 14)

$K$  is the base strength of the AICD, with dimension of inverse area squared, defined as:

$$K = a_{AICD} \cdot q^{x-2} \quad \text{Eq. 3.240}$$

where

$a_{AICD}$  is defined as the strength of the AICD (see [item 4](#))

and all the other terms are as described in the [WSEGSICD](#) keyword, apart from the viscosity of the fluid mixture at local segment conditions which is given by:

$$\mu_{mix} = \alpha_o \cdot \mu_o + \alpha_w \cdot \mu_w + \alpha_g \cdot \mu_g \quad \text{Eq. 3.241}$$

where

$\alpha_{o,w,g}$  is the volume fraction of the free oil, water and gas phases at local conditions.

$\mu_{o,w,g}$  is the viscosity of the oil, water and gas phases at local conditions.

---

**Note:** The guidance given in the [WSEGSICD](#) keyword on the placement of such inflow control device segments should also be followed for [WSEGAICD](#) segments.

---

The [WSEGAICD](#) keyword is followed by a number of data records, each containing the following items of data. Unless otherwise stated, entering a negative value for an item defaults the item. Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing just a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

The well must previously have had its segments defined with keyword [WELSEGS](#).

2. Segment number at the start of the range

An integer between 2 and the NSEGMX mnemonic in the [WSEGDIMS](#) keyword.

3. Segment number at the end of the range

An integer between 2 and NSEGMX, not less than item 2.

All segments in this range (that is, with segment numbers between these two values) are treated as ICD segments, and the following data items in this record apply to them. To enter data for a single segment, set item 2 and item 3 equal.

4. The strength of the AICD,  $a_{AICD}$

This is an empirical constant based on measurements of fluid flow through a particular type of ICD. The units depend on the value of the flow rate exponent,  $x$ .

UNITS: bars/((kg/m<sup>3</sup>)(rm<sup>3</sup>/day)<sup>x</sup>) (METRIC), psi/((lb/ft<sup>3</sup>)(rft<sup>3</sup>/day)<sup>x</sup>) (FIELD), atm/((gm/cc)(rcc/hr)<sup>x</sup>) (LAB), atm/((kg/m<sup>3</sup>)(rm<sup>3</sup>/day)<sup>x</sup>) (PVT-M)

5. The length of the ICD,  $l_{ICD}$

This value is used (together with [item 11](#)) to determine a scaling factor which is used to scale the flow from the reservoir in order to establish the flow,  $q_{ICD}$ , through each ICD. The calculation is described in "[Flow scaling](#)".

There are three possibilities for the calculation of the flow scaling factor:

- a. The scale factor is equal to the length of the ICD,  $l_{ICD}$ , divided by the length of the tubing segment that is the parent of the ICDs to account for the fact that the ICD segment may represent a number of ICDs in parallel. (item 11 = 0)
- b. The scale factor is equal to the absolute value of  $l_{ICD}$ . (item 11 = 1)
- c. The scale factor is equal to the length of the ICD,  $l_{ICD}$ , divided by the total length of the completions which supply the ICD. (item 11 = 2)

item 11 allows you to specify explicitly which of these options is used. If item 11 is defaulted, then option a) is used whenever  $l_{ICD}$  is positive, and option b) when  $l_{ICD}$  is negative.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: 12 m, 39.37 ft, 1,200 cm

6. The density of the calibration fluid,  $\rho_{cal}$

UNITS: kg/m<sup>3</sup> (METRIC), lb/ft<sup>3</sup> (FIELD), gm/cc (LAB), kg/m<sup>3</sup> (PVT-M)

DEFAULT: 1000.25 kg/m<sup>3</sup> 62.416 lb/ft<sup>3</sup>, 1.00025 gm/cc

7. The viscosity of the calibration fluid,  $\mu_{cal}$

UNITS: cP (METRIC), cP (FIELD), cP (LAB), cP (PVT-M)

DEFAULT: 1.45 cP

ECLIPSE 100 only

By setting [item 88](#) of the OPTIONS keyword to 2 or 3, the mixture viscosity can be changed from a local volume fraction weighted average to the emulsion viscosity model described in "[Emulsion viscosity](#)". Note that the emulsion viscosity model is the default model for the [WSEGSICD](#) keyword.

ECLIPSE 300 only

By setting [item 169](#) of the OPTIONS3 keyword to 2 or 3, the mixture viscosity can be changed from a local volume fraction weighted average to the emulsion viscosity model described in "[Emulsion viscosity](#)". Note that the emulsion viscosity model is the default model for the [WSEGSICD](#) keyword.

If this option is enabled, items 8-10 can be used to input the necessary parameters.

8. The critical value of the local water in liquid fraction used to select between a water-in-oil or oil-in-water equation for the emulsion viscosity; this is described in [Emulsion viscosity](#).

UNITS: dimensionless

DEFAULT: 0.5

9. The width of the transition region about the critical value of the local water in liquid fraction (see [item 8](#)). For water in liquid fractions within this region, the emulsion viscosity is a linear interpolation between the water-in-oil and oil-in-water viscosity values either side of the region. This transition region is needed to ensure that viscosity is a continuous function of the water in liquid fraction as described in [Emulsion viscosity](#).

UNITS: dimensionless

DEFAULT: 0.05

10. The maximum permitted value of the ratio of the emulsion viscosity to continuous phase viscosity. This usually only affects the water-in-oil viscosity and results in a 'plateau' region within which the emulsion viscosity is at its maximum permitted value as shown in [figure 3.21](#). In this figure, the plateau is bounded by the transition between oil continuous and water continuous emulsions (see [item 8](#)). This is described in [Emulsion viscosity](#).

UNITS: dimensionless

DEFAULT: 5.0

11. An integer which determines how the flow scaling factor is calculated. The calculation is described in [Flow scaling](#).

0 The flow scale factor is equal to the ICD length ([item 5](#)) divided by the length of the tubing segment that is the parent of the ICD device, which is taken directly from the [WELSEGS](#) keyword (case a)

1 The flow scale factor is equal to the absolute value of [item 5](#) (case b)

2 The flow scale factor is equal to the ICD length ([item 5](#)) divided by the total length of all completions which feed the ICD (case c).

If this integer is set to a negative value then, if [item 5](#) is positive then the flow scaling factor is equal to the ICD length divided by the length of the encased tubing segment, and if [item 5](#) is negative then the flow scaling factor is the absolute value of [item 5](#).

DEFAULT: -1

12. The maximum absolute value of  $q_{ICD}$  for which [equation 3.239](#) holds. This value will typically be the maximum flow-rate for which the device was calibrated. Above this value the equation will be extrapolated linearly.

UNITS: m<sup>3</sup>/day (METRIC), ft<sup>3</sup>/day (FIELD), cc/hr (LAB), m<sup>3</sup>/day (PVT-M)

DEFAULT: No limit set

13. Volume flow rate exponent. This quantity should be greater than or equal to 0.0.
14. Viscosity function exponent.
15. Flag to indicate whether the device is open or shut

OPEN ICD is open and flow is allowed through the device

SHUT ICD is shut and flow is not allowed through the device. Crossflow, if enabled, will still be allowed in the branch.

DEFAULT: OPEN

End the data record with a slash (/).

End the set of data records with a slash.

## Notes

- A segment can only represent a single device at any one time. Any previous devices generated with the [WSEGLABY](#), [WSEGFLIM](#), [WSEGVALV](#), [WSEGPULL](#) and [WSEGSICD](#) keywords will be replaced.
- Because the device pressure drop is reported via the segment's friction pressure drop, friction effects must be included in any multisegment well for which this keyword is specified (see item 6 of [WELSEGS](#)).

## Example

```

WSEGAICD
--Well Segments ICD ICD unused scale max flow visc
--Name From To strength length param factor qicd rate fnc
-- exp exp
PROD1 23 23 0.00021 1* 5* 1* 10 2.3 1.5 /
PROD1 24 24 0.00021 1* 5* 1* 10 2.8 1.5 /
PROD1 25 25 0.00042 15 5* 2 10 2.3 1.5 /
/

```

## WSEGDFIN Drift flux inclination factor for multisegment wells

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword may be used to enter a table of inclination factors for the Drift Flux slip model used in the multisegment wells (see "The drift flux slip model" in the *ECLIPSE Technical Description*). ECLIPSE will use this table to determine the inclination factor  $m(\theta)$ , which multiplies the drift velocity  $v_d$  if TABLE has been requested in item 2 of keyword [WSEGDFMD](#).

The table defaults to the results of Shi, H. *et al.* [Ref. 97], which is consistent with the option SHI-03 in item 1 of keyword [WSEGDFMD](#). The built-in default table is shown in the example for this keyword. ECLIPSE will use the default table if TABLE has been requested in item 2 of keyword [WSEGDFMD](#) and [WSEGDFIN](#) has not been entered.

The keyword is followed by a single table having 3 columns and up to 10 rows. The table must be terminated with a slash (/).

Column:

1. Angle of deviation from vertical.

The values must lie between 0 and 90 degrees, and must increase monotonically down the column.

UNITS: degrees (METRIC), degrees (FIELD), degrees (LAB), degrees (PVT-M)

2. Inclination factor for gas-liquid slip.
3. Inclination factor for oil-water slip.

The following rules will be used to extrapolate the table outside the range of angles entered in column 1:

- If the first deviation angle is  $> 0$  degrees, the corresponding inclination factors will apply between this angle and 0 (vertical). That is, the table is extrapolated towards zero deviation with constant inclination factors.
- If the last deviation angle is  $< 90$  degrees, the inclination factors will be linearly extrapolated to 0.0 at 90 degrees.
- If the last deviation angle = 90 degrees, both the inclination factors **must** be entered as 0.0.
- For deviations  $> 90$  degrees (where the direction of positive flow is downward), the inclination factors are assumed to vary in the same way as for upward inclinations:  $m(180-\theta) = m(\theta)$

The table is interpolated linearly with deviation angle. Individual values in columns 2 and 3 may be defaulted by entering 1 followed by an asterisk (1 \*) instead of a number, in which case the table is interpolated linearly between the adjacent non-defaulted points.

If any drift velocity multipliers are specified in keyword [WSEGDFPA](#) (items 1 and 7) or keyword [WSEGFMOD](#) (item 5), these will be applied to the drift velocity after it is multiplied by the inclination factor.

---

**Note:** The inclination factor table is **not** written to the Restart files. Accordingly, it must be present in any restarted data set if it has been altered from its default values with this keyword.

---

### Example

The default table of inclination factors is as follows:

```
WSEGDFIN
-- dev   gas-liq  oil-wat
--angle  factor    factor
```

0	1.28	1.02
5	1.36	1.03
45	2.49	2.22
70	2.20	3.78
80	1.67	3.53
88	1.43	2.27
90	0.0	0.0 /

	SUMMARY
x	SCHEDULE

This keyword may be used to define the Drift Flux slip model used in multisegment wells (see "[The drift flux slip model](#)" in the *ECLIPSE Technical Description*). The model definition governs the default set of parameter values used in the drift flux slip calculations. If you wish to give some of the parameters different values from their model defaults, you can do so by **subsequently** entering the [WSEGDFPA](#) keyword. Some of these parameters can also be set separately for individual segments with the keyword [WSEGFMOD](#).

If you wish to use WSEGDFMD, this keyword should be entered **before** the segments are defined with [WELSEGS](#), and **before** changing any of the parameters from their model default values with the keyword [WSEGDFPA](#).

The WSEGDFMD keyword is followed by a data record consisting of three items, terminated with a slash (/).

### 1. Drift flux model definition.

The parameter values for each choice of model are listed in the two tables below. To see how these parameters feature in the model, refer to "[The drift velocity](#)" in the *ECLIPSE Technical Description*.

ORIGINAL The original implementation of the model.

SHI-03 The optimized parameters determined by Shi *et al* (2003) [[Ref. 97](#)].

SHI-04 The optimized parameters determined by Shi *et al* (2004) [[Ref. 96](#)].

DEFAULT: ORIGINAL

### 2. Inclination factor calculation.

H-K Uses the formula of Hasan and Kabir [[Ref. 48](#)], as recommended in the original implementation of the model.  $m(\theta) = (\cos \theta)^{0.5}(1 + \sin \theta)^2$

TABLE Allows separate inclination factors for gas-liquid slip and oil-water slip to be defined as a table vs. inclination angle, entered with keyword [WSEGDFIN](#)

If no table is entered with [WSEGDFIN](#), a built-in table will be used that reflects the results of Shi *et al* (2003) [[Ref. 97](#)], which is consistent with the option SHI-03 in item 1.

SHI-04 Uses the formulae determined by Shi *et al* (2004) [[Ref. 96](#)]:

$$m(\theta) = 1.85(\cos \theta)^{0.21}(1 + \sin \theta)^{0.95} \text{ for gas-liquid slip, and}$$

$$m(\theta) = 1.07\cos \theta + 3.23 \sin 2\theta - 2.32\sin 3\theta; (\theta \leq 88^\circ) \text{ for oil-water slip}$$

DEFAULT: H-K

### 3. Gas effect on oil-water slip.

NO Oil-water slip is unaffected by the presence of free gas.

SHI-04 Free gas disrupts the slip between oil and water, depending on the pipe inclination, as described by Shi *et al* (2004) [[Ref. 96](#)].

See "[Three-phase flow and oil-water slip](#)" in the *ECLIPSE Technical Description*.

DEFAULT: NO

End the data record with a slash (/).

Parameter	ORIGINAL	SHI-03	SHI-04
Profile coefficient A	1.2	1.2	1.0
Profile coefficient B	0.3	0.6	irrelevant
Profile multiplier $F_v$	1.0	1.0	irrelevant
Drift velocity ramp parameter $a_1$	0.2	0.05	0.06
Drift velocity ramp parameter $a_2$	0.4	0.13	0.21

Table 3.52: Parameters for gas-liquid slip

Parameter	ORIGINAL	SHI-03	SHI-04
Profile coefficient A	1.2	1.0	1.0
Profile coefficient $B_1$	0.4	irrelevant	irrelevant
Profile coefficient $B_2$	0.7	irrelevant	irrelevant
Drift velocity exponent $n'$	2.0	0.95	1.0

Table 3.53: Parameters for oil-water slip

## Example

To use the optimized parameter set derived by Shi *et al.* and the corresponding values of the inclination factor, enter the following keyword before the segments are first defined with [WELSEGS](#):

```

WSEGDFMD
SHI-03 TABLE / (This reproduces the model of Shi et al., 2003)
WSEGDFMD
SHI-04 SHI-04 SHI-04 / (Reproduces the model of Shi et al., 2004)

```

## WSEGDFPA Drift flux parameters for multisegment wells

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword may be used to alter the parameters that control the Drift Flux slip model in multisegment wells (see "[The drift flux slip model](#)" in the *ECLIPSE Technical Description*). Their default values depend on the Drift Flux model definition that is selected with keyword [WSEGDFMD](#). You need to use WSEGDFPA only if you wish to alter one or more of the parameters from its default value. In this case you must enter WSEGDFPA only **after** defining the model with WSEGDFMD but before introducing any segments with [WELSEGS](#).

The parameters entered here will apply to all segments using the Drift Flux model in all wells. However, it is possible to set some of these parameters separately for individual segments with the keyword [WSEGFMOD](#), after the segments have been introduced with WELSEGS.

The WSEGDFPA keyword is followed by a data record consisting of the following items, terminated with a slash (/).

1. Multiplying factor for the gas-liquid drift velocity  $v_d$

The drift velocity is calculated as for a vertical pipe, then scaled automatically according to the segment's inclination (see "[The drift velocity](#)" in the *ECLIPSE Technical Description*). A multiplying factor entered here applies to the scaled drift velocity.

A value of 0.0 turns off the local slip between gas and liquid.

DEFAULT: 1.0

2. Parameter  $a_1$  in the expression for the gas-liquid drift velocity coefficient  $K(\alpha_g)$

This sets the start of the transition between the two expressions for  $K(\alpha_g)$  (see "[The drift velocity](#)" in the *ECLIPSE Technical Description*).

DEFAULT: depends on the model definition selected in WSEGDFMD.

3. Parameter  $a_2$  in the expression for the gas-liquid drift velocity coefficient  $K(\alpha_g)$

This sets the end of the transition between the two expressions for  $K(\alpha_g)$  (see "[The drift velocity](#)" in the *ECLIPSE Technical Description*).

DEFAULT: depends on the model definition selected in WSEGDFMD

4. Coefficient A for the gas-liquid profile parameter  $C_0$

This represents the value of the gas-liquid profile parameter at low values of the gas holdup fraction and flow velocity.

$$C_0 = \frac{A}{[1 + (A-1)\beta^{*2}]} \quad \text{Eq. 3.242}$$

The equations for  $C_0$  are discussed in "[The profile parameter](#)" in the *ECLIPSE Technical Description*.

A value of 1.0 turns off the profile slip.

The value of A must not be less than 1.0

DEFAULT: 1.2

5. Coefficient B for the gas-liquid profile parameter  $C_0$

This represents the value of the gas holdup fraction or the flooding velocity fraction above which the profile parameter starts to decrease.

$$\beta^* = \frac{(\beta - B)}{(1 - B)} \quad \text{Eq. 3.243}$$

subject to  $0 \leq \beta^* \leq 1$

where

$$\beta = \max\left(\alpha_g, F_v \frac{\alpha_g |j|}{v_{sgf}}\right) \quad \text{Eq. 3.244}$$

A and B must obey the relation  $B < (2 - A) / A$

DEFAULT: depends on the model definition selected in [WSEGDFMD](#)

6. Multiplier  $F_v$  of the flooding velocity fraction in the profile reduction term  $\beta$  in the gas-liquid profile parameter  $C_0$

A value of 1.0 reduces the profile parameter to 1.0 when the gas superficial velocity reaches the flooding velocity.

A value of 0.0 makes the profile parameter independent of the flow velocity.

DEFAULT: 1.0

7. Multiplying factor for the oil-water drift velocity  $v'_d$

The drift velocity is calculated as for a vertical pipe, then scaled automatically according to the segment's inclination (see "[Three-phase flow and oil-water slip](#)" in the *ECLIPSE Technical Description*). A multiplying factor entered here will be applied to the scaled drift velocity.

A value of 0.0 turns off the local slip between oil and water.

If a negative value is entered, the multiplier for the oil-water drift velocity is given the same value as the multiplier for the gas-liquid drift velocity set in item 1.

DEFAULT: Negative (implies the same value as item 1)

8. Coefficient A for the oil-water profile parameter  $C'_0$

This represents the value of the oil-water profile parameter at low values of the oil holdup fraction.

The equations for  $C'_0$  are discussed in "[Three-phase flow and oil-water slip](#)" in the *ECLIPSE Technical Description*.

$$\begin{aligned} C'_0 &= A \quad \text{when } (\alpha_{ol} \leq B1) \\ C'_0 &= 1 \quad \text{when } (\alpha_{ol} \geq B2) \\ C'_0 &= A - (A - 1) \left( \frac{\alpha_{ol} - B1}{B2 - B1} \right) \quad \text{when } (B1 < \alpha_{ol} < B2) \end{aligned} \quad \text{Eq. 3.245}$$

DEFAULT: depends on the model definition selected in [WSEGDFMD](#)

9. Coefficient B1 for the oil-water profile parameter  $C'_0$

DEFAULT: depends on the model definition selected in [WSEGDFMD](#)

10. Coefficient B2 for the oil-water profile parameter  $C'_0$

In the ORIGINAL model, B1 and B2 must obey the relation  $B1 \leq (2-A)B2$

DEFAULT: depends on the model definition selected in WSEGDFMD

11. Exponent  $n'$  in the expression for the oil-water drift velocity  $v'_d$

$$v'_d = 1.53v'_c(1-\alpha_{ol})^{n'} \quad \text{Eq. 3.246}$$

DEFAULT: depends on the model definition selected in WSEGDFMD

End the data record with a slash (/).

	SCHEDULE

This keyword is required if the multisegment well model is used (see "[Multisegment wells](#)" in the *ECLIPSE Technical Description*). It reserves storage space for the multisegment well data.

The data consists of four items and must be terminated by a slash (/).

1. NSWLMX The maximum number of multisegment wells in the model.

DEFAULT: 0

2. NSEGMX The maximum number of segments per well.

In ECLIPSE 300, it is recommended that there should be no more than 25 segments per well, in order to ensure a reasonable level of performance if several multisegment wells are present in compositional runs.

DEFAULT: 1

3. NLBRMX The maximum number of branches (including the main stem) per multisegment well.

DEFAULT: 1

4. NCRDMX The maximum number of segment chord links per well.

DEFAULT: 0

ECLIPSE 100

Large values for item 1 and, especially, item 2 will lead to poor performance in parallel. Therefore, it is recommended that you adjust these items to the actual maximum numbers.

### Example

```
WSEGDIMS
 2   30   3   1 /

## WSEGXSS Segment external source/sink

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword provides the capability to import or remove fluids to or from a segment in a multisegment well (see "Multisegment wells" in the *ECLIPSE Technical Description*), either at a specified rate or as a function of the segment's pressure. The source or sink for this fluid is external to the reservoir grid. The available options are:

- Import water or gas at a rate specified in item 4.
- Import water or gas at a rate given by

$$Q = R(P_{ext} - P_{seg}) \quad \text{Eq. 3.247}$$

while  $P_{ext} > P_{seg}$ , where

$Q$  is the volumetric import rate measured at surface conditions

$R$  is a constant set in item 5

$P_{ext}$  is an external pressure set in item 6

$P_{seg}$  is the segment's pressure

The import rate is subject to an upper limit set in item 4.

ECLIPSE 300

- Remove segment fluid at a rate given by

$$Q = R(P_{seg} - P_{ext}) \quad \text{Eq. 3.248}$$

while  $P_{seg} > P_{ext}$ , where

$Q$  is the volumetric rate of fluid removal

The fluid removal rate can either be expressed as an equivalent wet gas volume rate or an equivalent water volume rate, depending on the entry (FREMP or WREMP) in item 3. The choice should depend on whether the fluid in the segment is predominantly hydrocarbon or water/steam. The wet gas rate is related to the moles removed using a unity Z-factor at surface conditions. The equivalent water volume rate is related to the moles removed using the density of water at surface conditions.

The removal rate is subject to an upper limit set in item 4.

The constant  $R$  and the external pressure  $P_{ext}$  are set in items 5 and 6.

The composition of the removed fluid is the current composition in the segment.

There are a number of possible applications for this facility. Gas import may be used to model the effects of lift gas injection. Water import may be used to take account of the water used to power a downhole hydraulic pump if this is injected into the wellbore. The fluid removal facility is intended for use with the Thermal Option to model recirculating wells.

When a well has an external source/sink, the reported production (or injection) rate refers to the fluid flowing out of (or into) the top of the well. Thus, for a production well with fluid import from an external source, the reported production rate will be the fluid production from the formation plus the import rate. For an injection well with fluid import, the fluid injected into the formation is the sum of the reported injection rate and the fluid import rate.

Fluid import or removal is turned off whenever the well is shut.

If injection or production from a well is entirely determined by import or removal, it is better to specify the well as stopped, for example with a [WCONINJE](#) or [WCONPROD](#) keyword, than to specify the well as an injector or producer with a zero rate.

When fluid import is requested, a smaller rate/unit drawdown usually produces better convergence and robustness.

Wells that have external source/sinks usually run more robustly when they are allowed to crossflow.

Segment fluid import/removal rates and cumulative totals may be written to the Summary file using the SUMMARY section mnemonics  $S(W, G) IM(R, T)$  in ECLIPSE 100 and  $S(O, W, G) (IM, RM) (R, T)$  in ECLIPSE 300.

*ECLIPSE 100 only*

Fluid imported will be pure water or gas; it will not contain tracers or other components such as polymer, brine, surfactant, foam or solvent.

The WSEGEXSS keyword is followed by a number of data records to define the well, the location of the segment and the import/removal parameters. Only one external source/sink is allowed per segment. If a segment is specified more than once, its previous source/sink parameters are replaced with the new data.

Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing just a slash.

The data items in each record are:

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

The well must previously have had its segments defined with keyword [WELSEGS](#).

2. Segment number containing the external source/sink

An integer between 2 and the NSEGMX mnemonic in the [WSEGDIMS](#) keyword.

3. A character string specifying the source/sink type

The string must be one of the following:

WIMPR Water import at a specified rate

GIMPR Gas import at a specified rate

WIMPP Water import with a specified external pressure, equation [3.247](#)

GIMPP Gas import with a specified external pressure, equation [3.247](#)

*ECLIPSE 300 only*

FREMP Fluid removal with a specified external pressure, equation [3.247](#), with the removal rate expressed as an equivalent **wet gas** volume rate

*ECLIPSE 300 only*

WREMP Fluid removal with a specified external pressure, equation [3.247](#), with the removal rates expressed as an equivalent **water** volume rate

NONE This removes the external source/sink from the segment

DEFAULT: NONE

4. Volumetric import rate of water or gas at surface conditions, for WIMPR or GIMPR, or upper limit to the water or gas import rate, for WIMPP or GIMPP or the upper limit to the water or wet gas removal rate, for WREMP or FREMP.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC), stb/day or Mscf/day (FIELD), scc/hr (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

DEFAULT: No upper limit, for WIMPP, GIMPP, WREMP or FREMP;  
0.0 for WIMPR or GIMPR

5.  $R$ , the import/removal rate per unit pressure difference, for WIMPP, GIMPP, FREMP or WREMP

UNITS:  $\text{sm}^3/\text{day}/\text{bars}$  (METRIC), stb/day/psi or Mscf/day/psi (FIELD), scc/hr/atm (LAB),  $\text{sm}^3/\text{day}/\text{atm}$  (PVT-M)

DEFAULT: 0.0

6.  $P_{ext}$ , the external pressure, for WIMPP, GIMPP, FREMP or WREMP

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

DEFAULT: 0.0

ECLIPSE 300 only

This item **must** also be set if WIMPR is selected when running the Thermal Option. The pressure is used together with the temperature (specified in item 8) to calculate the enthalpy of the imported water.

ECLIPSE 300 only

7. Wellstream name to specify the imported hydrocarbon composition, for GIMPR or GIMPP

The wellstream composition must be specified with keyword [WELLSTRE](#).

If this item is defaulted, the imported gas composition is set to that of the field separator gas.

ECLIPSE 300 only

8. Temperature of imported fluid

UNITS:  $^{\circ}\text{C}$  (METRIC),  $^{\circ}\text{F}$  (FIELD),  $^{\circ}\text{C}$  (LAB),  $^{\circ}\text{C}$  (PVT-M)

This item **must** be set if WIMPR, GIMPR, WIMPP or GIMPP is selected when running the Thermal Option. Otherwise, this item should be left defaulted.

Thermal option only

9. Quality of imported water

If the source/sink type is WIMPR or WIMPP in item 3 above, then the quality of the imported water can be set. In this case, either the external pressure in item 6 must be set, or the external temperature in item 8 must be set. If both are set, then the external pressure will be used.

UNITS: dimensionless

End the data record with a slash (/).

End the set of data records with a slash.

## WSEGFLIM Defines segments to represent a flow limiting valve

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword designates specific well segments to represent a flow limiting valve in a multisegment well (see "[Multisegment wells](#)" in the *ECLIPSE Technical Description*). This is a hypothetical device that limits the flow rate of oil, water or gas (at surface conditions) through the segment to a specified maximum value, by sharply increasing the frictional pressure drop across the segment if the limit is exceeded. The device can be used to

- limit the production of associated water and gas through a section of tubing
- control the distribution of production or injection between the branches of a multilateral well
- prevent branch-to-branch crossflow in a multilateral well.

The frictional pressure drop across the segment is calculated as

$$\delta P_f = \delta P_1 + \delta P_2 \quad \text{Eq. 3.249}$$

where

$$\begin{aligned} \delta P_1 &= A_1(Q_1 - \text{Lim}_1) \quad \text{when } (Q_1 > \text{Lim}_1) \\ \delta P_2 &= A_2(Q_2 - \text{Lim}_2) \quad \text{when } (Q_2 > \text{Lim}_2) \end{aligned} \quad \text{Eq. 3.250}$$

The  $A$  terms are coefficients, which should be large to provide a steeply increasing pressure drop. The  $Q$  terms represent the flow rate of a chosen phase (oil, water, gas or liquid) through the segment, at surface conditions, while the  $\text{Lim}$  terms represent their specified limiting values. It is therefore possible to limit two flows in one valve segment. Each pressure drop term is zero while its flow limit is not exceeded. The hydrostatic and acceleration pressure drop components are calculated in the usual way and added to the friction pressure drop. The flow is treated as homogeneous within these segments; there is no slip between the phases.

If a  $\text{Lim}$  term is set negative, its pressure drop term acts to impede the negative flow when its magnitude increases beyond the limit; it does not prevent positive flows. The term becomes

$$\delta P = A(Q - \text{Lim}) \quad \text{when } (Q < \text{Lim} < 0) \quad \text{Eq. 3.251}$$

Thus negative limits can be used to limit flows in injection well branches, and small negative flow limits can be used to restrict crossflow in production wells.

### ECLIPSE 100

Because of the non-linear nature of the pressure drop term, it is advisable to use the keyword [WSEGITER](#) to activate the more robust iteration scheme.

Care should be taken to ensure that a flow limiting valve does not conflict with the overall flow control of the well; this would be the case if it was placed downstream of all connections in a producer or upstream of all connections in an injector and the limited phase was the same as the control phase for the well.

See also keyword [WSEGMULT](#) which provides an alternative means of impeding flow at high values of the WOR or GOR, and the section on "[The pressure loss calculation](#)" in the *ECLIPSE Technical Description*.

The WSEGFLIM keyword is followed by a number of data records, each containing the following items of data. Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing just a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names

should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword `WLIST`.

The well must previously have had its segments defined with keyword `WELSEGS`.

2. Segment number at the start of the range

An integer between 2 and the `NSEGMX` mnemonic in the `WSEGDIMS` keyword.

3. Segment number at the end of the range

An integer between 2 and `NSEGMX`, not less than item 2.

All segments in this range (that is, with segment numbers between these two values) will be treated as flow limiting valve segments, and the following data items in this record are applied to them. To enter data for a single segment, set items 2 and 3 equal.

4. Phase limited in the first pressure drop term

`OIL` The total oil flow rate at surface conditions

`WAT` The water flow rate at surface conditions

`GAS` The total gas flow rate at surface conditions

`LIQ` The liquid flow rate (oil + water) at surface conditions

`NONE` The first pressure drop term is zero

DEFAULT: `NONE`

5. The flow limit in the first pressure drop term

The limit applies to the phase defined in item 4. A positive value restricts production flows while a negative value restricts injection flows.

UNITS:  $\text{sm}^3/\text{day}$  (`METRIC`),  $\text{stb}/\text{day}$  or  $\text{Mscf}/\text{day}$  (`FIELD`),  $\text{scc}/\text{hr}$  (`LAB`),  $\text{sm}^3/\text{day}$  (`PVT-M`)

6. The coefficient *A* in the first pressure drop term

The larger the value, the more effective the operation of the valve is in preventing the flow rate exceeding the limit. If the flow limit is being exceeded by a significant amount, the value of this coefficient should be increased. However, too high a value may retard the convergence of the well iterations.

The coefficient must not be negative.

7. Phase limited in the second pressure drop term

The choices are the same as for item 4.

DEFAULT: `NONE`

8. The flow limit in the second pressure drop term

The limit applies to the phase defined in item 7. A positive value restricts production flows while a negative value restricts injection flows.

UNITS:  $\text{sm}^3/\text{day}$  (`METRIC`),  $\text{stb}/\text{day}$  or  $\text{Mscf}/\text{day}$  (`FIELD`),  $\text{scc}/\text{hr}$  (`LAB`),  $\text{sm}^3/\text{day}$  (`PVT-M`)

9. The coefficient *A* in the second pressure drop term

10. Flag to indicate whether the device is open or shut

OPEN ICD is open and flow is allowed through the device

SHUT ICD is shut and flow is not allowed through the device. Crossflow, if enabled, will still be allowed in the branch.

DEFAULT: OPEN

End the data record with a slash (/).

End the set of data records with a slash.

If both items 4 and 7 are NONE, the segment ceases to act as a flow limiting valve and its pressure drop is calculated as for a normal segment.

---

**Note:** A segment can only represent a single device at any one time. Any previous devices generated with the `WSEGLABY`, `WSEGVALV`, `WSEGPULL`, `WSEGSICD` and `WSEGAICD` keywords will be replaced.

---

## Example

In the top branch of well PROD1 (segment 12) limit the water production to 1000 stb/day.

In the bottom branch of well PROD1 (segment 20) prevent crossflow of oil and limit the gas production to 2500 Mscf/day.

Stop the crossflow of water (that is water production) in segment 10 of the water injection well WINJ1.

```

WSEGFLIM
-- Well      Segments  Phase 1  Lim 1  A 1  Phase 2  Lim 2  A 2
-- Name      From  To
  PROD1      12  12      WAT      1000  100  /

  WINJ1      10  10      WAT       1     100  /
/

```

## WSEGFMOD Specifies the multi-phase flow model

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies the multiphase flow model that is used to calculate the pressure losses within individual segments of a multisegment well (see "[Multisegment wells](#)" in the *ECLIPSE Technical Description*). The choices are a no-slip homogeneous flow model, in which all the phases flow with the same velocity, and a drift flux model, which allows slip between the phases and can result in countercurrent flow - heavy and light phases flowing in opposite directions - at low flow rates (see "[The drift flux slip model](#)" in the *ECLIPSE Technical Description*). Alternatively, individual segments can have their pressure losses either obtained from a VFP table (see keyword [WSEGTABL](#)) or calculated from a built-in model of a particular flow control device (see keywords [WSEGVALV](#), [WSEGFLIM](#) and [WSEGLABY](#)).

Segments not specified in keyword WSEGFMOD, WSEGTABL, WSEGVALV, WSEGFLIM or WSEGLABY will use the default flow model selected in item 7 of Record 1 of keyword [WELSEGS](#).

The WSEGFMOD keyword is followed by a number of data records, each containing the following items of data. Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing just a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

The well must previously have had its segments defined with keyword [WELSEGS](#).

2. Segment number at the start of the range

An integer between 2 and NSEGMX (see item 2 in the keyword [WSEGDIMS](#) keyword).

3. Segment number at the end of the range

An integer between 2 and NSEGMX, not less than item 2.

The following data items in this record are applied to all the segments in the range. To enter data for a single segment, set items 2 and 3 equal.

4. Multiphase flow model used for pressure drop calculations

HO No-slip homogeneous flow model.

All the phases flow with the same velocity.

DF Drift flux model.

Slip between the phases is a combination of profile slip (a velocity ratio) and local slip (a vertical relative velocity). At low flow rates the local slip can cause countercurrent flow, when the heavy and light phases flow in opposite directions.

If the drift flux model is requested for **any** segment, the well's flow model in item 7 of Record 1 of keyword [WELSEGS](#) must also be set to DF.

DEFAULT: HO

5. Multiplying factor for the gas-liquid drift velocity (drift flux model only)

The drift velocity is calculated as for a vertical pipe, then scaled automatically according to the segment's inclination (see "The drift velocity" in the *ECLIPSE Technical Description*). A multiplying factor entered here will be applied to the scaled local slip velocity.

A value of 0.0 turns off the local slip.

The oil-water drift velocity multiplier is set for all segments in item 7 of keyword `WSEGDFPA`.

DEFAULT: as set in item 1 of keyword `WSEGDFPA`.

6. Coefficient A for the gas-liquid profile parameter (drift flux model only)

This represents the value of the profile parameter at low values of the gas holdup fraction and flow velocity.

$$C_0 = \frac{A}{[1 + (A-1)\beta^{*2}]} \quad \text{Eq. 3.252}$$

The equations for  $C_0$  are discussed in "The profile parameter" in the *ECLIPSE Technical Description*.

A value of 1.0 turns off the profile slip.

The value of A must not be less than 1.0

The oil-water profile parameter coefficient A is set for all segments in item 8 of keyword `WSEGDFPA`.

DEFAULT: as specified in keyword `WSEGDFMD` or item 4 of keyword `WSEGDFPA`

7. Coefficient B for the gas-liquid profile parameter (drift flux model only)

This represents the value of the gas holdup fraction or the flooding velocity fraction above which the profile parameter starts to decrease.

$$\beta^* = \frac{(\beta-B)}{(1-B)} \quad \text{subject to} \quad 0 \leq \beta^* \leq 1 \quad \text{Eq. 3.253}$$

where

$$\beta = \max\left(\alpha_g, F_v \frac{\alpha_g |j|}{v_{sgf}}\right) \quad \text{Eq. 3.254}$$

A and B must obey the relation  $B < (2-A)/A$

DEFAULT: as specified in keyword `WSEGDFMD` or item 5 of keyword `WSEGDFPA`

8. Multiplier  $F_v$  of the flooding velocity fraction in the profile reduction term  $\beta$  in the gas-liquid profile parameter (drift flux model only)

A value of 1.0 reduces the profile parameter to 1.0 when the gas superficial velocity reaches the flooding velocity.

A value of 0.0 makes the profile parameter independent of the flow velocity.

DEFAULT: as set in item 6 of keyword `WSEGDFPA`

9. Coefficient B1 for the oil-water profile parameter  $C_0'$  (drift flux model only)

$$\begin{aligned}
 C_0' &= A && \text{when } (\alpha_{ol} \leq B1) \\
 C_0' &= 1 && \text{when } (\alpha_{ol} \geq B2) \\
 C_0' &= A - (A - 1) \left( \frac{\alpha_{ol} - B1}{B2 - B1} \right) && \text{when } (B1 < \alpha_{ol} < B2)
 \end{aligned}$$

Eq. 3.255

The equations for  $C_0'$  are discussed in "Three-phase flow and oil-water slip" in the *ECLIPSE Technical Description*. The value of A is set from item 6.

DEFAULT: as specified in keyword WSEGDFMD or item 9 of keyword WSEGDFPA

10. Coefficient B2 for the oil-water profile parameter (drift flux model only)

B1 and B2 must obey the relation  $B1 \leq (2-A)B2$

DEFAULT: as specified in keyword WSEGDFMD or item 10 of keyword WSEGDFPA

End the data record with a slash (/).

End the set of data records with a slash.

**Note:** If WSEGFMOD is applied to a segment that has previously been declared as a sub-critical valve (WSEGVVALV), a flow limiting valve (WSEGFLLIM), a labyrinth device (WSEGLLABY) or a VFP table lookup segment (WSEGTABL), it loses its former attributes and become a standard segment using either the homogeneous or the drift flux flow model according to item 4.

The top segment (segment 1) always uses the homogeneous flow model. There are no pressure losses calculated along this segment.

## WSEGHEAT Segment heat transfer coefficient

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

In a Thermal run, this keyword allows a heat transfer coefficient to be specified at a segment in a multisegment well (see "[Multisegment wells](#)" in the *ECLIPSE Technical Description*). Heat transfer can take place from the segment to the reservoir grid, to another segment, or to a specified fixed external temperature. The well's segment structure must previously have been defined with the [WELSEGS](#) keyword.

The heat transfer rate  $Q_{ht}$  to/from the segment is

$$Q_{ht} = L \cdot (T_{seg} - T_{is,ic,ex}) / R_h$$

where

$L$  is the thermal contact length. See "[Thermal contact lengths](#)" in the *ECLIPSE Technical Description*

$T_{seg}$  is the temperature in the segment,

$T_{is,ic,ex}$  is the temperature of a target segment or completion grid block or external fixed temperature

$R_h$  is the specific thermal resistance.

See "[Conductive heat transfer](#)" in the *ECLIPSE Technical Description*

For heat transfer between segments, a semi-implicit heat transfer rate is used, given by

$$Q_{ht}^{N+1} = S_{int} \cdot Q_{ht} + (1 - S_{int}) \cdot Q_{ht}^N$$

where

$S_{int}$  is an interpolation constant and

$Q_{ht}^N$  is the N time level heat transfer.

The keyword is followed by a number of data records to define the well, a segment range, type of heat transfer coefficient and the target segment or external temperature. If a segment is specified more than once, then its properties are changed. This option is not active when wells are shut.

Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing just a slash.

The data items in each record are:

1. Well name
2. Segment number at the start of the range  
An integer between 1 and NSEGMX (see item 2 in the [WSEGDIMS](#) keyword).
3. Segment number at the end of the range  
An integer between 1 and NSEGMX.
4. A character string specifying the heat transfer coefficient type:  
The string must be one of the following:

- COMP Heat transfer to a previously defined completion. (This replaces all previously defined heat transfer coefficients.)
- SEG Heat transfer to a another segment. (This replaces all previously defined heat transfer coefficients.)
- TEMP Heat transfer to a specified fixed external temperature. (This replaces all previously defined heat transfer coefficients.)
- NONE This is equivalent to the default type and removes the segment from the list of external source/sinks. (This deletes all previously defined heat transfer coefficients.)

The above definitions will replace or delete all previously defined heat transfer coefficients for this segment. If more than one heat transfer coefficient is required, a maximum of one completion transfer coefficient, one formation transfer coefficient and up to five segment-to-segment heat transfer coefficients may be specified concurrently by appending + to COMP, SEG or TEMP above. These will be interpreted as follows:

- COMP+ Add a heat transfer to a previously defined completion to the existing set of heat transfer coefficients. This will add a previously undefined or replace a previously defined transfer coefficient of this type but will not alter other heat transfer coefficients currently associated with this segment.
- SEG+ Add a heat transfer coefficient to another segment. If this has not been previously specified, this will add a new segment-to-segment heat transfer coefficient to the set associated with this segment up to a maximum of five. If this has been previously specified, the properties will be updated. If the addition of a new transfer coefficient would cause the maximum to be exceeded, the new transfer coefficient will be ignored.
- TEMP+ Add a heat transfer to a specified fixed external temperature to the existing set of heat transfer coefficients. This will add a previously undefined or replace a previously defined transfer coefficient of this type but will not alter other heat transfer coefficients currently associated with this segment.

One or more previously defined heat transfer coefficients may be also removed without removing the remainder by appending - to COMP, SEG or TEMP above. These will be interpreted as follows:

- COMP- Remove a heat transfer coefficient to a previously defined completion from the existing set of heat transfer coefficients. This will not alter other heat transfer coefficients currently associated with this segment.
- SEG- Remove a heat transfer coefficient to a another segment from the existing set of heat transfer coefficients. This will not alter other heat transfer coefficients currently associated with this segment.
- TEMP- Remove a heat transfer to a specified fixed external temperature from the existing set of heat transfer coefficients. This will not alter other heat transfer coefficients currently associated with this segment.

5. Specific Thermal Resistance:

UNITS:  $(\text{kJ/m/day/K})^{-1}$  (METRIC),  $(\text{Btu/ft/day/}^{\circ}\text{R})^{-1}$  (FIELD),  $(\text{J/cm/hr/K})^{-1}$  (LAB),  $(\text{kJ/m/day/K})^{-1}$  (PVT-M)

6. Target segment number if item 4, the heat transfer coefficient type, is SEG :  
An integer between 1 and NSEGMX mnemonic in the [WSEGDIMS](#) keyword.
7. External fixed temperature if item 4, the heat transfer coefficient type, is TEMP:  
UNITS: °C (METRIC), °F (FIELD), °C (LAB), °C (PVT-M)
8. Interpolation constant if item 4, the heat transfer coefficient type, is SEG:  
DEFAULT: 0.5
9. Contact length, if item 4, the heat transfer coefficient type, is SEG or TEMP  
UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)  
DEFAULT:  $(L_n + L_{n+1})/2$  where  $L_n$  and  $L_{n+1}$  are the lengths of segments either side of the segment node.

## Example

```

## WSEGINIT Sets initial conditions for well segments

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword may be used to specify the initial conditions for segments in a multisegment well (see "[Multisegment wells](#)" in the *ECLIPSE Technical Description*), namely the pressure and the initial fluid contents in each segment.

It will normally be adequate to let ECLIPSE set the initial conditions of new wells automatically. However, it could be useful to set them manually if you are interested in modeling the very early time behavior of the well immediately on startup. Segments that are **not** initialized with this keyword have their initial conditions set automatically, according to the following rules. For production wells, the initial fluid contents approximately reflect the average saturations in the connecting grid blocks, and the pressure is set somewhat below that of the connecting grid blocks. For injection wells, the segments contain the injected fluid and the pressure is set somewhat above that of the connecting grid blocks.

The WSEGINIT keyword is followed by a number of data records, each containing the following items of data. Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing just a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

The well must previously have had its segments defined with keyword [WELSEGS](#).

2. Segment number at the start of the range

An integer between 1 and NSEGMX, which is the maximum number of segments per well (item 2 in [WSEGDIMS](#)).

3. Segment number at the end of the range

An integer between 1 and NSEGMX, not less than item 2 above.

The following initial conditions in this record apply to all the segments in the range. To enter the initial conditions for a single segment, set items 2 and 3 equal.

4. Initial pressure

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

5. Initial water holdup fraction

This is the fraction of the volume of the segment that is occupied by water. The value must lie between 0.0 and 1.0.

6. Initial gas holdup fraction

This is the fraction of the volume of the segment that is occupied by free gas. The value must lie between 0.0 and 1.0.

7. Dissolved gas concentration in the oil, Rs, in runs with live oil

ECLIPSE limits this so as not to exceed the saturated value at the initial pressure.

UNITS: sm<sup>3</sup>/sm<sup>3</sup> (METRIC), Mscf/stb (FIELD), scc/scc (LAB), sm<sup>3</sup>/sm<sup>3</sup> (PVT-M)

DEFAULT: 0.0

8. Vaporized oil concentration in the gas,  $R_v$ , in runs with wet gas

ECLIPSE limits this so as not to exceed the saturated value at the initial pressure.

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC),  $\text{stb/Mscf}$  (FIELD),  $\text{scc/scc}$  (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: 0.0

9. API gravity of the oil

This item must be set if the API tracking option is active (keyword `API` in the RUNSPEC section). It is ignored in runs that do not use this option.

UNITS: °API

10. Polymer concentration

This item may be used if the polymer flood model is active (keyword `POLYMER` in the RUNSPEC section).

UNITS:  $\text{kg}/\text{sm}^3$  (METRIC),  $\text{lb}/\text{stb}$  (FIELD),  $\text{gm}/\text{scc}$  (LAB),  $\text{kg}/\text{sm}^3$  (PVT-M)

DEFAULT: 0.0

11. Brine concentration

This item may be used if the polymer flood model is active (keyword `POLYMER` in the RUNSPEC section).

UNITS:  $\text{kg}/\text{sm}^3$  (METRIC),  $\text{lb}/\text{stb}$  (FIELD),  $\text{gm}/\text{scc}$  (LAB),  $\text{kg}/\text{sm}^3$  (PVT-M)

DEFAULT: 0.0

End the data record with a slash (/).

End the set of data records with a slash.

## Example

```

WSEGINIT
-- Name      Segments  Pres   Hw   Hg   Rs   Rv   API
  PROD1      1  10    3500  0.0  1.0 / gas region

## WSEGITER Iteration parameters for multisegment wells

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword controls the iteration sequence for the solution of multisegment wells (see "Multisegment wells" in the *ECLIPSE Technical Description*). These wells are often harder to converge than 'standard' wells, and would benefit from a more robust iteration sequence. By default, if the WSEGITER keyword is not entered, each well is allowed up to MXWSIT iterations (set in item 5 of the 3<sup>rd</sup> record of keyword TUNING) to converge its solution. If it cannot converge in this number of iterations a 'problem' message is issued and the latest (unconverged) well solution is used. This may hamper the convergence of the non-linear iterations of the timestep. However, if the WSEGITER keyword is entered ECLIPSE invokes a sequence of iteration cycles that gives the well a greater chance of converging its solution. The method, which applies only to multisegment wells, is described below.

In ECLIPSE 300, the WSEGITER convergence sequence is only called after a predictor is called.

If a well does not converge in a cycle of MXWSIT iterations, the pressure equation in each of its segments is altered by averaging its pressure drop with the value at the beginning of the iteration cycle, using an adjustable weighting factor  $W_p$

$$P_{seg} = P_{out} + W_p \Delta P + (1 - W_p) \Delta P_{prev} \quad \text{Eq. 3.256}$$

$P_{seg}$  is the pressure in a segment

$P_{out}$  is the pressure in its outlet segment (towards the wellhead)

$\Delta P$  is the calculated pressure drop across the segment

$\Delta P_{prev}$  is the pressure drop at the previous converged iteration cycle.

The effect of the weighting factor is to reduce the amount by which the segment pressure drop changes from its previous converged value. If the well does not converge in a cycle of MXWSIT iterations, the weighting factor  $W_p$  is reduced by a factor  $F_R$  ( $W_p \leftarrow F_R \times W_p$ ) and a new iteration cycle is begun. If the iterations still do not converge,  $W_p$  is reduced again by the same factor and another iteration cycle is begun.  $W_p$  can be reduced a specified maximum number of times  $N_R$  before ECLIPSE gives up and finally declares the well solution unconverged. When an iteration cycle converges with a reduced value of  $W_p$  its value is increased by a factor  $F_I$  ( $W_p \leftarrow F_I \times W_p$ ) and a new iteration cycle is begun.  $W_p$  is successively increased in this manner until it reaches the value 1.0, and when this iteration cycle converges the well solution is finally declared converged. Overall, this process traverses 'difficult' regions of the residual function by taking small steps in the pressure variable.

You must take care when selecting the iteration parameters. If the factors  $F_R$  and  $F_I$  are too small it can take many iteration cycles for  $W_p$  to reach unity again. It can take up to  $N_C$  cycles of iterations to converge a well after its maximum allowed number of reductions in  $W_p$ , where

$$N_C = N_R + 1 + N_R \frac{\log(1/F_R)}{\log(F_I)} \quad \text{Eq. 3.257}$$

The WSEGITER keyword is followed by a data record consisting of the following items, terminated with a slash (/).

1. Maximum number of well iterations per cycle, MXWSIT

This item overwrites any value previously entered in item 5 of the 3<sup>rd</sup> record of keyword TUNING (or TUNINGL or TUNINGS).

ECLIPSE 100

DEFAULT: 20

ECLIPSE 300

DEFAULT: 40

- Maximum number of times,  $N_R$ , that a new iteration cycle with a reduced  $W_p$  will be started following an unconverged iteration cycle.

The well will finally be declared unconverged if there are more than  $N_R$  unconverged iteration cycles.

DEFAULT: 5

- Reduction factor  $F_R$

$W_p$  will be reduced by this factor following an unconverged iteration cycle.

A value between 0.01 and 0.9 is allowed.

DEFAULT: 0.3

- Increase factor  $F_I$

$W_p$  will be increased by this factor following each converged iteration cycle, until it reaches the value 1.0.

The value must not be less than 1.2

DEFAULT: 2.0

End the data record with a slash (/).

---

**CAUTION:** If the TUNING keyword is entered after WSEGITER, the value of MXWSIT in the third record of TUNING overwrites the value entered in item 1 of this keyword.

---

## Example

```
WSEGITER
 25  5  0.1  3.0 /
```

## WSEGLABY Defines segments to represent a labyrinth inflow control device

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword designates specific well segments to represent a labyrinth inflow control device in a multisegment well (see "Multisegment wells" in the *ECLIPSE Technical Description*). This type of device is used to control the inflow profile along a horizontal well or branch by imposing an additional pressure drop between the sand face and the tubing. The device is placed around a section of the tubing and diverts the fluid inflowing from the adjacent part of the formation into a series of small channels before it enters the tubing. The additional pressure drop that it imposes depends upon the length of the flow path through the system of channels, which is adjustable. A series of labyrinth devices with different channel settings can be placed along the length of a horizontal well or branch, with the aim, for example, of reducing the variation in drawdown along it.

The pressure drop across the device is calculated as

$$\delta P = \delta P_{\text{form}} + \delta P_{\text{fric}} \quad \text{Eq. 3.258}$$

$\delta P_{\text{form}}$  accounts for geometric effects and the loss through the inlet section of the channel (including a pre-packed screen) and the outlet section of the channel (including a kill filter). It is calculated as

$$\delta P_{\text{form}} = C_u (\gamma_{\text{inlet}} + (N_c - 1)\gamma_{\text{labyr}} + \gamma_{\text{outlet}}) \rho v^2 \quad \text{Eq. 3.259}$$

where

$\gamma$  is a dimensionless coefficient for each loss mechanism

$N_c$  is the 'configuration number' of the device, which determines the length of the channel flow path through the labyrinth

$\rho$  is the density of the fluid mixture

$v$  is the flow velocity of the mixture through the channel

$C_u$  is a units conversion constant:

1.0E-5 (METRIC)

2.159E-4 (FIELD)

9.869E-7 (LAB)

9.869E-6 (PVT-M).

$\delta P_{\text{fric}}$  is the standard expression for the homogeneous flow frictional pressure loss through the channel system,

$$\delta P_{\text{fric}} = 2C_u f \frac{L}{D} \rho v^2 \quad \text{Eq. 3.260}$$

$f$  is the Fanning friction factor

$D$  is the diameter of each channel

$L$  is the effective length of the channel system, which depends on the configuration number

$N_c$  of the device,

$$L = L_1 + (N_c - 1)L_2 \quad \text{Eq. 3.261}$$

where  $L_1$  and  $L_2$  are constants for the device.

To include a series of these devices in a multisegment well, the devices should be represented by segments branching off the tubing as shown in figure 3.19. The grid block connections should be located in the labyrinth segments instead of the segments representing the well tubing. Each labyrinth segment can contain a length of one or more labyrinth device joints, depending on the overall length of the grid block connections that it contains. Note that labyrinth segments should be arranged in parallel, not in series.

The labyrinth segments should be introduced in the normal way using keyword `WELSEGS`, then defined as labyrinth segments with keyword `WSEGLABY`. Labyrinth segments should be given a very small length in keyword `WELSEGS` (of the order, say, of the wellbore radius); this length is **not** used in any pressure loss calculations, but it will influence the location of the connections in `COMPSEGS` or `COMPSEGL`. The labyrinth segments should be given the same depth as their ‘parent’ tubing segments, so that there will be no hydrostatic head across them. The pressure loss sum  $\delta P = \delta P_{\text{fric}} + \delta P_{\text{form}}$  across a labyrinth segment is reported as the friction pressure loss; the acceleration pressure loss is set to zero.

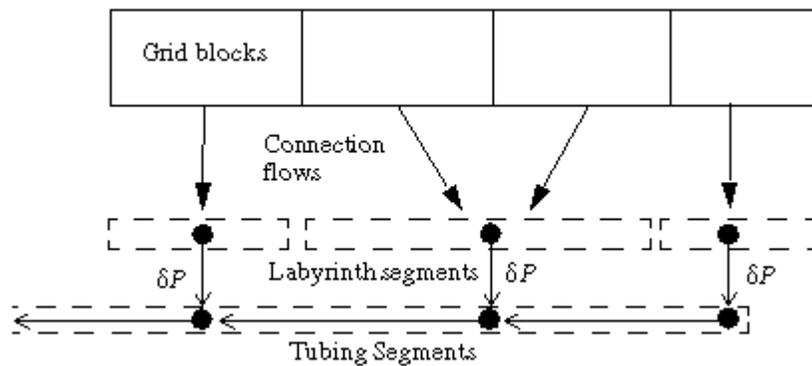

Figure 3.19. Labyrinth segments branching from the tubing

The `WSEGLABY` keyword is followed by a number of data records, each containing the following items of data. Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing just a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword `WLST`.

The well must previously have had its segments defined with keyword `WELSEGS`.

2. Segment number at the start of the range

An integer between 2 and the `NSEGMX` mnemonic in the `WSEGDIMS` keyword.

3. Segment number at the end of the range

An integer between 2 and NSEGMX, not less than item 2.

All segments in this range (that is, with segment numbers between these two values) are treated as labyrinth segments, and the following data items in this record apply to them. To enter data for a single segment, set items 2 and 3 equal.

4. The configuration number,  $N_c$  (an integer)

If the number entered is 0 or negative, the labyrinth pressure drop  $\delta P$  is set equal to zero, as if the device were removed. The total pressure drop along the segment is then the hydrostatic pressure drop only.

---

**Note:** A segment with a non-positive configuration number cannot be specified as a secondary link segment in the [WSEGLINK](#) keyword.

---

5. The number of separate channel systems within this segment

The flow through this segment is apportioned equally between the specified number of channel systems. The number of channel systems is related to the number of labyrinth device joints contained within the segment. Normally, each device joint is 12 m long and contains two separate channel systems.

DEFAULT: 2

6. Cross-section area for flow in each channel system

This quantity is used to convert the volumetric flow rate of fluid through each channel system into a flow velocity.

The total cross-section area for flow (that is the product of item 6 and item 5) replaces the area entered in item 9 of keyword [WELSEGS](#).

UNITS: m<sup>2</sup> (METRIC), ft<sup>2</sup> (FIELD), cm<sup>2</sup> (LAB), m<sup>2</sup> (PVT-M)

DEFAULT: 6.0E-5 m<sup>2</sup>, 6.46E-4 ft<sup>2</sup> 0.6 cm<sup>2</sup>

7. The base length of the channel path,  $L_1$

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: 0.1863 m, 0.6112 ft, 18.63 cm

8. Incremental length of the channel path for each configuration number,  $L_2$

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: 0.2832 m, 0.9291 ft, 28.32 cm

9. The channel diameter,  $D$

This quantity is used in calculation of the friction pressure loss. For non-circular channels, use the equivalent diameter (4 x area / perimeter).

The value entered here replaces the diameter entered in item 7 of keyword [WELSEGS](#).

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: 6.316E-3 m, 2.072E-2 ft, 0.6316 cm

10. The absolute roughness of the channel wall

This quantity is used to calculate the Fanning friction factor in the friction pressure loss.

The value entered here replaces the roughness entered in item 8 of keyword WELSEGS.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: 1.0E-5 m, 3.281E-5 ft, 1.0E-3 cm

11. The dimensionless form loss coefficient for the inlet,  $\gamma_{inlet}$

DEFAULT: 0.35

12. The dimensionless form loss coefficient for the outlet,  $\gamma_{outlet}$

DEFAULT: 0.5

13. Incremental form loss coefficient for each configuration number,  $\gamma_{labyr}$

DEFAULT: 0.55

14. Flag to indicate whether the device is open or shut

OPEN ICD is open and flow is allowed through the device

SHUT ICD is shut and flow is not allowed through the device. Crossflow, if enabled, will still be allowed in the branch.

DEFAULT: OPEN

End the data record with a slash (/).

End the set of data records with a slash.

## Notes

- A segment can only represent a single device at any one time. Any previous devices generated with the [WSEGLIM](#), [WSEGVAlV](#), [WSEGPULL](#), [WSEGSICD](#) and [WSEGAICD](#) keywords will be replaced.
- Because the device pressure drop is reported using the segment's friction pressure drop, friction effects must be included in any multisegment well for which this keyword is specified (see item 6 of [WELSEGS](#)).

## Example

```

WSEGLABY
-- Well      Segments  Nc   Chnls   Area   L1   L2   Diam   Rough   Cin   Cou   Claby

## WSEGLINK Defines the chord segment links for specifying looped flow paths

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword is used to specify any chord segment links required to form looped flow paths in multisegment wells. (See "[Multisegment wells](#)" in the *ECLIPSE Technical Description*.)

These chord segment links cause the nodes of two specified segments to have the same multisegment well solution variable values (segment pressure and phase flowing fractions in ECLIPSE 100, segment pressure and molar densities in ECLIPSE 300). One of these segments must be at the end of a branch.

The two segments involved are called the **primary** link segment and the **secondary** link segment. By default, the first segment specified in the pair will be the primary link segment, but it will be the secondary link segment if it is the only segment in the pair that is at the end of a branch.

The segment structure of any multisegment wells which have chord segment links specified using this keyword must have already been specified using the [WELSEGS](#) keyword.

The maximum number of chord segment links that can be specified for a particular well is specified in item 4 of the [WSEGDIMS](#) keyword.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name
2. Segment number of the first segment in the chord segment link  
DEFAULT: Undefined
3. Segment number of the second segment in the chord segment link  
DEFAULT: Undefined

---

**Note:** Each new instance of the WSEGLINK keyword will add to the existing list of chord segment links. If one of the segment numbers is defaulted then all the segment links associated with the other segment in the named well will be deleted. If both the segments are defaulted, then all segment links associated with the named well will be deleted.

---

**Note:** Any multisegment well for which this keyword is specified must have friction effects included in the segment pressure drop calculation (see item 6 of [WELSEGS](#)).

---

See "[Restrictions](#)" in the *ECLIPSE Technical Description* for a list of restrictions on which segments can be primary and secondary segments in a chord link.

### Example

In this example, the first record deletes any existing chord segment links in well PROD, the second record deletes any existing chord segment links which involve segment 18 of well INJ1, and the third record creates a chord segment link between segments 22 and 31 of well PROD.

```

## WSEGMULT Multipliers for segment frictional pressure drops

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies a scaling factor by which the frictional pressure drop calculated across a segment is multiplied, in a multisegment well (see "[Multisegment wells](#)" in the *ECLIPSE Technical Description*). The scaling factor may either be a constant or vary as a function of the water-oil ratio and gas-oil ratio of the mixture flowing through the segment's outlet junction. A variable scaling factor may be applied, for example, to progressively choke off a branch as its produced gas-oil ratio increases, or to model the operation of an adjustable flow control device whose purpose is to cut off production from completions with high water cuts.

The frictional pressure loss calculated over the segment is multiplied by the function

$$\max \left[ A + B(WOR)^C + D \left( \frac{GOR}{GOR_{min}} \right)^E, 1.0 \right] \quad \text{Eq. 3.262}$$

where  $A$  to  $E$  and  $GOR_{min}$  are coefficients defined in items 4-9.

It is thus possible to select a set of coefficients which, for example, would begin to reduce flow through a segment once its gas-oil ratio increases above a certain value.

---

**Note:** If the segment's pressure drop is obtained from a VFP table (see keyword [WSEGTABL](#)), the **total** pressure drop interpolated from the table will be multiplied by this function. If the segment uses the Drift Flux Flow Model (see "[The drift flux slip model](#)" in the *ECLIPSE Technical Description*), the phase ratios reflect the in-situ fluid mixture instead of the flowing mixture (the flowing phase ratios could go negative if counter-current flow occurs). In fact, it is best to represent the flow control device by a segment that uses either a VFP table or the homogeneous flow model for its pressure drop calculation.

---

The keyword is followed by a number of data records, each containing the following items of data. Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing just a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

The well must previously have had its segments defined with keyword [WELSEGS](#).

2. Segment number at the start of the range

An integer between 2 and the NSEGMX mnemonic in the [WSEGDIMS](#) keyword.

3. Segment number at the end of the range

An integer between 2 and NSEGMX, not less than item 2.

The following data items apply to all the segments in the range. To enter data for a single segment, set items 2 and 3 equal.

4. Value of the constant  $A$  in the multiplying function

DEFAULT: 1.0

5. Value of the coefficient  $B$  in the multiplying function

DEFAULT: 0.0

6. Value of the power  $C$  in the multiplying function

The power  $C$  must be set  $> 0.0$  if the coefficient  $B$  is non-zero.

DEFAULT: 0.0

7. Value of the coefficient  $D$  in the multiplying function

DEFAULT: 0.0

8. Value of the power  $E$  in the multiplying function

The power  $E$  must be set  $> 0.0$  if the coefficient  $D$  is non-zero.

DEFAULT: 0.0

9. Value of  $GOR_{\min}$  in the multiplying function

$GOR_{\min}$  must be set  $> 0.0$  if the coefficient  $D$  is non-zero.

UNITS:  $\text{sm}^3/\text{sm}^3$  (METRIC), Mscf/stb (FIELD), scc/scc (LAB),  $\text{sm}^3/\text{sm}^3$  (PVT-M)

DEFAULT: 0.0

End the data record with a slash (/).

End the set of data records with a slash.

---

**Note:** If both the coefficients  $B$  and  $D$  are zero, the pressure loss multiplier will take the constant value  $A$ , which will **not** be subject to a minimum value of 1.0. However, in this case,  $A$  must not be set to a negative value. Apart from this case, any of the coefficients  $A$ ,  $B$  and  $D$  may be set negative, if required.

---

The value of the segment frictional pressure drop multiplier can be written to the Summary file using the [SUMMARY](#) section keywords [SPRDM](#).

See also keyword [WSEGFLIM](#), which provides an alternative means of restricting the flow of associated water and gas through a segment.

## Example

```

This keyword may be used to modify properties of individual segments in a multisegment well (see "[Multisegment wells](#)" in the *ECLIPSE Technical Description*) during the simulation, as an alternative to re-entering the segment data with keyword [WELSEGS](#).

The keyword is followed by a number of data records, each containing the following items of data. Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing just a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

The well must previously have had its segments defined with keyword [WELSEGS](#).

2. Segment number at the start of the range

An integer between 2 and the NSEGMX mnemonic in the [WSEGDIMS](#) keyword.

3. Segment number at the end of the range

An integer between 2 and NSEGMX, not less than item 2.

The following segment properties in this record apply to all the segments in the range. To enter properties for a single segment, set items 2 and 3 equal.

4. Tubing internal diameter (or equivalent diameter for annular cross-section)

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: unchanged from previous value

5. The effective absolute roughness of the tubing

This quantity is used to calculate the Fanning friction factor.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: from previous value

6. Cross-sectional area for fluid flow

UNITS: m<sup>2</sup> (METRIC), ft<sup>2</sup> (FIELD), cm<sup>2</sup> (LAB), m<sup>2</sup> (PVT-M)

DEFAULT:  $\pi(D^2/4)$  if diameter is set in item 4, otherwise unchanged from previous value

7. Volume of the segment

UNITS: m<sup>3</sup> (METRIC), ft<sup>3</sup> (FIELD), cc (LAB), m<sup>3</sup> (PVT-M)

DEFAULT:  $A \cdot L$  if diameter is set in item 4, otherwise unchanged from previous value

8. **Thermal Option only:** Cross-sectional area of the pipe wall (see note 3 of keyword [WELSEGS](#)). For tubing with circular cross-sections the area can be calculated using the formula  $A = \pi \cdot (r_o^2 - r_i^2)$  where  $r_o$  is the outer radius of and  $r_i$  is the inner radius.

UNITS: m<sup>2</sup> (METRIC), ft<sup>2</sup> (FIELD), cm<sup>2</sup> (LAB), m<sup>2</sup> (PVT-M)

DEFAULT: Unchanged from previous value.

9. **Thermal Option only:** Volumetric heat capacity of the pipe wall.

UNITS: kJ/m<sup>3</sup>/K (METRIC), Btu/ft<sup>3</sup>/°R (FIELD), J/cc/K (LAB), kJ/m<sup>3</sup>/K (PVT-M)

DEFAULT: Unchanged from previous value.

10. **Thermal Option only:** Thermal conductivity of the pipe wall.

UNITS: kJ/m/day/K (METRIC), Btu/ft/day/°R (FIELD), J/cm/hr/K (LAB), kJ/m/day/K (PVT-M)

DEFAULT: Unchanged from previous value.

End the data record with a slash (/).

End the set of data records with a slash.

## Example

```

## WSEGPULL Defines a segment to represent a pullthrough pump for a down-hole separator

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword designates a well segment to represent a pullthrough pump for a downhole water separator in a multisegment well. A pullthrough pump can be used to control the rate of water removal from the separator and its reinjection into the formation. The pump should be situated in the water offtake segment of the separator (item 3 of keyword [WSEGSEP](#)) or anywhere further along the water injection branch. For further information on downhole separators, see "[Down-hole separators \(ECLIPSE 100\)](#)" in the *ECLIPSE Technical Description*.

The pressure differential across the device is the difference of two components:

$$\delta P = \delta P_{\text{pump}} - \delta P_{\text{reduc}} \quad \text{Eq. 3.263}$$

$\delta P_{\text{pump}}$  represents the pressure boost from a pump working at a specific net power,

$$\delta P_{\text{pump}} = \min\left(C_u \frac{\text{Pow}_{\text{max}}}{V}, \delta P_{\text{max}}\right) \quad \text{Eq. 3.264}$$

$C_u$  is a units conversion constant, given in [table 3.54](#)

$\text{Pow}_{\text{max}}$  is the maximum net power of the pump (set in item 3)

$V$  is the local volumetric flow rate of fluid through the pump

$\delta P_{\text{max}}$  is a maximum pressure boost (set in item 4).

If the pump power is too low, the flow rate of water along the offtake branch may not be able to keep up with the flow of water from the formation into the separator. In this case the excess water remains in the production flow stream that goes to the surface. On the other hand, if the pump power is too high the flow of fluid along the offtake branch may exceed the flow of water from the formation into the separator. In this case the flow in the outlet branch also includes some of the oil from the formation, which is reinjected along with the water. For optimum separation, the flow in the outlet branch should be maintained at a rate that matches the inflow of water into the separator. The pressure reduction term is designed to reduce the pump pressure boost when an excessive amount of oil is carried over into the water injection stream. It reduces the pressure boost by an amount that increases sharply with the excess oil flow rate in the water outlet branch:

$$\delta P_{\text{reduc}} = F(Q_o - Q_{o \text{ lim}}), \quad \text{when } (Q_o > Q_{o \text{ lim}}) \quad \text{Eq. 3.265}$$

$F$  is a gradient factor (set in item 6)

$Q_o$  is the flow rate of oil through the device, from the water outlet of the separator

$Q_{o \text{ lim}}$  is the oil rate limit that triggers the pressure reduction (set in item 5).

To achieve optimum separation, therefore, the pump power and maximum pressure boost should be at least sufficient to reinject all the produced water and the gradient factor in item 6 should be set to a value that enables  $\delta P_{\text{reduc}}$  to cancel out  $\delta P_{\text{pump}}$  over an acceptable range of oil carry-over rates. A large gradient factor may hinder the convergence of the multisegment well; you are recommended to use [WSEGITER](#) to assist the convergence.

The actual applied power of the pump,  $\delta P \ V / C_u$ , can be written to the Summary file with the SUMMARY section keyword SPPOW.

Unit system	$C_u$	power	flow rate	pressure
METRIC	864.0	kW	m <sup>3</sup> /day	bar
FIELD	3.301E5	hp	ft <sup>3</sup> /day	psi
LAB	3.553E4	W	cc/hr	atm
PVT-M	852.7	kW	m <sup>3</sup> /day	atm

Table 3.54: Conversion constant in each unit system

The WSEGPULL keyword is followed by a number of data records, each containing the following items of data. Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing only a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

The well must previously have had its segments defined with keyword [WELSEGS](#).

2. Segment number to contain the pullthrough pump.

An integer between 2 and the NSEGMX mnemonic in the [WSEGDIMS](#) keyword.

The pump should be situated in the water offtake segment of the separator (item 3 of keyword [WSEGSEP](#)) or anywhere further along the water injection branch.

3. Maximum pump power

UNITS: kW (METRIC), hp (FIELD), W (LAB), kW (PVT-M)

4. Maximum pressure boost,  $\delta P_{\max}$

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

5. Limiting rate of oil carryover from the water offtake through the pump,  $Q_{o\lim}$

UNITS: sm<sup>3</sup>/day (METRIC), stb/day (FIELD), scc/hr (LAB), sm<sup>3</sup>/day (PVT-M)

DEFAULT: 0.0

6. Gradient factor,  $F$ , for the pressure reduction term

UNITS: bars/(sm<sup>3</sup>/day) (METRIC), psi/(stb/day) (FIELD), atm/(scc/hr) (LAB), atm/(sm<sup>3</sup>/day) (PVT-M)

DEFAULT: 0.0

End the data record with a slash (/).

End the set of data records with a slash.

---

**Note:** A segment can only represent a single device at any one time. Any previous devices generated with the `WSEGLABY`, `WSEGFLIM`, `WSEGVALV`, `WSEGSICD` and `WSEGAICD` keywords will be replaced.

---

## Example

## WSEGSEP Defines a segment to represent a down-hole separator

x	ECLIPSE 100
	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

A down-hole separator can separate water or free gas from the flowing mixture within a multisegment well (see "[Multisegment wells](#)" in the *ECLIPSE Technical Description*), and send it along a lateral branch to reinject into the formation. This keyword designates a well segment as a downhole separator. The segment must have three segments connecting with it:

- An inlet segment, from which the well stream enters the separator.
- A water or gas offtake segment, which should be the beginning of the lateral branch that injects the separated fluid back into the formation.
- An outlet segment, through which the remaining fluid flows to continue its journey towards the wellhead; this should normally be the separator segment's outlet segment on the same branch.

The offtake segment, or any other segment on the offtake branch, may contain a pump to control the flow rate of fluid through the offtake. This pump should be modeled either by a VFP table with negative flow values (since the flow is in the direction away from the wellhead) or, for water separation, by a pull-through pump device model (keyword [WSEGPULL](#)). A pump may also be placed elsewhere in the well, but not in the separator segment itself.

For a more detailed description of the downhole separator model, please refer to "[Down-hole separators \(ECLIPSE 100\)](#)" in the *ECLIPSE Technical Description*.

The WSEGSEP keyword is followed by a number of data records, each containing the following items of data. Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing just a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

The well must previously have had its segments defined with keyword [WELSEGS](#).

2. Segment number of the down-hole separator segment

An integer between 2 and the NSEGMX mnemonic in the [WSEGDIMS](#) keyword.

3. Segment number of the offtake segment

An integer between 2 and NSEGMX .

The offtake segment should be situated on a lateral branch and must connect with the separator segment. The separator segment must have been designated as the **outlet** segment of the offtake segment in [WELSEGS](#), since the separator should be the offtake's neighbor in the direction of the wellhead. Note that the actual flow is normally in the opposite direction.

4. The separated phase that the offtake preferentially removes

WAT The offtake preferentially removes water from the fluid in the separator

GAS The offtake preferentially removes free gas (at the separator segment's pressure) from the fluid in the separator

NONE The offtake acts as a standard outlet/inlet to the segment in item 2, which ceases to act as a downhole separator.

DEFAULT: NONE

5. The maximum separation efficiency for the offtake,  $E_{max}$

A number between 0.0 and 1.0

The holdup fraction,  $\alpha^{of}$ , of the offtake's preferential phase is equal to this value, as long as the phase's holdup fraction within the remaining mixture in the separator segment keeps above the value specified in item 6.

DEFAULT: 1.0

6. The limiting holdup fraction,  $\alpha_{lim}$ , below which the separation efficiency begins to decrease

When the phase's holdup fraction remaining in the separator segment,  $\alpha^{sep}$ , lies below the value  $\alpha_{lim}$ , the separation efficiency decreases proportionally towards zero,  $E = E_{max}(\alpha^{sep} / \alpha_{lim})$ .

The value of  $\alpha_{lim}$  must be greater than zero and must not exceed 1.0. The smaller the value is, the smaller the fraction of the separated phase remaining is within the separator to flow towards the wellhead. However, very small values ( $< .001$ ) may result in convergence difficulties.

DEFAULT: 0.01

End the data record with a slash (/).

End the set of data records with a slash.

**Note:** The separator segment should use the homogeneous flow model. If it has previously been set up to use the drift flux model, ECLIPSE automatically changes it to homogeneous flow.

The operation of a down-hole separator may increase the number of well model iterations required to converge the well solution. In cases of convergence difficulty, use keyword [WSEGITER](#) to increase the number of iterations and/or iteration cycles.

## Example

```

WSEGSEP
-- Well      Separator  Offtake  Offtake  Maximum  Limiting
-- Name      Segment    Segment  Phase    Efficiency Holdup Fr
  PROD1      3          14      'WAT'    1.0      0.001 /
/

```

## WSEGSICD Defines segments to represent a spiral inflow control device

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword designates specific well segments to represent a spiral inflow control device (ICD) in a multisegment well (see "[Multisegment wells](#)" in the *ECLIPSE Technical Description*). This type of device is used to control the inflow profile along a horizontal well or branch by imposing an additional pressure drop between the sand face and the tubing. The device is placed around a section of the tubing and diverts the fluid inflowing from the adjacent part of the formation through a sand screen and then into a spiral before it enters the tubing.

The pressure drop across the device is calculated from calibration data, adjusted to allow for the varying density and viscosity of the reservoir fluid flowing through the device:

$$\delta P = \left( \frac{\rho_{cal}}{\rho_{mix}} \cdot \frac{\mu_{mix}}{\mu_{cal}} \right)^{1/4} \cdot \frac{\rho_{mix}}{\rho_{cal}} \cdot K \cdot q^2 \quad \text{Eq. 3.266}$$

where

$\rho_{mix}$  is the density of the fluid mixture in the segment at local conditions

$\rho_{cal}$  is the density of the fluid used to calibrate the ICD (see [item 6](#))

$\mu_{mix}$  is the viscosity of the fluid mixture in the segment at local conditions

$\mu_{cal}$  is the viscosity of the fluid used to calibrate the ICD (see [item 7](#))

$K$  is the base strength of the ICD, with dimension of inverse area squared, defined as:

$$K = \frac{a_{SICD}}{\rho_{cal}} \quad \text{Eq. 3.267}$$

where

$a_{SICD}$  is defined as the strength of the SICD (see [item 4](#))

$q$  is the volume flow rate of fluid mixture through the ICD at local conditions, which is equal to the volume flow rate through the ICD segment multiplied by a scaling factor that depends on the length of the device (see [item 5](#)).

The density of the fluid mixture at local segment conditions is given by:

$$\rho_{mix} = \alpha_o \cdot \rho_o + \alpha_w \cdot \rho_w + \alpha_g \cdot \rho_g \quad \text{Eq. 3.268}$$

where

$\alpha_{o,w,g}$  is the volume fraction of the free oil, water, gas phases at local conditions

$\rho_{o,w,g}$  is the density of the oil, water, gas phases at local conditions.

The viscosity of the fluid mixture at local segment conditions is given by:

$$\mu_{mix} = (\alpha_o + \alpha_w) \cdot \mu_{emul} + \alpha_g \cdot \mu_g \quad \text{Eq. 3.269}$$

where

$\mu_{emul}$  is the viscosity of the oil-water emulsion at local conditions

$\mu_g$  is the gas viscosity at local conditions.

The calculation of  $\mu_{emul}$  is described in "[Emulsion viscosity](#)".

To include a series of these devices in a multisegment well, the devices should be represented by segments branching off the tubing as shown in figure 3.20. The grid block connections should be located in the ICD segments instead of the segments representing the well tubing.

The ICD segments should be introduced in the normal way using keyword `WELSEGS`, then defined as ICD segments with keyword `WSEGSICD`. ICD segments should be given a very small length in keyword `WELSEGS` (of the order, say, of the wellbore radius); this length is **not** used in any pressure loss calculations, but it will influence the location of the connections in `COMPSEGS` or `COMPSEGL`. The ICD segments should be given the same depth as their 'parent' tubing segments, so that there will be no hydrostatic head across them. The pressure loss across an ICD segment is reported as the friction pressure loss; the acceleration pressure loss is set to zero.

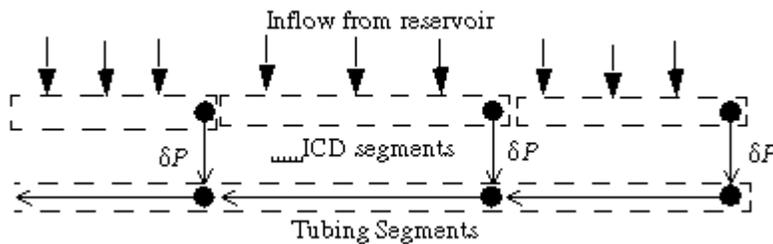

Figure 3.20. ICD segments branching from the tubing

The figure shows a typical configuration of ICD segments. If, however, you wish to define a more complicated configuration where the flow may pass through more than one ICD segment you must declare the ICD segments in `WSEGSICD` in order with upstream segments (that is those further from the wellhead) declared before downstream segments.

The `WSEGSICD` keyword is followed by a number of data records, each containing the following items of data. Unless otherwise stated, entering a negative value for an item defaults the item. Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing just a slash.

1. Well name, well name template, well list or well list template.

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword `WLIST`.

The well must previously have had its segments defined with keyword `WELSEGS`.

2. Segment number at the start of the range.

An integer between 2 and the argument `NSEGMX` in the `WSEGDIMS` keyword.

3. Segment number at the end of the range

An integer between 2 and NSEGMX, not less than [item 2](#).

All segments in this range (that is, with segment numbers between these two values) are treated as ICD segments, and the following data items in this record apply to them. To enter data for a single segment, set [item 2](#) and [item 3](#) equal.

4. The strength of the SICD,  $a_{SICD}$

This is an empirical constant based on measurements of the calibrating fluid flow through a particular type of ICD.

UNITS: bars/(rm<sup>3</sup>/day)<sup>2</sup> (METRIC), psi/(rft<sup>3</sup>/day)<sup>2</sup> (FIELD), atm/(rcc/hr)<sup>2</sup> (LAB), atm/(rm<sup>3</sup>/day)<sup>2</sup> (PVT-M)

5. The length of the ICD,  $l_{ICD}$

This value is used (together with [item 11](#)) to determine a scaling factor which is used to scale the flow from the reservoir in order to establish the flow,  $q_{ICD}$ , through each ICD. The calculation is described in "[Flow scaling](#)".

There are three possibilities for calculation of the flow scaling factor:

- The scale factor is equal to the length of the ICD,  $l_{ICD}$ , divided by the length of the tubing segment that is the parent of the ICDs to account for the fact that the ICD segment may represent a number of ICDs in parallel. (item 11 = 0)
- The scale factor is equal to the absolute value of  $l_{ICD}$ . (item 11 = 1)
- The scale factor is equal to the length of the ICD,  $l_{ICD}$ , divided by the total length of the completions which supply the ICD. (item 11 = 2)

item 11 allows you to specify explicitly which of these options is used. If item 11 is defaulted, then option a) is used whenever  $l_{ICD}$  is positive, and option b) when  $l_{ICD}$  is negative.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: 12 m, 39.37 ft, 1,200 cm

6. The density of the calibration fluid,  $\rho_{cal}$

UNITS: kg/m<sup>3</sup> (METRIC), lb/ft<sup>3</sup> (FIELD), gm/cc (LAB), kg/m<sup>3</sup> (PVT-M)

DEFAULT: 1000.25 kg/m<sup>3</sup>, 62.416 lb/ft<sup>3</sup>, 1.00025 gm/cc

7. The viscosity of the calibration fluid,  $\mu_{cal}$

UNITS: cP (METRIC), cP (FIELD), cP (LAB), cP (PVT-M)

DEFAULT: 1.45 cP

8. The critical value of the local water in liquid fraction used to select between a water-in-oil or oil-in-water equation for the emulsion viscosity; this is described in the "[Emulsion viscosity](#)".

UNITS: dimensionless

DEFAULT: 0.5

9. The width of the transition region about the critical value of the local water in liquid fraction (see item 8). For water in liquid fractions within this region, the emulsion viscosity is a linear interpolation between the water-in-oil and oil-in-water viscosity values either side of the region. This transition region is needed to ensure that viscosity is continuous function of water in liquid fraction as described in the "[Emulsion viscosity](#)".

UNITS: dimensionless

DEFAULT: 0.05

10. The maximum permitted value of the ratio of the emulsion viscosity to continuous phase viscosity. This usually only affects the water-in-oil viscosity and results in a 'plateau' region within which the emulsion viscosity is at its maximum permitted value as shown in figure 3.21. In this figure, the plateau is bounded by the transition between oil continuous and water continuous emulsions (see item 8). This is described in the "[Emulsion viscosity](#)".

UNITS: dimensionless

DEFAULT: 5.0

11. An integer which determines how the flow scaling factor is calculated.

0 The flow scale factor is equal to the ICD length ([item 5](#)) divided by the length of the tubing segment that is the parent of the ICD device, which is taken directly from the [WELSEGS](#) keyword (case a)

1 The flow scale factor is equal to the absolute value of item 5 (case b)

2 The flow scale factor is equal to the ICD length (item 5) divided by the total length of all completions which feed into the ICD (case c).

If this integer is set to a negative value, then the pre-2008.2 behavior is obtained. That is, if item 5 is positive then the flow scaling factor is equal to the ICD length divided by the length of the encased tubing segment, and if item 5 is negative then the flow scaling factor is the absolute value of item 5.

DEFAULT: -1

12. The maximum absolute value of  $q_{ICD}$  for which equation 3.266 holds. This value will typically be the maximum flow-rate for which the device was calibrated. Above this value the equation will be extrapolated linearly.

UNITS: m<sup>3</sup>/day (METRIC), ft<sup>3</sup>/day (FIELD), cc/hr (LAB), m<sup>3</sup>/day (PVT-M)

DEFAULT: No limit set

13. Flag to indicate whether the device is open or shut.

OPEN ICD is open and flow is allowed through the device

SHUT ICD is shut and flow is not allowed through the device. Crossflow, if enabled, will still be allowed in the branch.

DEFAULT: OPEN

End the data record with a slash (/).

End the set of data records with a slash.

## Emulsion viscosity

The emulsion viscosity is a function of the local phase volume fractions in the segment and has differing functional forms at low water in liquid fractions (when oil is the continuous phase) and high water in liquid fractions (when water is the continuous phase). A critical water in liquid fraction (see [item 8](#)) is used to select between these equations given below ([\[Ref. 77\]](#) and [\[Ref. 114\]](#) in the *ECLIPSE Technical Description*):

$$\mu_{wio} = \mu_o \cdot \left( \frac{1}{1 - \left( \frac{0.8415}{0.7480} \cdot \alpha_{wl} \right)} \right)^{2.5} \quad \text{Eq. 3.270}$$

$$\mu_{oiw} = \mu_w \cdot \left( \frac{1}{1 - \left( \frac{0.6019}{0.6410} \cdot \alpha_{ol} \right)} \right)^{2.5} \quad \text{Eq. 3.271}$$

where

$\mu_{wio}$  is the water-in-oil emulsion viscosity (when oil is the continuous phase)

$\mu_{oiw}$  is the oil-in-water emulsion viscosity (when water is the continuous phase)

$\mu_o$  is the oil viscosity at local conditions

$\mu_w$  is the water viscosity at local conditions

$\alpha_{wl}$  is the local water in liquid fraction,  $= \alpha_w / (\alpha_w + \alpha_o)$

$\alpha_{ol}$  is the local oil in liquid fraction,  $= \alpha_o / (\alpha_w + \alpha_o)$

The water-in-oil viscosity is subject to an upper limit expressed as a maximum ratio of water-in-oil viscosity to oil viscosity (see [item 10](#)). This usually results in a ‘plateau’ region within which the water-in-oil viscosity is at its maximum permitted value as shown schematically in [figure 3.21](#), with the maximum viscosity ratio set at 5.0. This upper limit also applies to the oil-in-water viscosity, but is less commonly encountered.

At the critical water in liquid fraction there is a jump in emulsion viscosity as the continuous phase changes. Such a discontinuity would cause stability problems in the simulator and a transition region is defined about the critical water in liquid fraction to avoid this. In this region the emulsion viscosity is linearly interpolated between the water-in-oil and oil-in-water viscosities at the edges of the region; the viscosity is thus a continuous function of the water in liquid fraction. The width of the transition region is defined in [item 9](#) above. This transition region is shown schematically in [figure 3.21](#), with the linear interpolation shown in red between points B and C.

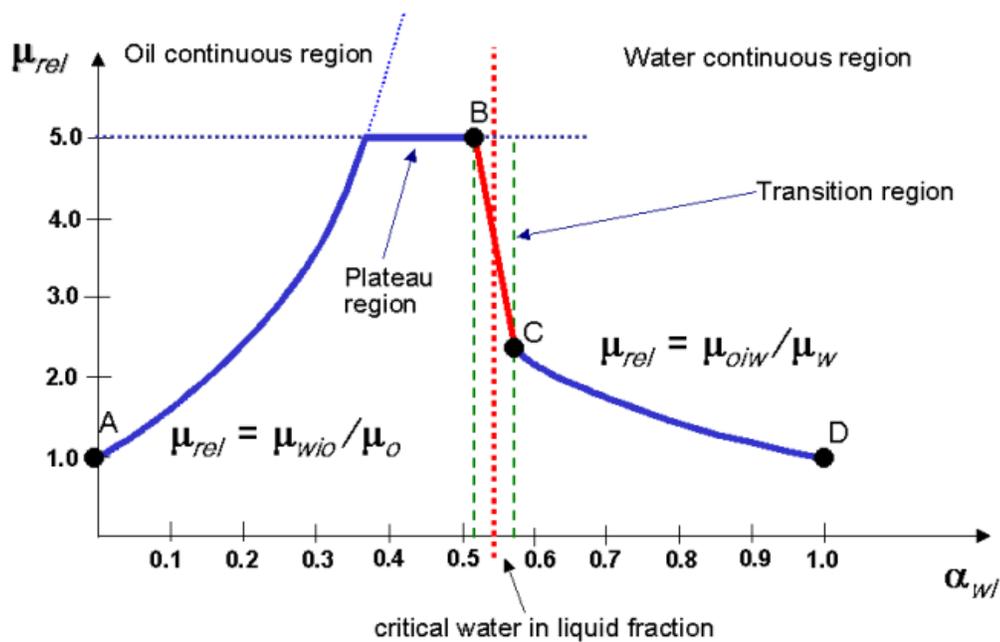

Figure 3.21. Relative emulsion viscosity versus water in liquid fraction

The following rules are used to obtain an emulsion viscosity for a given local water in liquid fraction:

- For local water in liquid fractions below the critical value and outside the transition region (A to B) the water-in-oil emulsion viscosity equation, equation 3.270 is used, subject to a maximum permitted viscosity ratio supplied in item 10.
- For local water in liquid fractions within the transition region about the critical value (B to C), the emulsion viscosity is a linear interpolation between the water-in-oil viscosity calculated at the continuous oil region edge and the oil-in-water viscosity calculated at the continuous water region edge.
- For local water in liquid fractions above the critical value and outside the transition region (C to D) the oil-in-water emulsion viscosity equation, equation 3.271 is used, subject to a maximum permitted viscosity ratio supplied in item 10.

ECLIPSE 100 only

The emulsion viscosity model may be disabled by setting item 88 to 1 or 3 in the OPTIONS keyword. Note that the value of 3 also activates the emulsion viscosity model for the WSEGAICD keyword.

ECLIPSE 300 only

The emulsion viscosity model may be disabled by setting item 169 to 1 or 3 in the OPTIONS3 keyword. Note that the value of 3 also activates the emulsion viscosity model for the WSEGAICD keyword.

The mixture viscosity used in equation 3.266 becomes a local volume fraction weighted sum of each phase's viscosity:

$$\mu_{mix} = \alpha_o \cdot \mu_o + \alpha_w \cdot \mu_w + \alpha_g \cdot \mu_g \quad \text{Eq. 3.272}$$

## Flow scaling

An ICD segment may represent a number of ICDs in parallel. Thus the flow rate passing through each ICD is equal to the flow rate through the segment divided by the number of ICDs it represents.

To estimate the number of ICDs in parallel contained in an ICD segment, we compare the length of a single ICD with the length of the tubing segment that the devices encase. We take this tubing segment to be the ICD segment's immediate neighbor towards the wellhead, that is, its outlet segment as shown in figure 3.20. This assumes that the tubing is encased by a contiguous series of ICDs, into which the fluid from the formation flows.

Thus the segment flow is scaled as follows:

$$q_{ICD} = q_{seg} \times \frac{l_{ICD}}{l_{tubing}} \quad \text{Eq. 3.273}$$

where

$q_{ICD}$  is the scaled volume flow rate to be used in the pressure drop equation 3.266

$q_{seg}$  is the volume flow rate from the reservoir into the ICD segment, which is equal to the actual flow rate through the segment

$l_{ICD}$  is the length of an actual ICD (see item 5)

$l_{tubing}$  is the length of the tubing segment that is the parent of the ICD segment. This length is taken directly from the WELSEGS keyword.

This flow scaling equation 3.273 is still used if the tubing segment length is smaller than the ICD length. A non-integer scaling factor will be applied if the tubing segment is not an exact multiple of the ICD length (that is the scaling is **not** adjusted to the nearest integer).

Alternatively, the number of ICDs in parallel contained in an ICD segment can be estimated by comparing the length of the ICD with the total length of all completions which feed it. The length of all completions on the ICD segment and on any upstream segment (including branches) are included in the total length. However, if any other devices (as generated by the WSEGSICD, WSEGLABY, WSEGFLIM, WSEGVALV, WSEGPULL, WSEGAICD and WSEGTABL keywords) are present on upstream segments, only completions encountered prior to these devices are included.

Thus the segment flow is scaled as follows:

$$q_{ICD} = q_{seg} \times \frac{l_{ICD}}{l_{comp}} \quad \text{Eq. 3.274}$$

where

$q_{ICD}$  is the scaled volume flow rate to be used in the pressure drop equation 3.266

$q_{seg}$  is the flow rate through the ICD segment

$l_{ICD}$  is the length of an actual ICD (see item 5)

$l_{comp}$  is the total length of all completions upstream of the ICD and hence which feed into it.

For more complicated circumstances, the scaling calculations above may not be appropriate. If this is the case you can enter the scaling factor manually into item 5 (either by setting both items 5 and 11 to negative values or setting item 11 to 1). It will not then be interpreted as the ICD length, but its absolute value directly multiplies the segment flow rate,  $q_{seg}$ , to give the flow rate used in the pressure drop,  $q_{ICD}$ .

---

**Note:** A segment can only represent a single device at any one time. Any previous devices generated with the [WSEGLABY](#), [WSEGFLIM](#), [WSEGVALV](#), [WSEGPULL](#) and [WSEGAICD](#) keywords will be replaced.

---

**Note:** Because the device pressure drop is reported via the segment's friction pressure drop, friction effects must be included in any multisegment well for which this keyword is specified (see item 6 of [WELSEGS](#)).

---

## Example

## WSEGSOLV Sets parameters affecting the multisegment well iterative linear solver

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
x	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword controls the iterative linear solver that is used for multisegment wells that contain segment chord links, that is, loops specified using the [WSEGLINK](#) keyword. (See "[Multisegment wells](#)" in the *ECLIPSE Technical Description*). This keyword also allows this solver to be applied to multisegment wells without loops.

Due to the additional matrix terms caused by the additional flowpaths in looped wells, additional storage would be required while solving the well's linear system within each Newton iteration, so to avoid this additional storage requirement, these wells are solved using an iterative linear solver.

This iterative solver uses an incomplete LU factorization (ILU) pre-conditioner. You can specify how close this incomplete factorization approximates the true LU factorization using the fill level and drop tolerance that are items 4 and 5 of this keyword respectively.

For wells without loops, as long as the segments are ordered carefully, there is no fill-in when calculating the LU-factorization of the well linear system (that is, no additional non-zero entries are generated). Hence a direct solver, in particular a technique known as the "cheap LU factorization", is used. However, the default implementation has some inefficiencies so the memory requirement and computational expense is higher than strictly necessary. For this reason, it can be preferable to choose the multisegment well iterative solver, which should solve the well linear system directly (and efficiently) purely in the pre-conditioning step without the need for iterations. If the multisegment well iterative linear solver is used for a well with no loops, then the "cheap LU factorization" form of the ILU pre-conditioner is automatically used.

The WSEGSOLV keyword is followed by a data record consisting of the following items, terminated with a slash (/).

1. Whether to use the iterative linear solver for wells which do not have any segment chord links (see the [WSEGLINK](#) keyword).

YES Use the iterative solver for all multisegment wells, even if they do not have a chord segment link. (This can reduce the memory requirement for runs with large numbers of segments per well.)

NO Only use the iterative solver for multisegment wells which have a chord segment link.

DEFAULT: NO

2. Maximum number of iterations of the linear solver when solving the multisegment well linear systems

DEFAULT: 30

3. Target convergence tolerance in the multisegment well iterative linear solver. This is the absolute target for the L2-norm of the well equation residuals.

DEFAULT: 1.0E-10

4. Fill level of the ILU pre-conditioner in linear solver. This indicates how much fill-in is allowed when calculating the incomplete LU-factorization of the well linear system - this incomplete factorization is used as a pre-conditioner in the linear iterations.

The higher the level of fill, the greater the memory requirement for the pre-conditioner.

DEFAULT: 2

5. Drop tolerance level in the ILU pre-conditioner in linear solver. In the LU decomposition of the well linear system, any fill-in values which would have an absolute value below this drop tolerance are ignored. This value has no effect if the fill level specified in item 4 is zero.

The lower the drop tolerance, the greater the memory requirement for the pre-conditioner.

DEFAULT: 0.0

6. Limit beneath which the pressure drop derivative with respect to total flow is linearized for segments which represent ICDs. This is used to avoid a zero derivative at low flows which can cause problems for the iterative linear solver. This item only affects secondary linked segments containing devices specified with the `WSEGAICD`, `WSEGSICD`, `WSEGLABY` or `WSEGVALV` keywords. If you increase the number of iteration cycles or reduction factor in the `WSEGITER` keyword you may find it is also necessary to increase this number.

DEFAULT: 1.0E-8

*ECLIPSE 100 only*

7. Looped well flow chop threshold.

During the non-linear solving of looped multisegment wells, spurious high flows are occasionally generated. Using items 7 and 8 of `WSEGSOLV`, these flows can be controlled. Any attempt by the solver to increase a segment total flow control variable from an absolute value above the threshold (item 7) by a factor greater than the multiplier (item 8) will be chopped to the maximum allowed value. Negative values disable the flow chops. The total flow control variable is a weighted sum of phase flows. Although optimum values will vary from case to case, a value of 10 for each of items 7 and 8 is reasonable.

UNITS:  $\text{sm}^3/\text{day}$  (METRIC),  $\text{stb}/\text{day}$  (FIELD),  $\text{scc}/\text{hr}$  (LAB),  $\text{sm}^3/\text{day}$  (PVT-M)

DEFAULT: -1.0

*ECLIPSE 100 only*

8. Looped well flow chop multiplier. See item 7 for a description.

DEFAULT: -1.0

```

## WSEGTABL Calculate segment pressure drops from VFP tables

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword designates specific segments in a multisegment well to have their pressure drops obtained from a VFP table instead of a built-in flow model (see "Pressure drops from VFP tables" in the *ECLIPSE Technical Description*).

The keyword is followed by a number of data records, each containing the following items of data. Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing just a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "Well name and well list template matching" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

The well must previously have had its segments defined with keyword [WELSEGS](#).

2. Segment number at the start of the range

An integer between 2 and the NSEGMX mnemonic in the [WSEGDIMS](#) keyword.

3. Segment number at the end of the range

An integer between 2 and NSEGMX, not less than item 2.

The following data items in this record will be applied to all the segments in the range. To enter data for a single segment, set items 2 and 3 equal.

4. Production VFP table number

A production well VFP table with this number must previously have been entered with keyword [VFPPROD](#). The second item in its first record is interpreted as either its datum **length** or datum **depth span**, to allow ECLIPSE to scale the interpolated pressure drop along each segment in proportion to its length or depth span (see item 7). The table may extend into negative flows, which are interpreted as flow in the direction away from the wellhead (positive flows are towards the wellhead). There must be no point at zero flow, since the WFR and GFR values are singular there.

If the value 0 is entered, the pressure drop calculation reverts to the Homogeneous Flow Model.

DEFAULT: 0

5. Components of the pressure drop that are included in the VFP table

FH Friction and Hydrostatic.

The VFP table contains the sum of the friction and hydrostatic pressure drops. The combined pressure drop interpolated from the VFP table is reported in the output as a friction pressure drop, since the table contains no information to resolve it into the two components.

F- Friction only.

The hydrostatic pressure drop is calculated from the fluid density in the segment and added to the friction pressure drop interpolated from the VFP table. This option is useful to apply to undulating sections of tubing, to overcome the need to have a separate table for each inclination angle.

The acceleration pressure drop is calculated separately, and added to the friction and hydrostatic pressure drops, if HFA was entered in item 6 of Record 1 of keyword **WELSEGS**. It is calculated using the segment's diameter and area entered in **WELSEGS** or **WSEGPROP**. (See "Pressure drop components" in the *ECLIPSE Technical Description*.)

DEFAULT: FH

6. Procedure for handling flows that are more negative (or less positive) than the first flow value in the VFP table

REV Reverse the flows and pressure losses in the table.

This procedure is recommended for use in horizontal segments or segments representing chokes, or with friction only VFP tables (see item 5), in which the table's pressure drop has no hydrostatic component. In these cases the pressure drop can simply be reversed when the flow reverses. The first flow value in the VFP table should be positive. For negative flows, the mirror image of the table is used. For flows in between + and - the first value, the pressure loss is linearly interpolated between these two points.

FI Fix the lookup value of the flow rate at the first flow point in the table.

This procedure is recommended for use in vertical or inclined segments in which the friction pressure loss in reverse flow is expected to be small compared with the hydrostatic pressure loss. (The REV option is not suitable in these cases as the hydrostatic pressure loss does not reverse when the flow reverses.) If the first flow value in the VFP table is positive, it should be low enough to give a negligible friction pressure drop, so that the calculated friction pressure drop remains negligible during reverse flow.

EXT Extrapolate the pressure drop linearly with flow.

This should be used with caution, as substantial extrapolation (especially into the negative flow region) may result in stability problems.

DEFAULT: there is **no** default for this item, as the appropriate choice depends on the type of segment.

---

**Note:** For flows that lie above the highest value in the table, the table is extrapolated linearly as normal. For WFR and GFR values that lie outside their range of tabulated values, the lookup value of the respective quantity is fixed at its nearest tabulated point. This is to avoid stability problems that can arise when the table is extrapolated substantially in these quantities.

---

7. Instruction for scaling the interpolated pressure drop according to the length or depth span of each segment

LEN The interpolated pressure drop is scaled in proportion to the **length** of the segment relative to the table's **datum length**.

The second item in the first record of **VFPPROD** is interpreted as the table's datum length.

DEP The interpolated pressure drop is scaled in proportion to the depth span of the segment (that is the change in depth over the segment's length) relative to the table's **datum depth span**.

The second item in the first record of **VFPPROD** is interpreted as the table's datum depth span.

NO The interpolated pressure drop is not scaled automatically according to the segment properties. (This option is recommended if the VFP table represents the pressure loss across a choke.)

DEFAULT: LEN

(See "Pressure drop scaling" in the *ECLIPSE Technical Description*.)

8. ALQ value used in the table look-up. User defined arguments can be set with keywords `UDQ` and `UDADIMS`.

UNITS: These depend on what the ALQ was meant to represent when the table was created. Refer to section "Record 6:ALQ values" in the description of keyword `VFP`. For example, if the table was created by `VFP i` to model pressure loss across a choke (with an ALQ definition of `BEAN`), the ALQ represents the choke diameter in units of mm (`METRIC`), 1/64<sup>th</sup> in (`FIELD`)

DEFAULT: 0.0

9. Flag to indicate whether the segment is open or shut

`OPEN` Segment is open and flow is allowed

`SHUT` Segment is shut and flow is not allowed through. Crossflow, if enabled, will still be allowed in the branch.

DEFAULT: `OPEN`

End the data record with a slash (/).

End the set of data records with a slash.

## WSEGVAlV Defines a segment to represent a sub-critical valve

x	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword designates specific well segments to represent a sub-critical valve in a multisegment well (see "Multisegment wells" in the *ECLIPSE Technical Description*). This imposes an additional pressure drop in the segment due to flow through a constriction with a specified area of cross-section.

The WSEGVAlV keyword is followed by a number of data records, each containing the following items of data. Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing only a slash.

1. Well name, well name template, well list or well list template.

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "Well name and well list template matching" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

The well must previously have had its segments defined with keyword [WELSEGS](#).

2. Segment number to contain the valve.

An integer between 2 and the NSEGMX argument in the [WSEGDIMS](#) keyword.

3. The dimensionless flow coefficient for the valve,  $C_v$
4. Cross-section area for flow in the constriction,  $A_c$

This quantity is used to convert the volumetric flow rate of fluid through the segment into the flow velocity at the constriction,  $v_c$ .

UNITS:  $m^2$  (METRIC),  $ft^2$  (FIELD),  $cm^2$  (LAB),  $m^2$  (PVT-M)

5. Additional length of pipe for the friction pressure drop,  $L$

Set this to zero if there is no additional friction pressure loss across this segment.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: length of the segment as derived from the [WELSEGS](#) data

6. The pipe diameter,  $D$ , for the frictional pressure drop calculation.

For non-circular pipes, use the equivalent diameter ( $4 \times \text{area} / \text{perimeter}$ ).

The value entered here replaces the diameter entered in item 7 of keyword [WELSEGS](#).

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: no change; the initial value is taken from item 7 of keyword [WELSEGS](#) unless a previous instance of [WSEGVAlV](#) defined a value.

7. The absolute roughness of the pipe wall.

This quantity is used to calculate the Fanning friction factor in the friction pressure loss.

The value entered here replaces the roughness entered in item 8 of keyword [WELSEGS](#).

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: no change; the initial value is taken from item 8 of keyword WELSEGS unless a previous instance of WSEGVALV defined a value.

8. The pipe cross-section area,  $A_p$ , for the frictional pressure drop calculation.

This quantity is used to convert the volumetric flow rate of fluid through the segment into the flow velocity in the pipe,  $v_p$ .

The value entered here replaces the area entered in item 9 of keyword WELSEGS.

UNITS:  $m^2$  (METRIC),  $ft^2$  (FIELD),  $cm^2$  (LAB),  $m^2$  (PVT-M)

DEFAULT: no change; the initial value is taken from item 9 of keyword WELSEGS unless a previous instance of WSEGVALV defined a value.

9. Flag to indicate whether the device is open or shut.

OPEN ICD is open and flow is allowed through the device

SHUT ICD is shut and flow is not allowed through the device. Crossflow, if enabled, will still be allowed in the branch.

DEFAULT: OPEN

10. The maximum cross-sectional area for flow in the constriction,  $A_{max}$ .

DEFAULT:  $A_{max}$  is taken from item 8, if defined, or else from item 9 of keyword WELSEGS.

UNITS:  $m^2$  (METRIC),  $ft^2$  (FIELD),  $cm^2$  (LAB),  $m^2$  (PVT-M)

End the data record with a slash (/).

End the set of data records with a slash.

## The valve modeling

The pressure drop across the device is calculated using a homogeneous model of sub-critical flow through a pipe containing a constriction:

$$\delta P = \delta P_{cons} + \delta P_{fric} \quad \text{Eq. 3.275}$$

$\delta P_{cons}$  accounts for the effects of the constriction, and is calculated as:

$$\delta P_{cons} = C_u \frac{\rho v_c^2}{2C_v^2} \quad \text{Eq. 3.276}$$

$C_u$  is a units conversion constant, which is given in table 3.55,

$\rho$  is the density of the fluid mixture,

$v_c$  is the flow velocity of the mixture through the constriction,

$C_v$  is a dimensionless flow coefficient for the valve.

Unit system	$C_u$	Density	Velocity	Pressure
METRIC	1.0E-5	kg/m <sup>3</sup>	m/s	bars
FIELD	2.159E-4	lb/ft <sup>3</sup>	ft/s	psi
LAB	9.869E-7	gm/cc	cm/s	atm
PVT-M	9.869E-6	kg/m <sup>3</sup>	m/s	atm

Table 3.55: Conversion constant in each unit system for the pressure drop across a device

$\delta P_{\text{fric}}$  accounts for any additional friction pressure loss in the segment containing the valve. It is the standard expression for the homogeneous flow frictional pressure loss through a pipe:

$$\delta P_{\text{fric}} = 2C_u f \frac{L}{D} \rho v_p^2 \tag{Eq. 3.277}$$

$f$  is the Fanning friction factor

$L$  is the additional length of piping in the segment

$D$  is the diameter of the pipe (**not** the constriction)

$v_p$  is the flow velocity of the mixture through the pipe.

Obviously  $v_c$  and  $v_p$  depend on the respective cross-section areas of the constriction and the pipe and the local volumetric flow rate  $q_m$  of the mixture through the segment,

$$q_m = v_c A_c = v_p A_p \tag{Eq. 3.278}$$

The pressure loss sum  $\delta P = \delta P_{\text{fric}} + \delta P_{\text{cons}}$  across a valve segment is reported as the friction pressure loss; the acceleration pressure loss is set to zero.

Using the relationship from equation 3.278  $\delta P_{\text{cons}}$  can be expressed as:

$$\delta P_{\text{cons}} = C'_u \frac{\rho q_m |q_m|}{2C_v^2 A_c^2} \tag{Eq. 3.279}$$

$A_c$  is the cross-sectional area of the valve constriction and takes a minimum value of 1.0E-10,

$C'_u$  is the modified unit conversion factor, which is given in the following table.

Unit system	$C'_u$	Density	Volume flow	Pressure
METRIC	1.340E-15	kg/m <sup>3</sup>	m <sup>3</sup> /day	bars
FIELD	2.892E-14	lb/ft <sup>3</sup>	ft <sup>3</sup> /day	psi
LAB	7.615E-14	gm/cc	cc/hour	atm
PVT-M	1.322E-15	kg/m <sup>3</sup>	m <sup>3</sup> /day	atm

Table 3.56: Modified conversion constant in each unit system for the pressure drop across a device

The base strength of the device,  $K$ , with dimension of inverse area squared, can be defined from equation 3.279 as:

$$K = \frac{C_u'}{(2C_v^2 A_c^2)} \quad \text{Eq. 3.280}$$

If the strength of the valve is greater than 0.1 it will cause the valve to shut. The setting of the device, how open it is relative to the maximum constriction area, is defined as:

$$\frac{A_c}{A_{max}} \quad \text{Eq. 3.281}$$

$A_{max}$  is the maximum constriction area.

## Notes

- A segment can only represent a single device at any one time. Any previous devices generated with the [WSEGLABY](#), [WSEGFLIM](#), [WSEGPULL](#), [WSEGSICD](#) and [WSEGAICD](#) keywords will be replaced.
- Because the device pressure drop is reported using the segment's friction pressure drop, friction effects must be included in any multisegment well for which this keyword is specified (see item 6 of [WELSEGS](#)).
- When defining a valve, to ensure that the setting of SUMMARY keyword SFOPN for the device is accurate for the entirety of the run, the keyword should include the maximum cross-sectional area in the constriction for flow. This is done in item 10,  $A_{max}$ . If no value is given, it will be defaulted to item 8, if defined, otherwise it will be defaulted to item 9 of keyword [WELSEGS](#).

## Example

```

WSEGVAlV
-- Well      Seg      Cv      Ac      L      D      Rough  Ap
-- Name      No
  PROD1     23      0.66   0.01   0.0 / no friction length
  PROD1     24      0.66   0.01   / pipe data taken from WELSEGS /

```

## WSEGWELL Segment secondary well name

	ECLIPSE 100
x	ECLIPSE 300
x	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword provides the facility to associate a specified segment of a multisegment well with a secondary well name (see "Multisegment wells" in the *ECLIPSE Technical Description*). When this association has been established, a number of secondary well controls may be applied to the segment via its secondary well name alias. The WSEGWELL keyword is followed by one or more data records to define the well, the segment number, the secondary well name and the group to which it belongs. Each record is terminated with a slash (/), and the set of records must end with an additional blank record containing just a slash.

The data items in each record are:

1. Well name

A character string of up to eight characters in length.

The well must have previously been defined as a multisegment well and had its segments defined with keyword [WELSEGS](#).

2. Segment number to be associated with the secondary well name

An integer between 2 and the NSEGMX mnemonic in the [WSEGDIMS](#) keyword. The specified segment must previously have been defined for this well.

3. Secondary well name

A character string of up to eight characters in length.

This must not be a previously defined well name.

4. Group name

A character string of up to eight characters in length.

DEFAULT: The group to which the well defined in item 1 currently belongs.

If specified, the group name must already have been defined.

The use of the WSEGWELL and [WSEGXSS](#) keywords is mutually exclusive for a given segment number of a multisegment well.

### Example

```

-- Establish associations between segments and secondary well names
WSEGWELL
-- Well   Segment   Sec      Group
-- Name  Number    Name     Name
  PROD    4          PROD-S4  FIELD /
  INJ     21         GLIFT21  /

## WSEPCOND Specify the separator conditions for wells

	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword associates separator conditions with a well. In compositional runs WSEPCOND must be used to assign separator conditions to a well.

The keyword is followed by any number of records, each containing the items of data described below, and each terminated with a slash (/).

The records can be terminated early with a slash, the remaining items taking default values. Defaults can also be specified by a null repeat count of the form  $n^*$ , where  $n$  is the number of consecutive items to be defaulted.

The set of records is ended by a blank record, containing only a slash.

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. The name of the separator associated with the well.

This must be a mnemonic previously entered with [SEPCOND](#).

### Related keywords

For well production, surface volumes are calculated using a well separator identified using the WSEPCOND keyword. If a well separator is not defined, the group separator defined by the SEPCOND keyword is used. If the group separator is not defined, the field separator defined by the [FIELDSEP](#) keyword is used. If the field separator is not defined, a single flash to standard conditions given by [STCOND](#) is used.

### Example

```
WSEPCOND
P11 SEP1 /
'A*' SEP2 /
/
```

## WSF

## Water saturation functions (GASWAT/CO2STORE cases)

	EDIT
x	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword is used to input the two-phase water relative permeabilities in [GASWAT](#) or [CO2STORE](#) (non-thermal) cases. The gas relative permeability and the gas-water capillary pressure are entered using the [GSF](#) keyword.

The data specified consists of a number of tables of two-phase water saturation data, each terminated with a slash (/). Each table consists of two columns of data. The number of tables should be equal to be number of saturation tables in the run, specified by the [TABDIMS](#) keyword, and defaulting to 1.

Column:

1. The water saturation.

Values should be between 0 and 1 and should increase monotonically down the column.

2. The corresponding water relative permeability.

Values should be between 0 and 1 and should be level or increasing down the column. The first value in the column must be 0.

There must be the same number of entries in each column of a given table, and the number of rows should be less than or equal to the maximum number of rows of saturation data specified with [TABDIMS](#).

### Example

```

WSF
 0      0
.2      0
.4      .004
.5      .036
.6      .146

	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword can be used to add (or subtract) a specified amount to a well control target or limit. The control data must initially have been fully specified using [WCONPROD](#) or [WCONINJE](#). This keyword should **not** be used on a history matching well (see keywords [WCONHIST](#) and [WCONINJH](#)).

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Definitions of the control or constraint quantity to be changed are listed below. This item can be a user defined quantity (UDA) and can be set with the keywords [UDQ](#) and [UDADIMS](#). The values in the brackets are the corresponding values to identify the control quantity if UDA is used for this item.

ORAT [ 1 ] Oil rate

WRAT [ 2 ] Water rate

GRAT [ 3 ] Gas rate

LRAT [ 4 ] Liquid rate

CRAT [ 5 ] Linearly combined rate (coefficients must be set with [LINCOM](#))

RESV [ 6 ] Reservoir fluid volume rate

BHP [ 7 ] Bottom hole pressure

THP [ 8 ] Tubing head pressure (A non-zero VFP table number must first have been set)

LIFT [ 9 ] Artificial lift quantity (A non-zero VFP table number must first have been set)

GUID [ 10 ] Guide rate (For group controlled wells)

The guide rate can only be modified if the well has a user-specified guide rate set for a given phase in keyword [WGRUPCON](#).

*ECLIPSE 300 only* CVAL [ 11 ] Calorific rate.

*ECLIPSE 300 only* NGL [ 12 ] NGL rate.

3. Amount to add for this quantity. This quantity can be a UDA and can be set with the keywords [UDQ](#) and [UDADIMS](#).

UNITS: the units depend upon the quantity chosen. Negative numbers are allowed. The appropriate units are listed in the specification for keywords [WCONPROD](#) and [WCONINJE](#).

4. Number of times addition will be performed. Note that addition will be performed at report timesteps only and this item is active only when a UDA is used for item 3. This item will be truncated to the

greatest integer lower than or equal to its value. Also note that any value less than 1 will be defaulted to 1.

DEFAULT: 1

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

See also keyword [WELTARG](#).

## Example

```
WTADD
  PROD1  ORAT  -200 /
  PROD2  RESV  1000 /
/

## WTAKEGAS Order in which subtractions are taken from gas production

	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies the order in which fuel, sales and reinjection gas are extracted from the production gas stream of a source group or a reinjection control group. See the notes below for a definition of these groups.

All six possible orderings are allowed: FRS, FSR, RFS, RSF, SFR, SRF.

The default is FSR - fuel (keyword [GRUPFUEL](#)), then sales (keyword [GRUPSALE](#)), the remainder being available for reinjection. If there is insufficient gas to satisfy all the three requirements, these are prioritized in the order given.

Possible data item values are:

FSR Fuel, then ReInjection, then Sales

FSR Fuel, then Sales, then ReInjection

RFS ReInjection, then Fuel, then Sales

RSF ReInjection, then Sales, then Fuel

SFR Sales, then Fuel, then ReInjection

SRF Sales, then ReInjection, then Fuel.

### Notes

- A source group is a group whose vapor production supplies the stream for gas injection. For group injection (see keyword [GINJGAS](#) or [GRUPINJE](#)), or for well injection (see keyword [WINJGAS](#) or [WELLINJE](#)), the source group is named in item 3 if the fluid injection stream in item 2 is GV. (For injection streams other than GV, there is no source group.)
- If the injection stream comes from a source group, the amount of gas from this source that is available to reinject is taken into account when calculating injection rates if the availability flag is set (that is, if keyword [WAVAILIM](#) has been entered). The gas available to reinject is by default equal to the source group's gas production rate minus its fuel rate minus its sales target. However, by entering the appropriate item in WTAKEGAS it is possible to prioritize reinjection ahead of fuel and/or sales. Any advance gas allocated to the group (keyword [GADVANCE](#)) is also added to the available gas.
- If the injection stream comes from a single separator stage (see [GINJGAS](#) item 5), the composition of the fuel and sales gas depends on the amount that is reinjected. When there are fuel or sales targets that take precedence over injection, the injection calculation is still performed first, in order to determine the composition of the gas left for fuel and sales, but the injection rate is limited by the requirement to satisfy the higher priority fuel and sales targets.
- A reinjection control group is a group whose gas production rate is used to control the reinjection rate. In [GCONINJE](#) it is the group named in item 11. In [GRUPINJE](#) it is the group named in item 12 if item 11 is set to G. In [WELLINJE](#) it is the group named in item 14 if item 13 is set to G. A reinjection control group is only relevant if a non-zero reinjection fraction has been set ([GCONINJE](#) item 6, [GRUPINJE](#) item 10, [WELLINJE](#) item 12).

- If a specified fraction of a control group's surface gas production rate is being reinjected, the reinjection fraction multiplies the control group's available produced gas rate. The available produced gas rate is by default equal to the control group's gas production rate, plus any advance gas allocated to it (keyword **GADVANCE**), minus its fuel rate minus its sales target. However, if R precedes F in the **WTAKEGAS** item then its fuel rate is not subtracted. Similarly, if R precedes S in the **WTAKEGAS** item then its sales target is not subtracted.
- The fuel, sales and reinjection gas account calculations are performed at the group level with a reinjection target/limit set in item 6 on **GCONINJE**. If a group with fuel/sales/reinjection requirements contains gas injection wells that are not subject to group control (see item 2 of **WGRUPCON**), then these wells may inject gas at a rate that exceeds the reinjection rate calculated for the group after fuel and sales requirements are met (in an FSR case). In this case, the fuel and sales requirements will be equally scaled back so that the total gas usage does not exceed the gas production for the group. If item 95 of **OPTIONS3** is set to 1, the lowest priority out of the fuel and sales gas will be scaled back first. If this item in **OPTIONS3** is set to 2, no scaling back of gas usage will be performed and it will thus exceed the gas production.

See also "[Group injection control options](#)" in the *ECLIPSE Technical Description*.

## Instructions for periodic testing of closed wells

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/). The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Testing interval

This must be greater than zero.

UNITS: day (METRIC), day (FIELD), hr (LAB), day (PVT-M)

The well is tested at the beginning of the first timestep that starts after the specified interval has elapsed since it was closed. Subsequent tests are performed at each timestep that starts after the specified interval has elapsed since the previous test.

If the testing interval is very small (for example, 1 day), the well is tested at the beginning of each timestep (unless of course the timesteps are smaller than this).

3. Closure reason(s) valid for testing

A string of up to 5 characters.

If the string contains a P: The well is tested if it has been closed for any **physical** reason (for example failure to operate at its BHP or THP limit). It is opened if the test shows that it can operate again.

If the string contains an E: The well is tested if it has been closed due to an **economic** limit set in the keywords [WECON](#), [CECON](#) or, for ECLIPSE 100, [WECONINJ](#). If it has at least one open connection, the well is opened if it obeys all the limits set in WECON. Any closed connections will not be reopened. However, if the well has no open connections, it must have been closed after a workover resulting from a water cut, GOR or WGR limit violation. In this case, all connections that were closed by automatic workovers are tested individually. A connection is reopened if its water cut, GOR and WGR do not exceed the limits set in WECON and CECON. Connections that were closed manually are not tested. The well is opened if at least one connection is reopened.

If the string contains a G: The well is opened if it has been closed due to a GROUP or FIELD limit set in keyword [GECON](#) or the GCON----family. The well is opened unconditionally, since it cannot be tested in isolation. If it causes a group or field limit to be broken, the remedial action is performed at the end of the timestep in the usual manner. If the well has no open connections, all connections closed by automatic workovers are reopened.

*ECLIPSE 100 only*

If the string contains a D: The well is tested if it has been closed on exceeding its maximum THP design limit set in keyword [WTHPMAX](#). It is reopened if its THP has fallen below a maximum limit for reopening, when flowing at a specified rate (subject to obeying its other rate and pressure limits). The rate limit applied for the test, and the maximum THP for reopening, are set in keyword [WTHPMAX](#).

ECLIPSE 100 only

If the string contains a C: Connections closed in automatic workovers are tested individually for reopening **while the well is still open**. A connection is reopened if it does not violate any of the limits set in [WECON](#) or [CECON](#). Any connections that were closed manually are not reopened. The difference between this type of test and the test triggered by an E is that the E test is only performed after the whole well has been closed by an economic limit, while the C test is performed while one or more connections have been closed but the well is still producing through other connections. The testing interval (item 2) prevents testing until the specified number of days have elapsed since the most recent automatic closure of **any** connection in that well. Since the well itself does not have to be reopened after a successful C test, the start-up time (item 5) does not apply.

Wells (and, with the C option, connections) that were closed manually are not tested.

DEFAULT: '' (an empty string, which turns off the testing process for the well)

4. Number of times the well can be tested

An integer between 0 and 32767

After the well has been tested this number of times (regardless of whether any tests are successful), it is not tested any more unless this item is reset in a subsequent use of the [WTEST](#) keyword.

A value of 0 allows the well to be tested an unlimited number of times.

DEFAULT: 0

ECLIPSE 100 only

5. Start-up time

The well's efficiency factor is steadily ramped up over the specified start-up time when it is reopened after a successful test. During each timestep after reopening, its efficiency factor is multiplied by the quantity

$$(T - T_o) / (\text{start-up time})$$

where

$T$  is the time at the end of the timestep

$T_o$  is the time the well was reopened

for as long as  $T - T_o < \text{start-up time}$ .

Thus if the start-up time is large compared to the timestep size, the well is brought on gradually, avoiding the timestep convergence difficulties sometimes observed when a high-rate well is suddenly opened.

The start-up time also applies to wells turned on by automatic cycling (see keyword [WCYCLE](#)).

UNITS: day ([METRIC](#)), day ([FIELD](#)), hr ([LAB](#)), day ([PVT-M](#))

DEFAULT: 0.0, which gives an instantaneous start-up.

End the data record with a slash (/).

End the set of records with a blank record containing just a slash.

```

## WTHPMAX Maximum THP design limit data

x	ECLIPSE 100
	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword controls an option to close a well if its tubing head pressure increases above a specified upper limit, such as the maximum pressure design limit for the wellhead. A high THP could occur if the well's GOR increases, for example due to gas coning. A closed well can be tested periodically for reopening (if requested with keyword [WTEST](#)). The well is reopened when its THP falls below the specified reopening limit, for example when the gas cone has subsided to cause a sufficient reduction in GOR.

The well's operating THP is checked against its maximum design limit at the end of each timestep, when the economic limits are checked (for example keyword [WECON](#)). If the THP exceeds the upper limit, the well is shut or stopped, depending on the instructions in item 9 of keyword [WELSPECS](#). The action takes place at the end of the timestep, so the THP limit is exceeded for one timestep. However, in common with the economic limits, if the limit is violated by proportionately more than the tolerance fraction set in keyword [WLIMTOL](#) ECLIPSE repeats the timestep after closing the well.

Wells closed on violating their maximum THP limit may be tested periodically to see if they can be reopened. The testing must be requested with keyword [WTEST](#), and the closure reason string in item 3 of that keyword must contain a D. During testing, the THP of the well is calculated when the well is flowing either at a specified rate of a given phase, or the rate it was flowing at when it was last closed, subject to obeying its BHP limit and any rate limits on other phases set in keyword [WCONPROD](#) or [WELTARG](#). The test is performed at the beginning of the timestep, using the current conditions in the grid cells containing the well's connections. If the well's THP has fallen below a specified upper limit, the well is reopened and flows until closed again by its maximum THP design limit or for any other reason.

The WTHPMAX keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Maximum THP design limit

The well will be shut or stopped (see item 9 of keyword [WELSPECS](#)) at the end of the timestep if its operating THP exceeds this limit.

A default, zero or negative value switches off this limit.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

3. Rate limit applied (see item 4) when testing the well to see if it can be reopened after being closed on violating its maximum THP limit

ORAT Oil rate

WRAT Water rate

GRAT Gas rate

LRAT Liquid rate

RESV Reservoir fluid volume rate

DEFAULT: ORAT

4. Value of the rate limit (see item 3) applied when testing the well to see if it can be reopened

The units depend upon the quantity chosen in item 3. The appropriate units are listed in the specification for keyword [WCONPROD](#).

A default, zero or negative value sets the value of the rate limit equal to the well's flow rate of the associated quantity when it was last closed after exceeding its maximum THP design limit.

5. Maximum THP limit for reopening the well during a test

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

The well will be reopened if its THP has fallen below the value set here. The value must not exceed the maximum design limit set in item 2.

A default, zero or negative value applies the same limit as set in item 2.

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

---

**Note:** items 3, 4 and 5 apply only if the well is to be tested periodically for reopening after being closed on violating its maximum THP design limit. If you wish to have the well tested periodically, you must set the appropriate instructions in keyword [WTEST](#), and ensure that the closure reason string in item 3 of that keyword contains a 'D'.

---

## Example

```

WTHPMAX
-- well   max THP   testing   testing   max THP
-- name   limit     limit     limit value to reopen
  PROD1   1000      ORAT      500        800 /
  PROD2   1000      RESV      1*         800 /
/
    
```

This keyword can be used to multiply a control target or limit for a well by a specified factor. The control data must initially have been fully specified using [WCONPROD](#) or [WCONINJE](#). This keyword should **not** be used on a history matching well (see keywords [WCONHIST](#) and [WCONINJH](#)).

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Definitions of the control or constraint quantity to be changed are listed below. This item can be a user defined quantity (UDA) and can be set with the keywords [UDQ](#) and [UDADIMS](#). The values in the brackets are the corresponding values to identify the control quantity if UDA is used for this item.

ORAT [ 1 ] Oil rate

WRAT [ 2 ] Water rate

GRAT [ 3 ] Gas rate

LRAT [ 4 ] Liquid rate

CRAT [ 5 ] Linearly combined rate (coefficients must be set with [LINCOM](#))

RESV [ 6 ] Reservoir fluid volume rate

BHP [ 7 ] Bottom hole pressure

THP [ 8 ] Tubing head pressure (A non-zero VFP table number must first have been set)

LIFT [ 9 ] Artificial lift quantity (A non-zero VFP table number must first have been set)

GUID [ 10 ] Guide rate (For group controlled wells)

The guide rate can only be modified if the well has a user-specified guide rate set for a given phase in keyword [WGRUPCON](#).

*ECLIPSE 300 only* CVAL [ 11 ] Calorific rate.

*ECLIPSE 300 only* NGL [ 12 ] NGL rate.

3. Multiplying factor for this quantity. This quantity can be a UDA and can be set with the keywords [UDQ](#) and [UDADIMS](#).

UNITS: dimensionless

4. Number of times multiplication will be performed. Note that multiplication will be performed at report timesteps only and this item is active only when a UDA is used for item 3. This item will be truncated

to the greatest integer lower than or equal to its value. Also note that any value less than 1 will be defaulted to 1.

DEFAULT: 1

End data record with a slash (/).

End the set of records with a blank record, containing just a slash.

See also keyword [WELTARG](#).

## Example

```

## WTRACER Sets tracer concentrations for injection wells

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies the value of the concentration of a tracer in the injection streams of its associated phase. If a tracer does not appear in the list of tracer names in the WTRACER keyword, a concentration of 0.0 is assumed.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template.

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

Each well must previously have been declared as an injector.

2. Name of the tracer

(Up to 3 characters)

3. Value of the tracer concentration in the injection stream,  $T_{\text{conc}}$ . This quantity can be a user defined argument (UDA), and can be set with keywords [UDQ](#) and [UDADIMS](#).

*ECLIPSE 100*

If a cumulative tracer factor is specified in item 4, then  $T_{\text{conc}}$  is taken as the maximum tracer concentration.

*ECLIPSE 100 only*

4. The value of the cumulative tracer factor,  $T_{\text{cum}}$ . This quantity can be a user defined argument (UDA), and can be set with keywords [UDQ](#) and [UDADIMS](#).

The cumulative tracer factor allows the tracer concentration to be specified as a linear function of the total cumulative injection of the well. This can be useful when modeling H<sub>2</sub>S generating processes.

If a cumulative tracer factor is specified, then the tracer concentration in the injection stream is given by:

$$T_c = \text{MIN}(CI \cdot T_{\text{cum}}, T_{\text{conc}}) \quad \text{Eq. 3.282}$$

where

CI Total cumulative injection at the previous timestep

$T_{\text{cum}}$  Cumulative tracer factor

$T_{\text{conc}}$  Tracer concentration entered in item 3.

UNITS: 1/sm<sup>3</sup> (METRIC), 1/stb for liquid phase tracers, 1/Mscf for gas phase tracers (FIELD), 1/scc (LAB)

*ECLIPSE 100 only*

5. The group whose produced tracer concentration should be used for the tracer concentration of the injection stream for the well.

If no group is specified, the concentration in item 3 will be used.

End data record with a slash (/).

End the set of records with a blank record, containing just a slash (/).

---

**Note:** When using group reinjection, the concentration used by the well will lag the group's concentration by one timestep.

---

## Example

```
WTRACER
INJ1 WT1 1.0 /
INJ1 WT2 0.0 /
INJ2 WT1 0.0 /
INJ2 WT2 1.0 /
INJ3 IGS 1.0 /
/
```

## WVFPDP

## Adjusts a well's BHP obtained from the VFP tables

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword specifies a pressure adjustment, which is added to the value of the well BHP obtained by interpolating the VFP tables. It can be used, for example, to help match a well's flow rate at a given THP, by adjusting the effective pressure loss between the bottom hole and the tubing head. A positive adjustment increases the BHP and makes a production well less productive. Conversely, a negative adjustment improves the production. The reverse holds for injection wells.

In addition, a tubing pressure loss scaling factor may be specified. ECLIPSE adjusts the well's BHP obtained from the VFP table by multiplying the tubing pressure loss (BHP - THP) by this factor. A scaling factor greater than 1.0 increases the BHP and make a production well less productive.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/). The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2.  $\Delta P$  the pressure adjustment to be added to the well's BHP

UNITS: bars (METRIC), psi (FIELD), atm (LAB), atm (PVT-M)

3. Tubing pressure loss scaling factor,  $F_p$

The well's BHP will be adjusted to BHP\* according to the equation

$$\text{BHP}^* = \text{THP} + F_p \cdot (\text{BHP}_{\text{tab}} - \text{THP}) \quad \text{Eq. 3.283}$$

DEFAULT: 1.0

**Note:** ECLIPSE automatically adjusts the well's BHP to take account of any difference between its BHP reference depth (item 5 in keyword [WELSPECS](#)) and that of the VFP table (item 2 in record 1 of [VFPPROD](#) or [VFPINJ](#)), by adding or subtracting a hydrostatic pressure correction based on the density of the fluid in the well bore. This is done independently of the use of this keyword.

### Example

```

WVFPDP
'P*'      10.0 /
PROD2     -14.3 /
PROD3     0.0 1.15 /
/

```

## WVFPEXP

## Options to overcome certain problems with THP controlled wells

x	ECLIPSE 100
x	ECLIPSE 300
	<b>SPECIAL</b>
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

The WVFPEXP keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. Implicit/explicit flag

(See Note 1, below)

IMP The well interpolates its VFP table with the implicit (latest) values of the water and gas flowing fractions

EXP The well interpolates its VFP table with the explicit (previous timestep's) values of the water and gas flowing fractions

DEFAULT: IMP

3. Close the well if it is found to be operating on the stabilized part of its VFP curve?

(See Note 2, below)

NO The check is not performed.

YES At the end of each timestep, ECLIPSE checks the well if it is a THP-controlled producer to see if it is operating on a stabilized region of its VFP curve, identified by a zero gradient of BHP versus flow rate. If the well is found to be operating in this region it is closed.

DEFAULT: NO

4. Prevent the well changing from rate control to THP control when it is constrained to operate on the unstable side of its VFP curve?

(See Note 3, below)

---

**Note:** In ECLIPSE 300 the switch to THP control is always prevented if this would result in hunting. This item only controls whether or not this action is reported.

---

NO In ECLIPSE 100, changes in the control mode are not prevented. Under some circumstances the well may 'hunt' between THP control and rate control.

YES1 While operating on rate control (including group control), the well is **not** switched to THP control if it is constrained by a low rate limit to operate on the unstable side of the VFP curve, provided that the well would produce at a higher rate under THP control.

A message is printed the first time the well is prevented from changing its control mode.

YES2 As YES1, except that a message is printed **every** time the well is prevented from changing its control mode.

DEFAULT: NO

- ECLIPSE 300 only* 5. Control on how VFP tables are extrapolated for water fraction, gas fraction and Artificial Lift Quantity (ALQ) values that fall outside the range of values in the table.

VFP tables for production wells are constructed with a range of values for flow, THP, water fraction, gas fraction and ALQ. If the table is queried with a value that falls outside of its table range, then in the case of flow and THP, the table is linearly extrapolated in this value. For water fraction and gas fraction values, linear extrapolation can result in non-monotonic or non-U shaped VFP curves; such curves may cause convergence problems, or the well to die prematurely. This item allows you to restrict the extrapolation in water and gas fractions and, for back compatibility, ALQ values.

WG Constant value extrapolation is used for water fraction and gas fraction values in VFP table look ups. So, for example, if a VFP table is queried with a gas fraction that is greater than the maximum value in the table, the look up will be made at the table's maximum gas fraction. The table is linearly extrapolated in ALQ.

WGA Constant value extrapolation is used for water fraction, gas fraction and ALQ values in VFP table look ups. Prior to the 2005A release, this was the extrapolation behavior of ECLIPSE 300.

NONE Linear extrapolation is used for water fraction, gas fraction and ALQ values that fall outside of the bounding values in the VFP table. This is the ECLIPSE 100 behavior.

DEFAULT: WG

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

## Notes

### Implicit/explicit water and gas fractions

When a well is under THP control, its flow rate is determined by the intersection of its inflow performance relationship (IPR) and the VFP curve interpolated at the current value of its water and gas flowing fractions, on a plane of BHP versus flow rate. Often the VFP curve is U-shaped, and when there are two intersections the one with the higher flow rate is chosen (the other being unstable). If the IPR does not intersect the VFP curve, the well is deemed to have died.

Engineering calculations of the intersection point usually plot the VFP curve at a constant water cut and GOR. However, if the well is completed in a number of layers having different water cut values, the overall water cut of the well will depend on the BHP, especially if due to poor vertical communication the layers are at different pressures. Because ECLIPSE uses the latest (implicit) values of the water and gas fractions to interpolate the VFP tables, it sees a VFP curve that is plotted at water cut and GOR values that vary with the BHP. This can alter the shape of the VFP curve away from its usual monotonic or U-shaped nature, perhaps introducing extra minima and unstable regions. If the well enters one of these extra unstable regions, ECLIPSE thinks the well has died and will close it prematurely.

This problem can be overcome by using the explicit (previous timestep's) values of the well's flowing water and gas fractions to look up the VFP table. The VFP curve is no longer be distorted by the variation of water cut or GOR with BHP, thus reducing the risk of premature shut-in. The `WVFPEXP` keyword can be used to designate particular wells to have their VFP tables interpolated at explicit values of the water and gas fractions. Furthermore, if ECLIPSE detects that a well has entered an unstable region of the VFP curve while using implicit values of the flowing fractions, it will automatically change the well to use explicit values, and print a warning message.

**Note:** Explicit water and gas fractions are only used to look up the VFP tables to obtain the flowing BHP. The actual water cut and GOR of the well are still calculated implicitly as usual.

ECLIPSE 100

Item 2 essentially replaces `OPTIONS` keyword [item 9](#). However, for back-compatibility, if `OPTIONS` item 9 is set greater than zero then all wells use explicit values of the water and gas fractions to interpolate the VFP tables, irrespective of any instructions in `WVFPEXP`.

### Stabilized VFP curves

Another use of the `WVFPEXP` keyword is to activate a check for wells operating on the flat part of a stabilized VFP curve. The VFP *i* program can output stabilized VFP tables, in which the unstable part of the VFP curves to the left of the minimum is replaced with a horizontal line at the minimum BHP value. This can overcome problems caused by the sudden death of a well when its IPR drops off the minimum of the VFP curve, since the flow continuously reduces to zero as the grid block pressure decreases instead of stopping suddenly. However, it does allow wells to continue to operate at lower flow rates when physically they would be unable to flow. By setting item 3 in this keyword, ECLIPSE can be instructed to shut the well in at the end of the timestep when it has converged on a solution in the stabilized part of the VFP curve, which is identified by a zero gradient of BHP versus flow rate. In ECLIPSE 100, the switch also prevents wells being reopened by the `WTEST` keyword if they would be operating on the flat stabilized part of the VFP curve.

### Flow limits within the unstable region

The U-shape of a VFP curve can also cause problems if a well is constrained by a rate limit (or a group control rate target) to operate within the unstable part of the curve. In this region the THP of the flowing well decreases as the flow rate decreases, and at a low enough flow rate the THP may fall below its minimum limit. The well would normally then switch to THP control, and it could either start hunting between control modes or die prematurely. ECLIPSE 100 and ECLIPSE 300 differ in their behavior at this point as described below.

ECLIPSE 100

By setting item 4 to `YES1` or `YES2` the well is prevented from changing to THP control as long as it would produce at a **higher** rate under THP control. Under these circumstances the well continues to operate at its rate constraint, while its calculated THP is allowed to fall below the minimum limit. But it is still allowed to die if its IPR falls off the bottom of the VFP curve. This item replaces [item 73](#) in `OPTIONS` keyword, which was formerly used to prevent control mode switching from happening in these circumstances for all wells.

ECLIPSE 300

The well will **always** be prevented from changing to THP control if it would produce at a **higher** rate under THP control. item 4 only controls the reporting of this action.

WVFPEXP
'PROD*' EXP YES YES1 /
/
```

## WWPAVE

## Individual well block average pressure controls

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

This keyword controls the calculation of well block average pressures for individual wells. The well block average pressures are computed using the same formulae as those employed by the [WPAVE](#) keyword. They represent the average pressure of the grid blocks containing connections to a given well, and optionally their adjacent and diagonal neighbors. Neighbor contributions can be weighted according to either the connection transmissibility factors or the grid block pore volumes. The [WWPAVE](#) keyword overwrites any current controls specified by the [WPAVE](#) keyword and in turn can be overwritten by any subsequent use of the [WPAVE](#) keyword.

The average pressures can be written to the Summary file using the SUMMARY section keywords [WBP](#), [WBP4](#), [WBP5](#) and [WBP9](#). Well PIs based on these average pressures can also can be written to the Summary file using the SUMMARY section keywords [WPI1](#), [WPI4](#), [WPI5](#) and [WPI9](#) (see "[SUMMARY section](#)").

The averages relate to a Cartesian grid and should not be used in a radial grid. The averages are used for reporting purposes only, and will not affect any other results.

The keyword is followed by any number of records, each containing the following items of data, and each terminated with a slash (/).

The set of records must end with a blank record, containing only a slash (/).

1. Well name, well name template, well list or well list template

A template enclosed in quotes can be used to refer to multiple wells or well lists. See "[Well name and well list template matching](#)" in the *ECLIPSE Technical Description* for further details. Well list names should be enclosed in quotes and begin with an asterisk (\*). Well lists are constructed with the keyword [WLIST](#).

2. F1, the weighting factor between the inner block and the outer ring of neighboring blocks, in the connection factor weighted average.

If the value lies between 0.0 and 1.0, the average is calculated by equation [3.236](#). The value 1.0 gives total weighting to the inner blocks, containing the well connections. The value 0.0 gives total weighting to the 4 or 8 blocks neighboring each inner block.

A value of  $F1 < 0.0$  is used to indicate that the pressure of the inner block and its outer ring of neighboring blocks should be averaged according to their pore volumes. The average block pressure for each connection is calculated by equation [3.237](#).

DEFAULT: 0.5

---

**Note:** For one-block averages ([WBP](#)) F1 is effectively 1.0, whatever the value entered here.

---

3. F2, the weighting factor between the connection factor weighted average and the pore volume weighted average, used by [3.234](#).

The value should lie between 0.0 and 1.0. The value 1.0 gives a purely connection factor weighted average, and 0.0 gives a purely pore volume weighted average.

DEFAULT: 1.0

4. Depth correction flag

This flag controls how the grid block pressures are corrected to the well's bottom hole reference depth (see item 5 in keyword [WELSPECS](#)), or to an alternative reference depth if specified in keyword

**WPAVEDEP**, by applying a hydrostatic head between each grid block center and the well's reference depth.

**WELL** The hydrostatic head is calculated using the density of the fluid in the wellbore at the well connections.

**RES** The hydrostatic head is calculated using a representative density for the fluid in the reservoir. This density is calculated by averaging over fluid density for all the grid blocks associated with the well's connections. The average over phases is weighted by the phase saturation, and the average over grid blocks is weighted by pore volume. Whether the averaging is performed over all grid blocks with declared connections to the well or only those with currently open connections is determined by item 4.

**NONE** Grid block pressures are not depth corrected.

DEFAULT: WELL

---

**Note:** The wellbore fluid density is set to zero whenever the well is shut. Thus if **WELL** is selected there is a discontinuity in the reported pressure average when the well's status changes between shut and open/stopped.

---

#### 5. Well connection flag

This flag controls whether the grid blocks associated with **all** the well's declared connections contribute to the average pressure, or just those associated with the currently **open** connections.

**OPEN** Only grid blocks associated with currently open connections are included in the averaging calculation.

**ALL** Grid blocks associated with all currently defined connections (whether open or closed) are included in the averaging calculation.

DEFAULT: OPEN

---

**Note:** If **OPEN** is selected there is a discontinuity in the reported pressure average whenever new connections are opened or existing ones are closed. This may be avoided by selecting **ALL** and defining all the well's connections at the start of the run (whether initially open or closed).

---

If this keyword is not present, all items assume their default values, giving a connection factor weighted average, evenly weighted between the inner blocks and the outer ring of neighbors. The depth correction uses the wellbore density and only grid blocks associated with currently open well connections are included in the average.

---

**Note:** In dual porosity runs the wells are completed in the fracture system. A **WBPn** average reports the average pressure in the surrounding fracture cells.

---

End the data record with a slash (/).

End the set of records with a blank record, containing just a slash.

## Example

# Specifies cell initial oil composition

	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies the initial oil composition values for each cell. The keyword should be followed by  $N_x \cdot N_y \cdot N_z \cdot N_c$  values in normal order, with the X index changing fastest. For thermal runs with water  $N_x \cdot N_y \cdot N_z$  extra values are required, all set to zero.

This keyword may be used to specify the initial solution explicitly, as an alternative to equilibration using [EQUIL](#), the usual method of initializing a compositional run.

Explicit initialization is expected if the [PRESSURE](#) keyword is present. The same information may be obtained from a Restart file using the [GETSOL](#) keyword, or composition may be entered as a function of pressure using [XMFVP](#).

When using explicit initialization, you must ensure that the initial solution is stable and physically reasonable. This is potentially difficult in the case of two-phase hydrocarbon cells, and XMF should be used with caution.

XMF values that do not sum to 1.0 are normalized provided the error is less than 10%. An error greater than 10% is flagged as a data error.

See "[Initial composition with respect to depth](#)" in the *ECLIPSE Technical Description* for further information.

## Example

```
XMF
300*0.0021
300*0.0294
300*0.6599
300*0.0869
300*0.0591
300*0.0967
300*0.0472
300*0.0153
300*0.0034 /
```

## XMFVP

## Liquid composition with respect to pressure tables

The data comprises a table of liquid composition with respect to pressure data for each equilibration region. Each table consists of  $N_c$  columns of data, and is terminated with a slash (/).

Column:

1 Pressure values.

The values should increase monotonically down the column.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

2 to  $N_c + 1$  The corresponding values of  $x_i$ , the liquid phase mole fractions.

The  $N_c$  mole fractions specified must add up to unity, and the program checks that this is the case.

For pressure values outside the interval specified, constant value extrapolation is performed.

The default maximum number of rows per table is 50; this may be reset using the third item in keyword [EQLDIMS](#). The number of equilibration regions is entered using the first item in keyword [EQLDIMS](#).

See keyword [XMF](#) and "[Initial composition with respect to depth](#)" in the *ECLIPSE Technical Description* for further information.

### Example

In this case a constant composition with respect to pressure.

```
XMFVP

x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies the initial gas composition values for each cell. The keyword should be followed by  $N_x \cdot N_y \cdot N_z \cdot N_c$  values in normal order, with the X index changing fastest. For thermal runs with water,  $N_x \cdot N_y \cdot N_z$  extra values are required, giving the fraction of water in the gas phase.

This keyword may be used to specify the initial solution explicitly, as an alternative to equilibration using [EQUIL](#), which is the normal method of initializing a compositional run.

Explicit initialization is expected if the [PRESSURE](#) keyword is present.

The same information may be obtained from a Restart file using the [GETSOL](#) keyword, or composition may be entered as a function of pressure using [YMFVP](#).

When using explicit initialization, you must ensure that the initial solution is stable and physically reasonable. This is potentially difficult in the case of two-phase hydrocarbon cells, and YMF should be used with caution.

YMF values that do not sum to 1.0 are normalized provided the error is less than 10%. An error greater than 10% is flagged as a data error.

See "[Initial composition with respect to depth](#)" in the *ECLIPSE Technical Description* for further information.

### Example

```

YMF
300*1.0
300*0.0
300*0.0
300*0.0
300*0.0
300*0.0
300*0.0
300*0.0
300*0.0
300*0.0
300*0.0 /

```

## YMFVP

## Vapor composition with respect to pressure tables

The data comprises a table of vapor composition with respect to pressure data for each equilibration region. Each table consists of  $N_c$  columns of data, and is terminated with a slash (/).

Column:

1 Pressure values.

The values should increase monotonically down the column.

UNITS: barsa (METRIC), psia (FIELD), atma (LAB), atma (PVT-M)

2 to  $N_c + 1$  The corresponding values of  $y_i$ , the vapor phase mole fractions.

The NCOMPS mole fractions specified must add up to unity, and the program will check that this is the case.

For pressure values outside the interval specified, constant value extrapolation is performed.

The default maximum number of rows per table is 50; this may be reset using the third item in keyword [EQLDIMS](#). The number of equilibration regions is entered using the first item in keyword [EQLDIMS](#).

See keyword [YMF](#) and "[Initial composition with respect to depth](#)" in the *ECLIPSE Technical Description* for further information.

### Example

In this case a constant composition with respect to pressure.

```

YMFVP
1000.0 0.0121 0.0194 0.6597 0.0869 0.0591 0.0967 0.0472 0.0153 0.0034
10000.0 0.0121 0.0194 0.6597 0.0869 0.0591 0.0967 0.0472 0.0153 0.0034
/

	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

This keyword has no effect if `GEOMECH` is not specified in the `RUNSPEC` section.

The keyword should be followed by one non-negative real number for every grid block in the current input box, specifying the rock Young's modulus. The data must be terminated by a slash (/).

UNITS: bars (`METRIC`), psi (`FIELD`), atm (`LAB`), atm (`PVT-M`)

Grid blocks are ordered with the X-axis index cycling fastest, followed by the Y- and Z-axis indices.

Repeat counts may be used for repeated values (for example `115*208.4`). Spaces may not be inserted on either side of the asterisk.

---

**Note:** There is no default for the Young's modulus. The simulation will stop if the `GEOMECH` keyword is specified but this data is not supplied.

---

### Example

```

-- Field units (psi)
YOUNGMOD
81*1.45E6 81*1.E4 81*1.E5 81*1.8E5 /

```

## Specifies gas composition at standard conditions

This keyword specifies the gas composition associated with surface volume rates in the Flux Boundary option.

This is required when a Flux file generated from a black oil run is used in either a compositional or a thermal run.

For further information, see "[Flux boundary conditions](#)" in the *ECLIPSE Technical Description*.

### Example

```
YSTC
.0121 .0194 .6599 .0869 .0591 .0967 .04745 .01515 .0033 /
```

## **Z**

This section contains an alphabetic listing of keywords starting with the letter Z.

## ZCORN

## Depths of grid block corners

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
x	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
	SCHEDULE

Each grid block has 8 corners. This keyword enables the depths of each corner of each grid block to be separately specified. It is used for specifying depths for corner point geometry.

The ZCORN data are entered for the current box. If a **BOX** keyword is currently active (**ENDBOX** has not cancelled it) when ZCORN is encountered, then the number of values entered must be the number for that box. If no **BOX** keyword is currently active, then the default box spanning the global grid is assumed, which is defined by the **DIMENS** keyword.

The keyword must be followed by

2 \* NDX \* 2 \* NDY \* 2 \* NDZ

values, where NDX, NDY, NDZ are the dimensions of the current box. For cell  $i$ , the 8 ZCORN values are  $z_{i,1}$ ,  $z_{i,2}$ ,  $z_{i,3}$ ,  $z_{i,4}$ ,  $z_{i,5}$ ,  $z_{i,6}$ ,  $z_{i,7}$ ,  $z_{i,8}$ . Here values 1-4 are for the top face, with  $z_{i,1}$  on the near left corner,  $z_{i,2}$  on the near right corner,  $z_{i,3}$  on the far left corner, and  $z_{i,4}$  on the far right corner. Values 5-8 have the same function for the bottom face. Then the arrangement of the ZCORN values within this range are:

- for the first row of NDX cells, input the near top values  $z_{1,1}$ ,  $z_{1,2}$ ,  $z_{2,1}$ ,  $z_{2,2}, \dots$ ,  $z_{i,1}$ ,  $z_{i,2}, \dots$ ,  $z_{NDX,1}$ ,  $z_{NDX,2}$ , followed by the far top values  $z_{1,3}$ ,  $z_{1,4}$ ,  $z_{2,3}$ ,  $z_{2,4}, \dots$ ,  $z_{i,3}$ ,  $z_{i,4}, \dots$ ,  $z_{NDX,3}$ ,  $z_{NDX,4}$ .
- Repeat for each subsequent row of NDX cells in the top plane.
- Now repeat the last two steps for the **bottom** values of the top plane.
- Finally, repeat all previous steps for each plane in the grid.

The resulting data will lie on the grid constructed by the corner points in space, with “touching” corners of adjacent cells separated by a small margin. The separation is only for visualizing the grid, and does not affect the ZCORN values.

The last value is followed by a slash (/).

As the data for this keyword can be quite voluminous, it is suggested that the data should be prepared using a grid pre-processor (for example PETREL).

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

DEFAULT: <undefined>

If fine control is required in positioning the corner points in local grid refinements (see "[Local grid refinement and coarsening](#)" in the *ECLIPSE Technical Description*), then ZCORN can also be used in a **CARFIN** or **REFINE** block. In this case, the ZCORN values will be checked for consistency with the parent grid. The current box here is for the local grid.

ECLIPSE 300

If the average value of  $DZ \leq 10^{-6}$  for any cell, the cell will be either be made inactive or in thermal cases it may become rock-filled.

## Example

Here NDX=3, NDY=2, NDZ=2:, and the two z-planes are horizontal with all cells touching exactly.

```
ZCORN
24*1000
24*1020
24*1020
24*1040 /
```

This keyword can only be used with the [THERMAL](#) option.

Z-factors are used to determine molar volumes using the relationship  $V = ZRT / P$ . In a live oil thermal run the Z-factors are assumed to be:

$$Z = Z_0 - Z_1 \cdot \frac{P}{RT}$$

where the coefficient  $Z_0$  and  $Z_1$  are given by keywords [ZFACTOR](#) and ZFACT1 respectively. They are also used in determining the pressure dependence of the gas component enthalpy

$$\frac{\partial H}{\partial P} = -Z_1$$

The coefficient  $Z_1$  can be determined from the Joule-Thomson coefficient  $\mu^c$  and the average gas molecular weight  $MW_{gas}$  and the average gas specific heat  $C_{gas}$ :

$$Z_1^c = \mu^c \cdot MW_{gas} \cdot C_{gas}$$

There should be one value for each component.

UNITS: m<sup>3</sup>/kg-M (METRIC), ft<sup>3</sup>/lb-M (FIELD), cc/gm-M (LAB), m<sup>3</sup>/kg-M (PVT-M)

DEFAULT: 0.0

If multiple equations of state are being used, a set of data should be entered for each reservoir. The number of reservoir equation of state regions is entered as item 9 of [TABDIMS](#). Use of multiple EoS regions is discussed in "[Reservoir equation of state](#)" in the *ECLIPSE Technical Description*.

## Turns on automatic timestep selection control

x	ECLIPSE 100
x	ECLIPSE 300
	SPECIAL
	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
	SOLUTION
	SUMMARY
x	SCHEDULE

ECLIPSE chooses its timestep by referring to a number of conditions; it takes the most restrictive. These conditions are explained elsewhere. The basic principle is that, subject to accuracy, ECLIPSE takes the largest timestep possible. However, the biggest timestep is not necessarily the most efficient in terms of computational cost per simulated day. Use of this keyword adds another constraint on the timestep selection that takes a smaller timestep if it is predicted that this is more efficient.

The aim of this keyword is to provide a near optimal performance run with one keyword call using no, or minimal, *a priori* knowledge of the problem. This is to be compared with the number of calls to [TUNING](#) and the amount of *a posteriori* knowledge that would be required to achieve the same result using conventional means.

When using LGRs the timestep restriction applies to the global grid only. This restriction does not apply when used with LGRs-in-place; see the [LGRLOCK](#) keyword.

The feature can be turned off by using the [ZIPP2OFF](#) keyword.

---

**CAUTION:** The problem of timestep selection has not been solved for the general case. Using this keyword on many ‘well-behaved’ datasets increases the run time unless the right combination of options is selected--which is no improvement over the [TUNING](#) keyword. Use of ZIPPY2 in such cases is not recommended.

---

There is one group of problems, though, where use of this keyword will make a significant impact on the run times. These are runs that are very choppy, where the “NON-LINEAR EQUATION CONVERGENCE FAILURE” message is occurs throughout the run, or large portions of it.

There follows a full list of possible options within ZIPPY2. After this listing a selection of recommended choices is given. All the options must be enclosed in quotation marks ‘ ’.

Many of the options contain integer or real number data items and these should be input in the usual ECLIPSE manner of ‘KEYWORD = integer’. In some case two numbers are required; these should be separated with a comma, for example, ‘KEYWORD =1,5’.

*ECLIPSE 100 only*

‘NEWTON = integer’ Sets the maximum number of Newton iterations.

Included as an alternative to setting it in the [TUNING](#) keyword. Note that setting it here overwrites any previous value set with the [TUNING](#) keyword and that any subsequent use of the [TUNING](#) keyword overwrites any value entered here.

*ECLIPSE 100 only*

‘MINCHOP = real’ Sets the minimum choppable timestep.

Included as an alternative to setting it in the [TUNING](#) keyword. Note that setting it here overwrites any value set previously with the [TUNING](#) keyword and that any subsequent use of the [TUNING](#) keyword overwrites any value entered here.

‘MINSTEP = real’ Sets the minimum timestep

Included as an alternative to setting it in the [TUNING](#) keyword. Note that setting it here overwrites any value set previously with the [TUNING](#) keyword and that any subsequent use of the [TUNING](#) keyword overwrites any value entered here.

<i>ECLIPSE 100 only</i>	‘ MAXSTEP = <i>real</i> ’	<p>Sets the maximum timestep.</p> <p>Included as an alternative to setting it in the TUNING keyword. Note that setting it here overwrites any value set previously with the TUNING keyword and that any subsequent use of the TUNING keyword overwrites any value entered here.</p>
<i>ECLIPSE 100 only</i>	‘ NEXTSTEP = <i>real</i> ’	<p>Sets the next timestep.</p> <p>Included as an alternative to setting it in the TUNING keyword. Note that setting it here overwrites any value set previously with the TUNING keyword and that any subsequent use of the TUNING keyword overwrites any value entered here. The same applies to the use of the <a href="#">NEXTSTEP</a> keyword.</p>
<i>ECLIPSE 100 only</i>	‘ TIGHTEN = <i>real</i> ’	<p>Sets the amount to tighten convergence tolerances by.</p> <p>Included as an alternative to setting it in the TUNING keyword. Note that setting it here overwrites any values set previously with the TUNING keyword and that any subsequent use of the TUNING keyword overwrites any value entered here.</p>
	‘ SIM = <i>real</i> ’	<p>Simple timestep selection algorithm</p> <p>Attempts to select timesteps so that the user-given number of Newtons is needed to solve it. A real number is preferable to an integer. No other keywords are needed if this option is selected.</p>
<i>ECLIPSE 100 only</i>	‘ AGGRESSIVE=YES ’	Can only be used with the SIM option above
	‘ AGGRESSIVE=NO ’	<p>Attempts to increase timesteps faster when it feels safe to do so.</p> <p>This option performs better with higher values of SIM (see example below), and will result in more chops but will also often lead to a reduction in CPU time.</p>

## Data

These options determine the amount of data to be used in approximating the cost function. These options can only be used with ECLIPSE 100.

<i>ECLIPSE 100 only</i>	Use of ‘ NPTS ’ is compulsory
<i>ECLIPSE 100 only</i>	Use of ‘ PARTITION ’ is optional.
<i>ECLIPSE 100 only</i>	‘ NPTS = <i>integer</i> ’      Number of different timesteps for which data is stored.
<i>ECLIPSE 100 only</i>	‘ PARTITION = <i>integer</i> ’      Number of data partitions.
	<p>Partitions the data into the specified number of groups by size of timestep. New data overwrites the oldest data in the group to which it belongs. This can stop or delay the loss of data for large timesteps because of being overwritten by newer small timestep data and vice versa.</p> <p>DEFAULT: 1 Definition of the cost</p>

These options define the cost function (measure of efficiency of a timestep) to be used. These options can only be used with ECLIPSE 100.

ECLIPSE 100 only Use of either ' CPU ' or ' SOLVER ' is compulsory.

ECLIPSE 100 only Use of SPRING is optional.

' CPU ' Uses CPU times from the machine.

---

**CAUTION:** This is the true cost of a timestep and in many ways must therefore be preferred. However, the CPU time 'flutters', which then feeds into the timestep selection. If this cost function is used, results are **not** repeatable, because different timesteps will be used in each run.

---

ECLIPSE 100 only ' SOLVER = integer1\*number of newtons + integer2\*number of  
integer1,  
integer2 ' linear.

The CPU cost, apart from very small problems, is dominated by the time spent calculating the Jacobian terms for the Newton iteration and solving the resulting linear system. Using this cost function does mean that the same timestepping can be repeated between two runs. Also note that the integer values **do not** have to be chosen so that cost equals CPU cost; it only needs to be proportional.

ECLIPSE 100 only ' SPRING = real, integer ' Multiplies the cost function by an additional, newton-weighted, factor.

The cost of the timestep, as defined by one of the means above, is multiplied by the following function:

$$\left(1 + \text{real} \left( \frac{\text{NEWT}}{\text{NEWTMX}} \right)^{\text{integer}} \right)$$

where NEWT is the number of Newtons used for this timestep and NEWTMX is the maximum number of Newtons allowed. This non-linearly penalizes timesteps that use more Newton iterations. The situations when this might be useful are described below.

### Fitting function type

These keywords define how the cost function, defined above, is going to be approximated based on the discrete data (defined by data keywords) that has been stored about it. These keywords can only be used with ECLIPSE 100

Use of **one** of the following is compulsory.

'BEZIER=  
integer' Uses a Bezier polynomial with *integer* coefficients to fit the data.

Note that *integer* coefficients means that the resulting polynomial is of degree *integer-1*.

'BEZIER2=  
integer' Uses a Bezier polynomial with *integer* coefficients to fit the data. The coefficients are constrained to be positive.

Note that *integer* coefficients means that the resulting polynomial is of degree *integer-1*.

'POLY= integer' Uses a polynomial with *integer* coefficients to fit the data.

Note that *integer* coefficients means that the resulting polynomial is of degree *integer-1*.

'PADE= *integer*' Uses a Padé polynomial with *integer* coefficients to fit the data.

The Padé approximation used is not totally general, in that the same degree polynomial is used in the numerator and the denominator. The integer value supplied must be of the form  $2n+1$ .

'OTW= *integer*' For developer use only.

## Discussion and recommendations

It has already been stated that ZIPPY2 is not capable of speeding up all runs and is most effective for those that chop repeatedly. ZIPPY2 can, however, be used when only a small part of the run is affected.

### Cosmetic Improvements

As an alternative to using [TUNING](#) to reduce the maximum timestep before a problem starts and then untuning it afterwards, the ZIPPY2 keyword can be used to achieve a similar effect without the need to know what a workable maximum timestep is. For this situation the recommendation is simply to use Example 1 above.

## Examples

### Example 1

```
ZIPPY2
'SIM=3.1' 'MINSTEP=0.000001' /
```

```
ZIPPY2
'SIM=6.1' 'MINSTEP=0.000001' 'AGGRESSIVE=YES' /
```

It is strongly recommended that the [ZIPP2OFF](#) keyword is used once the problem period is over, otherwise there may be a significant loss of efficiency.

The very small value of MINSTEP entered is only to ensure that the simulator does not accept un-converged timesteps due to being unable to take smaller timesteps; the simulator will not take timesteps as small as this unless it really needs to. (In ECLIPSE 100, setting MINCHOP to a small value is also a good safety precaution.)

The value of 3.1 Newtons is a little conservative and, in most cases, will not be the most efficient. A more efficient value is probably between 4 and 5, but every case is different and it is impossible to generalize with any great success. Integer values should be avoided.

One strategy is to use ZIPPY2 to find what timestep values are appropriate. This information can then be used to guide the choice of where to place the [TUNING](#) keywords and what maximum timesteps can be reasonably set.

*ECLIPSE 100 only*

When the 'SIM' option is not being used the rest of the options attempt to represent the cost per simulated day as a function of the timestep taken. This function is then minimized to give the most efficient timestep.

### Example 2

It is strongly recommended that the [ZIPP2OFF](#) keyword is used once the problem period is over. There may otherwise be a significant loss of efficiency.

**To improve efficiency**

ECLIPSE chops the timestep for one reason: because it failed to converge within the given number of Newton iterations. However, there are two reasons why this happens.

- The first case is when the Newton iteration may be diverging; in this case increasing the maximum number of Newtons means that more time is wasted.
- The second case is when the Newton iterations are converging, but do not make the set tolerances before the maximum Newton limit is reached.

It is sometimes possible to distinguish which might be the case by comparing the length of timestep with the number of Newtons needed. If the ratio of timesteps is roughly equal to the ratio of Newtons used then the case is probably the latter. If a small increase in timestep leads to an unexpectedly large growth in the number of Newtons then there may well be divergence.

**Example 3 - Diverging Iterations**

In this case it is best to start with the simple device of:

```
ZIPPY2
'SIM=3.1' /
```

However, this choice can be very inefficient for converging problems.

**Example 4 – Converging Iterations or uncertainty**

ECLIPSE 100 only

Whilst every case is different, one of the most robust choices for ECLIPSE 100 seems to be:

```
ZIPPY2
'CPU' 'NPTS=15' 'SPRING=3.1,2' 'BEZIER=5' /
```

If it is important to be able to repeat the timestepping then replace 'CPU' with something like 'SOLVER=4,1'.

The SPRING option is included to penalize high numbers of iterations. In a converging case we do not want to predict a timestep, no matter how efficient it is predicted to be, if it is going to take even one more Newton than is allowed; hence the inclusion of this artificial penalty function.

Clearly the number of possible combinations is endless. One could soon waste as much time with them as with trying to get the maximum timestep right with the [TUNING](#) keyword. The combinations most worthy of trying are:

- Adding 'NEWTON=20', for example.

In the converging case this may allow larger timesteps to be taken if they are predicted to be more efficient. Beware, though, that when the code chops--none of these options guarantees no chopping--then with a higher maximum number of Newtons more time is wasted.

- Using 'BEZIER2=5'

Sometimes, more usually in the diverging iteration case, 'BEZIER2=5' is better than 'BEZIER=5'.

	RUNSPEC
	GRID
	EDIT
	PROPS
	REGIONS
x	SOLUTION
	SUMMARY
	SCHEDULE

This keyword specifies the initial total composition values for each cell. The keyword should be followed by  $N_x \cdot N_y \cdot N_z \cdot N_c$  values in normal order, with the X index changing fastest. For thermal runs with water,  $N_x \cdot N_y \cdot N_z$  extra values are required specifying the initial water composition for each cell.

This keyword is normally used to specify the initial solution explicitly, as an alternative to equilibration using [EQUIL](#), the usual method of initializing a compositional run. Explicit initialization will be expected if the [PRESSURE](#) keyword is present. The syntax follows that of [XMF](#) and [YMF](#). In this context, the keyword should only be used when the reservoir contains a single hydrocarbon phase (either oil or gas).

An alternative use of the keyword is to overwrite the hydrocarbon composition in a case that has been equilibrated. This can be useful as the equilibration process generates the water saturations, but an engineer may want a non-equilibrium start to handle areal variations in composition. In this case the [ZMF](#) keyword is used with the [EQUIL](#) keyword (not with the [PRESSURE](#) keyword). If this option is used then the usual data for equilibration (for example [ZMFVD](#)) needs to be entered to obtain the initial equilibrium solution.

[ZMF](#) values that do not sum to 1.0 are normalized provided the error is less than 10%. An error greater than 10% is flagged as a data error.

## Example

```
ZMF
324*0.0021
324*0.0294
324*0.6599
324*0.0869
324*0.0591
324*0.0967
324*0.0472
324*0.0153
324*0.0034 /
```

## Total composition with respect to depth tables

The data comprises a table of total composition with respect to depth data for each equilibration region. Each table consists of  $N_c + 1$  columns of data, and is terminated with a slash (/).

Column:

1. Depth values.

The values should increase monotonically down the column.

UNITS: m (METRIC), ft (FIELD), cm (LAB), m (PVT-M)

2. to  $N_c + 1$  The corresponding values of  $z_i$ , the total phase mole fractions. The  $N_c$  mole fractions specified must add up to unity, and the program will check that this is the case.

For depth values outside the interval specified, constant value extrapolation is performed. If the composition is independent of depth, only a single row is required.

The default maximum number of rows per table is 50; this may be reset using the third item in keyword [EQLDIMS](#). The number of equilibration regions is entered using the first item in keyword [EQLDIMS](#).

See also "[Initial composition with respect to depth](#)" in the *ECLIPSE Technical Description*.

### Example

In this case a constant composition with respect to depth for 2 equilibration regions, with a nine-component system:

```
ZMFVD
1000.0 0.0121 0.0194 0.6597 0.0869 0.0591
        0.0967 0.0472 0.0153 0.0034
10000.0 0.0121 0.0194 0.6597 0.0869 0.0591
        0.0967 0.0472 0.0153 0.0034 /
1000.0 0.0121 0.0194 0.6597 0.0869 0.0591
        0.0967 0.0472 0.0153 0.0034
10000.0 0.0121 0.0194 0.6597 0.0869 0.0591
        0.0967 0.0472 0.0153 0.0034 /
```
