

Sea bed diffraction and impact on 4D seismic data – *observations from synthetic modeling and field data*

B.Osdal, Statoil,
S.Grude and M.Landrø, NTNU

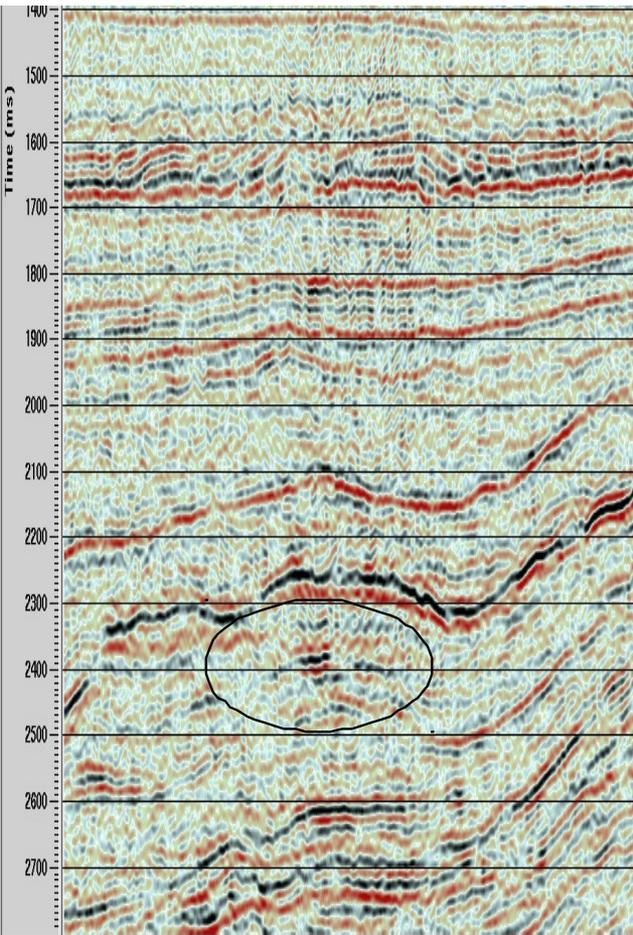

Objective

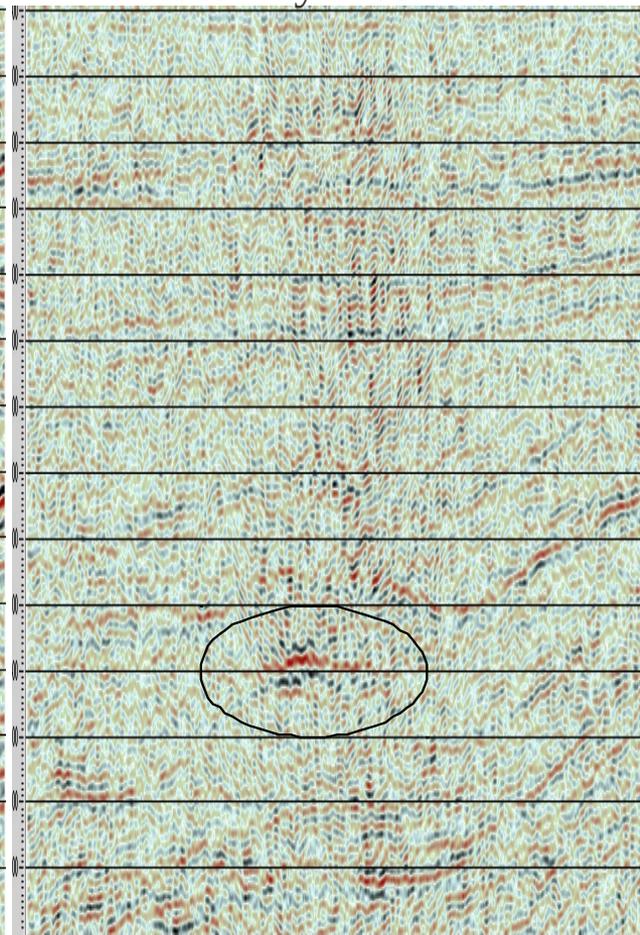

- **Better understand the influence of sea bed diffractions on water layer correction in 4D processing**
 - **Corrections for water layer changes very important in 4D processing**
 - **Diffracted multiples degrade 4D quality**

Motivation

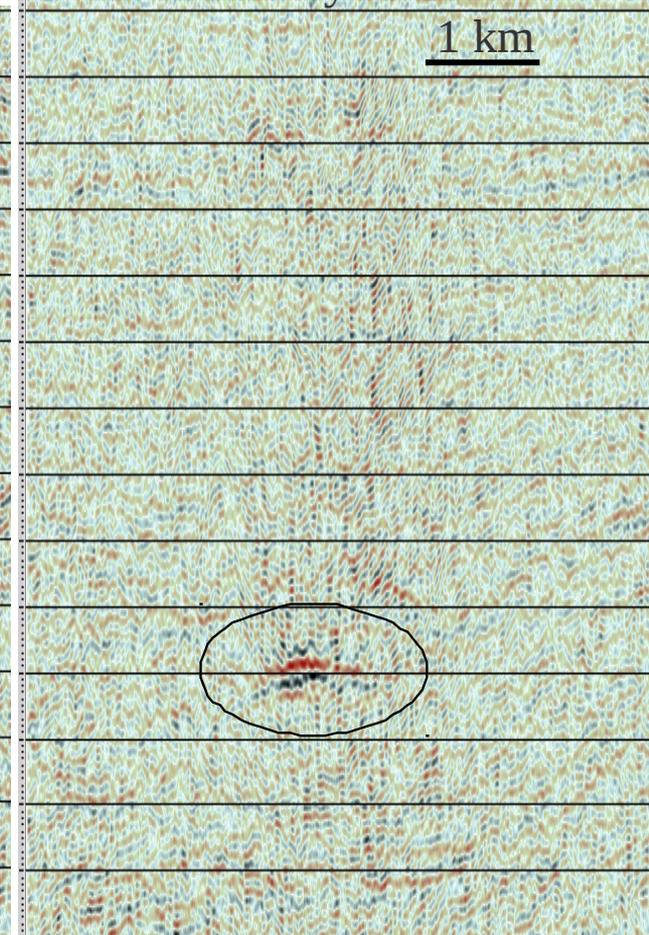

Migrated stack

4D difference
No water layer correction

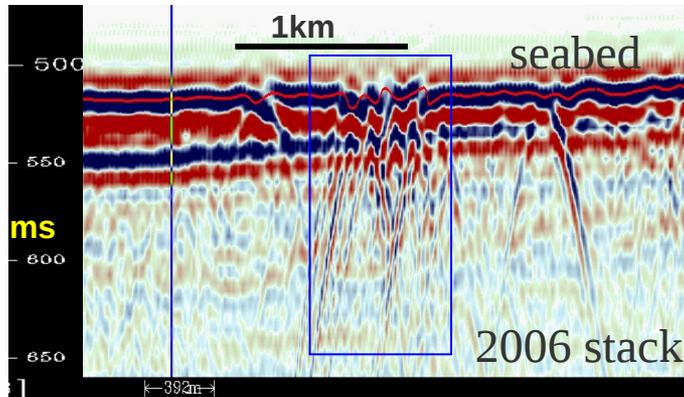

4D difference
With water layer correction

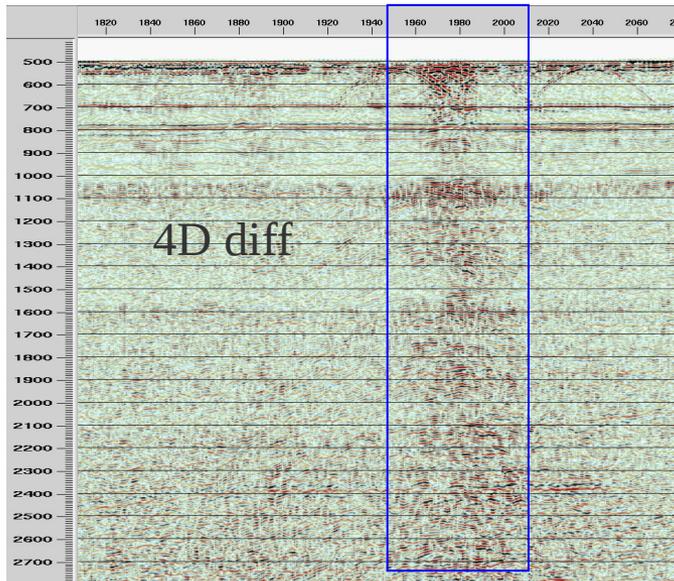

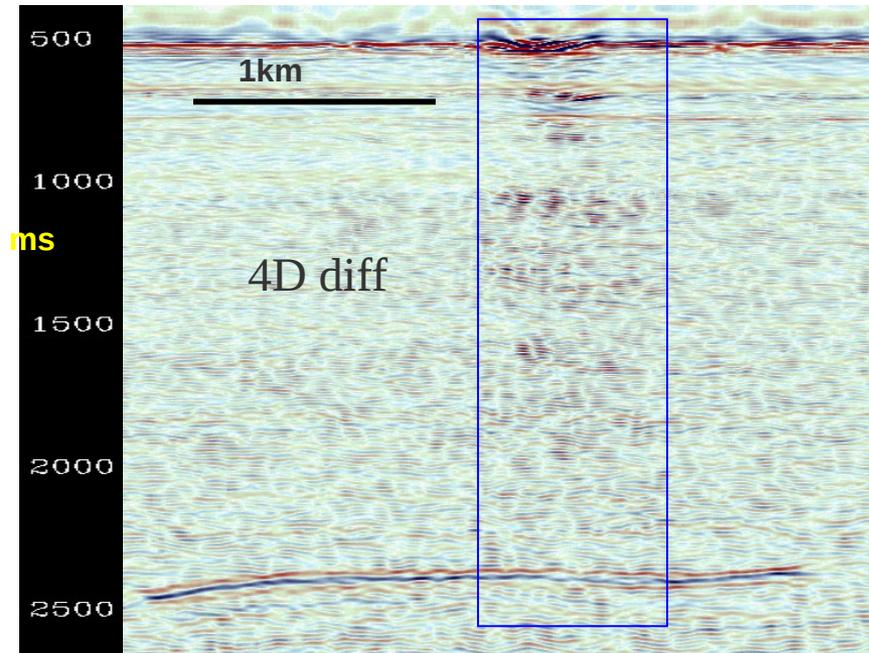

Motivation

Diffractions and diffracted multiples

Unmigrated

Final 3D migration

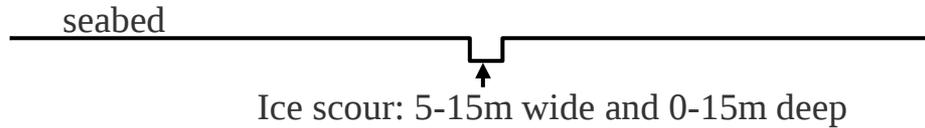

- Diffractions a problem in 4D
- difficult to repeat in 4D
 - difficult to remove in processing

Sea bed diffractions and impact on time shift correction

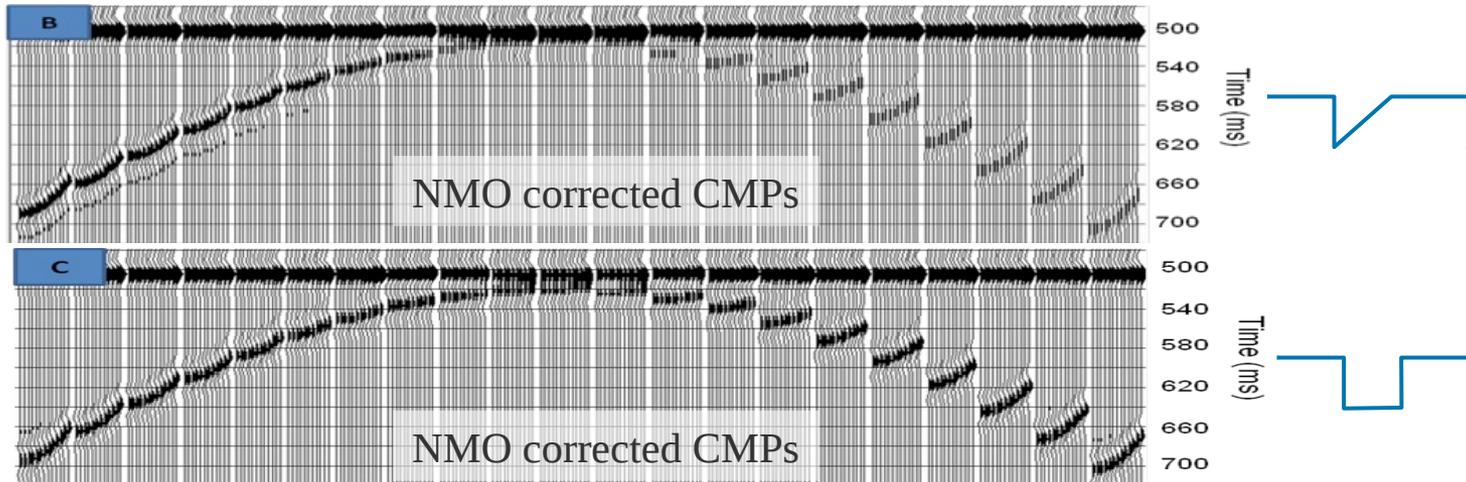

- Data examples
 - 2D FD modelling of seabed diffractions
 - Field data from Norne 2006 and 2008

2D modelling of point diffractions

Model

Modelling

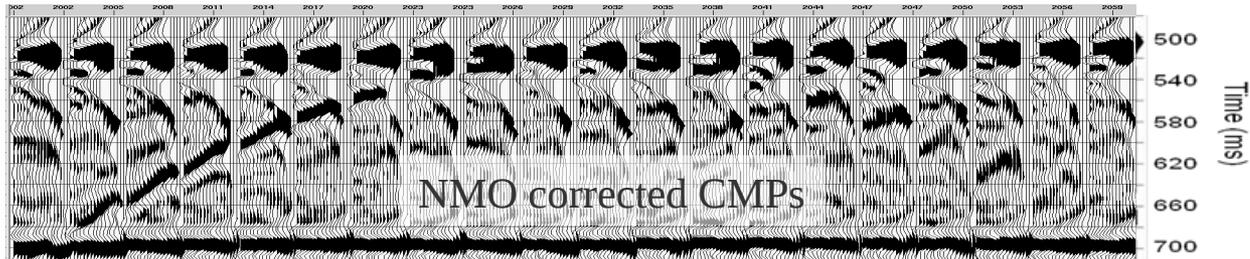

2D modelling of point diffractions

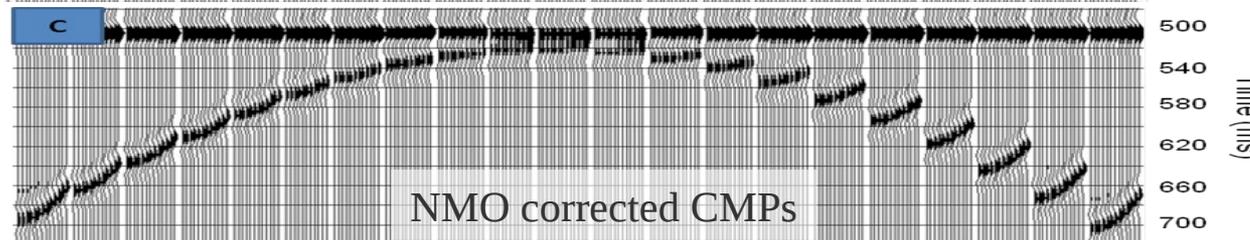

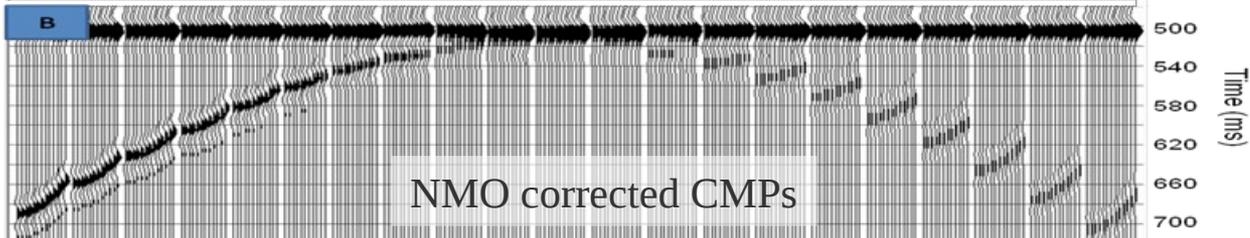

Observations:

- Diffractions can not be flattened using standard primary reflection NMO correction
- Asymmetrical amplitude strength → asymmetrical ice scour shape is likely

Real

Modelling

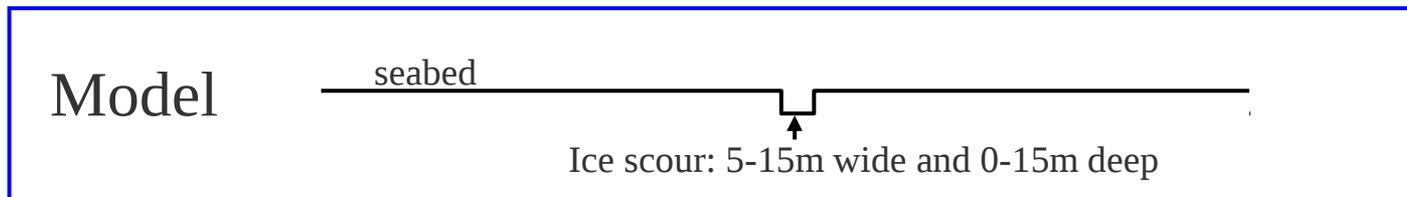

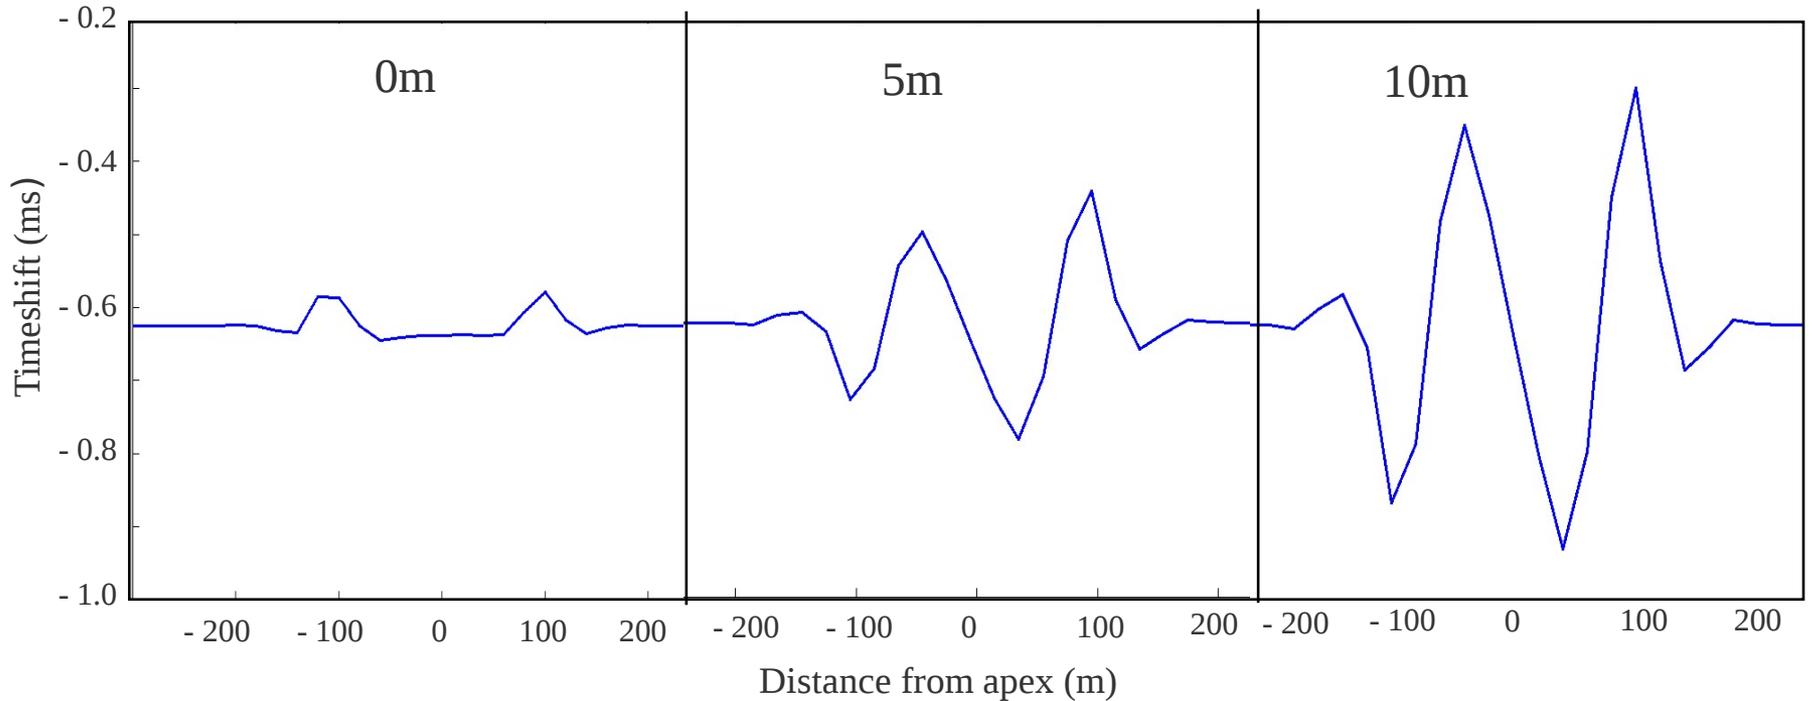

Factors controlling seabed time shift in diffraction tuning area – FD modelling

- Sea velocity changes → (2-3 m/s)
- Relative amplitude strength of diffraction → stronger contrast in ice scour than outside
- Acquisition mis-position → Varying

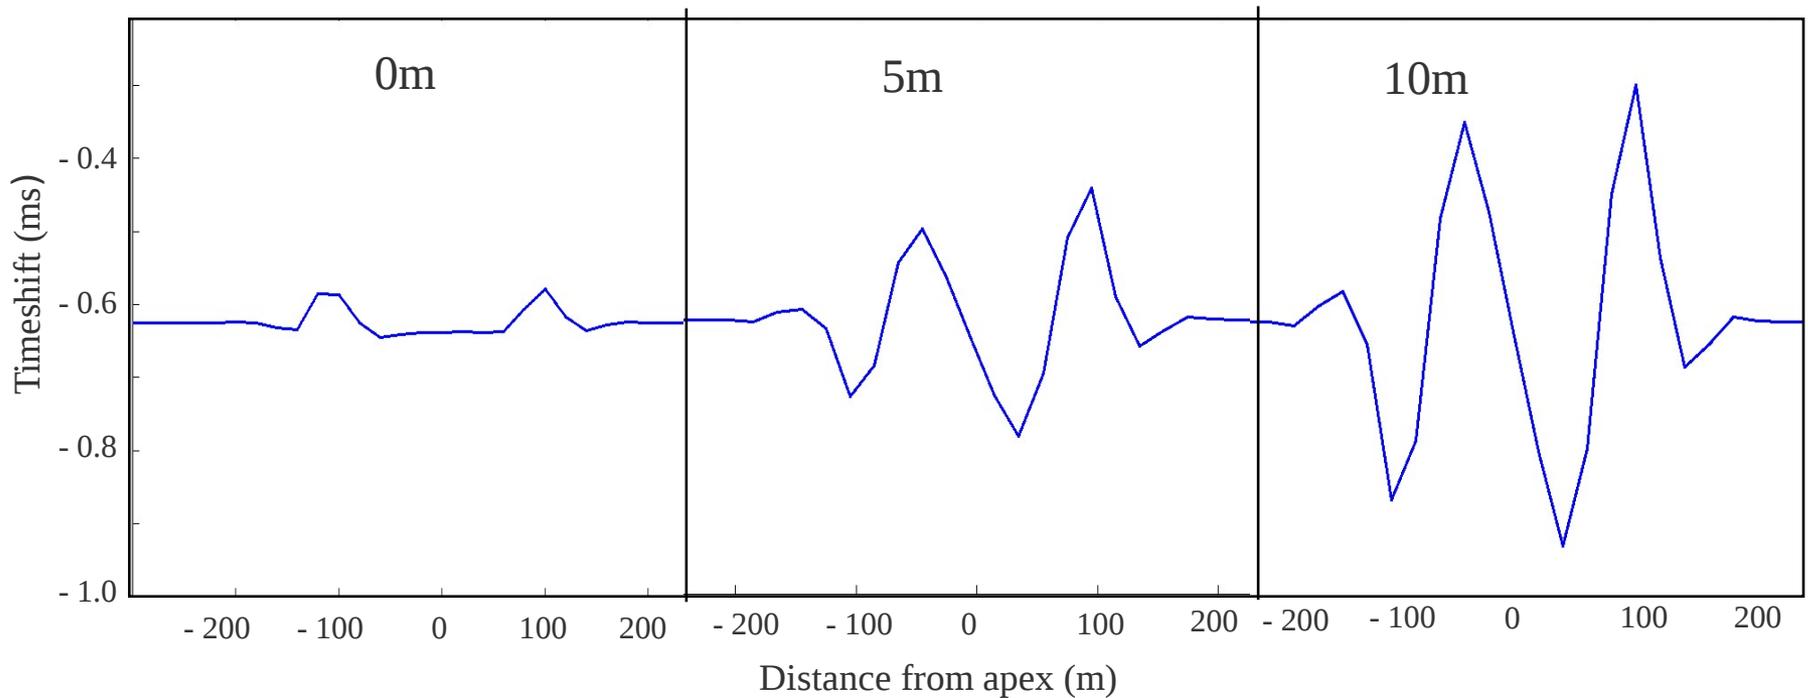

Acquisition mis-position and seabed time shift

- Acquisition mis-position

Acquisition mis-position and seabed time shift

- Acquisition mis-position

■ Mis-positioning creates non-negligible time shift error

Approximations for time shift error caused by tuning

assuming harmonic input signal

$$\tau = \frac{\frac{2h_2}{v_2} \left(1 + \alpha + \alpha \sqrt{1 + \frac{(x-a)^2}{h_2^2}} + \alpha^2 \sqrt{1 + \frac{(x-a)^2}{h_2^2}} \right) - \frac{2h_1}{v_1} \left(1 + \alpha + \alpha \sqrt{1 + \frac{x^2}{h_1^2}} + \alpha^2 \sqrt{1 + \frac{x^2}{h_1^2}} \right)}{(1 + \alpha)^2}$$

V_1, V_2 - base and monitor sea velocity

α - Amplitude ratio between seabed and diffraction

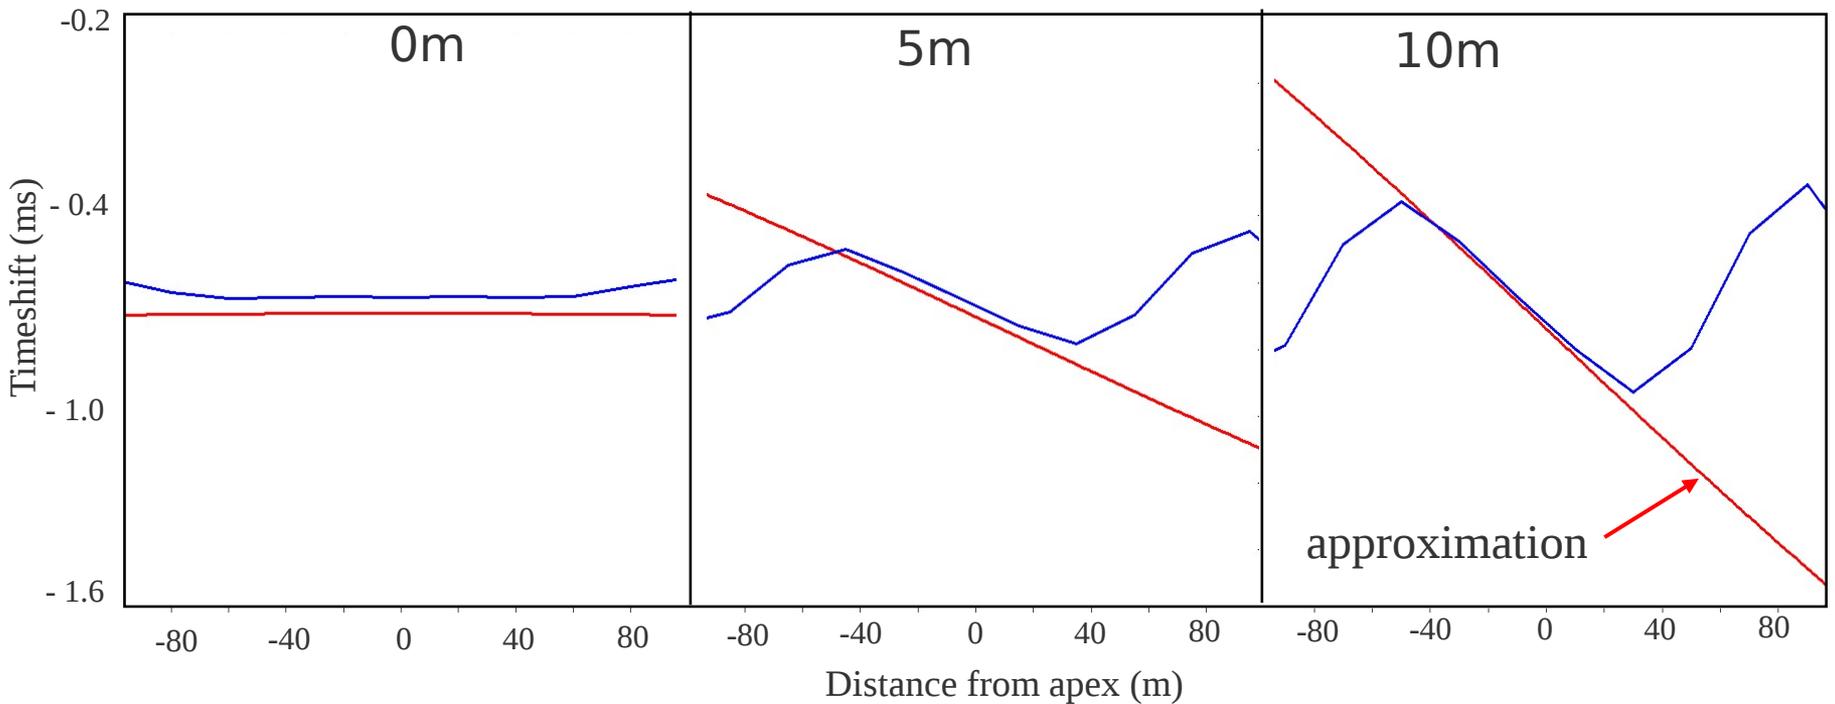

h - water depth

x - distance from diffraction apex

a = mis-positioning between base and monitor

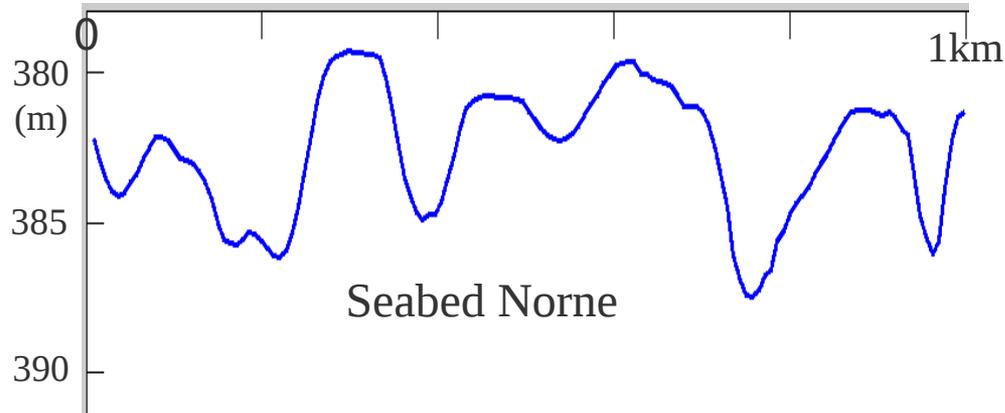

Valid for small offsets, where the two signal are inside same lobe

Approximations for time shift error caused by tuning

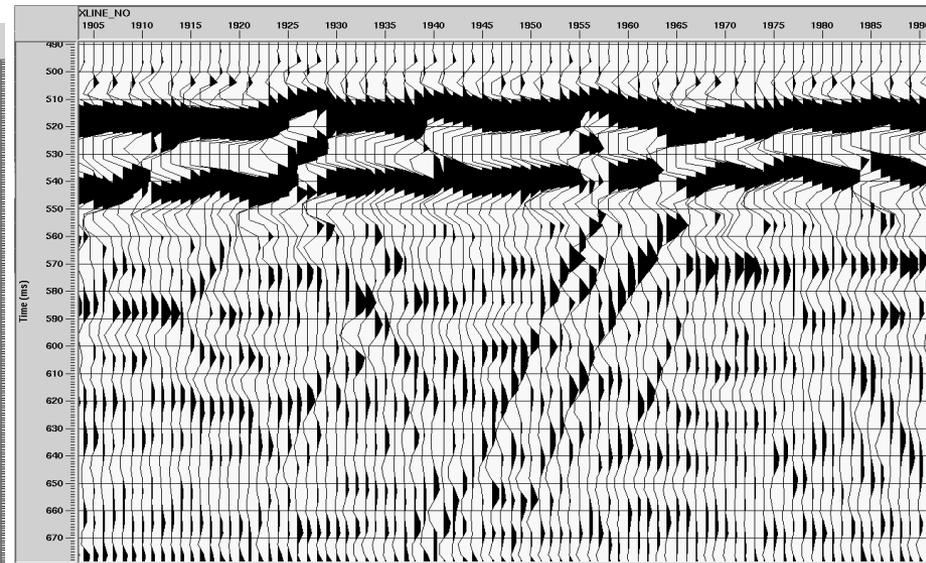

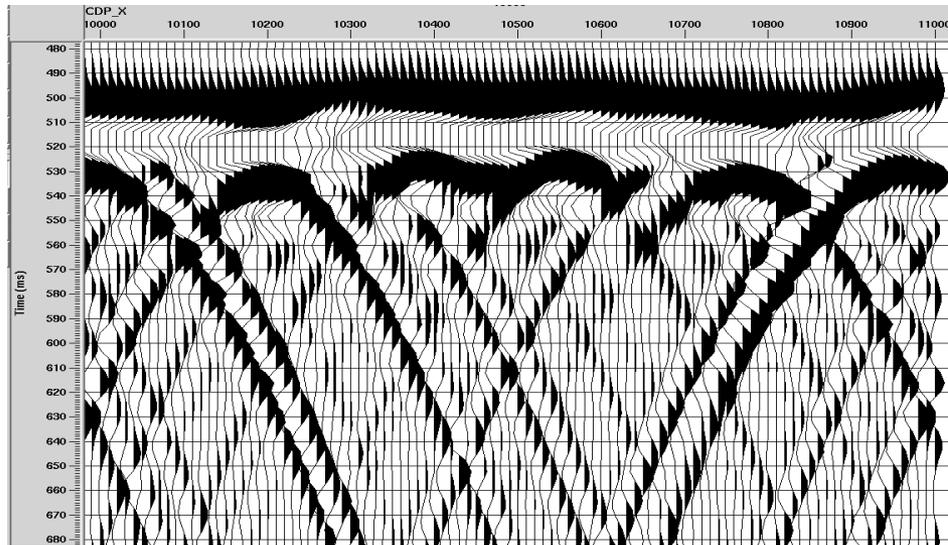

Approximation ok up to ca. 40m from apex point

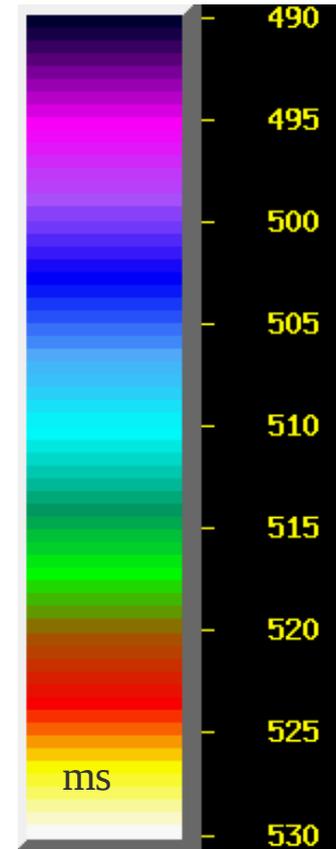

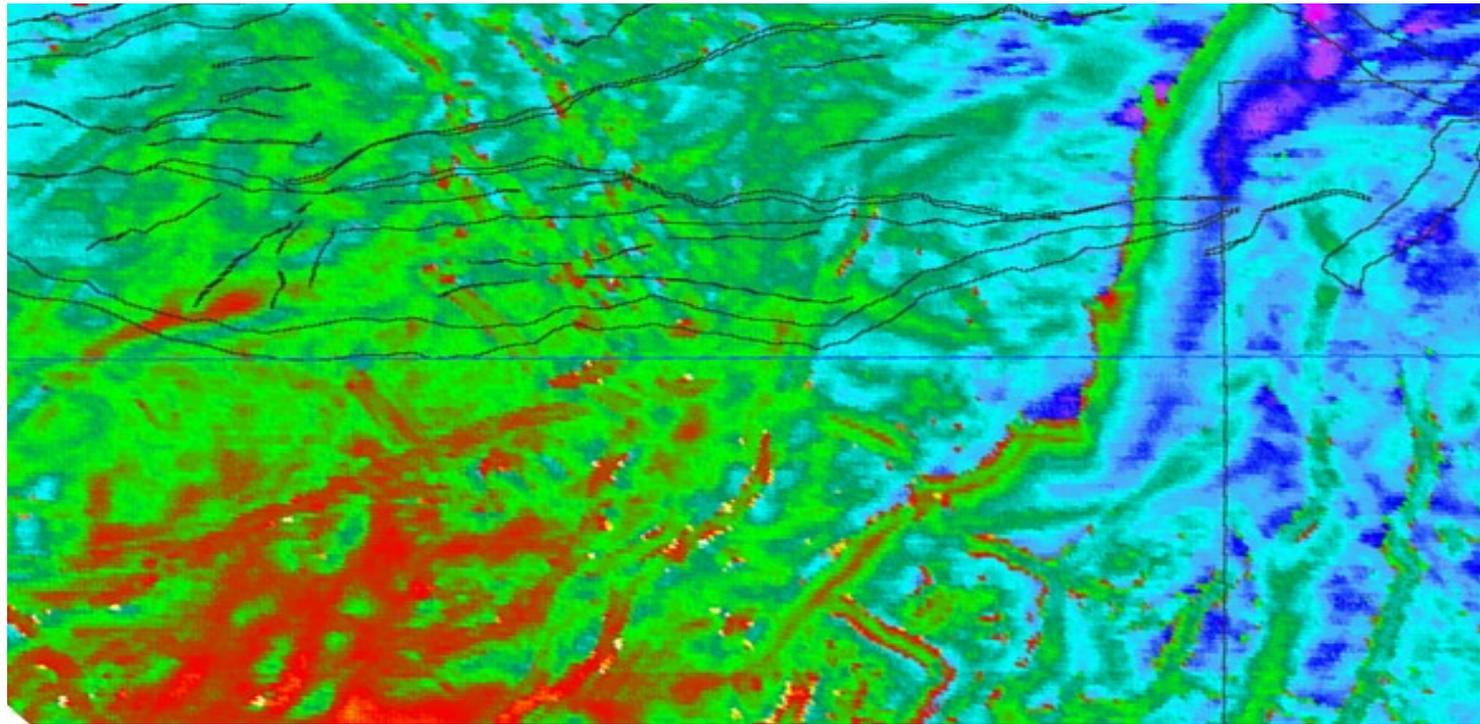

2D FD modelling and field data

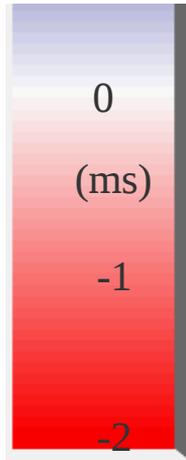

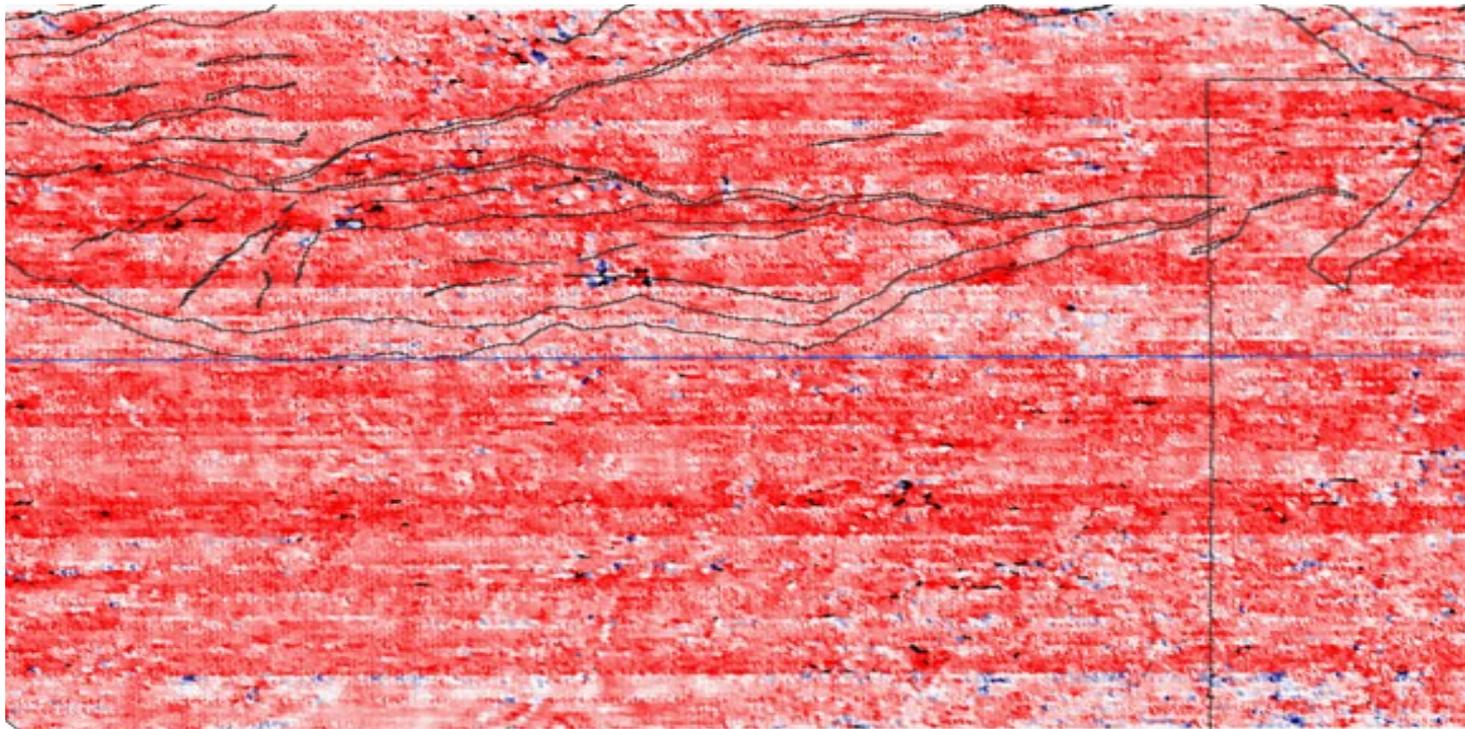

Field data Norne

Seabed time map Norne

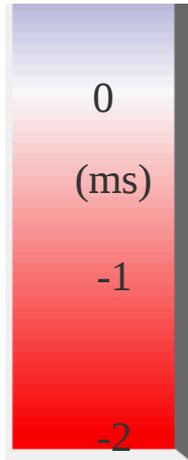

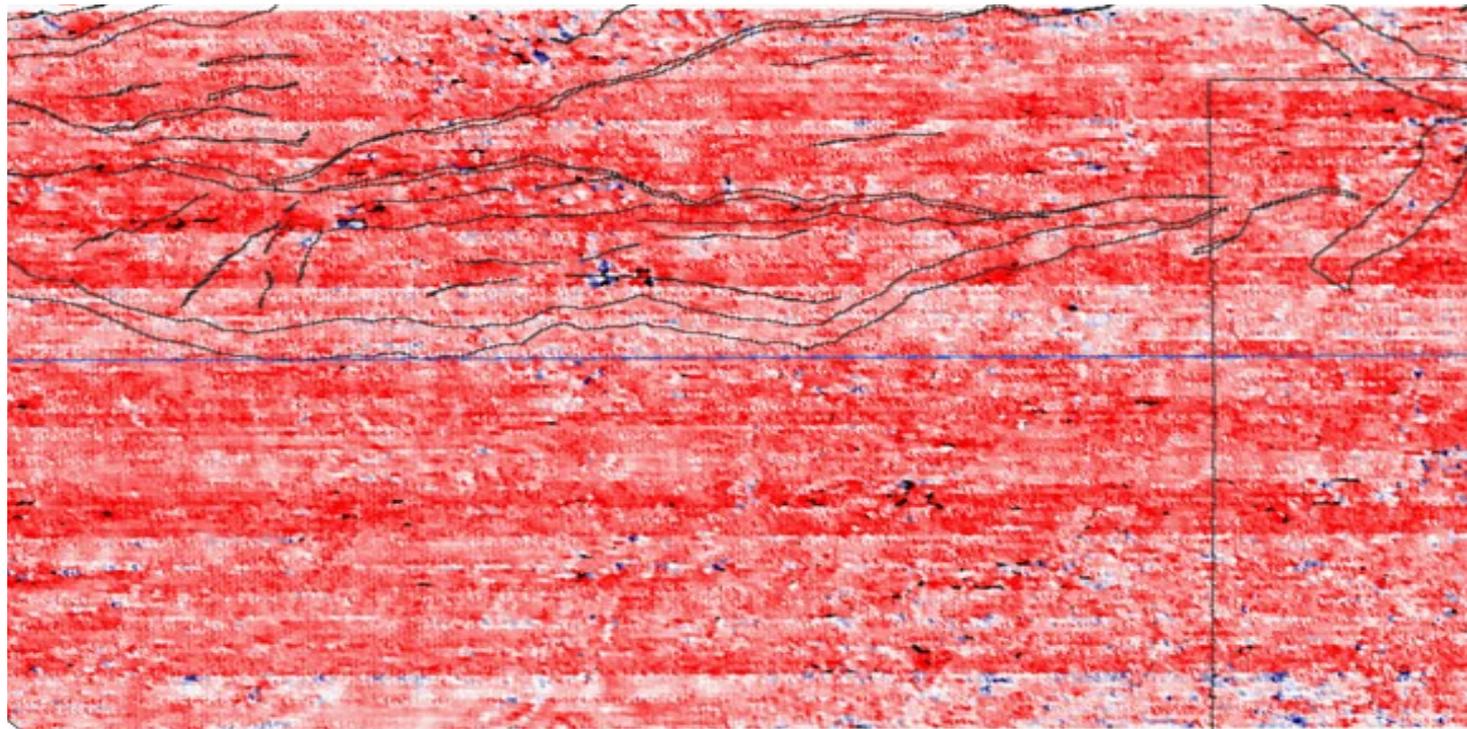

Seafloor time shift 2006-2008 After tidal correction

Time shift related to:

- Variation of sea velocity (lateral and with calendar time)
- Geometrical mis-positioning
- Error in tidal correction

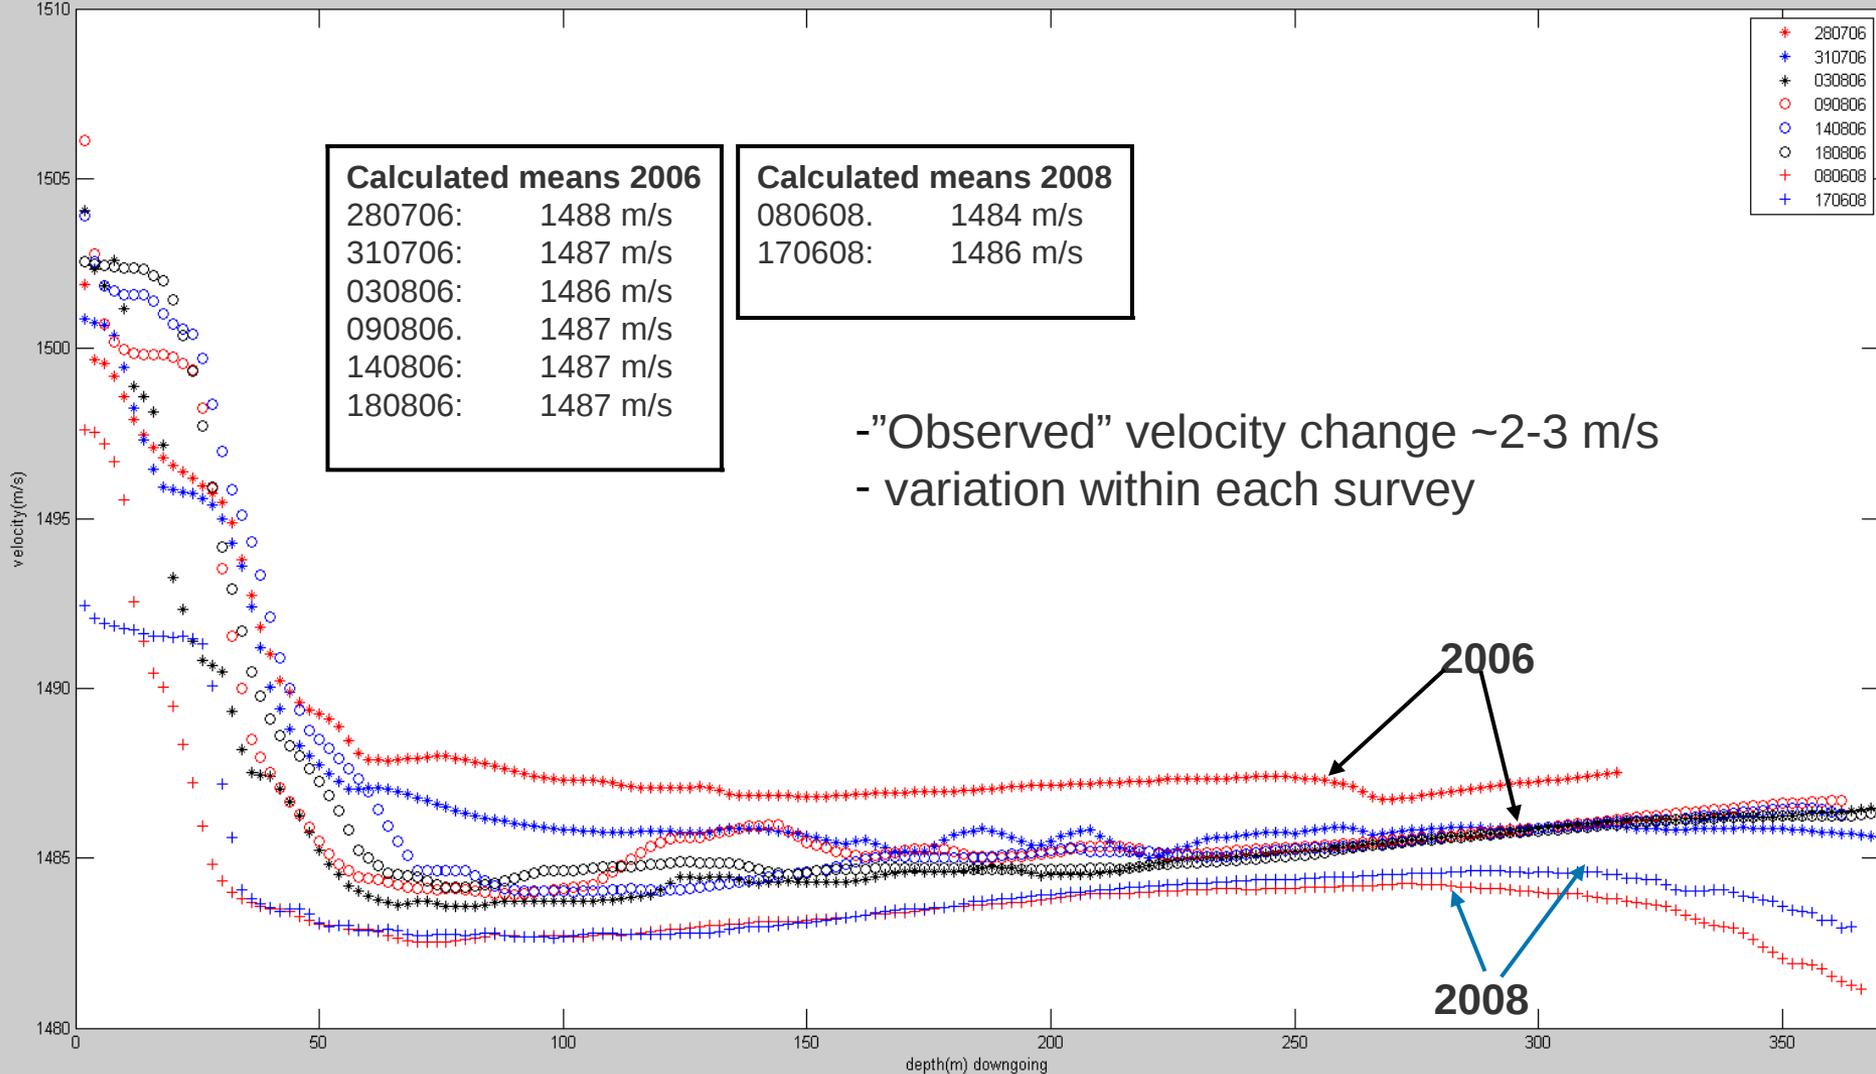

Seafloor time shift 2006-2008 After tidal correction

Time shift related to:

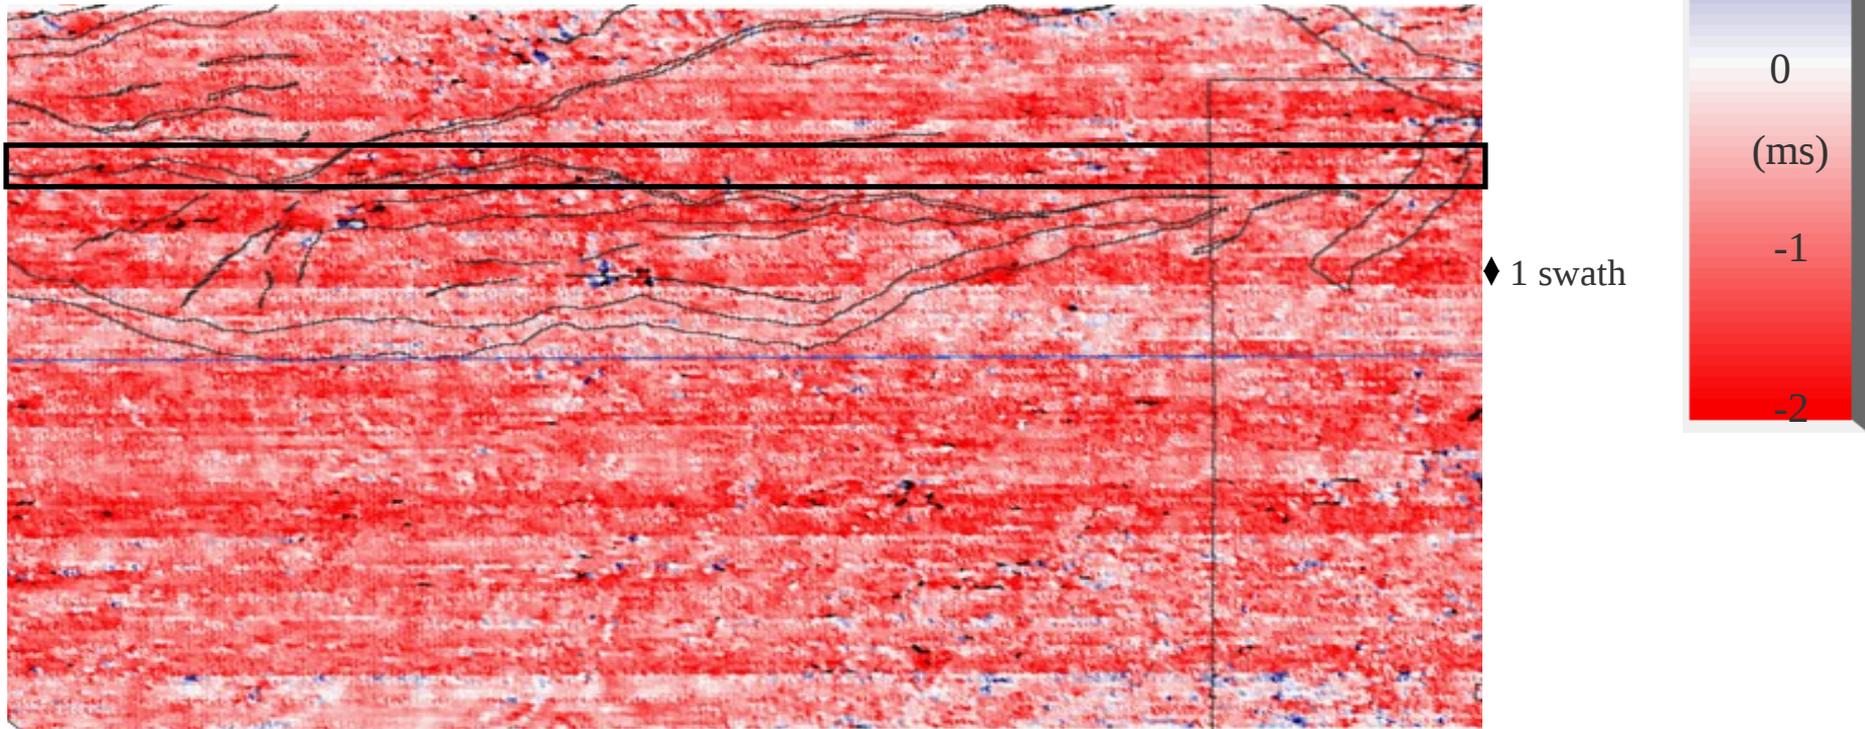

- Variation of sea velocity (lateral and with calendar time)
- Geometrical mis-positioning
- Error in tidal correction

Velocity profiles 2006 and 2008

Based on measured temperatures and salinities

Seafloor time shift 2006-2008 After tidal correction

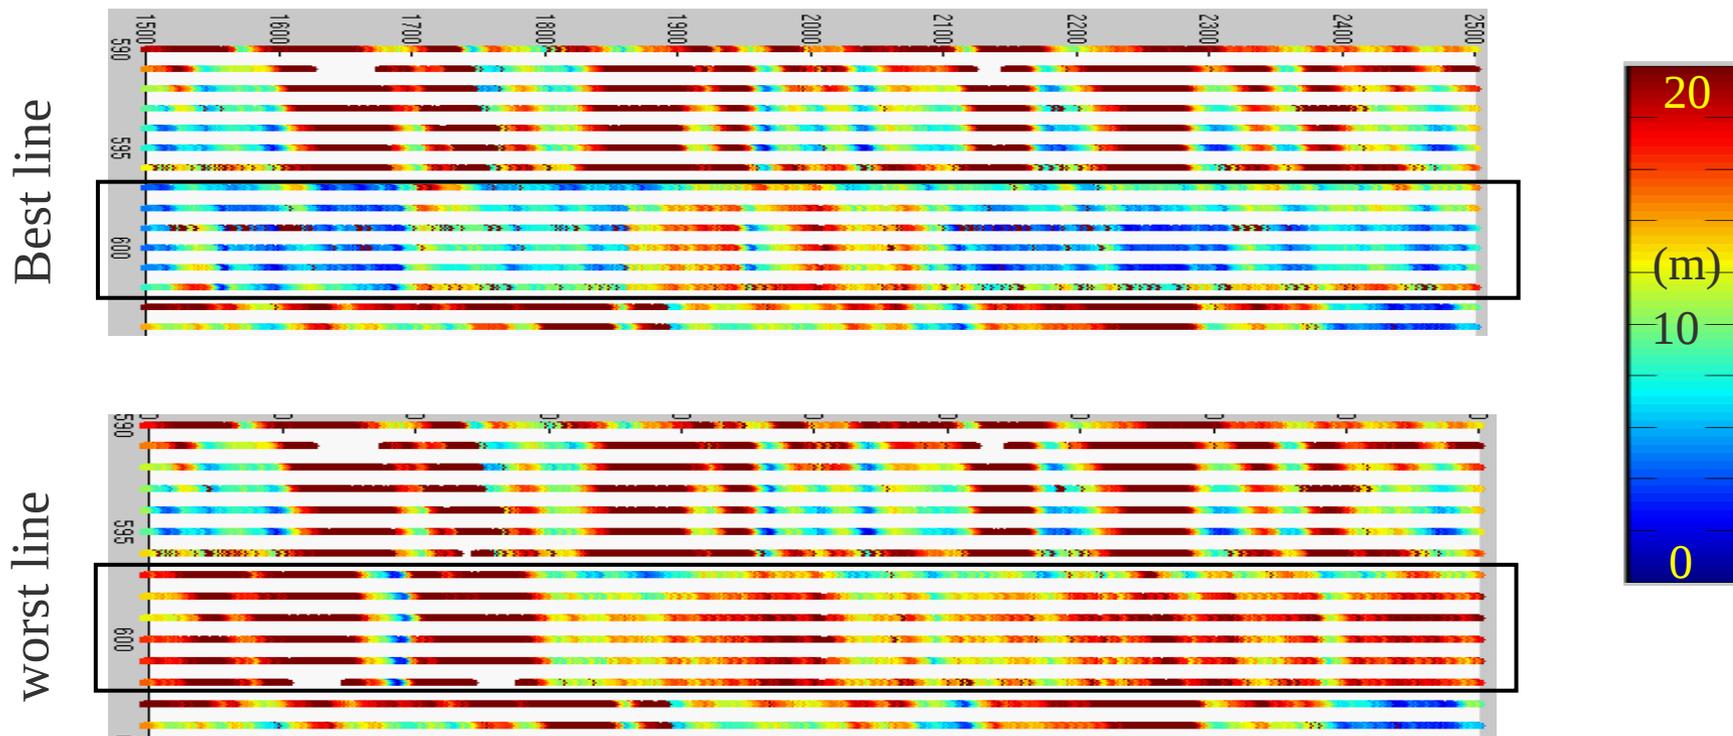

Time shift related to:

- Variation of sea velocity (lateral and with calendar time)
- Geometrical mis-positioning
- Error in tidal correction

Two examples of geometrical mis-position

$$D(\text{Source}) + D(\text{receiver})$$

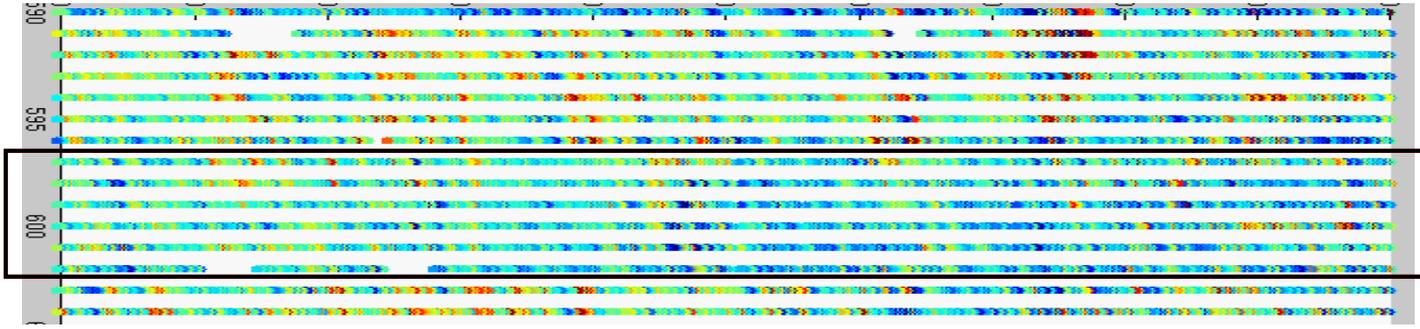

...and corresponding Seabed time shift

Time shift (ms)

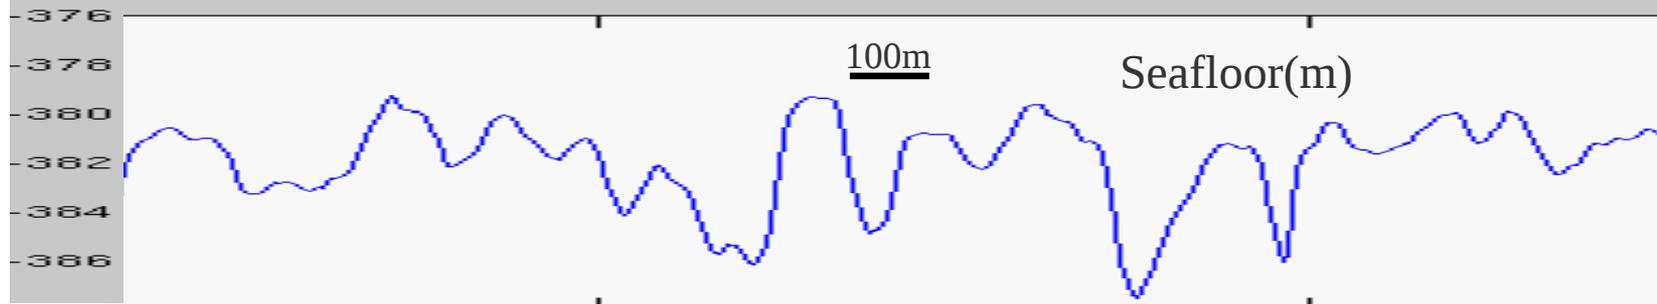

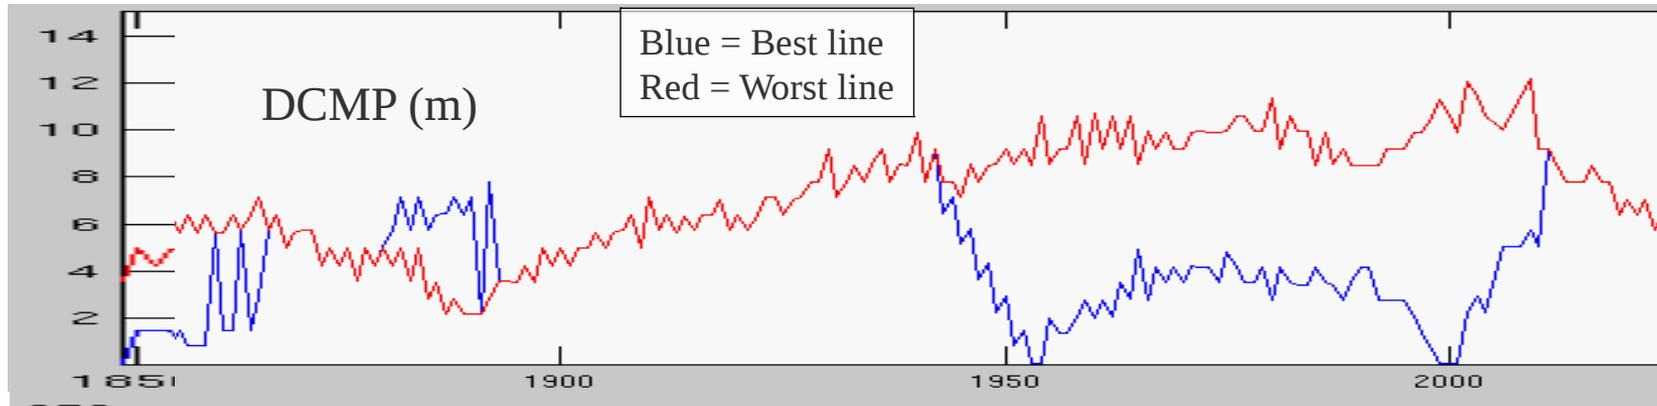

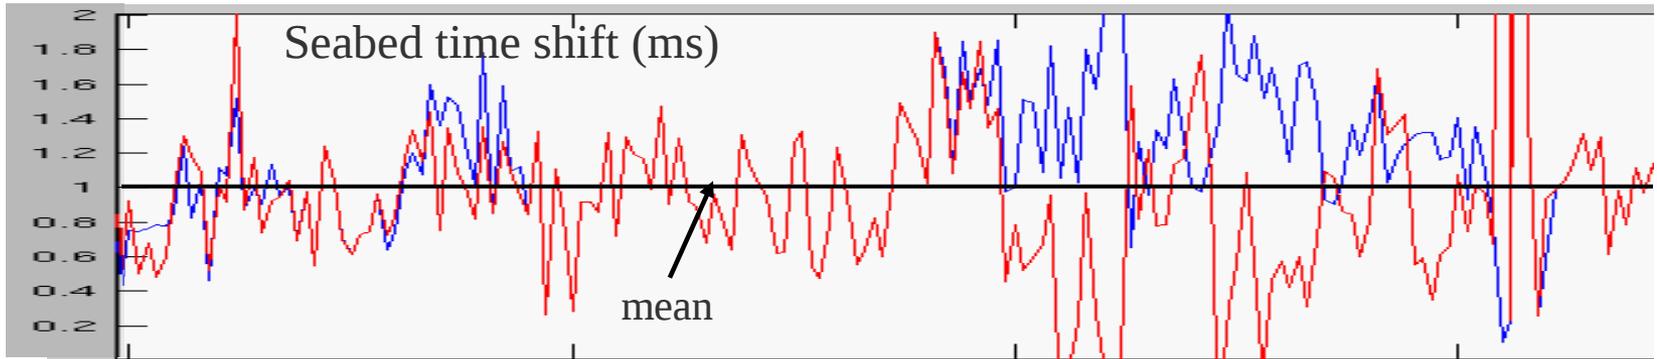

Best line

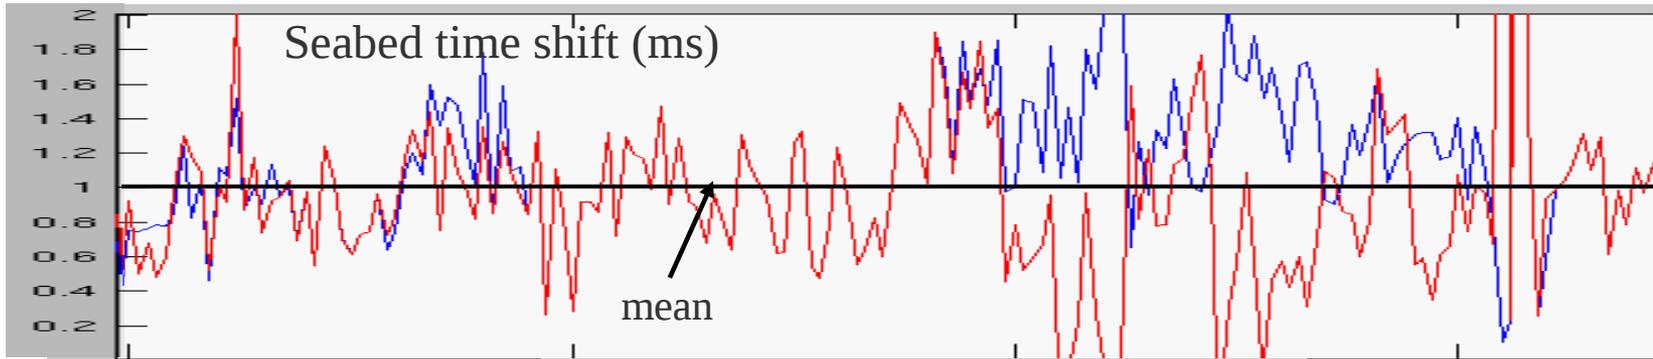

worst line

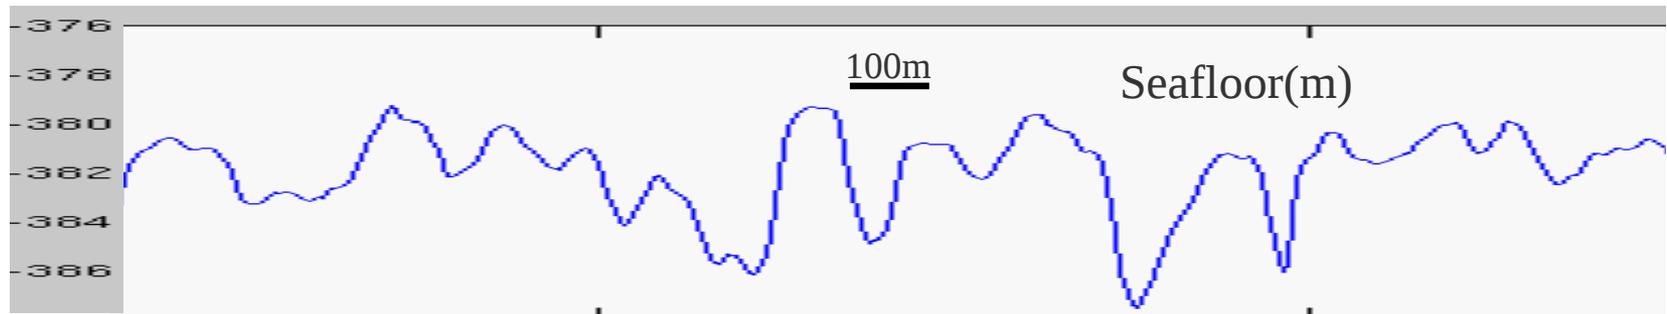

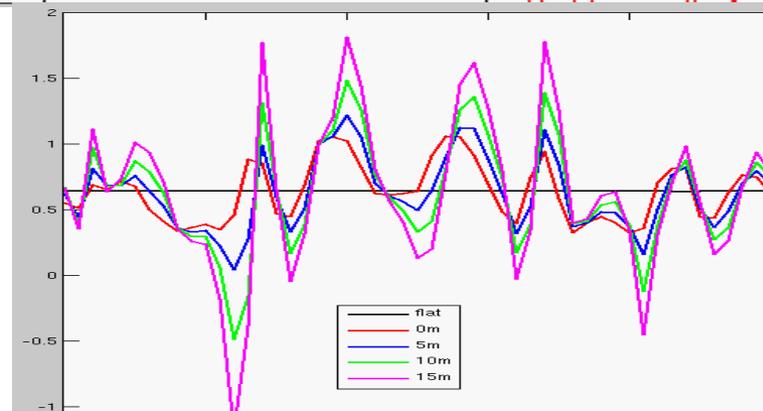

Time shift related to complex sea bottom and geometrical mis-position

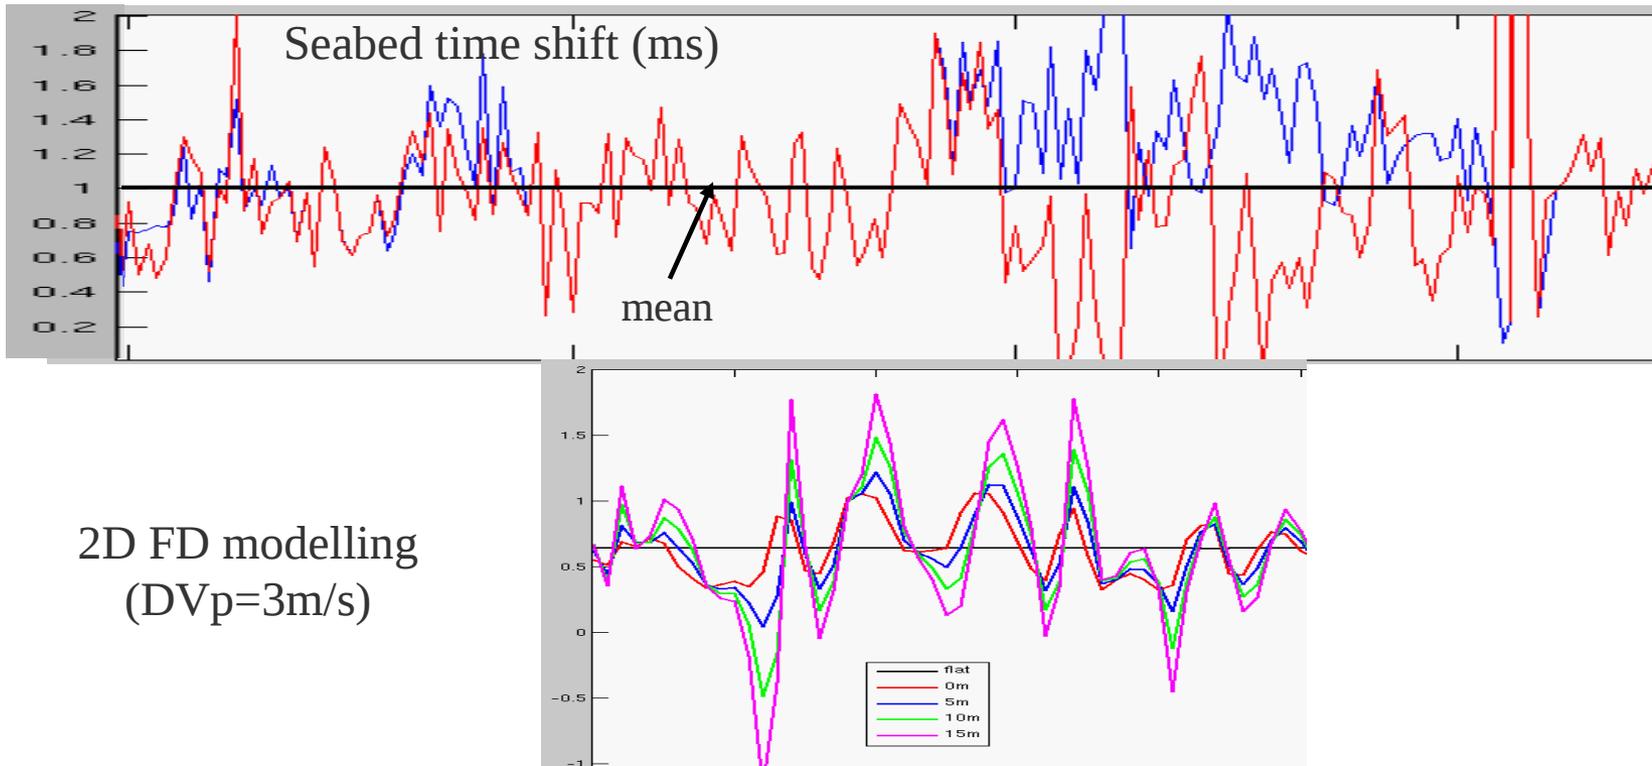

Time shift related to complex sea bottom and geometrical mis-position

2D FD modelling
($DV_p=3\text{m/s}$)

Time shift related to complex sea bottom and geometrical mis-position

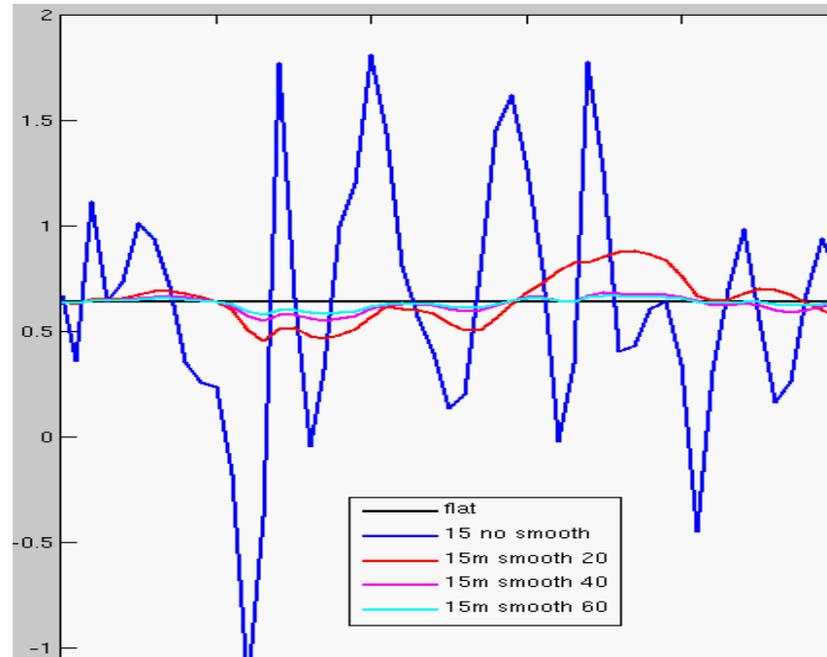

Observation

- Seabed time shift strongly dependent on geometrical repeatability and complexity of the seabed

Complex sea bottom and geometrical mis-position

Smoothing of time shift

Modelled data –
Seabed time shift (ms)

- Smoothing line by line remove much of the disturbance from complex sea bottom , but this is based on the assumption that the seabed irregularities do not create systematic time shift error

NTNU

Norwegian University of
Science and Technology

Conclusions

Statoil

- Seabed time shifts strongly depend on change in water velocity, geometrical repeatability and complexity of the seabed
- The effect of geometrical mis-positioning is important
- Smoothing line by line removes much of the disturbance from complex sea bottom and is the recommended method

Acknowledgments

- **Statoil and their partners ENI Norge AS and Petoro for permission to use their data**
- **NFR for financial support to the ROSE project at NTNU**
- **Børge Arntzen and Jon A. Haugen and for help and support with the FD modelling**
- **Hussein Mehdizadeh for Promax help**
